## ON DEFORMATIONS OF ISOLATED SINGULARITY FUNCTIONS

AURÉLIO MENEGON AND MIRIAM DA SILVA PEREIRA

ABSTRACT. We study multi-parameters deformations of isolated singularity functiongerms on either a subanalytic set or a complex analytic spaces. We prove that if such a deformation has no coalescing of singular points, then it has constant topological type. This extends some classical results due to Lê & Ramanujam (1976) and Parusiński (1999), as well as a recent result due to Jesus-Almeida and the first author. It also provides a sufficient condition for a one-parameter family of complex isolated singularity surfaces in  $\mathbb{C}^3$  to have constant topological type. On the other hand, for complex isolated singularity families defined on an isolated determinantal singularity, we prove that  $\mu$ -constancy implies constant topological type.

### INTRODUCTION

The study of deformations of maps and spaces plays a central role in Singularity Theory and in Complex Geometry. For holomorphic isolated singularity function-germs on a complex affine space  $\mathbb{C}^n$ , the topological behavior of small perturbations is related to the Milnor number, which is an analytic invariant with a very clear topological and algebraic meaning. In fact, when  $n \neq 3$  there is a classical result due to Lê & Ramanujam [4] in 1976, which states that a family  $f_s : (\mathbb{C}^n, 0) \to (\mathbb{C}, 0)$  is topologically trivial if and only if the Milnor number  $\mu(f_s)$  is constant, for  $s \in \mathbb{C}$  sufficiently small.

The case n = 3 is one of the main open problems in Singularity Theory, known as the  $\mu$ -constant conjecture. Here, topological triviality means that for each s small enough there exists a homeomorphism of germs  $h_s : (\mathbb{C}^n, 0) \to (\mathbb{C}^n, 0)$  that takes the germ of  $V(f_s) := f_s^{-1}(0)$  at the origin onto the germ of  $V(f_0) := f_0^{-1}(0)$  at the origin.

In 1999, Parusiński [6] extended Lê & Ramanujam's result for K-analytic isolated singularity families  $f_s : (\mathbb{K}^n, 0) \to (\mathbb{K}, 0)$ , with  $\mathbb{K} = \mathbb{C}$  or  $\mathbb{R}$ , even when n = 3, provided that the family depends linearly on the parameter  $s \in \mathbb{K}$ . This means that it has the form  $f_s = f_0 + s\varphi$ , for some K-analytic isolated singularity function-germ  $\varphi : (\mathbb{K}^n, 0) \to (\mathbb{K}, 0)$ .

Recently, Jesus-Almeida and the first author [5] studied K-analytic families  $f_s$ :  $(X, 0) \to (\mathbb{K}, 0)$  depending linearly on one parameter  $s \in \mathbb{K}$ , where  $(X, 0) \subset (\mathbb{K}^N, 0)$  is the germ of a subanalytic set, when  $\mathbb{K} = \mathbb{R}$ , or a complex analytic space, when  $\mathbb{K} = \mathbb{C}$ . In particular, it was proved that if such a family has no coalescing of singular points, then it has constant topological type. Here, having no coalescing of singular points means that there exist real numbers  $\delta > 0$  and  $\epsilon > 0$  such that  $\Sigma(f_s) \cap \mathbb{B}_{\epsilon} = \{0\}$  for every  $s \in \mathbb{D}_{\delta}$ , where  $\Sigma(f_s)$  denotes the singular locus of  $f_s$  (in the stratified sense, with respect to a given (w)-regular stratification) and  $\mathbb{B}_{\epsilon}$  denotes the closed ball around 0 in  $\mathbb{K}^N$ . Also, having constant topological type means that for each  $s \in (\mathbb{K}, 0)$  there exists a homeomorphism of germs  $h_s : (V(f_s), 0) \to (V(f_0), 0)$ . Clearly, this is weaker than having topological triviality in the sense of Lê & Ramanujam.

The first author was supported by the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Brazil.

The first goal of this paper is to study K-analytic isolated singularity families  $f_{s_1,\ldots,s_k}$ :  $(X,0) \to (\mathbb{K},0)$  depending linearly on k-many parameters  $s_1,\ldots,s_k \in \mathbb{K}$ , with k > 1. Then this will allow us to study one-parameter K-analytic isolated singularity families  $\mathbf{f}_s: (X,0) \to (\mathbb{K},0)$  that depend polynomially on  $s \in \mathbb{K}$ , which means it has the form

$$\mathbf{f}_s = f_0 + s^{a_1} \varphi_1 + s^{a_2} \varphi_2 + \dots + s^{a_k} \varphi_k \,,$$

with  $0 < a_1 < \cdots < a_k$ . This will be done by setting

$$f_{s_1,\ldots,s_k} := f_0 + s_1\varphi_1 + s_2\varphi_2 + \cdots + s_k\varphi_k \,,$$

so that  $f_s = f_{s^{a_1},...,s^{a_k}}$ .

Our main results are the following:

In Section 1, we give an easy criterium to assure that a K-analytic family  $f_{s_1,\ldots,s_k}$ :  $(X,0) \to (\mathbb{K},0)$  has isolated singularity or even no coalescing of critical points. This is Proposition 1.2. In Section 2, we prove:

**Theorem 0.1.** Let  $(X, 0) \subset (\mathbb{K}^N, 0)$  be the germ of either a subanalytic set, when  $\mathbb{K} = \mathbb{R}$ , or a complex analytic space, when  $\mathbb{K} = \mathbb{R}$ . Let S be a (w)-regular stratification of a representative X of (X, 0). Let  $(f_{s_1,...,s_k})$  be a family of  $\mathbb{K}$ -analytic isolated singularity function-germs on (X, 0) depending linearly on the parameters  $s_1, \ldots, s_k \in \mathbb{K}$ . If  $(f_{s_1,...,s_k})$  has no coalescing of singular points (with respect to S) then it has constant topological type.

As an important consequence, we have:

**Theorem 0.2.** Let  $\mathbf{f}_s : (X, 0) \to (\mathbb{K}, 0)$  be a one-parameter  $\mathbb{K}$ -analytic isolated singularity family depending polynomially on  $s \in \mathbb{K}$ . Let  $f_{s_1,\ldots,s_k} : (X, 0) \to (\mathbb{K}, 0)$  be the multi-parameter family associated to  $(\mathbf{f}_s)$ , defined as above. If  $(f_{s_1,\ldots,s_k})$  has no coalescing of singular points, then  $(\mathbf{f}_s)$  has constant topological type.

Corollary 0.2 relates to the  $\mu$ -constant conjecture, as it provides a sufficient condition for a one-parameter family of complex isolated singularity surfaces in  $\mathbb{C}^3$  to have constant topological type. Precisely, we have:

**Corollary 0.3.** Let  $\mathbf{f}_s : (\mathbb{C}^3, 0) \to (\mathbb{C}, 0)$  be an analytic isolated singularity family depending polynomially on  $s \in \mathbb{C}$ . Let  $f_{s_1,\ldots,s_k} : (\mathbb{C}^3, 0) \to (\mathbb{C}, 0)$  be the multi-parameter family associated to  $(\mathbf{f}_s)$ , as above. If  $(f_{s_1,\ldots,s_k})$  is  $\mu$ -constant, then  $(\mathbf{f}_s)$  has constant topological type.

The case when the family  $\mathbf{f}_s : (\mathbb{C}^3, 0) \to (\mathbb{C}, 0)$  depends analytically on  $s \in \mathbb{C}$  is analogous, by a well-known result of Samuel [7] (see also [4], Theorem 1.7).

In Section 3, we restrict our attention to the particular case of complex analytic isolated singularity families  $f_{s_1,\ldots,s_k}: (X,0) \to (\mathbb{C},0)$  depending linearly on the parameter  $s_1,\ldots,s_k \in \mathbb{C}$ , with  $k \geq 1$ , where  $(X,0) \subset (\mathbb{C}^N,0)$  is the germ of a complex isolated determinantal singularity (IDS). In this case, there is a well-defined Milnor number  $\mu(f_s)$  in the sense of [1].

We prove:

**Theorem 0.4.** Let  $(X, 0) \subset (\mathbb{C}^N, 0)$  be the germ of a complex isolated determinantal singularity. Let  $f_{s_1,\ldots,s_k} : (X, 0) \to (\mathbb{C}, 0)$  be a family of isolated singularity functiongerms depending linearly on  $s_1, \ldots, s_k \in \mathbb{C}$ , with  $k \ge 1$ . If  $(f_{s_1,\ldots,s_k})$  is  $\mu$ -constant, then it has constant topological type.

As a consequence, like before, we have:

**Corollary 0.5.** Let  $(X, 0) \subset (\mathbb{C}^N, 0)$  be the germ of a complex isolated determinantal singularity. Let  $\mathbf{f}_s : (X, 0) \to (\mathbb{C}, 0)$  be an analytic isolated singularity family depending polynomially on  $s \in \mathbb{C}$ , and let  $f_{s_1,\ldots,s_k} : (X, 0) \to (\mathbb{C}, 0)$  be the multi-parameter family associated to  $(\mathbf{f}_s)$ , as above. If  $(f_{s_1,\ldots,s_k})$  is  $\mu$ -constant, then  $(\mathbf{f}_s)$  has constant topological type.

## 1. Isolated singularity families and coalescing of singular points

Let  $(X, 0) \subset (\mathbb{K}^N, 0)$  be as above, and let  $\mathcal{S} = (\mathcal{S}_{\alpha})_{\alpha \in \Lambda}$  be a (w)-regular stratification of a representative X of (X, 0), in the sense of [8]. Without losing generality, we can suppose that  $\{0\}$  is a stratum of  $\mathcal{S}$ .

Let  $\tilde{f}_0 : (\mathbb{K}^N, 0) \to (\mathbb{K}, 0)$  be an analytic function-germ and let  $f_0 : (X, 0) \to (\mathbb{K}, 0)$ be the restriction of  $\tilde{f}_0$  to (X, 0). Clearly, the singular locus  $\Sigma(f_0)$  of  $f_0$  is formed by  $X \cap \Sigma(\tilde{f}_0)$ , the intersection of X with the critical set of  $\tilde{f}_0$ , together with the points  $x \in X \setminus \Sigma(\tilde{f}_0)$  such that the smooth manifold  $(\tilde{f}_0)^{-1}(\tilde{f}_0(x))$  intersects  $\mathcal{S}_{\alpha(x)}$  not transversally at x in  $\mathbb{K}^N$ , where  $\mathcal{S}_{\alpha(x)}$  denotes the stratum of the stratification  $\mathcal{S}$  that contains the point x.

Notice that since we chose a stratification S such that  $\{0\}$  is a stratum, the origin  $0 \in X \subset \mathbb{K}^N$  is a singular point of  $f_0$ , even if  $\tilde{f}_0$  is a submersion at  $0 \in \mathbb{K}^N$ .

We say that  $f_0: (X, 0) \to (\mathbb{K}, 0)$  has an *isolated singularity* if there exists a positive real number  $\epsilon > 0$  such that  $\Sigma(f_0) \cap \mathbb{B}_{\epsilon} = \{0\}$ . This means that the restriction of  $f_0$ to each stratum  $\mathcal{S}_{\alpha} \neq \{0\}$  is a submersion.

Now, if  $\tilde{f}_s : (\mathbb{K}^N, 0) \to (\mathbb{K}, 0)$  is a deformation of  $\tilde{f}_0$  depending continuously on the parameter  $s \in (\mathbb{K}^k, 0)$ , it induces a deformation  $f_s : (X, 0) \to (\mathbb{K}, 0)$  of  $f_0$  that obviously depends continuously on s. In the case when  $f_0$  has an isolated singularity, the next lemma relates the critical set of  $f_s$  with the critical set of  $\tilde{f}_s$  inside some small neighborhood of  $0 \in \mathbb{K}^N$ , whenever ||s|| is small enough.

We have:

**Lemma 1.1.** Suppose that  $f_0 : (X, 0) \to (\mathbb{K}, 0)$  has an isolated singularity, and let  $\epsilon > 0$  be such that  $\Sigma(f_0) \cap \overline{\mathbb{B}}_{\epsilon} = \{0\}$ . Then there exists  $\delta > 0$  sufficiently small such that for every  $s \in \mathbb{D}_{\delta}$  one has that

$$\Sigma(f_s) \cap \overline{\mathbb{B}}_{\epsilon} = \left(\Sigma(\tilde{f}_s) \cap X \cap \overline{\mathbb{B}}_{\epsilon}\right) \cup \{0\}.$$

Proof. Clearly, one has that  $\Sigma(\tilde{f}_s) \cap X \subset \Sigma(f_s)$ , so one inclusion is obvious. On the other hand, for every  $x \in X \cap \overline{\mathbb{B}}_{\epsilon}$  fixed, one has that either x is the origin or  $(\tilde{f}_0)^{-1}(\tilde{f}_0(x))$  is smooth at x and it intersects  $\mathcal{S}_{\alpha(x)}$  transversally at x in  $\mathbb{K}^N$ . Since transversality is a stable property, there exists  $\delta(x) > 0$  sufficiently small such that for every  $s \in \mathbb{D}_{\delta(x)}$  one has that either  $x \in \Sigma(\tilde{f}_s) \cup \{0\}$  or  $(\tilde{f}_s)^{-1}(\tilde{f}_s(x))$  is smooth at x and it intersects  $\mathcal{S}_{\alpha(x)}$  transversally at x in  $\mathbb{K}^N$ . Moreover, there exists a small neighborhood  $V_x$  of x in  $X \cap \overline{\mathbb{B}}_{\epsilon}$  such that for every  $x' \in V_x$  and for every  $s \in \mathbb{D}_{\delta(x)}$  one has that either  $x' \in \Sigma(\tilde{f}_s) \cup \{0\}$  or  $(\tilde{f}_s)^{-1}(\tilde{f}_s(x'))$  is smooth at x' and it intersects  $\mathcal{S}_{\alpha(x)}$  transversally at x' in  $\mathbb{K}^N$ . Therefore, since  $X \cap \overline{\mathbb{B}}_{\epsilon}$  is compact, there exists  $\delta > 0$  such that for every  $x \in X \cap \overline{\mathbb{B}}_{\epsilon}$  and for every  $s \in \mathbb{D}_{\delta}$  one has that either  $x \in \Sigma(\tilde{f}_s) \cup \{0\}$  or  $x \notin \Sigma(f_s)$ . Hence  $\Sigma(f_s) \cap \overline{\mathbb{B}}_{\epsilon} \subset (\Sigma(\tilde{f}_s) \cap X \cap \overline{\mathbb{B}}_{\epsilon}) \cup \{0\}$ .

We say that a family  $(f_s)$  as above is an *isolated singularity family* if for each  $s \in \mathbb{K}$  with ||s|| sufficiently small, the function-germ  $f_s : (X, 0) \to (\mathbb{K}, 0)$  has isolated

singularity. That is, if there exists  $\delta > 0$  such that for every  $s \in \mathbb{D}_{\delta}$  there is  $\epsilon(s) > 0$  such that  $\Sigma(f_s) \cap \mathbb{B}_{\epsilon(s)} = \{0\}$ .

An isolated singularity family  $(f_s)$  as above is said to have no coalescing of singular points if there exist real numbers  $\delta > 0$  and  $\epsilon > 0$  such that  $\Sigma(f_s) \cap \mathbb{B}_{\epsilon} = \{0\}$  for every  $s \in \mathbb{D}_{\delta}$ .

As an immediate consequence of Lemma 1.1, we have:

**Proposition 1.2.** Suppose that  $f_0 : (X, 0) \to (\mathbb{K}, 0)$  has isolated singularity. Then:

- (i) If  $(f_s)$  is an isolated singularity family, then  $(f_s)$  is also an isolated singularity family.
- (ii) If  $(f_s)$  has no coalescing of critical points, then  $(f_s)$  has no coalescing of singular points.

**Example 1.3.** Consider  $X = \{x^2 - y^2 = 0\} \subset \mathbb{K}^3$  with the stratification given by  $S_0 = X \setminus \{x = y = 0\}$  and  $S_1 = \{x = y = 0\}$ . Consider the family of function-germs  $f_s : (X, 0) \to (\mathbb{K}, 0)$  given by

$$f_s(x, y, z) = x^3 + y^4 + z^2 + sx^4 + s^2y^5$$
.

Since  $f_0$  has an isolated singularity and since the family  $(\tilde{f}_s)$  on  $\mathbb{K}^3$  is an isolated singularity family with no coalescing of critical points, it follows from Theorem 1.2 that  $(f_s)$  is an isolated singularity family with no coalescing of singular points.

# 2. One-parameter families of isolated singularities

Let  $(X,0) \subset (\mathbb{K}^N,0)$  and  $\mathcal{S} = (\mathcal{S}_{\alpha})_{\alpha \in \Lambda}$  be as above. Let  $g_s : (X,0) \to (\mathbb{K},0)$  be an isolated singularity family of  $\mathbb{K}$ -analytic function-germs depending linearly on the parameter  $s \in \mathbb{K}$ . This means that each  $g_s$  has the form

$$g_s(z) = g_0(z) + s\varphi(z) \,,$$

where  $g_0: (X,0) \to (\mathbb{K},0)$  and  $\varphi: (X,0) \to (\mathbb{K},0)$  are  $\mathbb{K}$ -analytic isolated singularity function-germs.

Define the map-germ

$$\begin{array}{rcl} \mathcal{F}: & (X,0) & \to & (\mathbb{K}^2,0) \\ & z & \mapsto & \left(g_0(z),\varphi(z)\right) \end{array},$$

and for each  $s \in \mathbb{K}$  define the line  $\mathcal{H}_s$  in  $\mathbb{K}^2$  given by

$$\mathcal{H}_s := \{(y_0, y_1) \in \mathbb{K}^2; y_0 + sy_1 = 0\}.$$

Notice that

$$(\mathcal{F})^{-1}(\mathcal{H}_s) = V(g_s) \,.$$

Following [5] (Definition 2.1), we say that the family  $(g_s)$  is  $\Delta$ -regular (with respect to the stratification  $\mathcal{S}$ ) if the line  $\mathcal{H}_0$  is not a limit of secant lines of the discriminant set  $\Delta(\mathcal{F})$  of  $\mathcal{F}$  at  $0 \in \mathbb{K}^2$ . This means that there exist a neighborhood U of 0 in  $\mathbb{K}^2$ and a real number  $\delta > 0$  such that

$$\mathcal{H}_s \cap \Delta(\mathcal{F}) \cap U \subset \{0\}$$

whenever  $||s|| < \delta$ . Now we give:

Now we give:

**Definition 2.1.** Let  $(g_s)$  be an isolated singularity family as above, and let  $\epsilon > 0$  be a small real number. We say that a real number  $\delta > 0$  is a good parameter-radius for  $(g_s)$  in  $\mathbb{B}_{\epsilon}$  if for every  $s \in \mathbb{D}_{\delta}$  one has that:

(i)  $\Sigma(g_s) \cap \mathbb{B}_{\epsilon} = \{0\};$ 

(ii)  $V(g_s) \setminus V(\varphi)$  intersects the sphere  $\mathbb{S}_{\epsilon}$  transversally in  $\mathbb{K}^n$ , in the stratified sense; (iii)  $\mathcal{H}_s \cap \Delta(\mathcal{F}) \cap U \subset \{0\}$ .

It follows from [5] (Lemma 3.2 together with Proposition 4.4) that if  $(g_s)$  has no coalescing of singular points, then for every  $\epsilon > 0$  small enough there exists a good parameter-radius  $\delta > 0$  for  $(g_s)$  in  $\mathbb{B}_{\epsilon}$ .

Then the next proposition easily follows from the proof of (5], Theorem 1.1).

**Proposition 2.2.** Let  $(g_s)$  be an isolated singularity family as above. If  $\epsilon > 0$  is small enough and if  $\delta > 0$  is a good parameter-radius for  $(g_s)$  in  $\mathbb{B}_{\epsilon}$ , then for each  $s \in \mathbb{D}_{\delta}$ there exists a homeomorphism

$$h_s: V(g_s) \cap \mathbb{B}_{\epsilon} \to V(g_0) \cap \mathbb{B}_{\epsilon}$$

that fixes the origin.

## 3. Multi-parameters families of isolated singularities

Let  $(X, 0) \subset (\mathbb{K}^N, 0)$  and  $\mathcal{S}$  be as above. Let  $f_{s_1, \dots, s_k} : (X, 0) \to (\mathbb{K}, 0)$  be an isolated singularity family of  $\mathbb{K}$ -analytic function-germs depending linearly on the parameters  $s_1, \dots, s_k$ , with k > 1. This means that each  $f_{s_1, \dots, s_k}$  has the form

$$f_{s_1,\ldots,s_k}(z) = f_0(z) + s_1\varphi_1(z) + \cdots + s_k\varphi_k(z) ,$$

where  $f_0: (X,0) \to (\mathbb{K},0)$  and  $\varphi_i: (X,0) \to (\mathbb{K},0)$  for  $i = 1, \ldots, k$  are  $\mathbb{K}$ -analytic isolated singularity function-germs.

If  $\mathbb{K} = \mathbb{R}$  set  $\xi := 1$ , and if  $\mathbb{K} = \mathbb{C}$  set  $\xi := 2$ . Then let  $\mathbb{S}^{\xi k-1}$  denote the unitary sphere around 0 in  $\mathbb{K}^k$ .

Now, for each point  $r = (r_1, \ldots, r_k) \in \mathbb{S}^{\xi k-1}$  fixed, consider the one-parameter isolated singularity family  $(g_s^r)$  given by

$$g_s^r(z) := f_{sr_1,\dots,sr_k}(z) \,.$$

As before, we define the map-germ

$$\begin{aligned} \mathcal{F}^r: & (X,0) &\to & (\mathbb{K}^2,0) \\ & z &\mapsto & \left( f_0(z), r_1 \varphi_1(z) + \dots + r_k \varphi_k(z) \right) \end{aligned},$$

so that

$$(\mathcal{F}^r)^{-1}(\mathcal{H}_s) = V(g_s^r)$$

We say that the family  $(f_{s_1,\ldots,s_k})$  is  $\Delta$ -regular if for each  $r \in \mathbb{S}^{\xi k-1}$  the corresponding one-parameter family  $(g_s^r)$  is  $\Delta$ -regular. This means that for each  $r \in \mathbb{S}^{\xi k-1}$  there exist a neighborhood  $U_r$  of 0 in  $\mathbb{K}^2$  and a real number  $\delta_r > 0$  such that

$$\mathcal{H}_s \cap \Delta(\mathcal{F}^r) \cap U_r \subset \{0\}$$

whenever  $||s|| < \delta_r$ . We have:

**Lemma 3.1.** If the family  $(f_{s_1,\ldots,s_k})$  is  $\Delta$ -regular, then there exist a neighborhood U of 0 in  $\mathbb{K}^2$  and a real number  $\delta > 0$  such that for every  $r \in \mathbb{S}^{\xi k-1}$  and for every  $s \in \mathbb{K}$  with  $||s|| < \delta$  one has

$$\mathcal{H}_s \cap \Delta(\mathcal{F}^r) \cap U \subset \{0\}.$$

*Proof.* By continuity, for each  $r \in \mathbb{S}^{\xi k-1}$  fixed, there exists some small open neighborhood  $N_r$  of r in  $\mathbb{S}^{\xi k-1}$  such that, for every  $w \in N_r$ , one has that  $\mathcal{H}_s \cap \Delta(\mathcal{F}^w) \cap U_r \subset \{0\}$  whenever  $||s|| < \delta_r$ . Then the result follows from the fact that  $\mathbb{S}^{\xi k-1}$  is compact.  $\Box$ 

Now suppose that the family  $(f_{s_1,\ldots,s_k})$  has no coalescing of singular points. Then it is clear that there exists  $\lambda > 0$  sufficiently small such that for every  $r \in \mathbb{S}^{\xi k-1}$  and for every  $||s|| \leq \lambda$  one has that  $\Sigma(g_s^r) \cap \mathbb{B}_{\epsilon} = \{0\}$ .

Moreover, it is not difficult to see that  $\lambda > 0$  can be chosen small enough so that it is also true that  $V(g_s^r) \setminus V(r_1\varphi_1 + \cdots + r_k\varphi_k)$  intersects the sphere  $\mathbb{S}_{\epsilon}$  transversally in  $\mathbb{K}^n$ , in the stratified sense, for every  $s \in \mathbb{D}_{\lambda}$  and for every  $r = (r_1, \ldots, r_k) \in \mathbb{S}^{\xi k-1}$ .

So if we set  $\delta' := \min\{\delta, \lambda\}$ , it follows that for every  $\epsilon > 0$  small enough,  $\delta'$  is a good parameter-radius for  $(g_s^r)$  in  $\mathbb{B}_{\epsilon}$ , for every  $r \in \mathbb{S}^{\xi k-1}$ . Then it follows from Proposition 2.2 that for each  $s = (s_1, \ldots, s_k) \in \mathbb{K}^k$  with  $\|s\| < \delta'$  there exists a homeomorphism

$$h_s: V(f_{s_1,\ldots,s_k}) \cap \mathbb{B}_{\epsilon} \to V(f_0) \cap \mathbb{B}_{\epsilon}$$

that fixes the origin.

This proves Theorem 0.1, and Theorem 0.2 follows easily.

**Example 3.2.** Recall the one-parameter isolated singularity family

$$\mathbf{f}_s(x, y, z) = x^3 + y^4 + z^2 + sx^4 + s^2 y^5$$

on  $X = \{x^2 - y^2 = 0\} \subset \mathbb{K}^3$ , as in Example 1.3. Consider the two-parameters family  $f_{s_1,s_2}(x, y, z) = x^3 + y^4 + z^2 + s_1 x^4 + s_2 y^5$ 

on X. Using Theorem 1.2, one can easily see that the family  $(f_{s_1,s_2})$  has no coalescing of singular points. So it follows from Theorem 0.2 that the family  $(\mathbf{f}_s)$  has constant topological type.

Finally, Corollary 0.3 follows from Theorem 0.2 together with the following:

**Lemma 3.3.** In the case when  $(X, 0) = (\mathbb{C}^n, 0)$ , an isolated singularity family  $(f_{s_1,...,s_k})$  has no coalescing of singular (critical) points if and only if it is  $\mu$ -constant.

Proof. First notice that in the case when k = 1 the result is well-known (see [3] for instance). So, in our case, where k > 1, it follows that  $(f_{s_1,\ldots,s_k})$  has no coalescing of critical points if and only for each  $r \in \mathbb{S}^{2k-1}$  there exists a real number  $\lambda_r > 0$  such that  $\mu(g_s^r)$  is constant for every  $s \in \mathbb{C}$  with  $||s|| < \lambda$ . But since  $\mathbb{S}^{2k-1}$  is compact, that happens if and only if there is a real number  $\lambda > 0$  such that  $\mu(f_{s_1,\ldots,s_k})$  is constant for every  $s \in \mathbb{C}^k$  with  $||s|| < \lambda$ .

**Example 3.4.** Consider the two-parameters isolated singularity family  $(f_{s_1,s_2})$  on  $\mathbb{C}^2$  given by

$$f_{s_1,s_2}(x,y) := x^3 + y^2 + x^2y + s_1(x^2 - x^2y) + s_2x^2$$

Note that it is not  $\mu$ -constant. In fact,  $\mu(f_0) = 2$ , while  $\mu(f_{0,s_2}) = 1$  for  $s_2 \neq 0$ . However, the one-parameter family  $(g_s)$  given by

$$g_s(x,y) := f_{s_1,-s_1}(x,y) = x^3 + y^2 + x^2y + s_1(-x^2y)$$

is clearly  $\mu$ -constant.

Clearly, if the multi-parameters family  $(f_{s_1,\ldots,s_k})$  associated to a one-parameter family  $(\mathbf{f}_s)$  on  $\mathbb{C}^n$  is  $\mu$ -constant, then  $(\mathbf{f}_s)$  is also  $\mu$ -constant. Thus our criterium for constancy of the topological type of  $(\mathbf{f}_s)$  is weaker then the criterium suggested by Le-Ramanujam's Conjecture when n = 3. So the natural question is:

**Question 3.5.** Is there an example of a  $\mu$ -constant isolated singularity family  $(\mathbf{f}_s)$  on  $\mathbb{C}^3$  such that the corresponding multi-parameters family  $(f_{s_1,\ldots,s_k})$  is not  $\mu$ -constant?

A negative answer to that question would imply that the  $\mu$ -constant conjecture is true.

# 4. Deformations of isolated singularity function-germs on IDS

Now let  $(X, 0) \subset (\mathbb{C}^N, 0)$  be the germ of a complex analytic isolated determinantal singularity (IDS), and let  $\tilde{f}_s : (\mathbb{C}^N, 0) \to (\mathbb{C}, 0)$  be a family of complex function-germs depending holomorphically on the parameter  $s = (s_1, \ldots, s_k) \in \mathbb{C}^k$ . This means that the map  $\tilde{F} : (\mathbb{C}^N \times \mathbb{C}^k, (0, 0)) \to (\mathbb{C}, 0)$  defined by  $F(x, s) := \tilde{f}_s(x)$  is holomorphic. The restriction of  $\tilde{F}$  to (X, 0) defines a family of complex function-germs

$$f_s: (X,0) \to (\mathbb{C},0)$$
.

If  $(f_s)$  is an isolated singularity family, then for each  $s \in (\mathbb{C}^k, 0)$  there is a well-defined Milnor number  $\mu(f_s)$  in the sense of [1]. It is the number of points in the critical locus of a morsification  $f'_s : X' \to \mathbb{C}$  of  $f_s$ , where X' is a smoothing of X near the origin.

In the particular case when X is an ICIS, it is well-know that  $\mu(f_s) \leq \mu(f_0)$  whenever ||s|| is small enough. Moreover, the family  $(f_s)$  has constant Milnor number if and only if it has no coalescing of singular points ([2] and [3]). This means that there exist positive real numbers  $\epsilon > 0$  and  $\delta > 0$  such that 0 is the only critical point of  $f_s$  in  $\mathbb{B}_{\epsilon}$ , for every  $s \in \mathbb{D}_{\delta}$ . These two facts come from the fact that when X is an ICIS, the Milnor number  $\mu(f_0, 0)$  of  $f_0$  at 0 has an algebraic expression as the dimension of a quotient ring that is Cohen-Macaulay. Then the principle of conservation of number gives that

(1) 
$$\mu(f_0, 0) = \sum_{x \in \Sigma(f_s)} \mu(f_s, x) \,,$$

where  $\mu(f_s, x)$  denotes the Milnor number of  $f_s$  at the singular point  $x \in \Sigma(f_s)$ .

When X is an arbitrary IDS there is no such algebraic expression for the Milnor number of  $f_s : (X, 0) \to (\mathbb{C}, 0)$ , so one cannot apply the same argument. However, a simple topological argument gives the same equality. Precisely, we have:

**Lemma 4.1.** Let  $f_s : (X, 0) \to (\mathbb{C}, 0)$  be an isolated singularity family defined on an *IDS*. Then there exists  $\delta > 0$  such that for every  $s \in \mathbb{D}_{\delta}$  equality (1) above holds.

Proof. Let  $f'_s : X' \to \mathbb{C}$  be a morsification (in family) of  $f_s$ . Since X is an IDS and since  $f_0$  has an isolated singularity, we can choose  $\epsilon > 0$  be small enough such that  $X \cap \mathbb{B}_{\epsilon} \setminus \{0\}$  is smooth and the restriction of  $f_0$  to  $X \cap \mathbb{B}_{\epsilon} \setminus \{0\}$  is a submersion. We can also assume that  $f'_0$  has exactly  $\mu(f_0)$ -many (Morse) critical points in  $X' \cap \mathbb{B}_{\epsilon}$ . Then there exists  $\delta > 0$  sufficiently small such that for every  $s \in \mathbb{D}_{\delta}$  one has that  $f'_s$  has exactly  $\mu(f_0)$ -many critical points in  $X' \cap \mathbb{B}_{\epsilon}$ . This follows from the fact that Morse points are stable under small perturbations. Thus equality (1) above follows.

As an immediate consequence, we have:

**Proposition 4.2.** Let  $f_s : (X, 0) \to (\mathbb{C}, 0)$  be an isolated singularity family defined on an IDS. Then there exists  $\delta > 0$  such that:

- (i) for every  $s \in \mathbb{D}_{\delta}$  one has  $\mu(f_s) \leq \mu(f_0)$ .
- (ii)  $\mu(f_s) = \mu(f_0)$  for every  $s \in \mathbb{D}_{\delta}$  if and only if  $(f_s)$  has no coalescing of singular points.

On the one hand, Proposition 4.2 gives a characterization for the  $\mu$ -constancy of deformations of functions on an IDS, in the spirit of [3] and [2].

On the other hand, if  $(X,0) \subset (\mathbb{C}^N,0)$  is an IDS and if  $f_s : (X,0) \to (\mathbb{C},0)$  is an isolated singularity family depending linearly on the parameters  $s_1, \ldots, s_k \in \mathbb{C}$ , Proposition 4.2 together with Theorem 0.2 give Theorem 0.4. Notice that Proposition 4.2 and Proposition 1.1 combined give the following Corollary, which is a good criterium to decide if the family  $(f_s)$  is  $\mu$ -constant:

**Corollary 4.3.** Let  $\tilde{f}_s : (\mathbb{C}^N, 0) \to (\mathbb{C}, 0)$  be an isolated singularity family depending holomorphically on  $s \in \mathbb{C}^k$ . Let  $(X, 0) \subset (\mathbb{C}^N, 0)$  be an IDS and suppose that the family  $f_s : (X, 0) \to (\mathbb{C}, 0)$  given by restriction to (X, 0) is also an isolated singularity family. If  $(\tilde{f}_s)$  is  $\mu$ -constant then  $(f_s)$  is  $\mu$ -constant.

**Example 4.4.** Let  $X \subset \mathbb{C}^4$  be the 2-dimensional IDS defined by the matrix

$$\begin{pmatrix} w & y & x \\ z & w & y \end{pmatrix}$$

Consider the  $\mu$ -constant family  $\tilde{f}_s : (\mathbb{C}^4, 0) \to (\mathbb{C}, 0)$  given by

$$\tilde{f}_s(x, y, z, w) := x^2 + y^2 + z^2 + w^2 + sx^3$$
,

and let  $f_s : (X, 0) \to (\mathbb{C}, 0)$  be its restriction to X. For each  $s \in \mathbb{C}$  fixed, the singular points of  $f_s$  are those points in X at which all the  $3 \times 3$ -minors of the following matrix vanish:

$$\begin{pmatrix} \alpha(x) & 2y & 2z & 2w \\ 0 & z & y & -2w \\ z & -w & x & -y \\ w & -2y & 0 & x \end{pmatrix},$$

where  $\alpha(x) := 2x + 3sx^2$ . Then some calculation shows that the singular locus of  $f_s$  is the finite set

$$\Sigma(f_s) = \{\alpha(x) = y = z = w = 0\} = \left\{(0, 0, 0, 0), \left(-\frac{2}{3s}, 0, 0, 0\right)\right\}.$$

Hence the family  $(f_s)$  has no coalescing of singular points. Thus if follows from Proposition 4.2 that  $f_s$  is a  $\mu$ -constant deformation of the function-germ  $f_0: (X,0) \to (\mathbb{C},0)$ .

On the other hand, consider the family  $g_s : (X, 0) \to (\mathbb{C}, 0)$  given by restriction to X of the family  $\tilde{g}_s : (\mathbb{C}^4, 0) \to (\mathbb{C}, 0)$  defined by

$$\tilde{g}_s(x, y, z, w) := x^3 + y^2 + z^2 + w^2 + sx^2$$

which has non-constant Milnor number. Setting  $\beta(x) := 3x^2 + 2sx$  one has that

$$\Sigma(g_s) = \{\beta(x) = y = z = w = 0\} = \left\{ (0, 0, 0, 0), \left(-\frac{2s}{3}, 0, 0, 0\right) \right\}.$$

Then the family  $(g_s)$  has coalescing of singular points and thus it is not a  $\mu$ -constant deformation.
