A FLOW METHOD FOR A GENERALIZATION OF L_p CHRISTOFELL-MINKOWSKI PROBLEM

BOYA LI, HONGJIE JU, AND YANNAN LIU

ABSTRACT. In this paper, a generalization of the L_p -Christoffel-Minkowski problem is studied. We consider an anisotropic curvature flow and derive the long-time existence of the flow. Then under some initial data, we obtain the existence of smooth solutions to this problem for $c = 1$.

1. INTRODUCTION

Recently, as important developments of the classical Brunn-Minkowski theory in convex geometry, the dual Brunn-Minkowski theory is developing rapidly. Dual curvature measures and their associated variational formulas was firstly introduced by Huang, Lutwak, Yang and Zhang in their recent groundbreaking work [\[8\]](#page-13-0). Then the dual curvature measures were extended into the L_p case in [\[13\]](#page-14-0) and then studied in $[1, 4, 9].$ $[1, 4, 9].$ $[1, 4, 9].$ $[1, 4, 9].$

In this paper, we consider the following fully nonlinear equation, which is a generalization of L_p -Christoffel-Minkowski problem

(1)
$$
\frac{h^{1-p}}{(h^2 + |\nabla h|^2)^{\frac{n-q}{2}}} \sigma_k(x) f(x) = c \text{ on } \mathbb{S}^{n-1}
$$

for some positive constant c. Here f is a given positive and smooth function on the unit sphere \mathbb{S}^{n-1} and h is the support function defined on \mathbb{S}^{n-1} . $\sigma_k(x,t)$ is the k-th elementary symmetric function for principal curvature radii and ∇ is the Levi-Civita connection on \mathbb{S}^{n-1} .

Equation [\(1\)](#page-0-0) is just the smooth case of L_p dual Minkowski problem when $k = n-1$.

When $q = n, k = n - 1$, Eq. [\(1\)](#page-0-0) reduces to the L_p -Minkowski problem, which has been extensively studied, see e.g. Schneider' book [\[14\]](#page-14-1). For $q = n, 1 \leq k < n - 1$, Eq. [\(1\)](#page-0-0) is known as the L_p -Christoffel-Minkowski problem and is the classical Christoffel-Minkowski problem for $p = 1$. Under a sufficient condition on the prescribed function, existence of solution for the classical Christoffel-Minkowski problem was given in [\[5\]](#page-13-4).

Key words and phrases. L_p -Christoffel-Minkowski problem, Existence of solutions, Anisotropic curvature flow.

This work was supported in part by the Natural Science Foundation of Beijing Municipality (No. 1212002) and the National Natural Science Foundation of China (Grant No.12071017, 11871432, 11871102).

The L_p -Christoffel-Minkowski problem is related to the problem of prescribing k-th p-area measures. Hu, Ma & Shen in [\[7\]](#page-13-5) proved the existence of convex solutions to the L_p -Christoffel-Minkowski problem for $p \geq k+1$ under appropriate conditions. Using the methods of geometric flows, Ivaki in [\[10\]](#page-13-6) and then Sheng & Yi in [\[15\]](#page-14-2) also gave the existence of smooth convex solutions to the L_p -Christoffel-Minkowski problem for $p \geq k+1$. In case $1 < p < k+1$, Guan & Xia in [\[6\]](#page-13-7) established the existence of convex body with prescribed k -th even p -area measures. In [\[3\]](#page-13-8), the authors considered a generalized L_p -Christoffel-Minkowski problem and gave the the existence of smooth solutions by curvature flow method. To the best of our knowledge, there is no other existence result about Eq. [\(1\)](#page-0-0)

The existence of smooth solutions for Eq. [\(1\)](#page-0-0) is concerned in this paper. In general, there is no variational structure, We use a flow method involving σ_k , support function and radial function to give the existence of smooth solutions for Eq. [\(1\)](#page-0-0) wich $c = 1$.

Let M_0 be a smooth, closed, strictly convex hypersurface in the Euclidean space \mathbb{R}^n , which encloses the origin and is given by a smooth embedding $X_0: \mathbb{S}^{n-1} \to \mathbb{R}^n$. Consider a family of closed hypersurfaces $\{M_t\}$ with $M_t = X(\mathbb{S}^{n-1}, t)$, where X: $\mathbb{S}^{n-1} \times [0,T) \to \mathbb{R}^n$ is a smooth map satisfying the following initial value problem:

(2)
$$
\frac{\partial X}{\partial t}(x,t) = f(\nu)\sigma_k(x,t)\langle X,\nu\rangle^{2-p}|X|^{q-n}\nu - \eta(t)X,
$$

$$
X(x,0) = X_0(x).
$$

Here ν is the unit outer normal vector of M_t at the point $X(x, t)$. $\langle \cdot, \cdot \rangle$ is the standard inner product in \mathbb{R}^n , η is a scalar function to be specified later, and T is the maximal time for which the solution exists. We use $\{e_{ii}\}, 1 \le i, j \le n-1$ and ∇ for the standard metric and Levi-Civita connection of \mathbb{S}^{n-1} respectively. Principal radii of curvature are the eigenvalues of the matrix

$$
b_{ij} := \nabla_i \nabla_j h + e_{ij} h
$$

with respect to $\{e_{ij}\}\text{. } \sigma_k(x,t)$ is the k-th elementary symmetric function for principal curvature radii of M_t at $X(x, t)$ and k is an integer with $1 \leq k < n-1$. In this paper, σ_k is normalized so that $\sigma_k(1,\ldots,1)=1$.

Geometric flows with speed of symmetric polynomial of the principal curvature radii of the hypersurface have been extensively studied, see e.g. [\[16\]](#page-14-3).

On the other hand, anisotropic curvature flows provide alternative methods to prove the existences of elliptic PDEs arising from convex geometry, see e.g. [\[2,](#page-13-9) [4,](#page-13-2) [10,](#page-13-6) [12,](#page-14-4) [15\]](#page-14-2).

The scalar function $\eta(t)$ in [\(2\)](#page-1-0) is usually used to keep M_t normalized in a certain sense, see for examples [\[4,](#page-13-2) [10,](#page-13-6) [15\]](#page-14-2). In this paper, η is given by

(3)
$$
\eta(t) = \frac{\int_{\mathbb{S}^{n-1}} \rho^{q-n} h \sigma_k \, dx}{\int_{\mathbb{S}^{n-1}} \frac{1}{f(x)} h^p \, dx},
$$

where $h(\cdot, t)$ and $\rho(u, t)$ are the support function and radial function of the convex hypersurface M_t .

To obtain the long-time existence of flow (2) , we need some constraints on f.

(A): Let s be the arc-length parameter and f be a smooth function on \mathbb{S}^{n-1} . On every great circle, f satisfies

$$
f_{ss} - \frac{1}{k+1} \left(k + \frac{q-n}{q-n-k-1} + \frac{p-2}{p+k-1} \right) f_s^2 f^{-1} + (p+k-1-q+n)f > 0.
$$

The main results of this paper are stated as follows.

Theorem 1. Assume M_0 is a smooth, closed and strictly convex hypersurface in \mathbb{R}^n . Suppose k is an integer with $1 \leq k < n-1$ and $k+1 < q-n < p-k-1$. Suppose f is a smooth positive function on \mathbb{S}^{n-1} satisfying (A). Then flow [\(2\)](#page-1-0) has a unique smooth solution M_t for all time $t > 0$. Moreover, when $t \to \infty$, a subsequence of M_t converges in C^{∞} to a smooth, closed, strictly convex hypersurface.

For the proof of Theorem [1,](#page-2-0) we will see it is enough to obtain the uniform positive upper and lower bounds for support functions of $\{M_t\}$ under condition $0 \leq q - n <$ $p - k - 1$. And the stronger condition $k + 1 < q - n < p - k - 1$ is only used to derive the uniform bound of principal curvature, see Lemma [5](#page-8-0) for details.

Corollary 1. Under the assumptions of Theorem [1,](#page-2-0) there exists a smooth solution to equation [\(1\)](#page-0-0) with $c=1$.

This paper is organized as follows. In section 2, we give some basic knowledge about the flow [\(2\)](#page-1-0) and evolution equations of some geometric quantities. In section 3, the long-time existence of flow [\(2\)](#page-1-0) will be obtained. First, we obtain the uniform positive upper and lower bounds for support functions of $\{M_t\}$. Based on the bounds of support functions, we obtain the uniform bounds of principal curvatures by constructing proper auxiliary functions. The long-time existence of flow [\(2\)](#page-1-0) then follows by standard arguments. In section 4, under some special initial condition, we prove that a subsequence of $\{M_t\}$ converges to a smooth solution to equation [\(1\)](#page-0-0) with $c = 1$, completing the proofs of Corollar [1.](#page-2-1)

2. Preliminaries

Let \mathbb{R}^n be the *n*-dimensional Euclidean space, and \mathbb{S}^{n-1} be the unit sphere in \mathbb{R}^n . Assume M is a smooth closed strictly convex hypersurface in \mathbb{R}^n . Without loss of generality, we may assume that M encloses the origin. The support function h of M is defined as

$$
h(x):=\max_{y\in M}\langle y,x\rangle,\quad\forall x\in\mathbb{S}^{n-1},
$$

where $\langle \cdot, \cdot \rangle$ is the standard inner product in \mathbb{R}^n .

Denote the Gauss map of M by ν_M . Then M can be parametrized by the inverse Gauss map $X : \mathbb{S}^{n-1} \to M$ with $X(x) = \nu_M^{-1}(x)$. The support function h of M can be computed by

(4)
$$
h(x) = \langle x, X(x) \rangle, \quad x \in \mathbb{S}^{n-1}.
$$

Note that x is just the unit outer normal of M at $X(x)$. Differentiating [\(4\)](#page-2-2), we have

$$
\nabla_i h = \langle \nabla_i x, X(x) \rangle + \langle x, \nabla_i X(x) \rangle.
$$

Since $\nabla_i X(x)$ is tangent to M at $X(x)$, we have

$$
\nabla_i h = \langle \nabla_i x, X(x) \rangle.
$$

It follows that

$$
(5) \t\t X(x) = \nabla h + hx.
$$

By differentiating [\(4\)](#page-2-2) twice, the second fundamental form A_{ij} of M can be computed in terms of the support function, see for example [\[16\]](#page-14-3),

$$
(6) \t\t A_{ij} = \nabla_{ij}h + he_{ij},
$$

where $\nabla_{ij} = \nabla_i \nabla_j$ denotes the second order covariant derivative with respect to e_{ij} . The induced metric matix g_{ij} of M can be derived by Weingarten's formula,

(7)
$$
e_{ij} = \langle \nabla_i x, \nabla_j x \rangle = A_{im} A_{lj} g^{ml}.
$$

The principal radii of curvature are the eigenvalues of the matrix $b_{ij} = A^{ik}g_{jk}$. When considering a smooth local orthonormal frame on \mathbb{S}^{n-1} , by virtue of [\(6\)](#page-3-0) and [\(7\)](#page-3-1), we have

(8)
$$
b_{ij} = A_{ij} = \nabla_{ij} h + h \delta_{ij}.
$$

We will use b^{ij} to denote the inverse matrix of b_{ij} .

From the evolution equation of $X(x, t)$ in flow [\(2\)](#page-1-0), we derive the evolution equation of the corresponding support function $h(x, t)$:

(9)
$$
\frac{\partial h(x,t)}{\partial t} = f(x)\sigma_k(x,t)h^{2-p}\rho^{q-n} - \eta(t)h(x,t).
$$

The radial function ρ of M is given by

$$
\rho(u) := \max\left\{\lambda > 0 : \lambda u \in M\right\}, \quad \forall \ u \in \mathbb{S}^{n-1}.
$$

Note that $\rho(u)u \in M$.

From (5) , u and x are related by

(10)
$$
\rho(u)u = \nabla h(x) + h(x)x
$$

and

$$
\rho^2 = |\nabla h|^2 + h^2.
$$

Let $x = x(u, t)$, by [\(10\)](#page-3-3), we have

$$
\log \rho(u, t) = \log h(x, t) - \log \langle x, u \rangle.
$$

Differentiating the above identity, we have

$$
\frac{1}{\rho(u,t)} \frac{\partial \rho(u,t)}{\partial t} = \frac{1}{h(x,t)} \Big(\nabla h \cdot \frac{\partial x(u,t)}{\partial t} + \frac{\partial h(x,t)}{\partial t} \Big) - \frac{u}{\langle x,u \rangle} \cdot \frac{\partial x(u,t)}{\partial t}
$$

$$
= \frac{1}{h(x,t)} \frac{\partial h(x,t)}{\partial t} + \frac{1}{h(x,t)} [\nabla h - \rho(u,t)u] \cdot \frac{\partial x(u,t)}{\partial t}
$$

$$
= \frac{1}{h(x,t)} \frac{\partial h(x,t)}{\partial t}.
$$

The evolution equation of radial function then follows from [\(9\)](#page-3-4),

(11)
$$
\frac{\partial \rho}{\partial t}(u,t) = f(x)\sigma_k(u,t)h^{1-p}\rho^{q-n+1} - \eta(t)\rho(u,t),
$$

where $\sigma_k(u, t)$ denotes the fundamental symmetric function of principal radii at $\rho(u, t)u \in M_t$ and f takes value at the unit normal vector $x(u, t)$.

In the rest of the paper, we take a local orthonormal frame $\{e_1, \dots, e_{n-1}\}$ on \mathbb{S}^{n-1} such that the standard metric on \mathbb{S}^{n-1} is $\{\delta_{ij}\}\$. Double indices always mean to sum from 1 to $n-1$. We denote partial derivatives $\frac{\partial \sigma_k}{\partial t}$ ∂b_{ij} and $\frac{\partial^2 \sigma_k}{\partial \mathbf{I} - \mathbf{\Omega}^T}$ $\partial b_{ab}\partial b_{mn}$ by σ_k^{ij} \mathbf{r}_k^{ij} and $\sigma_k^{ab,mn}$ k respectively. For convenience, we also write

$$
N = f(x)h^{2-p}\rho^{q-n},
$$

$$
F = N\sigma_k.
$$

By the flow equation [\(2\)](#page-1-0), we can derive evolution equations of some geometric quantities.

Lemma 1. The following evolution equations hold along the flow [\(2\)](#page-1-0).

$$
\partial_t b_{ij} - N \sigma_k^{ab} \nabla_{ab} b_{ij}
$$

= $(k+1) N \sigma_k \delta_{ij} - N \sigma_k^{ab} \delta_{ab} b_{ij} + N (\sigma_k^{ia} b_{ja} - \sigma_k^{ja} b_{ia})$
+ $N \sigma_k^{ab,mn} \nabla_j b_{ab} \nabla_i b_{mn} + (\sigma_k \nabla_{ij} N + \nabla_j \sigma_k \nabla_i N + \nabla_i \sigma_k \nabla_j N) - b_{ij} \eta(t)$

$$
\partial_t b^{ij} - N \sigma_k^{ab} \nabla_{ab} b^{ij}
$$

= $-(k+1) N \sigma_k b^{ia} b^{ja} + N \sigma_k^{ab} \delta_{ab} b^{ij} - N b^{ia} b^{jb} (\sigma_k^{ra} b_{rb} - \sigma_k^{rb} b_{ra})$
- $N b^{il} b^{js} (\sigma_k^{ab,mn} + 2 \sigma_k^{am} b^{nb}) \nabla_l b_{ab} \nabla_s b_{mn}$
- $b^{ia} b^{jb} (\sigma_k \nabla_{ab} N + \nabla_b \sigma_k \nabla_a N + \nabla_a \sigma_k \nabla_b N) + \eta(t) b^{ij}.$

For the specific computations, one can refer to Lemma 2.3 in [\[10\]](#page-13-6).

3. The long-time existence of the flow

In this section, we will give a priori estimates about support functions and curvatures to obtain the long-time existence of flow [\(2\)](#page-1-0) under assumptions of Theorem [1.](#page-2-0)

In the rest of this paper, we assume that M_0 is a smooth, closed, strictly convex hypersurface in \mathbb{R}^n and $h : \mathbb{S}^{n-1} \times [0,T) \to \mathbb{R}$ is a smooth solution to the Eq. [\(9\)](#page-3-4) with the initial $h(\cdot, 0)$ the support function of M_0 . Here T is the maximal time for which the solution exists. Let M_t be the convex hypersurface determined by $h(\cdot, t)$, and $\rho(\cdot, t)$ be the corresponding radial function.

We first give the uniform positive upper and lower bounds of $h(\cdot, t)$ and $\rho(u, t)$ for $t \in [0, T)$.

Lemma 2. Let h be a smooth solution of [\(9\)](#page-3-4) on $\mathbb{S}^{n-1} \times [0,T]$ and f be a positive, smooth function on \mathbb{S}^{n-1} . $p > 1$ and $0 \leq q - n < p - k - 1$. Then

(12)
$$
\frac{1}{C} \le h(x,t) \le C,
$$

1 $\mathcal{C}_{0}^{(n)}$ (13) $\frac{1}{C} \leq \rho(u,t) \leq C$,

where C is a positive constant independent of t .

Proof. Let $J(t) = \int_{\mathbb{S}^{n-1}} h^p \frac{1}{f(s)}$ $\frac{1}{f(x)}$ dx. We claim that $J(t)$ is unchanged along the flow [\(2\)](#page-1-0). It is because

$$
J'(t) = \int_{\mathbb{S}^{n-1}} ph^{p-1} \frac{1}{f(x)} \partial_t h \, dx
$$

= $p \int_{\mathbb{S}^{n-1}} h^{p-1} \frac{1}{f(x)} (\sigma_k h^{2-p} \rho^{q-n} f(x) - \eta(t) h) \, dx$
= 0.

For each $t \in [0, T)$, suppose that the maximum of radial function $\rho(\cdot, t)$ is attained at some $u_t \in \mathbb{S}^{n-1}$. Let

$$
R_t = \max_{u \in \mathbb{S}^{n-1}} \rho(u, t) = \rho(u_t, t)
$$

for some $u_t \in \mathbb{S}^{n-1}$. By the definition of support function, we have

$$
h(x,t) \ge R_t \langle x, u_t \rangle, \quad \forall x \in \mathbb{S}^{n-1}
$$

.

Denote the hemisphere containing u_t by $S_{u_t}^+ = \{x \in \mathbb{S}^{n-1} : \langle x, u_t \rangle > 0\}$. Since $p > 1$, we have

$$
J(0) = J(t) \ge \int_{S_{u_t}^+} h^p \frac{1}{f(x)} dx
$$

\n
$$
\ge \int_{S_{u_t}^+} R_t^p \langle x, u_t \rangle^p \frac{1}{f(x)} dx \ge \frac{1}{f_{\text{max}}} \int_{S_{u_t}^+} R_t^p \langle x, u_t \rangle^p dx
$$

\n
$$
= \frac{1}{f_{\text{max}}} \int_{S^+} R_t^p x_1^p dx,
$$

where $S^+ = \{x \in \mathbb{S}^{n-1} : x_1 > 0\}.$

Denote $S_1 = \{x \in \mathbb{S}^{n-1} : x_1 \ge 1/2\}$, then

$$
J(0) \ge \frac{1}{f_{\max}} \int_{S_1} R_t^p(\frac{1}{2})^p \, \mathrm{d}x = \frac{1}{f_{\max}} R_t^p(\frac{1}{2})^p |S_1|,
$$

which implies that R_t is uniformly bounded from above.

Now, we estimate the lower bound of h. First we explain that $\eta(t)$ is bounded from above.

Since mixed volumes are monotonic increasing, see [\[14,](#page-14-1) page 282], we have for each $t \in [0, T),$

(14)
$$
h_{\min}^{k+1}(t) \le \frac{\int_{\mathbb{S}^{n-1}} h \sigma_k \, dx}{\omega_{n-1}} \le h_{\max}^{k+1}(t),
$$

here $h_{\min}(t) = \min_{x \in \mathbb{S}^{n-1}} h(x, t)$ and $h_{\max}(t) = \max_{x \in \mathbb{S}^{n-1}} h(x, t)$.

Now we recall the definition of $\eta(t)$ and notice that $J(t)$ is unchanged along the flow [\(2\)](#page-1-0). From the upper bound of $h_{\text{max}}(t)$ and [\(14\)](#page-6-0), we have

 $\eta(t) \leq c_3$

for some positive constant c_3 independent of t .

Suppose the minimum of h is attained at a point (y_t, t) . It follows that

 $\sigma_k(y_t, t) \geq h_{\min}^k(t).$

Then in the sense of the lim inf of difference quotient, we have

$$
\frac{\partial h_{\min}(t)}{\partial t} \ge f_{\min} h_{\min}^{k+2-p+q-n} - c_3 h_{\min}.
$$

The right hand of the above inequality is positive for $h_{\min}(t)$ small enough if $k +$ $1 - p + q - n < 0$. The lower bound of $h_{\min}(t)$ follows from the maximum principle.

 \Box

Remark 1. When $\eta = 1$, $J(t)$ is not unchange along the flow any more. The upper bound of h can be estimated as follows.

Suppose the maximum of $h(x,t)$ is attained at a point (x_t, t) . At (x_t, t) ,

$$
\sigma_k(x_t, t) \le h_{\max}^k(t).
$$

Hence, we have

$$
\frac{\partial h_{\max}(t)}{\partial t} \le f_{\max} h_{\max}^{k+2-p+q-n} - h_{\max}.
$$

The right hand of the above inequality becomes negative for $h_{\text{max}}(t)$ large enough if $k+1-p+q-n<0$. The upper bound of $h_{\max}(t)$ follows. The lower bound $h(x,t)$ can be obtained by using the same method for the case $\eta(t) \neq 1$.

By the equality $\rho^2 = h^2 + |\nabla h|^2$, we can obtain the gradient estimate of support function from Lemma [2.](#page-5-0)

Corollary 2. Under the assumptions of Lemma [2,](#page-5-0) we have

$$
|\nabla h(x,t)| \le C, \quad \forall (x,t) \in \mathbb{S}^{n-1} \times [0,T),
$$

where C is a positive constant depending only on constants in Lemma [2.](#page-5-0)

The uniform bounds of $\eta(t)$ can be derived from Lemma [2.](#page-5-0)

Lemma 3. Under the assumptions of Lemma [2,](#page-5-0) $\eta(t)$ is uniformly bounded above and below from zero.

Proof. From the proof of Lemma [2,](#page-5-0) we know $\eta(t)$ has positive upper bound and

$$
h_{\min}^{k+1}(t) \le \frac{\int_{\mathbb{S}^{n-1}} h \sigma_k \, dx}{\omega_{n-1}} \le h_{\max}^{k+1}(t).
$$

Lemma [2](#page-5-0) also gives

$$
\int_{\mathbb{S}^{n-1}} \rho^{q-n} h \sigma_k \, \mathrm{d}x \ge c \int_{\mathbb{S}^{n-1}} h \sigma_k \, \mathrm{d}x,
$$

here c is a constant depending on the bounds of $h(x, t)$. This together with the uniform of $h(x, t)$ implies that $\eta(t)$ is bounded from below.

 \Box

To obtain the long-time existence of the flow [\(2\)](#page-1-0), we need to establish the uniform bounds on principal curvatures. By Lemma [2,](#page-5-0) for any $t \in [0, T)$, $h(\cdot, t)$ always ranges within a bounded interval $I' = [1/C, C]$, where C is the constant in Lemma [2.](#page-5-0) First, we give the estimates of σ_k .

Lemma 4. Under the assumptions of Lemma [2,](#page-5-0)

$$
\frac{1}{C} \le \sigma_k(x, t) \le C, \quad \forall (x, t) \in \mathbb{S}^{n-1} \times [0, T),
$$

where C is a positive constant independent of t .

Proof. Recall that $F = h^{2-p} \rho^{q-n} \sigma_k f(x)$. According to Lemma [2,](#page-5-0) uniform bounds of σ_k will follow from those of F.

First, we compute the evolution equation of F . Since

$$
\partial_t \sigma_k = \sigma_k^{ij} \partial_t (\nabla_{ij} h + \delta_{ij} h)
$$

\n
$$
= \sigma_k^{ij} \nabla_{ij} (\partial_t h) + \sigma_k^{ij} \delta_{ij} \partial_t h
$$

\n
$$
= \sigma_k^{ij} \nabla_{ij} F - \eta(t) \sigma_k^{ij} \nabla_{ij} h + \sigma_k^{ij} \delta_{ij} F - \eta(t) \sigma_k^{ij} \delta_{ij} h
$$

\n
$$
= \sigma_k^{ij} \nabla_{ij} F + \sigma_k^{ij} \delta_{ij} F - k \sigma_k \eta(t).
$$

The above equality and [\(11\)](#page-4-0) gives that

$$
\partial_t F = (2-p)f(x)h^{1-p}\rho^{q-n}\sigma_k \partial_t h + (q-n)f(x)h^{2-p}\rho^{q-n-1}\sigma_k \partial_t \rho + f(x)h^{2-p}\rho^{q-n}\partial_t \sigma_k
$$

=
$$
(q-n+2-p)\frac{F^2}{h} - (q-n+k+2-p)\eta(t)F + NF\sigma_k^{ij}\delta_{ij} + N\sigma_k^{ij}\nabla_{ij}F.
$$

Next, we consider the evolution equation of $\frac{F}{h} = f(x)h^{1-p}\rho^{q-n}\sigma_k$.

$$
\partial_t \left(\frac{F}{h} \right) - N \sigma_k^{ij} \nabla_{ij} \left(\frac{F}{h} \right)
$$
\n
$$
= \frac{1}{h} (\partial_t F - N \sigma_k^{ij} \nabla_{ij} F) - \frac{F}{h^2} (\partial_t h - N \sigma_k^{ij} \nabla_{ij} h) + 2 \frac{N}{h} \sigma_k^{ij} \nabla_i \left(\frac{F}{h} \right) \nabla_j h
$$
\n(15)\n
$$
= (q - n + k + 1 - p) \left(\frac{F}{h} \right)^2 - (q - n + k + 1 - p) \eta(t) \left(\frac{F}{h} \right)
$$
\n
$$
+ 2 \frac{N}{h} \sigma_k^{ij} \nabla_i \left(\frac{F}{h} \right) \nabla_j h.
$$

Since $\eta(t)$ is uniformly bounded and $q - n + k + 1 - p < 0$, we have $\frac{F}{h}$ is bounded from below and above. The uniform bounds on σ_k follow.

Now we can derive the upper bounds of principal curvatures $\kappa_i(x, t)$ of M_t for $i = 1, \cdots, n - 1.$

Lemma 5. Under the assumptions of Theorem [1,](#page-2-0) we have

$$
\kappa_i \le C, \quad \forall (x, t) \in \mathbb{S}^{n-1} \times [0, T),
$$

where C is a positive constant independent of t .

Proof. By rotation, we assume that the maximal eigenvalue of $\frac{b^{ij}}{l}$ h at t is attained at point x_t in the direction of the unit vector $e_1 \in T_{x_t} \mathbb{S}^{n-1}$. We also choose orthonormal vector field such that b^{ij} is diagonal.

By the evolution equation of b^{ij} in Lemma [1,](#page-4-1) we have

$$
\partial_t \left(\frac{b^{11}}{h} \right) - N \sigma_k^{ij} \nabla_{ij} \left(\frac{b^{11}}{h} \right)
$$
\n
$$
= \frac{2}{h} N \eta(t) \sigma_k^{ij} \nabla_i \frac{b^{11}}{h} \nabla_j h + \frac{N}{h^2} b^{11} \sigma_k^{ij} \nabla_{ij} h - (k+1) \frac{N}{h} \sigma_k (b^{11})^2 + \frac{N}{h} \sigma_k^{ij} \delta_{ij} b^{11}
$$
\n
$$
- \frac{N}{h} (b^{11})^2 (\sigma_k^{ij,mn} + 2 \sigma_k^{im} b^{nj}) \nabla_1 b_{ij} \nabla_1 b_{mn}
$$
\n
$$
- \frac{1}{h} (b^{11})^2 (\nabla_{11} N \sigma_k + 2 \nabla_1 \sigma_k \nabla_1 N) - \frac{b^{11}}{h^2} N \sigma_k + \frac{2b^{11}}{h} \eta(t)
$$
\n
$$
= \frac{2}{h} N \sigma_k^{ij} \nabla_i \frac{b^{11}}{h} \nabla_j h - (k+1) \frac{N}{h} \sigma_k (b^{11})^2 - \frac{N}{h} (b^{11})^2 (\sigma_k^{ij,mn} + 2 \sigma_k^{im} b^{nj}) \nabla_1 b_{ij} \nabla_1 b_{mn}
$$
\n
$$
- \frac{1}{h} (b^{11})^2 (\nabla_{11} N \sigma_k + 2 \nabla_1 \sigma_k \nabla_1 N) + (k-1) \frac{b^{11}}{h^2} N \sigma_k + \frac{2b^{11}}{h} \eta(t).
$$

According to inverse concavity of $(\sigma_k)^{\frac{1}{k}}$, we obtain by [\[16\]](#page-14-3)

$$
(\sigma_k^{ij,mn} + 2\sigma_k^{im}b^{nj})\nabla_1b_{ij}\nabla_1b_{mn} \ge \frac{k+1}{k}\frac{(\nabla_1\sigma_k)^2}{\sigma_k}.
$$

On the other hand, by Schwartz inequality, the following inequality holds

$$
2|\nabla_1 \sigma_k \nabla_1 N| \leq \frac{k+1}{k} \frac{N(\nabla_1 \sigma_k)^2}{\sigma_k} + \frac{k}{k+1} \frac{\sigma_k (\nabla_1 N)^2}{N}.
$$

Hence, we have at (x_t, t)

$$
\partial_t \frac{b^{11}}{h} \le -\frac{(b^{11})^2}{h} \sigma_k \left[\nabla_{11} N - \frac{k}{k+1} \frac{(\nabla_1 N)^2}{N} + (k+1)N + (1-k) \frac{Nb_{11}}{h} \right] + \frac{2b^{11}}{h} \eta(t).
$$

Let s be the arc-length of the great circle passing through x_t with the unit tangent vector e_1 . Notice that

$$
\nabla_{11}N - \frac{k}{k+1}\frac{(\nabla_1N)^2}{N} + (k+1)N = (k+1)N^{\frac{k}{k+1}}\left(N^{\frac{1}{k+1}} + (N^{\frac{1}{k+1}})_{ss}\right).
$$

It is easy to compute

$$
N_s = f_s h^{2-p} \rho^{q-n} + (2-p) f h^{1-p} \rho^{q-n} h_s + (q-n) f h^{2-p} \rho^{q-n-2} (h h_s + h_{ss} h_s)
$$

\n
$$
N_{ss} = f_{ss} h^{2-p} \rho^{q-n} + 2(2-p) h^{1-p} \rho^{q-n} f_s h_s + 2(q-n) h^{2-p} \rho^{q-n-2} f_s h_s b_{ss}
$$

\n
$$
+ 2(q-n)(2-p) f h^{1-p} \rho^{q-n-2} h_s^2 b_{ss} + (2-p)(1-p) f h^{-p} \rho^{q-n} h_s^2
$$

\n
$$
+ (q-n)(q-n-2) f h^{2-p} \rho^{q-n-4} b_{ss}^2 h_s^2 + (2-p) f h^{1-p} \rho^{q-n} h_{ss}
$$

\n
$$
+ (q-n) f h^{2-p} \rho^{q-n-2} (b_{ss}^2 - h b_{ss} + h_s^2 + h_{ssm} h_m).
$$

\n10

We have by direct computations

$$
1 + N^{-\frac{1}{k+1}} (N^{\frac{1}{k+1}})_{ss}
$$

= $1 + \frac{1}{k+1} N^{-1} N_{ss} - \frac{k}{(k+1)^2} N^{-2} N_s^2$
= $1 + \frac{1}{k+1} f_{ss} f^{-1} + \frac{1}{k+1} 2(2-p) h^{-1} f^{-1} f_s h_s + \frac{1}{k+1} 2(q-n) f^{-1} \rho^{-2} f_s h_s b_{ss}$
 $+ \frac{1}{k+1} 2(q-n) (2-p) h^{-1} \rho^{-2} h_s^2 b_{ss} + \frac{1}{k+1} (2-p) (1-p) h^{-2} h_s^2$
 $+ \frac{1}{k+1} (q-n) (q-n-2) \rho^{-4} b_{ss}^2 h_s^2 + \frac{1}{k+1} (2-p) h^{-1} h_{ss}$
 $+ \frac{1}{k+1} (q-n) \rho^{-2} (b_{ss}^2 - h b_{ss} + h_s^2 + h_{ssm} h_m)$
 $- \frac{k}{(k+1)^2} f_s^2 f^{-2} - \frac{k}{(k+1)^2} (2-p)^2 h^{-2} h_s^2 - \frac{k}{(k+1)^2} (q-n)^2 \rho^{-4} b_{ss}^2 h_s^2$
 $- \frac{k}{(k+1)^2} 2(2-p) f^{-1} h^{-1} f_s h_s - \frac{k}{(k+1)^2} 2(q-n) f^{-1} \rho^{-2} f_s h_s b_{ss}$
 $- \frac{k}{(k+1)^2} 2(2-p) (q-n) h^{-1} \rho^{-2} h_s^{-2} b_{ss}.$
= $1 + \frac{1}{k+1} f_{ss} f^{-1} - \frac{k}{(k+1)^2} f_s^2 f^{-2} + \frac{2-p}{k+1} h^{-1} h_{ss}$
 $+ \frac{2(2-p)}{(k+1)^2} h^{-1} f^{-1} f_s h_s + \frac{2(q-n)}{(k+1)^2} f^{-1} \rho^{-2} f_s h_s b_{ss}$
 $+ \frac{2}{(k+1)^2} (2-p) (q-n) h^{-1} \rho^{-2} h_s^2 b_{ss} + \frac{1}{(k+1)^2} (p-2) (p+k-1) h^{-2} h_s^2$
 $+ \frac{q-n}{$

At (x_t, t) , we have

$$
0 = \nabla_m \frac{b^{11}}{h} = \frac{\nabla_m b^{11}}{h} - \frac{b^{11}}{h^2} h_m.
$$

Then

$$
h_{ssm}h_m = (b_{ss} - h)_m h_m = b_{ssm}h_m - h_m^2
$$

= $-\frac{b_{ss}}{h}h_m^2 - h_m^2$.

From this we get

$$
b_{ss}^{2} - hb_{ss} + h_{s}^{2} + h_{ssm}h_{m}
$$

= $b_{ss}^{2} - hb_{ss} + h_{s}^{2} - \frac{b_{ss}}{h}h_{m}^{2} - h_{m}^{2}$
= $b_{ss}^{2} + h_{s}^{2} - \frac{b_{ss}}{h}\rho^{2} - \rho^{2} + h^{2}$.

Now, we have

$$
1 + N^{-\frac{1}{k+1}} \left(N^{\frac{1}{k+1}} \right)_{ss}
$$

= $1 + \frac{1}{k+1} f_{ss} f^{-1} - \frac{k}{(k+1)^2} f_s^2 f^{-2} + \frac{2-p}{k+1} h^{-1} h_{ss}$
 $+ \frac{2(2-p)}{(k+1)^2} h^{-1} f^{-1} f_s h_s + \frac{2(q-n)}{(k+1)^2} f^{-1} \rho^{-2} f_s h_s b_{ss}$
 $+ \frac{2}{(k+1)^2} (2-p)(q-n) h^{-1} \rho^{-2} h_s^2 b_{ss} + \frac{1}{(k+1)^2} (p-2)(p+k-1) h^{-2} h_s^2$
 $+ \frac{q-n}{(k+1)^2} (q-n-2k-2) \rho^{-4} b_{ss}^2 h_s^2$
 $- \frac{1}{k+1} (q-n) + \frac{1}{k+1} (q-n) \rho^{-2} (b_{ss}^2 - \frac{b_{ss}}{h} \rho^2 + h_s^2 + h^2).$

Since $1 > \rho^{-2} h_s^2$ and $q > n + k + 1$, we have

$$
\frac{2(q-n)}{(k+1)^2}f^{-1}\rho^{-2}f_sh_sb_{ss} + \frac{q-n}{(k+1)^2}(q-n-2k-2)\rho^{-4}b_{ss}^2h_s^2 + \frac{1}{k+1}(q-n)\rho^{-2}b_{ss}^2
$$

\n
$$
>\frac{2(q-n)}{(k+1)^2}f^{-1}\rho^{-2}f_sh_sb_{ss} + \frac{q-n}{(k+1)^2}(q-n-k-1)\rho^{-4}b_{ss}^2h_s^2
$$

\n
$$
= \frac{q-n}{(k+1)^2}\left((q-n-k-1)^{\frac{1}{2}}\rho^{-2}h_sb_{ss} + f_sf^{-1}\frac{1}{(q-n-k-1)^{\frac{1}{2}}}\right)^2
$$

\n
$$
-\frac{q-n}{(k+1)^2}\frac{1}{q-n-k-1}f_s^2f^{-2}.
$$

We also have

$$
\frac{2(2-p)}{(k+1)^2}h^{-1}f^{-1}f_sh_s + \frac{1}{(k+1)^2}(p-2)(p+k-1)h^{-2}h_s^2
$$

=
$$
\frac{(p-2)}{(k+1)^2}\left((p+k-1)^{\frac{1}{2}}h^{-1}h_s - \frac{1}{(p+k-1)^{\frac{1}{2}}}f_sf^{-1}\right)^2
$$

-
$$
\frac{(p-2)}{(k+1)^2}\frac{1}{p+k-1}f_s^2f^{-2}.
$$

Noticing that $p \geq 2$, we have

$$
1 + N^{-\frac{1}{k+1}} \left(N^{\frac{1}{k+1}}\right)_{ss}
$$

\n
$$
\geq \frac{p+n-q+k-1}{k+1} + \frac{2-p-q+n}{k+1}h^{-1}b_{ss} + \frac{2}{(k+1)^2}(2-p)(q-n)\rho^{-2}h^{-1}b_{ss}h_s^2
$$

\n
$$
+ \frac{1}{k+1}f_{ss}f^{-1} - \left(\frac{k}{(k+1)^2} + \frac{1}{(k+1)^2}\frac{q-n}{q-n-k-1} + \frac{1}{(k+1)^2}\frac{p-2}{p+k-1}\right)f_s^2f^{-2}
$$

\n
$$
= \frac{2-p-q+n}{k+1}h^{-1}b_{ss} + \frac{2}{(k+1)^2}(2-p)(q-n)\rho^{-2}h^{-1}b_{ss}h_s^2
$$

\n
$$
+ \frac{1}{k+1}f^{-1}\left(f_{ss} - \frac{1}{k+1}\left(k+\frac{q-n}{q-n-k-1} + \frac{p-2}{p+k-1}\right)f_s^2f^{-1} + (p+k-1-q+n)f\right)
$$

Since f satisfies (A) , we have

$$
\partial_t \frac{b^{11}}{h} \le -\left(\frac{b^{11}}{h}\right)^2 N \sigma_k (c_f h - c_0 b_{11}) + \frac{2b^{11}}{h} \eta(t).
$$

Here c_f is a positive constant depending on f and c_0 is a positive constant depending on the uniform bounds of h and $|\nabla h|$. By the uniform bounds on h, f, η and σ_k , we conclude

$$
\partial_t \frac{b^{11}}{h} \le -c_1 \left(\frac{b^{11}}{h}\right)^2 + c_2 \frac{b^{11}}{h}.
$$

Here c_1 and c_2 are positive constants independent of t. The maximum principle then gives the upper bound of b^{11} and the result follows.

proof of Theorem 1. Combining Lemma [4](#page-7-0) and Lemma [5,](#page-8-0) we see that the principal curvatures of M_t has uniform positive upper and lower bounds. This together with Lemma [2](#page-5-0) and Corollary [2](#page-7-1) implies that the evolution equation [\(9\)](#page-3-4) is uniformly parabolic on any finite time interval. Thus, the result of [\[11\]](#page-13-10) and the standard parabolic theory show that the smooth solution of [\(9\)](#page-3-4) exists for all time. And by these estimates again, a subsequence of M_t converges in C^{∞} to a positive, smooth, strictly convex hypersurface \overline{M}_{∞} in \mathbb{R}^n .

In general, the problem [\(9\)](#page-3-4) does not have any variational structure, we can not expect the convergence of the flow to a solution for all initial hypersurfaces. In the next section, we will choose an special to obtain the existence of smooth solutions for equation [\(9\)](#page-3-4) with $c = 1$.

4. Existence of solution

Since $q-n+k+1-p < 0$, we can choose initial hypersurface satisfying $\left(\frac{F}{h}-1\right)_{M_0}$ 0. We have proved that flow [\(2\)](#page-1-0) exists for all time when $\eta = 1$. We will use flow [\(9\)](#page-3-4) with $\eta = 1$ to obtain the convergence.

By (15) , we have

$$
\partial_t \left(\frac{F}{h} - 1 \right) - N \sigma_k^{ij} \nabla_{ij} \left(\frac{F}{h} - 1 \right)
$$

= $(q - n + k + 1 - p) \left(\frac{F}{h} - 1 \right) \frac{F}{h} + 2 \frac{N}{h} \sigma_k^{ij} \nabla_i \left(\frac{F}{h} \right) \nabla_j \left(\frac{F}{h} - 1 \right).$

From the assumption about the initial data, the positivity of $\frac{F}{h} - 1$ is preserved along the flow and

$$
\partial_t h = F - h > 0
$$

holds for all time. Since

Since h is positive and bounded from above and below, we have

$$
C \ge h(x, t) - h(x, 0) = \int_0^{+\infty} (F - h) dt
$$

This implies that there exists a subsequence of times $t_i \to \infty$ such that

$$
F(t_j) - h(t_j) \to 0 \text{ as } t_j \to \infty.
$$

By passing to the limit, we obtain

$$
\tilde{h}^{1-p}\tilde{\rho}^{q-n}\tilde{\sigma_k}(x)f(x) = 1 \text{ on } \mathbb{S}^{n-1},
$$

where $\widetilde{\sigma}_k$, h and $\widetilde{\rho}$ are the k-th elementary symmetric function for principal curvature radii, the support function and radial function of M_{∞} . The proof of Corollary [1](#page-2-1) is complected.
