# SPLITTING CRITERIA FOR PROJECTIVE MODULES OVER POLYNOMIAL ALGEBRAS 

SOURJYA BANERJEE AND MRINAL KANTI DAS

#### Abstract

This article investigates the splitting problem for finitely generated projective modules $P$ over polynomial algebras $A[T]$ on various base rings, where $\operatorname{rank}(P)=$ $\operatorname{dim}(A)$. Our main approaches are (1) in terms of generic sections, and (2) in terms of monic inversion principles. We prove that if $P$ has a complete intersection generic section, then it splits off a free summand of rank one, where $A$ is an affine algebra over an algebraically closed field of characteristic $\neq 2$. We give a partial answer to an old question due to Roitman on monic inversion principle for projective modules over affine $\mathbb{Z}$-algebras. Whenever $A$ is an affine algebra over $\overline{\mathbb{F}}_{p}$, we prove a monic inversion principle for ideals. We further exhibit some applications.

## 1. Introduction

Let $A$ be a commutative Noetherian ring of (Krull) dimension $d$ and $P$ be a finitely generated projective $A$-module. J. P. Serre [26] proved that $P$ splits off a free summand of rank one whenever $\operatorname{rank}(P)>d$. Due to a well-known example of the projective module corresponding to the tangent bundle of an even dimensional real sphere, this result is the best possible in general. Therefore, investigating conditions under which a projective module (having rank less than or equal to the dimension of the ring) to split off a free summand of rank one becomes one of the recurrent themes in this area.

In this article we investigate splitting criteria for projective modules defined over polynomial algebras using two approaches. We elaborate them below.
1.1. In terms of generic sections. Let $Q$ be a projective $A$-module. A remarkable result of Eisenbud-Evans [14] tells us that most of the $A$-linear maps $Q \rightarrow A$ has the property that the image ideal has height at least the rank of $Q$. A surjection $\alpha: Q \rightarrow I$ is called a generic surjection of $Q$ if $\operatorname{ht}(I)=\operatorname{rank}(Q)$ (in that case, $I$ will be called a generic section of $Q$ ). N. Mohan Kumar [19] proved the following:

[^0]Theorem 1.1. [19] Let $A$ be an affine algebra of dimension $d \geq 2$ over an algebraically closed field $k$ and $P$ be a projective $A$-module of rank $d$. Then $P$ splits off a free summand of rank one if and only if there exists a generic section I of $P$ such that $I$ is generated by $d$ elements.

Note that such a result is not possible if the ground field is not algebraically closed, as evidenced by the same example on the tangent bundle of the real 2 -sphere, mentioned earlier. Further, over algebraically closed ground fields, investigating the existence of such a criterion when $\operatorname{rank}(P)<\operatorname{dim}(A)$, becomes the next challenge in this theme. In this regard, we consider polynomial algebras. We prove the following theorem.

Theorem 1.2. (Theorem 3.5) Let $A$ be an affine algebra of dimension $d \geq 2$ over an algebraically closed field $k$ where char $(k) \neq 2$. Let $P$ be a projective $A[T]$-module of rank $d$ with trivial determinant. Assume that there exists a generic section I of $P$ such that $I$ is generated by d elements. Then $P$ splits a free summand of rank one.

In the case when $\operatorname{char}(k)=0$, the above result was proved by S. M. Bhatwadekar and R. Sridharan [8, Theorem 4.5].

With the same $A$ as in the above theorem, we obtain a corollary: Any stably free $A[T]-$ module of rank d always splits a free summand of rank one.

If the base field is $\overline{\mathbb{F}}_{p}, \mathrm{M}$. K. Das [11] proved that the nature of the generic section dictates the splitting problem for $P$ for $\operatorname{rank}(P)=\operatorname{dim}(A)-1$. In particular, he proved the following:

Theorem 1.3. [11, Theorem 5.1 and 5.8] Let $p \neq 2$ and $A$ be an affine algebra of dimension $d$ over $\overline{\mathbb{F}}_{p}$. Let $P$ be a projective $A$-module of rank $d-1$ with trivial determinant. Moreover assume that either of the following conditions hold:
(1) $d \geq 3$ and $A$ is smooth or;
(2) $d \geq 5$ and $\frac{1}{(d-1)!} \in A$.

Then $P$ splits off a free summand of rank one if and only if there exists a generic section I of $P$ such that I is generated by $d-1$ elements.

Here we would like to take the opportunity to remark on the significance of the hypothesis: "smoothness", or $(d-1)$ ! being invertible. A critical inspection of his proofs indicates that he used some cancellation results in his arguments. While dealing with cancellation problems, the hypothesis $(d-1)$ ! is invertible, is fundamental in the literature due to the seminal technique of factorial rows, introduced by Swan-Tower and Suslin. In the other situation whenever the ring is smooth, he used much stronger result due to Fasel [15], to establish the same. But whenever the ring has polynomial
structure, we show that one can give a complete solution, without even using such a strong cancellation result as of Fasel. In particular, we prove the following:

Theorem 1.4. (Theorem 7.3) Let $p \neq 2$ and $A$ be an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension $d \geq 2$. Let $P$ be a projective $A[T]$-module of rank $d$ with trivial determinant. Then $P$ splits off a free summand of rank one if and only if there exists a generic section I of $P$ such that I is generated by delements.

Using similar techniques as above we observe that, with the help of [13, Theorem 1.2] one can improve Theorem 1.3. In particular, we prove the following:

Theorem 1.5. Let $p \neq 2,3$ and $A$ be an affine algebra of dimension $d \geq 5$ over $\overline{\mathbb{F}}_{p}$. Let $P$ be a projective $A$-module of rank $d-1$ with trivial determinant. Then $P$ splits off a free summand of rank one if and only if there exists a generic section I of $P$ such that I is generated by $d-1$ elements.
1.2. In terms of monic inversion principles. Recall that the ring $A(T)$ is obtained from the polynomial ring $A[T]$ by inverting all monic polynomials. The following question is due to Roitman [25]:

Question 1.6. Let $A$ be a commutative Noetherian ring of dimension $d \geq 2$ and $P$ be a projective $A[T]$-module of rank $d$. Suppose that there exists a surjection $\alpha: P \rightarrow I$, where $I \subset A[T]$ is an ideal. Moreover assume that $I$ contains a monic polynomial in $T$. Then does $P$ split a free summand of rank one?

The above question is open in general. In the same paper Roitman answered the question affirmatively over local rings. Later S. M. Bhatwadekar and R. Sridharan [8, Theorem 3.4] gave an affirmative answer when the ring contains an infinite field.

We give an affirmative answer to the above question over finite $\mathbb{Z}$-algebras. We prove:

Theorem 1.7. (Theorem 4.2) Let $A$ be a finite $\mathbb{Z}$-algebra of dimension $d \geq 2$ such that there exists an integer $n \geq 2$ that is invertible in $A$. Let $P$ be a projective $A[T]$-module of rank $d$ with trivial determinant, and $I \subset A[T]$ be an ideal of height $d$ containing a monic polynomial in $T$. Suppose that there exists a surjection $\alpha: P \rightarrow I$. Then $P$ splits a free summand of rank one.

On a related note, let us recall the following question on "monic inversion principle" for ideals. The notation $\mu(-)$ stands for the minimal number of generators.
Question 1.8. Let $A$ be a commutative Noetherian ring of dimension $d \geq 2$ and $I \subset$ $R[T]$ be an ideal such that $\operatorname{ht}(I)=\mu\left(I / I^{2}\right)=d$. Moreover assume that $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+$
$I^{2}$. Suppose that there exists $F_{i} \in I A(T)$ such that $I A(T)=\left\langle F_{1}, \ldots, F_{d}\right\rangle$, with $F_{i}-f_{i} \in$ $I A(T)^{2}$. Then does there exist $g_{i} \in I$, such that $I=\left\langle g_{1}, \ldots, g_{d}\right\rangle$, with $g_{i}-f_{i} \in I^{2}$ ?

Question 1.8 has a negative answer for $d=2$ ( see [5, Example 3.15] ). Whenever $d \geq 3$ this question has an affirmative answer in the following cases:

- $A$ is a local ring [9, Proposition 5.8(1)].
- $A$ is an affine domain over an algebraically closed field of characteristic zero [9, Proposition 5.8(2)].
- $A$ is a regular domain which is essentially of finite type over an infinite perfect field $k$ of characteristic unequal to 2 [12, Theorem 5.11].
- $A$ is a real affine domain such that: either there are no real maximal ideals, or the intersection of all real maximal ideals has height at least one [1, Theorem 5.7].

We prove the following result, using methods entirely different from the works mentioned above.

Theorem 1.9. (Theorem 5.1) Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$ and $I \subset$ $R[T]$ be an ideal such that $h t(I)=\mu\left(I / I^{2}\right)=d$. Moreover assume that $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$. Suppose that there exists $F_{i} \in \operatorname{IR}(T)$ such that $\operatorname{IR}(T)=\left\langle F_{1}, \ldots, F_{d}\right\rangle$, with $F_{i}-f_{i} \in \operatorname{IR}(T)^{2}$. Then there exists $g_{i} \in I$, such that $I=\left\langle g_{1}, \ldots, g_{d}\right\rangle$, where $g_{i}-f_{i} \in I^{2}$.

As an application of the above result we prove some addition and subtraction principles on $R[T]$, where $R$ is an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Let $P$ be a projective $R[T]$-module of rank $d$ with a trivial determinant and $\chi: R[T] \cong \wedge^{d} P$ be an isomorphism. We then assign a "local orientation" $\left(I, \omega_{I}\right) \in E^{d}(R[T])$ to the pair $(P, \chi)$ and show that $P$ splits a free summand of rank one if and only if the image of $\left(I, \omega_{I}\right)$ in the group $E^{d}(R[T])$ vanishes. Here $E^{d}(R[T])$ is the $d$-th Euler class group of $R[T]$. Moreover assuming ( $d-1$ )! is invertible, we show that $E^{d}(R[T])$ is the obstruction group to dictate the splitting problem of $P$. In [11], M. K. Das showed that $E^{d-1}(A)$ is the precise obstruction group to dictate the splitting problem, where $A$ is a $d$-dimensional smooth $\overline{\mathbb{F}}_{p}$-algebra. Here we remark that, over smooth polynomial extensions since projective modules are extended, removing the "smoothness" hypothesis is crucial.

## 2. Preliminaries

We recollect various results from the literature. We start with a lemma of N. M. Kumar, recast slightly to suit our needs.

Lemma 2.1. [17] Let $A$ be a Noetherian ring and $I$ be an ideal of $A$. Let $J, K$ be ideals of A contained in $I$ such that $K \subset I^{2}$ and $I=J+K$. Then there exists $e \in K$ such that $e(1-e) \in J$ and $I=\langle J, e\rangle$.

The following lemma is known as "Moving Lemma". We restate it to suit our requirements. The proof is given in [16, Corollary 2.14], (one just needs to use [10, Theorem 2,4] in the appropriate place to establish this version).

Lemma 2.2. (Moving Lemma) Let $A$ be a commutative Noetherian ring and $I \subset A$ be an ideal such that $\mu\left(I / I^{2}\right)=n$. Let $I=\left\langle a_{1}, \ldots, a_{n}\right\rangle+I^{2}$. Then there exists an ideal $J \subset A$, either of height $n$ or $J=A$, with the property that $I \cap J=\left\langle b_{1}, \ldots, b_{n}\right\rangle$, with $a_{i}-b_{i} \in I^{2}$ and $I+J=A$. Moreover, if $A$ is an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $n+1$ and $h t(I) \geq 1$, then $J$ can be chosen to be co-maximal with any ideal of height $\geq 1$.

The next theorem is an accumulation of results from different authors. For a proof one can see [11, Corollary 2.4].

Theorem 2.3. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$, and let $I \subset R$ be an ideal such that $\operatorname{dim}(R / I) \leq 1$. Then, we have the following assertions:
(1) The canonical map $S L_{n}(R) \rightarrow S L_{n}(R / I)$ is surjective for $n \geq 3$.
(2) If $\operatorname{dim}(R)=3$, then the canonical map $S L_{2}(R) \rightarrow S L_{2}(R / I)$ is surjective.

Then next lemma is crucial to this paper. It can be deduced following the proof of [7. Lemma 5.3]. For the sake of completeness we give a proof. But before that we recall a notation which will be used frequently.
Notation. Let $R$ be a ring. For any two matrix $M \in M_{m \times m}(R)$ and $N \in M_{n \times n}(R)$, by $M \perp N$ we denote the matrix

$$
\left(\begin{array}{cc}
M & 0 \\
0 & N
\end{array}\right) \in M_{(m+n) \times(m+n)}(R) .
$$

Lemma 2.4. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d+1 \geq 3$ and $I \subset R$ be an ideal such that $h t(I)=\mu\left(I / I^{2}\right)=d$. Let $\bar{f} \in R / I$ be a unit. Let $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$. Let $\alpha \in G L_{d}(R / I)$, such that $\operatorname{det}(\alpha)-f^{2} \in I$ and $\left(g_{1}, \ldots, g_{d}\right)=\left(f_{1}, \ldots, f_{d}\right) \alpha$. If $f_{1}, \ldots, f_{d}$ can be lifted to a set of $d$ generators of $I$, then $g_{1}, \ldots, g_{d}$ can also be lifted to a set of $d$ generators of $I$.

Proof. Let $I=\left\langle h_{1}, \ldots, h_{d}\right\rangle$ where $h_{i}-f_{i} \in I^{2}$. Note that after an elementary transformation we may always assume $\operatorname{ht}\left(\left\langle h_{1}, \ldots, h_{i}\right\rangle\right)=i$, for $i=1, \ldots, d$. Let $B=R /\left\langle h_{3}, \ldots, h_{d}\right\rangle$ and 'bar' denote going modulo $\left\langle h_{3}, \ldots, h_{d}\right\rangle$. Then $\operatorname{dim}(B) \leq 3$.

Since $f$ is a unit modulo $I$, we have $g \in R$ such that $f g-1 \in I$. Note that $\left(\bar{g}^{2}, \bar{h}_{2},-\bar{h}_{1}\right) \in \operatorname{Um}_{3}(B)$. By a result Swan-Towber the unimodular row $\left(\bar{g}^{2}, \bar{h}_{2},-\bar{h}_{1}\right)$ is
completable to an invertible matrix in $\mathrm{SL}_{3}(B)$. Using [7, Lemma 5.2] we get $\tau \in M_{2}(B)$ such that $\left(\bar{h}_{1}, \bar{h}_{2}\right) \tau=\left(\bar{h}_{1}^{\prime}, \bar{h}_{2}^{\prime}\right)$, where $\bar{I}=\left\langle\bar{h}_{1}^{\prime}, \bar{h}_{2}^{\prime}\right\rangle$ and $\operatorname{det}(\tau)-f^{2} \in I$.

Thus in the ring $R$ we get, $I=\left\langle h_{1}^{\prime}, h_{2}^{\prime}, h_{3}, \ldots, h_{d}\right\rangle$. Define $\theta=\tau \perp I_{d-2} \in \mathrm{GL}_{d}(R / I)$. Then note that $\left(h_{1}, h_{2}, h_{3}, \ldots, h_{d}\right) \theta=\left(h_{1}^{\prime}, h_{2}^{\prime}, h_{3}, \ldots, h_{d}\right)$ and $\operatorname{det}(\theta)-f^{2} \in I$. Since $\operatorname{det}(\theta)-\operatorname{det}(\alpha) \in I$, there exists $\epsilon^{\prime} \in \mathrm{SL}_{d}(R / I)$ such that $\theta \epsilon^{\prime}=\alpha$. Since $\operatorname{dim}(R / I)=1$, by Theorem 2.3 the natural map $\mathrm{SL}_{d}(R) \rightarrow \mathrm{SL}_{d}(R / I)$ is surjective. Therefore we can lift $\epsilon^{\prime}$ and get $\epsilon \in \mathrm{SL}_{d}(R)$ such that they are equal modulo $I$. Let $\left(G_{1}, \ldots, G_{d}\right)=$ $\left(h_{1}^{\prime}, h_{2}^{\prime}, h_{3}, \ldots, h_{d}\right) \epsilon$. Then note that $I=\left\langle G_{1}, \ldots, G_{d}\right\rangle$. It only remains to show $G_{i}-g_{i} \in I^{2}$.

Consider any $d$-tuple $\left[\left(a_{1}, \ldots, a_{d}\right)\right]$ as a map $(R / I)^{d} \rightarrow I / I^{2}$ sending $e_{i} \rightarrow a_{i} \bmod \left(I^{2}\right)$. Then we have $\left[\left(G_{1}, \ldots, G_{d}\right)\right]=\left[\left(h_{1}^{\prime}, h_{2}^{\prime}, h_{3}, \ldots, h_{d}\right) \epsilon\right]=\left[\left(h_{1}, h_{2}, h_{3}, \ldots, h_{d}\right) \theta \epsilon\right]=\left[\left(h_{1}, \ldots, h_{d}\right) \theta \epsilon^{\prime}\right]=$ $\left[\left(h_{1}, \ldots, h_{d}\right) \alpha\right]=\left[\left(f_{1}, \ldots, f_{d}\right) \alpha\right]=\left[\left(g_{1}, \ldots, g_{d}\right)\right]$. This completes the proof.

We end this section with a lemma whose proof can be found in [16, Lemma 5.5].
Lemma 2.5. Let $A$ be a Noetherian ring and $J \subset A$ be an ideal of height $n$. Let $f \in A \backslash\{0\}$ such that $J_{f}$ is a proper ideal of $A_{f}$. Assume that $J_{f}=\left(a_{1}, \ldots, a_{n}\right)$, where $a_{i} \in J$. Then, there exists $\sigma \in S L_{n}\left(A_{f}\right)$ such that $\left(a_{1}, \ldots, a_{n}\right) \sigma=\left(b_{1}, \ldots, b_{n}\right)$, where $b_{i} \in J \subset A$ and $h t\left(\left\langle b_{1}, \ldots, b_{n}\right\rangle A\right)=n$.

## 3. A splitting criterion via projective generation of complete INTERSECTION CURVES OVER ALGEBRAICALLY CLOSED FIELD OF <br> $$
\text { CHARACTERISTICS } \neq 2
$$

In this section we will first prove a cancellation result in dimension two over certain $C_{1}$ field of characteristic $\neq 2$. If the ring is smooth, then it is essentially contained in [28, Theorem 2.4]. Here we drop the smoothness assumption of A. A. Suslin's proof using an observation, similar to Parimala's, which is crucial in our set-up. The remaining part of this section is devoted to rediscover some of its consequences for a splitting criterion of projective modules. We begin with recalling the following definition.
Definition 3.1. Let $R$ be a ring. A vector $\left(a_{1}, \ldots, a_{n}\right) \in R^{n}$ is called a unimodular row of length $n$ if there exists $\left(b_{1}, \ldots, b_{n}\right) \in R^{n}$ such that $a_{1} b_{1}+\ldots+a_{n} b_{n}=1$. We will denote $\operatorname{Um}_{n}(R)$ by the set of all unimodular rows of length $n$.

Theorem 3.2. Let $k$ be an algebraically closed field of characteristic $\neq 2$. Let $R$ be an affine algebra over the $C_{1}$ field $k(T)$ of dimension 2. Then any stably free $R$-module is free. In particular, $\operatorname{Um}_{3}(R)=e_{1} S L_{3}(R)$.

Proof. First we observe that, there exists an affine $k$-algebra $A$ such that $S^{-1} A=R$, where $S=k[T] \backslash\{0\}$. Let $\eta$ be the nilradical of $R$. Since the canonical map $\mathrm{SL}_{3}(R) \rightarrow$ $\rightarrow \mathrm{SL}_{3}(R / \eta)$ is surjective, it is enough to assume that $R$ is reduced. In particular, this
will imply that $A$ is reduced. Let $\Im_{A}$ be the ideal defining the singular locus of $A$. As $k$ is algebraically closed, we have $\operatorname{ht}\left(\mathfrak{I}_{A}\right) \geq 1$.

We claim that there exists a non-zero divisor $a \in R$ such that $R_{a}$ is smooth. Take a non-zero divisor $t \in \mathfrak{I}_{A}$. Now if we take $a=\frac{t}{1} \in S^{-1} \mathfrak{I}_{A}$, then $R_{a}=\left(S^{-1} A\right)_{\frac{t}{1}}=$ $S^{-1}\left(A_{t}\right)$. Since localization preserves smoothness, $R_{a}$ is smooth. As $a \in R$ is a nonzero divisor, we are done.

Let $\left(a_{1}, a_{2}, a_{3}\right) \in \mathrm{Um}_{3}(R)$. Let $B=R /\langle a\rangle$ and 'bar' denote going modulo $\langle a\rangle$. Then we note that $\operatorname{dim}(B) \leq 1$. Therefore, in the ring $B$ we have $\operatorname{Um}_{3}(B)=e_{1} E_{3}(B)$. Since the canonical map $E_{3}(R) \rightarrow E_{3}(B)$ is a surjection, we may replace ( $a_{1}, a_{2}, a_{3}$ ) by $\left(a_{1}, a_{2}, a_{3}\right) \epsilon$ for some suitable $\epsilon \in E_{3}(R)$ and assume that $a_{1}, a_{2} \in\langle a\rangle$ and $a_{3}-1 \in\langle a\rangle$. Notice that $\left\langle a_{1}, a_{2}, a_{3}\right\rangle R \not \subset \bigcup_{p \in \mathfrak{s}} p$, where $\mathfrak{s}$ is the set of all minimal prime ideals of $R$. Hence using prime avoidance lemma we may replace $a_{3}$ by $a_{3}+\lambda_{1} a_{1}+\lambda_{2} a_{2}$ and further assume that $a_{3} \not \subset \bigcup_{p \in \mathfrak{s}} p$. So, $a_{3}$ is a non-zero divisor. And we still have $a_{3}-1 \in\langle a\rangle$.

Let $C=R /\left\langle a_{3}\right\rangle$. Then note that since $a_{3}-1 \in\langle a\rangle$, the curve $C$ is in fact smooth. Let 'tilde' denote going modulo $\left\langle a_{3}\right\rangle$. As $p \neq 2$, applying [28, Proposition 1.4] we get $S K_{1}(C)$ is a 2-divisible group. Hence there exist $b_{1}, b_{2} \in A$ such that $\left[\tilde{a_{1}}, \tilde{a_{2}}\right]=$ $\left[{\tilde{b_{1}}}^{2}, \tilde{b_{2}}\right]$ in $S K_{1}(C)$. That is, for some suitably chosen $\alpha \in \mathrm{SL}_{2}(C) \cap E(C)$ we have $\left(\tilde{a_{1}}, \tilde{a_{2}}\right) \alpha=\left(\tilde{b}_{1}^{2}, \tilde{b_{2}}\right)$. It follows from [28, Proposition 1.7] that there exist a canonical isomorphism $S K_{1}(C) \cong K_{1} S p(C)$. Since $[\alpha]=0$ in $S K_{1}(C)$ this will imply that $[\alpha]=0$ in $K_{1} S p(C)$. In particular, we get $\alpha \in \mathrm{SL}_{2}(C) \cap E p(C)$. Now using [28, Lemma 2.1] we can find a lift $\beta \in \mathrm{SL}_{2}(R) \cap E p(R)$ of $\alpha$ such that $\alpha \equiv \beta \bmod \left(\left\langle a_{3}\right\rangle\right)$. This will give us $\left(a_{1}, a_{2}, a_{3}\right)(\beta \perp 1)=\left(b_{1}^{2}, b_{2}, a_{3}\right) \bmod \left(E_{3}(R)\right)$. Now it follows from a result of Swan-Towber [29] that $\left(b_{1}^{2}, b_{2}, a_{3}\right)$ is completable to an invertible matrix and therefore so is $\left(a_{1}, a_{2}, a_{3}\right)$. This concludes the proof.

Remark 3.3. Note that if $\operatorname{char}(k)=0$, then Theorem 3.2 follows from Suslin's proof of [28, Theorem 2.4] together with the observation made by Parimala (cf. [24, Proposition 3.1]).

Theorem 3.4. Let $k$ be an algebraically closed field of chaaracteristic $\neq 2$. Let $R$ be an affine algebra over $k(T)$ of dimension $d$, where $d \geq 2$. Let $I \subset R$ be an ideal such that $h t(I)=$ $\mu(I)=d$. Then any set of generators of $I / I^{2}$ has a lift to a set of generators of $I$.

Proof. Let $I=\left\langle a_{1}, \ldots, a_{d}\right\rangle$ and assume that $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$ is given. We prove that there exist $F_{1}, \cdots, F_{d} \in I$ such that $I=\left\langle F_{1}, \ldots, F_{d}\right\rangle$ where $F_{i}-f_{i} \in I^{2}, i=1, \cdots, d$.

Replacing $\left(a_{1}, \ldots, a_{d}\right)$ by $\left(a_{1}, \ldots, a_{d}\right) \epsilon$ for a suitable $\epsilon \in E_{d}(R)$, we may always assume that $\operatorname{dim}\left(R /\left\langle a_{3}, \ldots, a_{d}\right\rangle\right) \leq 2$. Let $B=R /\left\langle a_{3}, \ldots, a_{d}\right\rangle$. Let 'bar' denote reduction modulo $\left\langle a_{3}, \ldots, a_{d}\right\rangle$. As an $R / I$-module two sets of generators of $I / I^{2}$ must differ by some invertible matrix $\alpha \in \mathrm{GL}_{d}(R / I)$. Let $\operatorname{det}(\alpha)=a \in(R / I)^{*}$ and $b \in R$ be such that
$a b-1 \in I$. Then it follows from Theorem 3.2 that the unimodular row $\left(\bar{b}, \bar{a}_{2},-\bar{a}_{1}\right)$ is completable to an invertible matrix in $B$. Applying [7. Lemma 5.2] we get $\tau \in M_{2}(B)$ such that $\left(\bar{a}_{1}, \bar{a}_{2}\right) \tau=\left(\bar{a}_{1}^{\prime}, \bar{a}_{2}^{\prime}\right)$, where $\bar{I}=\left\langle\bar{a}_{1}^{\prime}, \bar{a}_{2}^{\prime}\right\rangle$ and $\operatorname{det}(\tau)-a \in I$.

Coming back to the ring $R$ we gather that $I=\left\langle a_{1}^{\prime}, a_{2}^{\prime}, a_{3}, \ldots, a_{d}\right\rangle$. We define $\theta=\tau \perp$ $I_{d-2} \in \mathrm{GL}_{d}(R / I)$. Then note that $\left(a_{1}, a_{2}, a_{3}, \ldots, a_{d}\right) \theta=\left(a_{1}^{\prime}, a_{2}^{\prime}, a_{3}, \ldots, a_{d}\right)$ and $\operatorname{det}(\theta)-a \in$ $I$. Since $\operatorname{det}(\theta)-\operatorname{det}(\alpha) \in I$, there exists $\epsilon^{\prime} \in \mathrm{SL}_{d}(R / I)$ such that $\theta \epsilon^{\prime}=\alpha$. As $\operatorname{dim}(R / I)=$ 0 , the natural map $E_{d}(R) \rightarrow \mathrm{SL}_{d}(R / I)=E_{d}(R / I)$ is surjective. Therefore, we can lift $\epsilon^{\prime}$ and get an $\epsilon \in E_{d}(R)$ such that they are equal modulo $I$. Let $\left(F_{1}, \ldots, F_{d}\right)=$ $\left(a_{1}^{\prime}, a_{2}^{\prime}, a_{3}, \ldots, a_{d}\right) \epsilon$. Then note that $I=\left\langle F_{1}, \ldots, F_{d}\right\rangle$. It only remains to show that $F_{i}-f_{i} \in$ $I^{2}$.

To see this consider any $d$-tuple $\left[\left(a_{1}, \ldots, a_{d}\right)\right]$ as a map $(R / I)^{d} \rightarrow I / I^{2}$ sending $e_{i} \rightarrow a_{i}$ $\bmod \left(I^{2}\right)$. Then we have $\left[\left(F_{1}, \ldots, F_{d}\right)\right]=\left[\left(a_{1}^{\prime}, a_{2}^{\prime}, a_{3}, \ldots, a_{d}\right) \epsilon\right]=\left[\left(a_{1}, a_{2}, a_{3}, \ldots, a_{d}\right) \theta \epsilon\right]=$ $\left[\left(a_{1}, \ldots, a_{d}\right) \theta \epsilon^{\prime}\right]=\left[\left(a_{1}, \ldots, a_{d}\right) \alpha\right]=\left[\left(f_{1}, \ldots, f_{d}\right)\right]$. This completes the proof.

We are now ready to give the proof of Theorem 1.2, as mentioned in the introduction.
Theorem 3.5. Let $k$ be an algebraically closed field of $\operatorname{char}(k) \neq 2$. Let $R$ be an affine algebra over $k$ of dimension $d$, where $d \geq 2$. Let $P$ be a projective $R[T]$-module of rank $d$ with a trivial determinant. Let $I \subset R[T]$ be an ideal of height $d$ such that there is a surjection $\phi: P \rightarrow I$. If $\mu(I)=d$, then $P$ has a unimodular element.

Proof. Note that if $I$ contains a monic polynomial $f \in R[T]$, then $P_{f}$ has a unimodular element via the map $\phi \otimes A[T]_{f}$. Hence using "monic inversion principle" for modules, as stated in [8, Theorem 3.4], it follows that $P$ has a unimodular element. Therefore, we assume that $I$ does not contain any monic polynomial.

Note that by [8, Theorem 3.4], it is enough to find a monic polynomial $f \in R[T]$, such that $P_{f}$ has a unimodular element. Fix a trivialization $\chi: R[T] \cong \wedge^{d} P$. Let $A=S^{-1} R[T]$, where $S=k[T] \backslash\{0\}$. Here we observe that $A$ is an affine $k(T)$-algebra of dimension $d$. Let $I A$ be the extension of the ideal $I$ in the ring $A$. Therefore, in the ring $A$ we have $h t(I A)=\mu(I A)=\mu\left(I A / I^{2} A\right)=d$. Applying Theorem [3.4 we get that any set of generators of $I A / I^{2} A$ can be lifted to a set of generators of $I A$. In particular, the set of generators induce by the triplet $(P \otimes A, \phi \otimes A, \chi \otimes A)$ lifts to a set of generators of $I A$. Therefore, using subtraction principle as stated in [7, Corollary 3.4] we conclude that the projective module $S^{-1} P$ has a unimodular element. Since $P$ is finitely generated, we obtain a monic polynomial $f \in k[T] \subset R[T]$, such that $P_{f}$ has a unimodular element.

Corollary 3.6. Let $k$ be an algebraically closed field of $\operatorname{char}(k) \neq 2$. Let $R$ be an affine algebra over $k$ of dimension $d$, where $d \geq 2$. Let $P$ be a stably free $R[T]$-module of rank $d$. Then $P$ has a unimodular element.

Proof. Since $P$ is stably free $R[T]$-module of rank $d$, we have a short exact sequence

$$
0 \longrightarrow(R[T])^{d} \longrightarrow R[T] \oplus P \xrightarrow{(b,-\alpha)} R[T] \longrightarrow 0 \text {, }
$$

for some suitably chosen $(b,-\alpha) \in R[T] \oplus P^{*}$. Using a theorem due to EisenbudEvans [14] (or one can see [7, Corollary 2.1]), we may replace $\alpha$ with $\alpha+b \gamma$, for some $\gamma \in P^{*}$, and assume that either $\operatorname{ht}(\alpha(P))=d$ or $\alpha(P)=R[T]$. Here we note that by this replacement of $\alpha$, the kernel remains unaltered. If $\alpha(P)=R[T]$, then this proves the theorem. So let us assume that $\alpha(P)=I \subset R[T]$ is a proper ideal of height $d$. Then it follows from [7, Lemma 2.8 (i)] that $\mu(I)=d$. We can now apply Theorem 3.5 to conclude the proof.

## 4. Monic inversion principle for modules: A question of Roitman

In this section we give an affirmative answer to a question asked by M. Roitman. The following proposition is crucial to our proof. The proof is motivated from [7, 3.3, 3.4].

Proposition 4.1. Let $A$ be a finite $\mathbb{Z}$-algebra of dimension $d \geq 3$ such that there exists an integer $n \geq 2$ with $\frac{1}{n} \in A$. Let $P$ be a projective $A$-module of rank $d$ with trivial determinant. Let $\chi: A \cong \wedge^{d} P$ be an isomorphism. Let $I, J \subset A$ be ideals such that $h t(I) \geq d-1$ and $h t(J) \geq d$. Moreover, assume that there exist surjections $\alpha: P \rightarrow I \cap J$ and $\beta: A^{d} \rightarrow I$. Let 'bar' denote going modulo I. Suppose that, there exists an isomorphism $\delta: \bar{A}^{d} \cong \bar{P}$ with the following properties:
(1) $\bar{\beta}=\bar{\alpha} \delta$;
(2) $\wedge^{d} \delta=\bar{\chi}$.

Then, there exists a surjection $\gamma: P \rightarrow J$ such that $\gamma \otimes A / J=\alpha \otimes R / J$.
Proof. Let $\beta$ correspond to the set of generators $I=\left\langle a_{1}, \ldots, a_{d}\right\rangle$. Here we observe that $\operatorname{dim}\left(A / J^{2}\right) \leq 0$. This will imply that any unimodular row in $A / J^{2}$ of length $d$ can be completed to the first row of an elementary matrix. Since the canonical map $E_{d}(A) \rightarrow$ $\rightarrow E_{d}\left(A / J^{2}\right)$ is surjective, going modulo $J^{2}$ we may assume the following:
(i) $\left\langle a_{1}, \ldots, a_{d-1}\right\rangle+J^{2}=A$;
(ii) $a_{d} \in J^{2}$.

Moreover, in view of prime avoidance lemma, we may replace $a_{i}$ by $a_{i}+\lambda_{i} a_{d}$ for some $\lambda_{i} \in A,(i=1, \ldots, d-1)$ and further assume that (iii) $\operatorname{ht}\left(\left\langle a_{1}, \ldots, a_{d-1}\right\rangle\right)=d-1$. Here we note that, we are not changing the notation of $a_{i} \mathrm{~s}^{\prime}$. From (i) it follows that there exists $\lambda \in\left\langle a_{1}, \ldots, a_{d-1}\right\rangle$ such that $\lambda-1 \in J^{2}$. After replacing $a_{d}$ by $a_{d}+\lambda$ we may also assume that (iv) $a_{d}-1 \in J^{2}$.

Consider the following ideals in $A[T]: K^{\prime}=\left\langle a_{1}, \ldots, a_{d-1}, a_{d}+T\right\rangle, K^{\prime \prime}=J[T]$ and $K=K^{\prime} \cap K^{\prime \prime}$. Then it is enough to show that there exists a surjection $\theta: P[T] \rightarrow K$ such that $\theta(0)=\alpha$. For, if we can achieve this, then specializing at $1-a_{d}$ we get $\gamma:=\theta\left(1-a_{d}\right): P \rightarrow J$. Since $a_{d}-1 \in J^{2}$, we have $\gamma \otimes A / J=\theta(0) \otimes A / J=\alpha \otimes A / J$. In the rest of the proof we will find such a $\theta$.

As $\operatorname{dim}\left(A[T] / K^{\prime}\right)=\operatorname{dim}\left(A /\left\langle a_{1}, \ldots, a_{d-1}\right\rangle\right) \leq 1$, the module $P[T] / K^{\prime} P[T]$ is a free $A[T] / K^{\prime}$-module of rank $d$. We choose an isomorphism $\kappa(T):\left(A[T] / K^{\prime}\right)^{d} \cong P[T] / K^{\prime} P[T]$ such that $\wedge^{d} \kappa(T)=\chi \otimes A[T] / K^{\prime}$. Therefore, we get $\wedge^{d} \kappa(0)=\wedge^{d} \delta$. This will imply that $\kappa(0)$ and $\delta$ differ by an element $\alpha^{\prime} \in \mathrm{SL}_{d}(A / I)$. It follows from [30, Theorem 16.4] that $S K_{1}(A / I)$ is trivial. As a consequence we get $\mathrm{SL}_{d}(A / I)=E_{d}(A / I)$ (as $d \geq 3$ ). Hence we can lift $\alpha^{\prime}$ to get some $\alpha \in E_{d}(A)$, and use this to alter $\kappa(T)$ so that $\kappa(0)=\delta$.

Sending the canonical basis vectors to $a_{1}, \ldots, a_{d-1}, a_{d}+T$ respectively we can define a surjection from $(A[T])^{d} \rightarrow K^{\prime}$. This will induce a surjection $\epsilon(T):\left(A[T] / K^{\prime}\right)^{d} \rightarrow$ $\rightarrow K^{\prime} / K^{\prime 2}$. Let $\phi(T):=\epsilon(T) \kappa(T)^{-1}: P[T] / K^{\prime} P[T] \rightarrow K^{\prime} / K^{\prime 2}$. Note that $\phi(0)=$ $\epsilon(0) \kappa(0)^{-1}=\alpha \otimes A / I$. Since $d \geq \operatorname{dim}\left(A[T] / K^{\prime}\right)+2=3$, using [21, Theorem 2.3] we get a surjection $\theta(T): P[T] \rightarrow K$ such that $\theta(0)=\alpha$. This completes the proof.

Theorem 4.2. Let $A$ be a finite $\mathbb{Z}$-algebra of dimension $d \geq 1$ such that there exists an integer $n \geq 2$ with $\frac{1}{n} \in A$. Let $P$ be a projective $A[T]$-module with trivial determinant of rank d. Let $J \subset A[T]$ be an ideal of height $d$ containing a monic polynomial. Assume that there exists a surjection $\alpha: P \rightarrow J$. Then, $P$ has a unimodular element.

Proof. For $d=1$ the theorem follows from the "Affine Horrocks theorem" [23] and for $d=2$ the proof is done in [3, Proposition 3.3]. Therefore, we may assume that $d \geq 3$.

Fix an isomorphism $\chi: A[T] \cong \wedge^{d} P$. Let 'bar' denote going modulo $J$. Since $P$ has a trivial determinant and $\operatorname{dim}(A[T] / J) \leq 1$, the module $P / I P$ is a free $A[T] / I$-module of rank $d$. Let $\delta:(A[T] / J)^{d} \cong P / J P$ be an isomorphism such that

$$
\begin{equation*}
\wedge^{d} \delta=\chi \otimes A[T] / J \tag{1}
\end{equation*}
$$

We define $\omega:=(\alpha \otimes A[T] / J) \delta:(A[T] / J)^{d} \rightarrow J / J^{2}$. Since $J$ contains a monic polynomial and $\operatorname{dim}(A[T] / J)+2 \leq 3 \leq d$, it follows from [18] and [20] that there exists a surjection $\beta:(A[T])^{d} \rightarrow J$ such that $\beta \otimes A[T] / J=\omega$.

Since $\wedge^{d} P$ is extended from the ring $A$, in a view of [8, Theorem 2.3] it is enough to show that $P / T P$ has a unimodular element. We will establish this with the help of Proposition 4.1. Let us define the following notations:

- $P(0):=P / T P, J(0):=J \otimes A[T] /\langle T\rangle ;$
- $\alpha(0):=\alpha \otimes A[T] /\langle T\rangle: P(0) \rightarrow J(0)$;
- $\beta(0):=\beta \otimes A[T] /\langle T\rangle: A^{d} \rightarrow J(0)$;
- $\omega(0):=\omega \otimes A / J(0):(A / J(0))^{d} \rightarrow J(0) / J(0)^{2}$;
- $\delta(0):=\delta \otimes A[T] /\langle T\rangle:(A / J(0))^{d} \xrightarrow{\sim} P(0) / J(0) P(0)$;
- $\chi(0):=\chi \otimes A[T] /\langle T\rangle: A \xrightarrow{\sim} \wedge^{d} P(0)$.

Since $J \cap A \subset J(0)$, we have ht $(J(0)) \geq d-1$. Now we observe that $\beta(0) \otimes A / J(0)=$ $(\alpha(0) \otimes A / J(0)) \delta(0)$, as both matches with $\omega(0)$. It follows from (1) that $\wedge^{d} \delta(0)=$ $\chi(0) \otimes A / J(0)$. This shows that all the hypotheses of Proposition 4.1 are satisfied. Now we may apply Proposition 4.1 (taking $J=A$ ) to obtain that $P(0)$ has a unimodular element.

## 5. MONIC INVERSION PRINCIPLE FOR IDEALS

Here we shall give a direct proof of a "monic inversion principle" for ideals in $R[T]$, where $R$ is an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Note that if one assumes that $p>(\operatorname{dim}(R))$ ! or that $R$ is smooth, one can obtain a proof using ([9] or [12]). We make no such assumption and our method is entirely different.

Theorem 5.1. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Let $I \subset R[T]$ be an ideal such that $h t(I)=\mu\left(I / I^{2}\right)=d$. Assume that, $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$. Suppose that there exist $F_{i} \in \operatorname{IR}(T)$ such that $\operatorname{IR}(T)=\left\langle F_{1}, \ldots, F_{d}\right\rangle$, with $F_{i}-f_{i} \in \operatorname{IR}(T)^{2},(i=1, \ldots, d)$. Then there exist $g_{i} \in I$, such that $I=\left\langle g_{1}, \ldots, g_{d}\right\rangle$, with $g_{i}-f_{i} \in I^{2}$.

Proof. We divide the proof into two cases.
Case 1. In this case we assume that $d=2$. Here we note that if the ideal $I$ contains a monic polynomial in $T$, then a lift exists by [10, Theorem 3.2]. Therefore, without loss of generality we may assume that $I$ does not contain a monic polynomial. Let $I=\left\langle f_{1}, f_{2}\right\rangle+I^{2}$ induce the surjection $\omega_{I}:(R[T] / I)^{2} \rightarrow I / I^{2}$, by sending the canonical basis $e_{i}$ to the image of $f_{i}$ in $I / I^{2}(i=1,2)$. Initial part of our proof in this case essentially follows [9, Theorem 7.1].

Using a standard patching argument there exists a projective $R[T]$-module $P$ with trivial determinant of rank 2 and a surjection $\alpha: P \rightarrow I$. Fix an isomorphism $\chi$ : $R[T] \cong \wedge^{2} P$. Let $\alpha$ and $\chi$ induce $I=\left\langle f_{1}^{\prime}, f_{2}^{\prime}\right\rangle+I^{2}$.

Let 'bar' denote going modulo $I^{2}$. We notice that any two set of generators of $I / I^{2}$ differs by an invertible matrix in $\mathrm{GL}_{2}(R[T] / I)$. Hence there exists $\bar{\sigma} \in \mathrm{GL}_{2}(R[T] / I)$ such that $\left(\bar{f}_{1}, \bar{f}_{2}\right)=\left(\bar{f}_{1}^{\prime}, \bar{f}_{2}^{\prime}\right) \bar{\sigma}$. Let $\operatorname{det}(\sigma)=\bar{f}$. Using [7, Lemma 2.7 and 2.8] we get another surjection $\beta: P_{1} \rightarrow I$ and an isomorphism $\chi_{1}: R[T] \xrightarrow{\sim} \wedge^{2} P_{1}$, where $P_{1}$ is projective $R[T]$-module of rank 2 having trivial determinant. Moreover, the triplet $\left\{P_{1}, \chi_{1}, \beta\right\}$ satisfy the property that if the set of generators of $I / I^{2}$ induced by $\beta, \chi_{1}$ and a fixed basis of $R[T]^{2}$, say $\left\{\eta_{1}, \eta_{2}\right\}$, is $\bar{h}_{1}, \bar{h}_{2}$, then $\left(\bar{h}_{1}, \bar{h}_{2}\right)=\left(\bar{f}_{1}^{\prime}, \bar{f}_{2}^{\prime}\right) \bar{\delta}$, where $\bar{\delta} \in$ $\mathrm{GL}_{2}(R[T] / I)$ has determinant $\bar{f}$. Let us define $\bar{\gamma}:=\bar{\sigma}^{-1} \bar{\delta} \in \mathrm{SL}_{2}(R[T] / I)$. Then, we
note that $\left(\bar{f}_{1}, \bar{f}_{2}\right) \bar{\gamma}=\left(\bar{h}_{1}, \bar{h}_{2}\right)$. Since by Theorem [2.3] the canonical map $\mathrm{SL}_{d}(R[T]) \rightarrow$ $\mathrm{SL}_{d}(R[T] / I)$ is surjective, we can find a $\gamma \in \mathrm{SL}_{2}(R[T])$ such that $\gamma$ is a lift of $\bar{\gamma}$.

Now here we observe that it is enough to lift the set of generators $I=\left\langle h_{1}, h_{2}\right\rangle+I^{2}$ to a set of generators of $I$. As suppose that we obtain such a lift $I=\left\langle a_{1}, a_{2}\right\rangle$ of $I=$ $\left\langle h_{1}, h_{2}\right\rangle+I^{2}$. Then we define $\left(g_{1}, g_{2}\right):=\left(a_{1}, a_{2}\right) \gamma^{-1}$. This implies that $\left(g_{1}-f_{1}, g_{2}-f_{2}\right)=$ $\left(a_{1}-h_{1}, a_{2}-h_{2}\right) \gamma^{-1} \in I^{2} \times I^{2}$. The remaining part of the proof in this case is dedicated to find a lift of $\left\{h_{1}, h_{2}\right\}$.

Since the set of generators $\left\{f_{1}, f_{2}\right\}$ and $\left\{h_{1}, h_{2}\right\}$ differs by a matrix in $\mathrm{SL}_{d}(R[T] / I)$, it follows from the hypothesis of the theorem that the set of generators $\left\{h_{1}, h_{2}\right\}$ lifts to a set of generators of $\operatorname{IR}(T)$. Therefore, applying [7. Corollary 3.4] we obtain that the projective module $P_{1} \otimes R(T)$ has a unimodular element. Since $P_{1}$ is a projective module of rank 2 having a trivial determinant, we actually obtain that $P_{1} \otimes R(T)$ is a free module. Now we may apply "Affine Horrocks theorem" [23] and obtain that the module $P_{1}$ is in fact a free module.

Therefore, we may choose an isomorphism $\eta:(R[T])^{2} \cong P_{1}$ such that $\wedge^{2} \eta=\chi_{1}$. Let us define $H_{i}=\beta \eta\left(\eta_{i}\right), i=1,2$. Then note that $I=\left\langle H_{1}, H_{2}\right\rangle$ and $\bar{H}_{1} \wedge \bar{H}_{2}=\bar{h}_{1} \wedge \bar{h}_{2}$ in $\wedge^{2}\left(I / I^{2}\right)$. Hence we can find $\sigma \in \mathrm{SL}_{2}(R[T] / I)$ such that $\left(\bar{H}_{1}, \bar{H}_{2}\right) \sigma=\left(\bar{h}_{1}, \bar{h}_{2}\right)$. Now using Theorem[2.3 there exists $\tau \in \mathrm{SL}_{2}(R[T])$ such that $\bar{\tau}=\sigma$. Let $\left(g_{1}, g_{2}\right)=\left(H_{1}, H_{2}\right) \tau$. Then $\left(\bar{g}_{1}, \bar{g}_{2}\right)=\left(\bar{H}_{1}, \bar{H}_{2}\right) \bar{\tau}=\left(\bar{H}_{1}, \bar{H}_{2}\right) \sigma=\left(\bar{h}_{1}, \bar{h}_{2}\right)$. This concludes the proof in the case of dimension two.
Case 2. Here we assume that $d \geq 3$. Again as before we may assume that none of the ideals which are going to appear in this proof, contain monic polynomials. There is a monic polynomial $f \in R[T]$ such that $I_{f}=\left\langle F_{1}, \ldots, F_{d}\right\rangle$, with $F_{i}-f_{i} \in I_{f}^{2}$. Let $B=R[T] /\langle f\rangle \cap I^{2}$ and 'bar' denote going modulo $\langle f\rangle \cap I^{2}$. Note that $\operatorname{dim}(B) \leq d$. In $B$ we have $\bar{I}=\left\langle\bar{f}_{1}, \ldots, \bar{f}_{d}\right\rangle+\bar{I}^{2}$. Using [10, Theorem 2.4] we can find $\bar{h}_{i} \in \bar{I}$ such that $\bar{I}=\left\langle\bar{h}_{1}, \ldots, \bar{h}_{d}\right\rangle$, with $\bar{f}_{i}-\bar{h}_{i} \in \bar{I}^{2}$. Therefore, $I=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I^{2} \cap\langle f\rangle$. Using Lemma 2.1) there exits $e \in I^{2} \cap\langle f\rangle$ such that $I=\left\langle h_{1}, \ldots, h_{d}, e\right\rangle$, and $e(1-e) \in\left\langle h_{1}, \ldots, h_{d}\right\rangle$. Using prime avoidance lemma (cf. [7, Corollary 2.13]) replacing $h_{i}$ by $h_{i}+e \lambda_{i}$ we may assume that $\operatorname{ht}\left(\left\langle h_{1}, \ldots, h_{d}\right\rangle\right)_{e}=d$ or $\left\langle h_{1}, \ldots, h_{d}\right\rangle_{e}=R[T]_{e}$. Note that if $\left\langle h_{1}, \ldots, h_{d}\right\rangle_{e}=R[T]_{e}$, then $e \in \sqrt{\left\langle h_{1}, \ldots, h_{d}\right\rangle}$. A local checking ensures that $I=\left\langle h_{1}, \ldots, h_{d}\right\rangle$. This will establish the theorem in this case. Hence the only non-trivial situation is when $\operatorname{ht}\left(\left\langle h_{1}, \ldots, h_{d}\right\rangle_{e}\right)=d$. From now onward we will make this assumption.

We define $I_{1}=\left\langle h_{1}, \ldots, h_{d}, 1-e\right\rangle$. Then note that we have the following:
(a) $I \cap I_{1}=\left\langle h_{1}, \ldots, h_{d}\right\rangle$;
(b) $I_{1}+\langle e\rangle=I_{1}+\langle f\rangle=I_{1}+I=R[T]$;
(c) $\operatorname{ht}\left(I_{1}\right)=d$.
(b) and (c) imply that $\operatorname{ht}\left(I_{1}\right)=d$. We observe that $\operatorname{ht}\left(\left(I_{1}\right)_{f}\right)=d$. Since $h_{i}-f_{i} \in I^{2}$, to prove the theorem it is enough to lift $I=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I^{2}$ to a set of generators of $I$. Now $I+I_{1}=R[T]$. Therefore $I \cap I_{1}=\left\langle h_{1}, \ldots, f_{d}\right\rangle$ will induce $I_{1}=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I_{1}^{2}$. In view of subtraction principle [2, Proposition 7.2] to prove the theorem, it is enough to lift $I_{1}=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I_{1}^{2}$ to a set of generators of $I_{1}$.

Note that in the ring $R[T]_{f}$, the set of generators $I_{f}=\left\langle h_{1}, \ldots, h_{d}\right\rangle R[T]_{f}+I_{f}^{2}$ lifts to a set of generators of $I_{f}$. Hence again by subtraction principle [2, Proposition 7.2] there exist $l_{i} \in\left(I_{1}\right)_{f}$, such that $\left(I_{1}\right)_{f}=\left\langle l_{1}, \ldots, l_{d}\right\rangle$, with $h_{i}-l_{i} \in\left(I_{1}\right)_{f}^{2}$. Let $k \geq 1$ be an integer such that $f^{2 k} l_{i} \in I_{1}$, for all $i$. Since $f$ is unit modulo $I_{1}$, to find a lift of $I_{1}=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I_{1}^{2}$ to a set of generators of $I_{1}$, by Lemma 2.4 it is enough to lift $I_{1}=\left\langle f^{2 k} l_{1}, \ldots, f^{2 k} l_{d}\right\rangle+I_{1}{ }^{2}$ to a set of generators of $I_{1}$. Therefore, we may replace $l_{i}$ with $f^{2 k} l_{i}$ and assume that $l_{i} \in I_{1}$. The remaining part of the proof is devoted to find such a lift of $I_{1}=\left\langle l_{1}, \ldots, l_{d}\right\rangle+I_{1}{ }^{2}$.

Using Lemma 2.5 we get $\epsilon \in \mathrm{SL}_{d}\left(R[T]_{f}\right)$ such that $\left(l_{1}, \ldots, l_{d}\right) \epsilon=\left(l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right)$, where $l_{i}^{\prime} \in I_{1}$ and $\operatorname{ht}\left(\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle R[T]\right)=d$. Let $\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle R[T]=\bigcap_{i=1}^{r} q_{i} \bigcap_{i=r+1}^{n} q_{i}$ be the reduced primary decomposition, where $q_{i}$ 's are $p_{i}$-primary ideal in $R[T]$, such that $f \notin p_{i}$ for $i \leq r$ and $f \in p_{i}$ for all $i>r$. Since $\left(I_{1}\right)_{f}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle_{f}$ is a proper ideal of height $d$, we must have $r \geq 1$. Let $I_{2}=\bigcap_{i=r+1}^{n} q_{i}$. Therefore, we get $\operatorname{ht}\left(I_{2}\right) \geq d$ and $f \in \sqrt{I_{2}}$.

We claim that $I_{1}=\bigcap_{i=1}^{r} q_{i}$. To prove this note that $\left(I_{1}\right)_{f}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle R[T]_{f}=\bigcap_{i=1}^{r} q_{i f}$ implies that $I_{1} \subset \bigcap_{i=1}^{r} q_{i}$. Assume, if possible, that there exists another $p$-primary ideal $q$ (where $p \neq p_{i}$, for any $i=1, \ldots, r$ ) in the reduced primary decomposition of the ideal $I_{1}$. Since $p_{f} \neq\left(p_{i}\right)_{f}$, for $i=1, \ldots, r$, and $\left(I_{1}\right)_{f}=\bigcap_{i=1}^{r} q_{i f}$ we must have $p_{f}=R[T]_{f}$. This implies that $f \in p$. But this is not possible as $I_{1}+\langle f\rangle=R[T]$ in particular, $p+\langle f\rangle=R[T]$. Therefore, $I_{1}=\bigcap_{i=1}^{r} q_{i}$.

Hence we obtain the following:
(1) $I_{2}$ contains a monic polynomial in particular, some power of $f$;
(2) $I_{1}+I_{2}=R[T]$ (as going modulo $I_{1}$ any power of $f$ is a unit);
(3) $I_{1} \cap I_{2}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle R[T]$.

Note that (3) gives us for any prime ideal $p \supset I_{2}$, we must have $\mu\left(\left(I_{2}\right)_{p}\right) \leq d$. Applying Krull's generalized principal ideal theorem we get $h t\left(I_{2}\right)=d$. Now, (3) will induce $I_{1}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle+I_{1}^{2}$ and $I_{2}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle+I_{2}^{2}$. Since $I_{2}$ contains a monic, using [10, Proposition 3.2] $I_{2}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle+I_{2}^{2}$ can be lifted to a set of generators of $I_{2}$. Therefore, applying the subtraction principle [2, Proposition 7.2] we can lift $I_{1}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle+I_{1}^{2}$ to a set of generators of $I_{1}$.

Since $f$ is a monic polynomial (in particular, a non zero $\operatorname{divisor),~} \operatorname{det}(\epsilon)=1$ in $R[T]_{f}$ implies that $\operatorname{det}(\epsilon)=1$ in the ring $R[T]$. From (b) it follows that $R[T] / I_{1}=\left(R[T] / I_{1}\right)_{f}$. Therefore, $\epsilon \in \mathrm{SL}_{d}\left(R[T] / I_{1}\right)$. As $I_{1}=\left\langle l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right\rangle+I_{1}^{2}$ has a lift to a set of generators of $I_{1}$
and $\left(l_{1}, \ldots, l_{d}\right) \epsilon=\left(l_{1}^{\prime}, \ldots, l_{d}^{\prime}\right)$, using [11, Lemma 4.1] we can lift $I_{1}=\left\langle l_{1}, \ldots, l_{d}\right\rangle+I_{1}^{2}$ to a set of generators of $I_{1}$. Therefore, we can lift $I_{1}=\left\langle h_{1}, \ldots, h_{d}\right\rangle+I_{1}^{2}$ to a set of generators of $I_{1}$. This completes the proof.

## 6. SPLITTING CRITERION VIA AN OBSTRUCTION CLASS IN AN OBSTRUCTION GROUP

Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$ and $P$ be a finitely generated projective $R[T]$-module of rank $d$, with trivial determinant. Let us fix an isomorphism $\chi: R[T] \simeq \wedge^{d} P$. The purpose of this section is to define an Euler cycle for the triplet $(P, \lambda, \chi)$, in the group $E^{d}(R[T])$ and show that the Euler cycle govern the splitting problem for $P$, where $\lambda$ is a generic section. First we will prove some addition and subtraction principles. For most of the proofs in this section we will frequently move to the ring $R(T)$, prove the results in $R(T)$ then using Theorem 5.1] we will come back to the ring $R[T]$. Some of the results below were proved for Noetherian ring containing $\mathbb{Q}$ in [9].

## Addition and subtraction principles.

Proposition 6.1. (Addition principle) Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Let $I, J \subset R[T]$ be two co-maximal ideals, each of height d. Suppose that $I=\left(f_{1}, \ldots, f_{d}\right)$ and $J=\left(g_{1}, \ldots, g_{d}\right)$. Then $I \cap J=\left(h_{1}, \ldots, h_{d}\right)$ where $h_{i}-f_{i} \in I^{2}$ and $h_{i}-g_{i} \in I^{2}$.

Proof. Since $\operatorname{ht}(I)=\operatorname{ht}(J)=d$, in the ring $R(T)$ both the ideals $I R(T)$ and $J R(T)$ are of height $\geq d$. We note that if one of them is of height $>d$, then there is nothing to prove. So without loss of generality we may assume that each ideal is of height $d$.

Since $I+J=R[T]$, using the Chinese Remainder Theorem we have $I \cap J /(I \cap J)^{2} \cong$ $I / I^{2} \oplus J / J^{2}$. Hence the given set of generators of $I$ and $J$ will induce a set of generators $a_{i}$ 's of $(I \cap J) /(I \cap J)^{2}$ such that $a_{i}-f_{i} \in I^{2}$ and $a_{i}-g_{i} \in J^{2}$. Thus to prove the theorem it is enough to find a lift of $I \cap J=\left\langle a_{1}, \ldots, a_{d}\right\rangle+(I \cap J)^{2}$ to a set of generators of $I \cap J$.

In the ring $R(T)$, we have $\operatorname{ht}(I)=\operatorname{ht}(J)=\operatorname{ht}(I \cap J)=\operatorname{dim}(R(T))=d$. Hence applying addition principle as stated in [7, Theorem 3.2] we can find $H_{i} \in(I \cap J) R(T)$ such that $(I \cap J) R(T)=\left\langle H_{1}, \ldots, H_{d}\right\rangle R(T)$, with $H_{i}-f_{i} \in I R(T)^{2}$ and $H_{i}-g_{i} \in J R(T)^{2}$. Now using Theorem 5.1] we are done.

Proposition 6.2. (Subtraction principle) Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Let $I, J \subset R[T]$ be two co-maximal ideals, each of height d. Suppose that $I=\left(f_{1}, \ldots, f_{d}\right)$ and $I \cap J=\left(h_{1}, \ldots, h_{d}\right)$ where $h_{i}-f_{i} \in I^{2}$. Then there exists $g_{i} \in J$ such that $J=\left(g_{1}, \ldots, g_{d}\right)$ with $h_{i}-g_{i} \in I^{2}$.

Proof. The proof uses the same arguments as in Proposition 6.1 with slight modification, hence we shall only sketch a proof. As before, without loss of generality we may assume that $\mathrm{ht}(I R(T))=\operatorname{ht}(J R(T))=\operatorname{ht}((I \cap J) R(T))=\operatorname{dim}(R(T))=d$. Since $I+J=R[T]$, we get $J=\left\langle h_{1}, \ldots, h_{d}\right\rangle+J^{2}$. Here we observe that, to prove the theorem it is enough to find a lift of $J=\left\langle h_{1}, \ldots, h_{d}\right\rangle+J^{2}$ to a set of generators of $J$. Applying subtraction principle as stated in [7, Theorem 3.3] in the ring $R(T)$ we can find $G_{i} \in J R(T)$ such that $G_{i}-h_{i} \in J R(T)^{2}$. Then as before we can use Theorem 5.1 to complete the proof.

## An obstruction group.

Proposition 6.3. Let $R$ be affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$ and $I \subset R[T]$ be an ideal of height $d$. Moreover suppose that $\alpha$ and $\beta$ are two surjections from $(R[T] / I)^{d} \rightarrow I / I^{2}$ such that there exists $\sigma \in S L_{d}(R[T] / I)$ with the property that $\alpha \sigma=\beta$. If $\alpha$ can be lifted to a surjection $\theta:(R[T])^{d} \rightarrow I$ then so is $\beta$.

Proof. Since $\operatorname{dim}(R[T] / I) \leq 1$, using Theorem 2.3, we can find $\epsilon \in \mathrm{SL}_{d}(R[T])$, which lifts $\sigma$. Since $\epsilon \in \mathrm{SL}_{d}(R[T])$ and $\theta$ is a surjection, it follows that $\theta \epsilon:(R[T])^{d} \rightarrow I$ is also a surjection. Thus it is only remains to show that $(\theta \epsilon) \otimes(R[T] / I)=\beta$. But this follows from the fact that $\epsilon \otimes R[T] / I=\sigma$ and $\theta \otimes R[T] / I=\alpha$.

Now we proceed to define the $d$-th Euler class group of $R[T]$ where $R$ is an affine algebra of dimension $d \geq 2$.
Definition 6.4. Let $I \subset R[T]$ be an ideal of height $d$ such that $I / I^{2}$ is generated by $d$ elements. Let $\alpha$ and $\beta$ be two surjections from $(R[T] / I)^{d} \rightarrow I / I^{2}$. We say $\alpha$ and $\beta$ are related if there exists $\sigma \in \mathrm{SL}_{d}\left((R[T] / I)^{d}\right.$ be such that $\alpha \sigma=\beta$. This defines an equivalence relation on the set of surjections from $(R[T] / I)^{d} \rightarrow I / I^{2}$. Let $[\alpha]$ denote the equivalance class of $\alpha$. If $f_{1}, \ldots, f_{d}$ generate $I / I^{2}$, we obtain a surjection $\alpha:(R[T] / I)^{d} \rightarrow I / I^{2}$, sending $e_{i}$ to $f_{i}$. We say $[\alpha]$ is given by the set of generators $f_{1}, \ldots, f_{d}$ of $I / I^{2}$.

Let $G$ be the free Abelian group on the set $B$ of pairs $\left(I, \omega_{J}\right)$, where:
(1) $I \subset R[T]$ is an ideal of height $d$;
(2) $\operatorname{Spec}(R[T] / I)$ is connected;
(3) $I / I^{2}$ is generated by $d$ elements; and
(4) $\omega_{I}:(R[T] / I)^{d} \rightarrow I / I^{2}$ is an equivalence class of surjections $\alpha:(R[T] / I)^{d} \rightarrow$ $I / I^{2}$.

Let $J \subset R[T]$ be a proper ideal. we get $J_{i} \subset R[T]$ such that $J=J_{1} \cap J_{2} \cap \ldots \cap J_{r}$, where $J_{i}$ 's are proper, pairwise co-maximal and $\operatorname{Spec}\left(R[T] / J_{i}\right)$ is connected. We shall say that $J_{i}$ are the connected components of $J$.

Let $K \subset R[T]$ be an ideal of height $d$ such that $K / K^{2}$ is generated by $d$ elements. Let $K=\cap K_{i}$ be the decomposition of $K$ into its connected components. Then note that for every $i, \operatorname{ht}\left(K_{i}\right)=d$. Therefore, applying Chinese Remainder Theorem $K_{i} / K_{i}^{2}$ is generated by $d$ elements. Let $\omega_{K}:(R[T] / I)^{d} \rightarrow K / K^{2}$ be a surjection. Then in a natural way $\omega_{K}$ gives rise to surjections $\omega_{K_{i}}:\left(R[T] / K_{i}\right)^{d} \rightarrow K_{i} / K_{i}{ }^{2}$. We associate the pair $\left(K, \omega_{K}\right)$, to the element $\sum_{i=1}^{r}\left(K_{i}, \omega_{K_{i}}\right)$ of $G$. We will call $\left(K, \omega_{K}\right)$ as a local orientation of $K$ induced by the surjection $\omega_{K}$.

Let $H$ be the subgroup of $G$ generated by the set $S$ of pairs $\left(J, \omega_{J}\right)$, where $\omega_{J}$ : $(R[T] / J)^{d} \rightarrow J / J^{2}$ has a surjective lift $\theta:(R[T] / J)^{d} \rightarrow J$. That is, $\theta$ is a surjection such that $\theta \otimes R[T] / J=\omega_{J}$. Then, we define the quotient group $G / H$ as the $d$-th Euler class group of $R[T]$ denoted as $E^{d}(R[T])$. A local orientation $\left(J, \omega_{J}\right)$ is said to be a global orientation if $\omega_{J}$ lifts to a set of generators of $J$.
Remark 6.5. Note that the decomposition of $K$ into its connected components is unique by [9, Lemma 4.5] as the proof of Lemma 4.5 does not require the assumption that the ring contains $\mathbb{Q}$.
Remark 6.6. The equivalence class of the pair $\left(I, \omega_{I}\right) \in E^{d}(R[T])$ defined above is welldefined by Proposition6.3.

Lemma 6.7. Let $R$ be an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension $d \geq 2$, and let $I \subset R[T]$ be an ideal of height $d$ such that $I / I^{2}$ is generated by $d$ elements. Let $\omega_{I}:(R[T] / I)^{d} \rightarrow I / I^{2}$ be a local orientation of $I$. Suppose that, the image of $\left(I, \omega_{I}\right)$ is zero in the $d$-th Euler class group $E^{d}(R[T])$. Then I is generated by delements and $\omega_{I}$ can be lifted to a surjection $\theta:(R[T])^{d} \rightarrow$ $\rightarrow I$.

Proof. The proof is done in [11, Theorem 4.7], with some additional assumption $p \neq 2$, whenever $d=3$, but this can be removed if one uses Proposition 6.2 in the appropriate places. Hence we opt to skip the proof to avoid repeating similar arguments.

## An obstruction class.

Definition 6.8. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$, and let $P$ be a projective $R[T]$-module of rank $d$ having trivial determinant. Let $\chi: R[T] \cong \wedge^{d} P$ be an isomorphism. To the pair $(P, \chi)$, we associate an element $e(P, \chi)$ of $E^{d}(R[T])$ as follows: let $\lambda: P \rightarrow I$ be a surjection, where $I$ is an ideal of $R[T]$ of height $d$. We obtain an induce surjection $\lambda \otimes R[T] / I: P / I P \rightarrow I / I^{2}$. Note that, since $P$ has trivial determinant and $\operatorname{dim}(R[T] / I) \leq 1$, the module $P / I P$ is in fact a free $R[T] / I$-module of rank $d$. We choose an isomorphism $\phi:(R[T] / I)^{d} \xrightarrow{\sim} P / I P$, such that $\wedge^{d} \phi=\chi \otimes R[T] / I$. Let $\omega_{I}$ be the surjection $(\lambda \otimes R[T] / I) \circ \phi:(R[T] / I)^{d} \rightarrow I / I^{2}$. We say that $\left(I, \omega_{I}\right)$ is an Euler cycle induced by the triplet $(P, \lambda, \chi)$.

Whenever the class of $\left(I, \omega_{I}\right) \in E^{d}(R[T])$, induced by the triplet $(P, \lambda, \chi)$ becomes independent of a certain choice of the pair $(\lambda, I)$, we shall call the image of $\left(I, \omega_{I}\right) \in$ $E^{d}(R[T])$ as the Euler class $e(P, \chi)$ of the pair $(P, \chi)$.
Notation. Continuing with the above notations we might omit $P$ sometimes and only say $\left(I, \omega_{I}\right)$ is induced by $(\lambda, \chi)$, if there are no confusions. By saying an Euler cycle induced by $(P, \chi)$ we mean to say an Euler cycle induced by the triplet $(P, \lambda, \chi)$, for some suitably chosen $\lambda \in P^{*}$.

In the next theorem we shall show that the vanishing of any Euler cycle of the triplet $(P, \lambda, \chi)$ is necessary and sufficient for the projective module $P$ to have a unimodular element.

Theorem 6.9. Let $R$ be an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension $d \geq 2$ and $P$ be a projective $R[T]$ module with trivial determinant of rank $d$. Let $(P, \lambda, \chi)$ induce an Euler cycle $\left(I, \omega_{I}\right)$, where $\lambda$ is a generic section of $P$. Then, the projective module $P$ has a unimodular element if and only if $\left(I, \omega_{I}\right)=0$ in $E^{d}(R[T])$.

Proof. Suppose assume that $\left(I, \omega_{I}\right)=0$. Recall that $(P, \lambda, \chi)$ induces $\left(I, \omega_{I}\right)$ means there exists an isomorphism $\phi:(R[T] / I)^{d} \xrightarrow{\sim} P / I P$, such that $\wedge^{d} \phi=\chi \otimes R[T] / I$ and $\omega_{I}=(\lambda \otimes R[T] / I) \circ \phi$. Note that, in a view of monic inversion principle for modules as stated in [8, Theorem 3.4] to show that $P$ has a unimodular element it is enough to show that $P \otimes R(T)$ has a unimodular element. The proof is devoted to show this only.

Since $\left(I, \omega_{I}\right)$ vanishes in $E^{d}(R[T])$, applying Lemma 6.7 we can find a surjection $\theta:(R[T])^{d} \rightarrow I$, such that $\theta \otimes R[T] / I=\omega_{I}$. Therefore, in the ring $R(T)$ we have the following:
(1) $\lambda \otimes R(T): P \otimes R(T) \rightarrow I R(T)$;
(2) $\theta \otimes R(T):(R(T))^{d} \rightarrow I R(T)$; and
(3) $\phi:(R[T] / I)^{d} \xrightarrow{\sim} P / I P$
such that $\omega_{I} \otimes R(T) / I R(T)=(\lambda \otimes R(T) / I R(T)) \circ(\phi \otimes R(T) / I R(T))$ and $\wedge^{d}(\phi \otimes$ $R(T) / I R(T))=\chi \otimes R(T) / I R(T)$. Hence using subtraction principle as stated in [7, Corollary 3.4] it follows that $P \otimes R(T)$ has a unimodular element.

Conversely, we assume that, $P=Q \oplus R[T]$. Let $\lambda=(\theta, a) \in Q^{*} \oplus R[T]$. Note that the since $Q$ has trivial determinant, without loss of generality we may assume that $\chi$ is induced by an isomorphism $\chi^{\prime}: R[T] \cong \wedge^{d-1} Q$.

Let us denote the image ideal $\theta(Q)=J$. Note that we can always replace $\alpha$ by an automorphism. Using a theorem due to Eisenbud-Evans [14], after performing an elementary automorphism we may assume that $\operatorname{ht}(J) \geq d-1$. Since $\operatorname{dim}(R[T] / J) \leq 2$, and $Q / J Q$ has trivial determinant, by [10, Corollary 2.10] there exists an isomorphism $\gamma:(R[T] / J)^{d-1} \cong Q / J Q$ such that $\wedge^{d-1} \gamma^{\prime} \cong \chi^{\prime} \otimes R[T] / J$. Let $\Gamma: R[T]^{d-1} \rightarrow J^{\prime} \subset J$
be a lift of $(\theta \otimes R[T] / J) \circ \gamma$. Then we have $J^{\prime}+J^{2}=J$. Applying Lemma 2.1] we can find an $e \in J^{2}$ such that $J=J^{\prime}+\langle e\rangle$. Moreover, since $I=J+\langle a\rangle$, we may further have $I=J^{\prime}+\langle b\rangle$, where $b=e+(1-e) a$. This will produce a surjection $(\Gamma, b): R[T]^{d} \rightarrow I$.

The only remaining part is to show $(\Gamma, b) \otimes R[T] / I=\omega_{I}$, as then it will imply that $\left(I, \omega_{I}\right)=0$. To show this, observe that we have a canonical isomorphism $\phi:=(\gamma, 1)$ : $(R[T] / I)^{d} \cong Q / I Q \oplus(R[T] / I)$ such that $\wedge^{d} \phi=\wedge^{d-1} \gamma \otimes(R[T] / I)=\chi^{\prime} \otimes(R[T] / I)=$ $\chi \otimes(R[T] / I)$. Since $b-a \in I^{2}$ and $\Gamma$ is a lift of $(\theta \otimes R[T] / J) \circ \gamma$, it follows that $(\Gamma, b)$ is a lift of $\omega_{I}$. This completes the proof.

The same proof will give us the following corollary and we therefore omit the proof.
Corollary 6.10. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Let $P$ and $Q$ be projective $R[T]$-modules of rank $d$ and $d-1$ respectively, such that their determinants are trivial. Let $\chi: \wedge^{d} P \cong \wedge^{d}(Q \oplus R[T])$ be an isomorphism. Let $I \subset R[T]$ be an ideal of height $d$ such that there exist surjections $\alpha: P \rightarrow I$ and $\beta: Q \oplus R[T] \rightarrow I$. Let 'bar' denote going modulo $I$. Suppose that, there exists an isomorphism $\delta: \bar{P} \cong \overline{Q \oplus R[T]}$ with the following properties:
(i) $\bar{\beta} \delta=\bar{\alpha}$;
(ii) $\wedge^{d} \delta=\bar{\chi}$.

Then $P$ has a unimodular element.
Remark 6.11. Here we would like to remark that with the advantages of the choice of our affine $\overline{\mathbb{F}}_{p}$-algebra, in this section we been able to proof results which mention till now, without the hypothesis " $\frac{1}{(d-1)!} \in R$ ". In [9] most of the results of this section has been proved with the assumption " $\frac{1}{(d-1)!} \in R$ ". We still do not know whether one can remove this hypothesis from [9] or not.

Theorem 6.12. Continuing with the notations as in Definition 6.8 furthermore, assume that $\frac{1}{(d-1)!} \in R$. Then, the assignment sending the pair $(P, \chi)$ to the element $e(P, \chi) \in E^{d}(R[T])$, as described in Definition 6.8, is well defined.

Proof. Let $\mu: P \rightarrow J$ be another surjection where $J \subset R[T]$ an ideal of height $d$. Let $\left(J, \omega_{J}\right)$ be obtain from $(\mu, \chi)$. Then to prove the theorem we need to show that $\left(I, \omega_{I}\right)=\left(J, \omega_{J}\right)$ in $E^{d}(R[T])$.

Applying Lemma [2.2, we get an ideal $K \subset R[T]$ such that $K$ is co-maximal with $I$, $J$ and there exists a surjection $\nu:(R[T])^{d} \rightarrow I \cap K$ such that $\nu \otimes R[T] / I=\omega_{I}$. Since $I$ and $K$ are co-maximal $\nu$ induces a local orientation $\omega_{K}$ of $K$. Therefore, we obtain $\left(I, \omega_{I}\right)+\left(K, \omega_{K}\right)=0$ in $E^{d}(R[T])$.

Let $L=K \cap J$. Then, again as before since $K$ and $J$ are co-maximal $\omega_{K}$ and $\omega_{J}$ will induce a local orientation $\omega_{L}$ of $L$. This will give us $\left(L, \omega_{L}\right)=\left(K, \omega_{K}\right)+\left(J, \omega_{J}\right)$ in
$E^{d}(R[T])$. Thus to prove the theorem it is enough to show that $\left(L, \omega_{L}\right)=0$. Moreover, in view of Theorem 5.1 it is enough to show that $\left(L \otimes R(T), \omega_{L} \otimes R(T)\right)=0$ in $E^{d}(R(T))$. But since $\frac{1}{(d-1)!} \in R$, by [7, Section 4] the Euler class $e(P \otimes R(T), \chi \otimes R(T))$ is welldefined in $E^{d}(R(T))$. This concludes the proof.
Remark 6.13. Let $R$ be an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension $d \geq 2$. Moreover, assume that $\frac{1}{(d-1)!} \in R$. Then Theorem 6.12 and Theorem6.9 say that the assignments of $(P, \lambda, \chi)$ to an element $e(P, \chi) \in E^{d}(R[T])$, is precisely the obstruction class for $P$ to have a unimodular element. In this case we shall call the Euler class group $E^{d}(R[T])$ is the obstruction group to detect the existence of a unimodular element in a projective $R[T]$ module (with trivial determinant) of rank equal to the dimension of $R$. Moreover in [11], taking $R$ to be smooth and $p \neq 2, \mathrm{M}$. K. Das defined the $(d-1)$-th Euler class group $E^{d-1}(R)$ and showed that $E^{d-1}(R)$ is the precise obstruction group to detect the splitting problem of projective $R$-module of rank $d-1$ (with trivial determinant). Here we would like to remark that in his work, we don't know how to remove or replace the "smoothness" assumption.

In terms of Euler class language we prove the following:
Corollary 6.14. Let $R$ be an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension $d \geq 2$ and $\frac{1}{(d-1)!} \in R$. Let $P$ be a projective $R[T]$-module with trivial determinant (via $\chi$ ) of rank $d$. Then $P$ has a unimodular element if and only if $e(P, \chi)=0$ in $E^{d}(R[T])$.

For the next result we shall sketch a proof to avoid repeating same arguments used earlier in this paper.

Theorem 6.15. Let $R$ be a smooth affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$ (for $d \geq 3$ with an additional assumption that $R$ is an integral domain). Let $I \subset R[T]$ be an ideal such that $\mu\left(I / I^{2}\right)=h t(I)=d$. Then any set of generators of $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$ can be lifted to a set of generators of $I$.

Proof. Case - 1. In this case we assume that $d=2$. Following the same proof of [Theorem [5.1, Case - 1] we get a projective $R[T]$-module $P_{1}$ (with trivial determinant) and a surjection $\beta: P_{1} \rightarrow I$. Since $R$ is smooth and $\operatorname{dim}(R) \leq 2$, the module $P_{1}$ is extended from $R$. Hence it is free by [11, Corollary 2.9]. Then again we can follow the last paragraph of the proof of [Theorem 5.1, Case - 1] to conclude the proof in this case. Case - 2. Let $d \geq 3$. Let $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$. Then to prove the theorem it is enough to find a lift of $f_{i}$ 's to a set of generators of $I$. Note that $I(0)=\left\langle f_{1}(0), \ldots, f_{d}(0)\right\rangle+I(0)^{2}$. By [10, Theorem 2.4] there exist $b_{i} \in I(0)$ such that $I(0)=\left\langle b_{1}, \ldots, b_{d}\right\rangle$ with $f_{i}(0)-b_{i} \in I(0)^{2}$. The elements $b_{i}$ 's together $f_{i}$ 's will induce a set of generators $I=\left\langle g_{1}, \ldots, g_{d}\right\rangle+I^{2} T$, where $g_{i}(0)=b_{i}$ and $f_{i}-g_{i} \in I^{2}$, for $i=1, \ldots, d$ (see [5, Remark 3.9]). Now we may use
[5, Corollary 3.8] to lift $I=\left\langle g_{1}, \ldots, g_{d}\right\rangle+I^{2} T$, to a set of generators of $I$. This completes the proof.

## 7. An analogue of Mohan Kumar's result

On polynomial $\overline{\mathbb{F}}_{p}$-algebras. This section is a sequel of Section 3. Here we have shown that one can strengthen the results of section 3 whenever the base field is $\overline{\mathbb{F}}_{p}$. We begin with the following remark.
Remark 7.1. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$. Note that following the arguments given in [9, Section 6] and using Theorem 5.1] one can define the $d$-th weak Euler class group $E_{0}^{d}(R[T])$ without the assumption that ring contains the field of rationals.

Lemma 7.2. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$, where $p \neq 2$. Let $I \subset R[T]$ be an ideal such that $h t(I)=\mu\left(I / I^{2}\right)=\mu(I)=d$. Then any set of generators of $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$ lifts to a set of generators of $I$. In particular, $E^{d}(R[T]) \cong E_{0}^{d}(R[T])$.

Proof. Let $S=\overline{\mathbb{F}}_{p}[T] \backslash\{0\}$ and $A=S^{-1} R[T]$. Then, we observe that $A$ is an affine algebra of dimension $d$ over the field $\overline{\mathbb{F}}_{p}(T)$. If $I$ containing a monic polynomial in $R[T]$, then it follows from [10, Theorem 3.2] that $I=\left\langle f_{1}, \ldots, f_{d}\right\rangle+I^{2}$ has a lift. Therefore, without loss of generality we may assume that $I$ does not contain a monic polynomial in $R[T]$. In particular, this will imply that $\operatorname{ht}(I A)=\mu(I A)=d$. Hence applying Theorem 3.4 we get $F_{i} \in I A$ such that $I A=\left\langle F_{1}, \ldots, F_{d}\right\rangle$, with $f_{i}-F_{i} \in I A^{2}$. Since $I$ does not contain a monic polynomial in $R[T]$, we also have $\operatorname{ht}(\operatorname{IR}(T))=\mu(\operatorname{IR}(T))=$ $\operatorname{dim}(R(T))=d$. Therefore, applying Theorem 5.1 we get a lift of $f_{i}$ 's to a set of generators of $I$. This completes the proof.

Theorem 7.3. Let $R$ be an affine algebra over $\overline{\mathbb{F}}_{p}$ of dimension $d \geq 2$, where $p \neq 2$. Let $P$ be a projective $R[T]$-module with trivial determinant of rank $d$, and let $I \subset R[T]$ be an ideal of height d. Moreover, there exists a surjection $\phi: P \rightarrow I$. Then $P$ has a unimodular element if and only if $\mu(I)=d$.

Proof. Since $P$ has a trivial determinant, we fix an isomorphism $\chi: R[T] \cong \wedge^{d} P$. Let $\left(I, \omega_{I}\right)$ be the Euler cycle induced by the triplet $(P, \chi, \phi)$.

Assume that $\mu(I)=d$. First we would like to mention that this part is essentially contained in Theorem [3.5. Here whenever the base field is $\overline{\mathbb{F}}_{p}$, we give a different proof using the machinery developed in Section 6. Applying Lemma 7.2 we get that the canonical homomorphism $E^{d}(R[T]) \rightarrow E_{0}^{d}(R[T])$ is in fact an isomorphism. Since $\mu(I)=d$, in particular, this will imply that $\left(I, \omega_{I}\right)=0$ in $E^{d}(R[T])$. Now we may apply Theorem6.9to obtain that $P$ has a unimodular element.

Conversely, assume that $P$ has a unimodular element. Therefore, using Theorem 6.9 it follows that $\left(I, \omega_{I}\right)=0$ in $E^{d}(R[T])$. Hence by Theorem6.7 we obtain that $\omega_{I}$ is a global orientation of $I$. In particular, this will imply that $\mu(I)=d$. This completes the proof.

On affine $\overline{\mathbb{F}}_{p}$-algebras. In the remaining part of the section we show that the "smoothness" assumption of [11, Theorem 5.6] can be removed. Before the main result we need some preparation.

Proposition 7.4. Let $A$ be a commutative Noetherian ring and $I \subset A$ be an ideal such that $I=\left\langle a_{1}, \ldots, a_{n}\right\rangle$. Let $u \in A$ such that the canonical image of $u$ in the ring $A / I$ is a unit. Let $v \in A$ be such that $u v-1 \in I$. Let $r$ be an even integer such that $2 \leq r \leq n$. Let $B=A /\left\langle a_{r+1}, \ldots, a_{n}\right\rangle$ and let 'bar' denote going modulo $\left\langle a_{r+1}, \ldots, a_{n}\right\rangle$. Furthermore, assume that the unimodular row ( $\bar{v}, \bar{a}_{2},-\bar{a}_{1}, \ldots, \bar{a}_{r},-\bar{a}_{r-1}$ ) can be completed to an invertible matrix in $B$. Then, there exists $\alpha \in M_{n \times n}(A)$ such that
(1) $\operatorname{det}(\alpha)-u \in I$;
(2) If we define $\left(b_{1}, \ldots, b_{n}\right):=\left(a_{1}, \ldots, a_{n}\right) \alpha$, then $I=\left\langle b_{1}, \ldots, b_{n}\right\rangle$.

Proof. Let $e_{i}$ be the canonical basis of $B^{r+1}$. Let $\delta \in \mathrm{SL}_{r+1}(B)$ such that

$$
e_{1} \delta=\left(\bar{v}, \bar{a}_{2},-\bar{a}_{1}, \ldots, \bar{a}_{r},-\bar{a}_{r-1}\right)
$$

Since $\delta \in \mathrm{SL}_{r+1}(B)$, the rows of $\delta$, say $\left\{e_{1} \delta, e_{2} \delta, \ldots, e_{r+1} \delta\right\}$, form a basis of $B^{r+1}$. Let us define a $B$-linear surjection

$$
f: B^{r+1} \rightarrow \bar{I} \text { by } f\left(e_{1}\right)=\overline{0}, \text { and } f\left(e_{i}\right)=\bar{a}_{i-1} \text { for } i \geq 2
$$

Then we note that $f\left(e_{1} \delta\right)=0$. We define $c_{i-1}:=f\left(e_{i} \delta\right)$, for all $2 \leq i \leq r+1$. This implies,

$$
\begin{equation*}
\bar{I}=\left\langle c_{1}, \ldots, c_{r}\right\rangle \tag{A}
\end{equation*}
$$

By our choice of the matrix $\delta$, it is of the form

$$
\delta=\left(\begin{array}{cc}
\bar{v} & \bar{a}_{2},-\bar{a}_{1}, \ldots, \bar{a}_{r},-\bar{a}_{r-1}  \tag{B}\\
* & \alpha^{\prime}
\end{array}\right),
$$

where $* \in B^{r}$ is a column vector and $\alpha^{\prime}=\left(\lambda_{i j}\right) \in M_{r \times r}(B)$. Hence we observe that

$$
\left(\widehat{e}_{i} \alpha^{\prime}\right)\left(\bar{a}_{1}, \ldots, \bar{a}_{r}\right)^{T}=\sum_{i=1}^{r} \lambda_{i j} \bar{a}_{i}=f\left(e_{j+1} \delta\right)\left(\text { as } f\left(e_{1}\right)=0\right)=c_{i},
$$

where $\widehat{e}_{i}$ is the canonical basis (row) vector of $B^{r}$, for all $i=1, \ldots, r$. In particular, this implies $\left(\bar{a}_{1}, \ldots, \bar{a}_{r}\right)\left(\alpha^{\prime}\right)^{T}=\left(c_{1}, \ldots, c_{r}\right)$. We choose $\beta \in M_{r \times r}(A)$ such that $\bar{\beta}=\left(\alpha^{\prime}\right)^{T}$.

Let 'tilde' denote going modulo $I$. Since $\delta \in \mathrm{SL}_{r+1}(B)$ we have $\widetilde{\delta} \in \mathrm{SL}_{r+1}(A / I)$. In particular, from (B) it follows that $\operatorname{det}(\beta)-u \in I$.

We define $\alpha:=\left(\beta \perp \mathrm{I}_{n-r}\right)$, where $\mathrm{I}_{n-r}$ is the identity matrix in $A$ of order $n-r$. Let $\left(b_{1}, \ldots, b_{n}\right)=\left(a_{1}, \ldots, a_{n}\right) \alpha$. Here we observe that $b_{r+i}=a_{r+i}$ for all $i=1, \ldots, n-r$. Moreover, from the definition of $\alpha$ we get $\widehat{\operatorname{det}(\alpha)}=\widehat{\operatorname{det}(\beta)}=\widetilde{u}$. Therefore, it only remains to establish (2). To see this we notice that it is enough to show that $\bar{I}=$ $\left\langle\bar{b}_{1}, \ldots, \bar{b}_{r}\right\rangle$. But since $\beta$ is a lift of $\left(\alpha^{\prime}\right)^{T}$ we have $c_{i}=\bar{b}_{i}$ for $i=1, \ldots, r$. Therefore, from (A) it follows that $\bar{I}=\left\langle\bar{b}_{1}, \ldots, \bar{b}_{r}\right\rangle$. This completes the proof.

Lemma 7.5. Let $R$ be an affine algebra of dimension $d \geq 5$ over $\overline{\mathbb{F}}_{p}$, where $p \neq 2,3$. Let $J \subset R$ be an ideal of height $d-1$ such that $\mu(J)=d-1$. Assume that, there exist $b_{i} \in J$ $(i=1, \ldots, d-1)$ such that $J=\left\langle b_{1}, \ldots, b_{d-1}\right\rangle+J^{2}$. Then, there exist $c_{1}, \ldots, c_{d-1} \in J$ such that $J=\left\langle c_{1}, \ldots, c_{d-1}\right\rangle$ and $b_{i}-c_{i} \in J^{2}$ for all $i=1, \ldots, d-1$.

Proof. Let $J=\left\langle a_{1}, \ldots, a_{d-1}\right\rangle$. We consider any $(d-1)$-tuple $\left[\left(a_{1}, \ldots, a_{d-1}\right)\right]$ as a map $(R / J)^{d-1} \rightarrow J / J^{2}$ sending $e_{i} \rightarrow a_{i} \bmod \left(J^{2}\right)$. Applying [4, Lemma 2.2] we can find a matrix $\delta \in \mathrm{GL}_{d-1}(A / J)$ such that $\left[\left(a_{1}, \ldots, a_{d-1}\right) \delta\right]=\left[\left(b_{1}, \ldots, b_{d-1}\right)\right]$. Let $\beta \in$ $M_{(d-1) \times(d-1)}(A)$ be a lift of $\delta$. Let $u \in A$ such that $u \operatorname{det}(\beta)-1 \in J$. Applying prime avoidance lemma (cf. [7. Corollary 2.13]), replacing $a_{i}{ }^{\prime}$ s suitably we may assume that $B=R /\left\langle a_{5}, \ldots, a_{d-1}\right\rangle$ is an affine $\overline{\mathbb{F}}_{p}$-algebra of dimension 5 . Let 'bar' denote going modulo $\left\langle a_{5}, \ldots, a_{d-1}\right\rangle$. Since $p \geq 5$, using [13, Theorem 1.2] we get the unimodular row $\left(\bar{u}, \bar{a}_{2},-\bar{a}_{1}, \bar{a}_{4},-\bar{a}_{3}\right) \in \operatorname{Um}_{5}(B)$ is completable to an invertible matrix in $B$. We may now apply Proposition 7.4 on the unimodular row ( $\bar{u}, \bar{a}_{2},-\bar{a}_{1}, \bar{a}_{4},-\bar{a}_{3}$ ) to obtain the following.
(1) $\theta \in M_{(d-1) \times(d-1)}(A)$ such that $\operatorname{det}(\theta)-\operatorname{det}(\beta) \in J$;
(2) if we take $\left(\beta_{1}, \ldots, \beta_{d-1}\right)=\left(a_{1}, \ldots, a_{d-1}\right) \theta$, then $J=\left\langle\beta_{1}, \ldots, \beta_{d-1}\right\rangle$.

Let 'tilde' denote going modulo $J$. Then, from (1) it follows that $(\widetilde{\theta})^{-1} \widetilde{\beta} \in \mathrm{SL}_{d-1}(A / J)$. We can now apply [10, Corollary 2.3] and lift $(\widetilde{\theta})^{-1} \widetilde{\beta}$ to a matrix $\gamma \in \mathrm{SL}_{d-1}(A)$. We define $\left(\beta_{1}, \ldots, \beta_{d-1}\right) \gamma=\left(c_{1}, \ldots, c_{d-1}\right)$. Then $J=\left\langle c_{1}, \ldots, c_{d-1}\right\rangle$. It only remains to show that $b_{i}-c_{i} \in J^{2}$ for all $i=1, \ldots, d-1$. But this follows from the following fact.

$$
\left[\left(c_{1}, \ldots, c_{d-1}\right)\right]=\left[\left(\beta_{1}, \ldots, \beta_{d-1}\right) \widetilde{\gamma}\right]=\left[\left(\beta_{1}, \ldots, \beta_{d-1}\right)(\widetilde{\theta})^{-1} \widetilde{\beta}\right]=\left[\left(a_{1}, \ldots, a_{d-1}\right) \widetilde{\delta}\right]=\left[\left(b_{1}, \ldots, b_{d-1}\right)\right]
$$

Theorem 7.6. Let $R$ be an affine algebra of dimension $d \geq 5$ over $\overline{\mathbb{F}}_{p}$, where $p \neq 2,3$. Let $P$ be a projective $R$-module of rank $d-1$ with trivial determinant. Then $P$ splits off a free summand of rank one if and only if there exists a generic section $I$ of $P$ such that $I$ is generated by $d-1$ elements.

Proof. If $P$ has a unimodular element, then the proof is essentially contained in [11, Theorem 5.1]. Therefore, we will only need to prove the 'only if' part. Suppose that, $\alpha: P \rightarrow I$ is a surjection where $\operatorname{ht}(I)=d=\mu(I)$. We fix an isomorphism $\chi: R \cong$ $\wedge^{d-1} P$. Since determinant of $P$ is trivial, it follows from [10, Corollary 2.10] that there exists $\delta:(R / I)^{d-1} \cong P / I P$ such that $\wedge^{d-1} \omega=\chi \otimes R / I$. Let $\omega:(R / I)^{d-1} \rightarrow I / I^{2}$ be the surjection defined by $\omega=(\alpha \otimes R / I) \circ \delta$. Since $\mu(I)=d-1$, applying Lemma 7.5we observe that any set of generators of $I / I^{2}$ lifts to a set of generators of $I$. In particular, the map $\omega$ has a surjective lift. Then, using the subtraction principle as stated in [11, Theorem 3.4] it follows that $P$ has a unimodular element.

Remark 7.7. For $d=2$, the above theorem is true trivially. Therefore, the only remaining cases are $d=3$ and 4 .
