THE DUD CANARD: EXISTENCE OF STRONG CANARD CYCLES IN \mathbb{R}^3

KRISTIANSEN, K. U.

Abstract. In this paper, we provide a rigorous description of the birth of canard limit cycles in slow-fast systems in \mathbb{R}^3 through the folded saddle-node of type II and the singular Hopf bifurcation. In particular, we prove – in the analytic case only – that for all $0 < \epsilon \ll 1$ there is a family of periodic orbits, born in the (singular) Hopf bifurcation and extending to $\mathcal{O}(1)$ cycles that follow the strong canard of the folded saddle-node. Our results can be seen as an extension of the canard explosion in \mathbb{R}^2 , but in contrast to the planar case, the family of periodic orbits in \mathbb{R}^3 is not explosive. For this reason, we have chosen to call the phenomena in \mathbb{R}^3 , the "dud canard". The main difficulty of the proof lies in connecting the Hopf cycles with the canard cycles, since these are described in different scalings. As in \mathbb{R}^2 we use blowup to overcome this, but we also have to compensate for the lack of uniformity near the Hopf, due to its singular nature; it is a zero-Hopf in the limit $\epsilon = 0$. In the present paper, we do so by imposing analyticity of the vector-field. This allows us to prove existence of an invariant slow manifold, that is not normally hyperbolic.

CONTENTS

1. INTRODUCTION

In this paper, we consider slow-fast systems of the form

$$
\dot{u} = \epsilon U(u, v, \epsilon), \n\dot{v} = V(u, v, \epsilon),
$$
\n(1)

with U and V sufficiently smooth and $0 < \epsilon \ll 1$. Systems of this form occur in many different applications, including neuroscience [\[1,](#page-24-1) [30,](#page-25-0) [43\]](#page-25-1), biology and chemical reaction networks [\[20,](#page-25-2) [24\]](#page-25-3) and many other areas, see [\[16,](#page-25-4) [40\]](#page-25-5) for further references. Geometric Singular Perturbation Theory [\[31\]](#page-25-6) is

a collection of methods, based upon the ground-breaking work of Fenichel [\[21,](#page-25-7) [22,](#page-25-8) [23\]](#page-25-9), that can be used to study systems of the form [\(1\)](#page-0-1) for $0 < \epsilon \ll 1$. The point of departure for this theory, is the critical manifold

$$
S = \{(u, v)|V(u, v, 0) = 0\},\
$$

which is a set of equilibria for the associated layer problem:

$$
\dot{u} = 0,
$$

\n
$$
\dot{v} = V(u, v, 0),
$$
\n(2)

obtained by setting $\epsilon = 0$ in [\(1\)](#page-0-1). S is said to be normally hyperbolic if all eigenvalues of $D_vV(u, v)$ for all $(u, v) \in S$ have nonzero real part. In particular, it is attracting (repelling) if the real part of these eigenvalues is negative (positive, respectively). Fenichel's theory, see [\[21,](#page-25-7) [22,](#page-25-8) [23,](#page-25-9) [31\]](#page-25-6), then says that compact submanifolds S_0 of S perturb to diffeomorphic locally invariant manifolds S_6 for all $0 < \epsilon \ll 1$. The reduced flow on S_{ϵ} is to leading order given by the reduced problem:

$$
u' = U(u, v, 0),
$$

$$
0 = V(u, v, 0),
$$

obtained by writing [\(1\)](#page-0-1) in terms of the slow time $\tau = \epsilon t$ with $\left(\right)' = \frac{d}{d\tau}$ and subsequently letting $\epsilon \to 0$. Moreover, stable and unstable manifolds of S_0 also perturb to $W^s(S_{\epsilon})$ and $W^u(S_{\epsilon})$, each having invariant foliations by fibers; for full details see e.g. [\[31\]](#page-25-6).

Following work by Dumortier and Roussarie on the blowup method [\[18\]](#page-25-10), there was in the early parts of the 2000s an effort [\[37,](#page-25-11) [38,](#page-25-12) [39,](#page-25-13) [44,](#page-25-14) [48\]](#page-26-0) to extend the geometric theory of Fenichel to points where normal hyperbolicity breaks down. The simplest type of breakdown, is perhaps observed in \mathbb{R}^2 and \mathbb{R}^3 with S having folds, that divide the critical manifold into attracting and repelling subsets. In these cases, canard solutions are solutions of [\(1\)](#page-0-1) for $0 < \epsilon \ll 1$ that – counter-intuitively – follow the attracting and repelling branches of the critical manifold by passing close to the fold. Canards are well described in \mathbb{R}^2 and \mathbb{R}^3 [\[18,](#page-25-10) [6,](#page-24-2) [5,](#page-24-3) [38,](#page-25-12) [44,](#page-25-14) [39,](#page-25-13) [47\]](#page-26-1) and play an important role in applications and in the global dynamics of systems of the form [\(1\)](#page-0-1), see e.g. [\[16,](#page-25-4) [42,](#page-25-15) [46\]](#page-25-16).

In \mathbb{R}^2 , canards of folded critical manifolds require an unfolding parameter [\[38\]](#page-25-12) and here canard orbits may be limit cycles. In fact, the reference [\[38\]](#page-25-12) proves that there is a family of periodic orbits – under some non-degeneracy conditions – that include small (i.e. of size $o(1)$) Hopf cycles, intermediate cycles (see also [\[19,](#page-25-17) [28\]](#page-25-18)) and canard cycles of size $\mathcal{O}(1)$. Under some additional global properties, such family may be extended further to include canards with "head", see [\[38\]](#page-25-12), and eventually relaxation oscillations, as in the van der Pol system [\[45,](#page-25-19) [38\]](#page-25-12). This situation is also known as the canard explosion [\[12\]](#page-25-20), due to the fact that the canard limit cycles of different amplitude differ in parameter values by an order of $\mathcal{O}(e^{-c/\epsilon})$ for all $0 < \epsilon \ll 1$, see full details in [\[38\]](#page-25-12).

In \mathbb{R}^3 , on the other hand, with $u \in \mathbb{R}^2$ and $v \in \mathbb{R}$ in [\(1\)](#page-0-1), canards of folded critical manifolds are generic, without parameters. They appear persistently at so-called folded singularities, which are singular points on the fold of a "desingularized" reduced problem, see [\[5,](#page-24-3) [44\]](#page-25-14). The folded singularities come in different generic versions: folded node, folded saddle and folded focus depending on the type of singularity, with only the former two producing canard solutions.

The folded node is of particular interest due to its connection to mixed-mode oscillations. In summary, the folded node gives rise to a weak canard (under a nonresonance condition) and a strong canard – essentially due to the weak and the strong directions of the linearization of the node – and close to folded singularity, it has been shown, using blowup [\[44\]](#page-25-14), that the tangent space of the attracting slow manifold twists a finite number of times along the weak canard. This implies, due to the contractivity towards the weak canard on the attracting side of the critical manifold, that an open set of points twists upon passage through the folded node. Upon composition with a global return mapping, this provides a simple mechanism for producing attracting limit cycles, see [\[13\]](#page-25-21), that are of mixed-mode type, see also [\[16\]](#page-25-4).

The folded saddle-node is a bifurcation of the folded singularity. It comes in different types I and II, but the unfolding of type $II - at$ the level of the reduced problem – produces a transcritical bifurcation of a true singularity and a folded one. In this paper, we will only focus on the type II and we will therefore continue to refer to this case simply as the folded saddle-node. This bifurcation is known to give rise to a Hopf bifurcation [\[39\]](#page-25-13). It is a singular Hopf bifurcation [\[9,](#page-24-4) [25\]](#page-25-22) due to the fact that the linearization (upon blowup) has eigenvalues of the form $\sim \pm i\omega, \sim \epsilon\lambda, \omega, \lambda \neq 0$ as $\epsilon \to 0$ at the Hopf; it is therefore a zero-Hopf bifurcation [\[3,](#page-24-5) [2\]](#page-24-6) for $\epsilon = 0$.

The interest in the folded saddle-node comes from the fact that it marks the onset (or termination) of mixed-mode oscillations through the folded node. However, in the author's opinion, the details of this onset/termination and the connection of mixed-mode oscillations with the Hopf cycles is still not fully understood. [\[13,](#page-25-21) Theorem 4.2] relates to the connection problem, but only indirectly. Specifically, the bifurcation described in this theorem – where a return mechanism transverses to the strong canard – does not relate to the Hopf bifurcation. The reference $[42]$ is another interesting study, based upon detailed numerical computations. Here the Hopf cycles are continued using the software package AUTO and it is demonstrated (for a fixed small value of $\epsilon > 0$) that these cycles are of relaxation type without mixed-modes. In particular, the periodic orbits of mixed-mode type in the model system of [\[42\]](#page-25-15) form isolas that are disconnected from the branch of Hopf cycles. At the same time, [\[25\]](#page-25-22) studies a normal form for a singular Hopf with two slow variables, computing the Lyapunov coefficient and demonstrating additional bifurcations (periodic doubling and torus) using numerical computations along the branch of period orbits that appear from the Hopf. [\[35\]](#page-25-23) describes the onset of mixed-modes in a cusped saddle-node in a system with symmetry.

It has also been speculated, following work on the Koper model [\[33,](#page-25-24) [34\]](#page-25-25), that the folded saddlenode may be associated with homoclinics and Shilnikov bifurcations. This was demonstrated for the Koper model in [\[27\]](#page-25-26) using sophisticated numerical methods, among other things. At the same time, it is by now known [\[2,](#page-24-6) [11\]](#page-24-7) that generic unfoldings of the zero-Hopf bifurcation produce Shilnikov bifurcations. In future work, the present author hopes to pursue these bifurcations rigorously in the context of the folded saddle-node. In preparation, we will in this paper extend the results of [\[38\]](#page-25-12) on the family of periodic canard orbits in \mathbb{R}^2 to the \mathbb{R}^3 -context. Whereas the family of canard cycles have "explosive growth" in the planar context, the growth rate is regular in \mathbb{R}^3 , with canard cycles of different amplitude corresponding (in general) to parameter values that differ by an $\mathcal{O}(1)$ -amount. For this reason, we have chosen to call the phenomena we describe as the "dud canard" instead of the canard explosion.

1.1. Setting. We consider the following normal form for the folded node/folded saddle-node [\[39\]](#page-25-13):

$$
\begin{aligned}\n\dot{x} &= \epsilon(y - (\mu + 1)z + F(x, y, z, \epsilon, \mu)), \\
\dot{y} &= \epsilon(\frac{1}{2}\mu + G(x, y, z, \epsilon, \mu)), \\
\dot{z} &= x + z^2 + zH(x, y, z, \epsilon, \mu),\n\end{aligned} \tag{3}
$$

in the regime $\epsilon > 0$, $\epsilon \sim 0$ and $\mu \sim 0$, where F, G and H are smooth and higher order in the following sense:

$$
F(x, y, z, \epsilon, \mu) = \mathcal{O}(x, \epsilon, (|y| + |z|)^2), \quad G(x, y, z, \epsilon, \mu) = \mathcal{O}(x, y, z, \epsilon),
$$

and

$$
H(x, y, z, \epsilon, \mu) = \mathcal{O}(xz, xy, z^2, \epsilon).
$$

(In comparison with [\[39\]](#page-25-13) we have zH instead of H. This plays little role, but the latter can be brought into the former by a transformation of x.) μ will be our bifurcation parameter.

The system is normalized in such a way that the layer problem has a critical manifold S of the form $x = m(y, z) := -z^2(1 + \mathcal{O}(y, z))$ with a fold along the line defined by $(0, y, 0)$. Locally, the manifold S is normally attracting along $z < 0$ and normally repelling along $z > 0$. Upon desingularization, the reduced problem takes the following form:

$$
y' = -z(1 + L(y, z, \mu))(\mu + 2G(m(y, z), y, z, 0, \mu)),
$$

\n
$$
z' = y - (\mu + 1)z + F(m(y, z), y, z, 0, \mu),
$$
\n(4)

with $x = m(y, z)$ and L smooth satisfying $L(0, 0, \mu) = 0$. Consequently, we have a folded singularity [\[44\]](#page-25-14) at $(x, y, z) = (0, 0, 0)$. In fact, $(y, z) = (0, 0)$ is partially hyperbolic for [\(4\)](#page-2-1) with $\mu = 0$ and a center manifold reduction shows that [\(4\)](#page-2-1) undergoes a transcritical bifurcation for $\mu = 0$ if

$$
\lambda := \partial_y G(\mathbf{0}) + \partial_z G(\mathbf{0}) \neq 0. \tag{5}
$$

It is this bifurcation that is known as a folded saddle-node (of type II [\[39\]](#page-25-13)) for the slow-fast system [\(3\)](#page-2-2). We illustrate the bifurcation in Fig. [1](#page-3-2) in terms of the slow time; in comparison with [\(4\)](#page-2-1) the

Figure 1. Illustration of the folded saddle-node of type II. It is a transcritical bifurcation of the desingularized reduced problem [\(4\)](#page-2-1). The dynamics illustrated here is in terms of the slow time. Consequently, in comparison with [\(4\)](#page-2-1), we have reversed the directions on the repelling sheet. The sign of λ (see [\(5\)](#page-2-3)) determines on what side of the two sheets the saddle point q appears. For $\lambda < 0$, shown in (a), q lies on the repelling sheet S_r , appearing for $\mu \geq 0$. For $\lambda > 0$, shown in (b), q lies on the the attracting sheet S_a , appearing for $\mu \leq 0$. In both cases, the folded singularity p is a folded node on one side of μ and folded saddle on the other side. The strong singular canard $\gamma_0(\mu)$ divides S_a into separate sets. In particular, for $\mu \geq 0$ and $\lambda < 0$, the dark shaded region in (a) is a funnel region. Here all points pass through p upon following the reduced flow.

On the other hand, for each $\mu \sim 0$, there exists a strong stable manifold $\gamma_0(\mu)$ of $(y, z) = 0$ for [\(4\)](#page-2-1), known as the strong singular canard in the (x, y, z) -space. It is well-known [\[44\]](#page-25-14) that $\gamma_0(\mu)$ persists as a (maximal) canard $\gamma_{\epsilon}(\mu)$ connecting fixed copies of Fenichel slow manifolds $S_{a,\epsilon}$ and $S_{r,\epsilon}$ as perturbations of (appropriate) compact subsets $S_{a,0}$ and $S_{r,0}$ of $S_a := S \cap \{z < 0\}$ respectively $S_r := S \cap \{z > 0\}$ for all $0 < \epsilon \ll 1$.

1.2. Main result. In this paper, we are interested in canard cycles, i.e. periodic orbits that follow $\gamma_0(\mu)$ on S. In particular, under the assumption [\(5\)](#page-2-3) and analyticity of F, G and H, we prove the existence of a family of periodic orbits:

Theorem 1.1. Suppose (5) (5) (5) and that F, G and H are analytic functions in the phase space variables x, y, z and smooth in ϵ and μ . Then there exists an $h_1 > 0$ such that for all $0 < \epsilon \ll 1$ the following holds: There is a Hopf bifucation of ([3](#page-2-2)) at $\mu = \mu_H(\sqrt{\epsilon})$, $\mu_H(0) = 0$, and a family of periodic orbits $\Gamma_{h,\epsilon}$, with $h \in (0, h_1]$ measuring the amplitude (to be defined later), along $\mu = \overline{\mu}(h,\epsilon)$, where $\overline{\mu}$ is continuous and satisfies $\overline{\mu}(0,\epsilon) = \mu_H(\sqrt{\epsilon})$. For each $h \in (0,h_1]$ fixed, $\Gamma_{h,\epsilon}$ converges as $\epsilon \to 0$ in

Haussdorff distance to a singular canard cycle, consisting of a segment of $\gamma_0(\bar{\mu}(h, 0))$ across the fold and a fast jump. The limit is uniform on compact subsets of $(0, h_1]$.

We do not aim to describe the stability of the cycles. This is more difficult, see Remark [2.13](#page-12-1) below. To prove Theorem [1.1,](#page-3-1) we follow [\[44\]](#page-25-14), and apply the following blowup transformation to the extended system $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ of the folded singularity:

$$
(r, (\bar{x}, \bar{y}, \bar{z}, \bar{\epsilon})) \mapsto \begin{cases} x & = r^2 \bar{x}, \\ y & = r \bar{y}, \\ z & = r \bar{z}, \\ \epsilon & = r^2 \bar{\epsilon}. \end{cases}
$$

for $r \geq 0$, $(\bar{x}, \bar{y}, \bar{z}, \bar{\epsilon}) \in S^3$ and $\mu \sim 0$. In contrast to [\[39\]](#page-25-13), we will not blowup $\mu = 0$ (at this stage, at least). We use two separate charts $\bar{x} = -1$ and $\bar{\epsilon} = 1$ with chart-specific coordinates $(\epsilon_1, r_1, y_1, z_1)$ and (r_2, x_2, y_2, z_2) defined by :

$$
(\epsilon_1, r_1, y_1, z_1) \mapsto \begin{cases} x = -r_1^2, \\ y = r_1 y_1, \\ z = r_1 z_1, \\ \epsilon = r_1^2 \epsilon_1, \\ \epsilon = r_1^2 z_2, \\ y = r_2 y_2, \\ z = r_2 z_2, \\ \epsilon = r_2^2, \end{cases} (7)
$$

respectively. The charts overlap on \bar{x} < 0 and here the change of coordinates are given by the expressions: √

$$
r_2 = r_1 \sqrt{\epsilon_1},
$$

\n
$$
x_2 = -\epsilon_1^{-1},
$$

\n
$$
y_2 = y_1/\sqrt{\epsilon_1},
$$

\n
$$
z_2 = z_1/\sqrt{\epsilon_1},
$$

\n(8)

for $\epsilon_1 > 0$.

In [\[25,](#page-25-22) [39\]](#page-25-13) the authors also describe the Hopf bifurcation in the $\bar{\epsilon} = 1$ -chart. The new contribution of Theorem [1.1](#page-3-1) is that we describe the family of periodic orbits bifurcating from the Hopf in a full (i.e. ϵ -independent) neighborhood of the folded saddle-node for all $0 < \epsilon \ll 1$. This family includes periodic orbits with amplitude $h = \mathcal{O}(1)$ following the strong canard $\gamma_0(\mu)$ for $\mu \sim 0$ and all $0 < \epsilon \ll 1$.

Our approach is similar to the approach for the analysis of the canard explosion in the planar case, see [\[38\]](#page-25-12). The paper [\[38\]](#page-25-12) also uses a Melnikov approach to extend the Hopf cycles in the associated scaling chart and then subsequently extend these to canard cycles by working in directional charts. The latter connection problem is already complicated in [\[38\]](#page-25-12). In the present paper, we feel that our proof in \mathbb{R}^3 is relatively simple. It basically extends the classical way of obtaining canard cycles in \mathbb{R}^2 , by flowing points forward and backward along the attracting and repelling sheets and then extending this close to the folded saddle-node through blowup (using the chart $\bar{x} = -1$). Shilnikov variables [\[15\]](#page-25-27) and normal forms [\[26,](#page-25-28) [29\]](#page-25-29) are used to study the necessary transition maps. This approach could also be used as an alternative to solving the connection problem in \mathbb{R}^2 , although we have not attempted to do so.

In contrast, the problem of connecting the Hopf cycles with the ones obtained by the Melnikov analysis is more complicated here in \mathbb{R}^3 than in the \mathbb{R}^2 -context of [\[38\]](#page-25-12). This is also related to our assumption on analyticity of F , G and H in Theorem [1.1,](#page-3-1) which may seem unusual for results in this direction. To explain the difficulty, we recall from [\[39\]](#page-25-13) that there is a one-dimensional critical manifold in the $\bar{\epsilon} = 1$ -chart for $\mu = r_2 = 0$ given by $x_2 = -y_2^2$, $z_2 = y_2$, $y_2 \in \mathbb{R}$. The linearization has imaginary eigenvalues at $y_2 = 0$ and the reduced problem has a hyperbolic equilibrium precisely at this point; this is what produces the Hopf bifurcation for all $0 < r_2 \ll 1$. However, it is nontrivial to study the Hopf cycles in a fixed (small) neighborhood of the Hopf since the eigenvalues are of the form $\pm(1+\mathcal{O}(r_2))i, r_2(\lambda+\mathcal{O}(r_2)),$ i.e. a zero-Hopf bifurcation occurs at $\mu=r_2=0$. As we see it, there are two ways to perform the analysis of the Hopf cycles: (i) Perform a center manifold reduction and apply the Hopf bifurcation theorem there. Or: (ii) Straighten out the (strong) unstable/stable manifold $(\lambda \geq 0,$ respectively), introduce polar coordinates in the transverse direction and apply Melnikov-like methods to construct the periodic orbits as fixed-points of a return map. However, both approaches are not uniform in $\epsilon \to 0$ in the smooth setting, due to the fact that the eigenvalue with the nonzero real part $\sim \epsilon \lambda$, providing the necessary hyperbolicity, goes to zero as $\epsilon \to 0$. Nevertheless, in the analytic case, we can extend the proof of the unstable/stable manifold to a fixed neighborhood (by following [\[14,](#page-25-30) Section 3]), and this allows us to apply approach (ii).

There is no clear way to extend (at least directly) the proof of the unstable/stable manifold in the smooth setting since this rests on the exponential estimates (that are nonuniform in the present context). Having said that, [\[7,](#page-24-8) [8\]](#page-24-9) both study a zero-Hopf bifurcation (in the case of [\[8\]](#page-24-9), also at a parameter value $\epsilon = 0$) in the smooth setting and prove existence of C^{∞} a one-dimensional invariant curve tangent to the zero eigenspace. However, these results do not directly apply in our setting and their methods would have to be modified. For example, in [\[7\]](#page-24-8) there is no parameter. Moreover, to bring the folded saddle-node near the Hopf into the normal form in [\[8\]](#page-24-9) we would have to perform an ϵ -dependent scaling of the variables; notice in particular, that [\[8,](#page-24-9) Equation (1)] does not depend upon the slow variable z for $\epsilon = 0$. We therefore leave the extension to C^{∞} (and potentially even C^{k}) to future work.

1.3. Overview. In the remainder of the paper, we work to prove Theorem [1.1.](#page-3-1) First in Section [2,](#page-5-1) we describe the small periodic orbits, extending all the way down to the Hopf bifurcation. Subsequently, in Section [3,](#page-12-0) we describe the "intermediate orbits" that connect small periodic orbits with the canard orbits. In Section [4,](#page-23-0) we complete the proof of the theorem. Finally, in Section [5](#page-23-1) we conclude the paper through a discussion of the results and potential future work.

2. Existence of small periodic orbits

In the scaling chart $\bar{\epsilon} = 1$, applying [\(7\)](#page-4-0) to ([\(3\)](#page-2-2), $\dot{\epsilon} = 0$) gives

$$
\begin{aligned}\n\dot{x}_2 &= y_2 - (\mu + 1)z_2 + r_2 F_2(x_2, y_2, z_2, r_2, \mu), \\
\dot{y}_2 &= \frac{1}{2}\mu + r_2 a_1 y_2 + r_2 a_2 z_2 + r_2^2 \overline{G}_2(x_2, y_2, z_2, r_2, \mu), \\
\dot{z}_2 &= x_2 + z_2^2 + r_2 z_2 H_2(x_2, y_2, z_2, r_2, \mu),\n\end{aligned}\n\tag{9}
$$

and $\dot{r}_2 = 0$. F_2 , \overline{G}_2 and H_2 are smooth, in particular analytic in the space variables x_2, y_2 and z_2 . Here the desingularization has been achieved by dividing the right hand side by r_2 . As in [\[39\]](#page-25-13), we have put $a_1 = \partial_y G(0)$, $a_2 = \partial_z G(0)$. Recall then that

$$
\lambda := a_1 + a_2 \neq 0,
$$

by assumption [\(5\)](#page-2-3). For $\mu \sim 0$, $r_2 \sim 0$ this system is slow-fast with x_2 and z_2 being fast and y_2 slow. In particular, $\mu = r_2 = 0$ gives an associated layer problem

$$
\begin{aligned}\n\dot{x}_2 &= y_2 - z_2, \\
\dot{y}_2 &= 0, \\
\dot{z}_2 &= x_2 + z_2^2.\n\end{aligned} \tag{10}
$$

Lemma 2.1. The set C_2 defined by $x_2 = -y_2^2$, $z_2 = y_2$, $y_2 \in \mathbb{R}$ is a critical manifold of ([10](#page-5-2)). It is normally attracting for $y_2 < 0$ and repelling for $y_2 > 0$.

On the other hand, $y_2 = 0$ is degenerate for C_2 with the linearization around $(0,0,0)$ having two imaginary eigenvalues $\pm i$. In particular, ([10](#page-5-2)) is time-reversible within $y_2 = 0$ and the orbit

$$
\gamma_{2,0}(0) : \begin{cases} x_2(t_2) &= -\frac{1}{4}t_2^2 + \frac{1}{2}, \\ z_2(t_2) &= \frac{1}{2}t_2, \end{cases} \tag{11}
$$

is a separatrix in the (x_2, z_2) -plane separating closed periodic orbits $\phi_h(t) = (x_{2h}(t), z_{2h}(t))$, $x_{2h}(0) =$ $-h$, $z_{2h}(0) = 0$ with period $T_0(h) > 0$ for any $h > 0$, from unbounded orbits.

Proof. The statement regarding the stability of C_2 follows from simple calculations. The analysis for $y_2 = 0$ is also straightforward, see [\[38\]](#page-25-12).

FIGURE 2. The layer problem [\(10\)](#page-5-2) in the (x_2, z_2) -plane. The canard orbit $\gamma_{2,0}$ (orange) separates bounded periodic orbits ϕ_h (green) from unbounded orbits.

We illustrate the dynamics in the (x_2, z_2) -plane in Fig. [2.](#page-6-1) The solution [\(11\)](#page-5-3) for $\mu = 0$ belongs to a μ -family of solutions

$$
\gamma_{2,0}(\mu) : \begin{cases} x_2(t_2) &= -\frac{1}{4}t_2^2 + \frac{1}{2}, \\ y_2(t_2) &= \frac{\mu}{2}t_2, \\ z_2(t_2) &= \frac{1}{2}t_2, \end{cases}
$$
(12)

of [\(9\)](#page-5-4) for $r_2 = 0$. It corresponds to the blowup of the strong canard $\gamma_0(\mu)$, see [\[44\]](#page-25-14).

To describe the reduced problem on C_2 , we consider the scaling

$$
\mu = r_2 \mu_2. \tag{13}
$$

Then with μ_2 fixed, $r_2 = 0$ implies $\mu = 0$. [\[39\]](#page-25-13) also uses this scaling, but it is strictly speaking not necessary for the present analysis. In fact, it will be crucial to our approach not to scale μ for the description of the intermediate periodic orbits that we study later in the paper.

With (13) , we obtain the following reduced problem on C_2 :

$$
y_2' = \frac{1}{2}\mu_2 + \lambda y_2,
$$

in terms of a slow time. For $\lambda \neq 0$, we have a hyperbolic equilibrium at

$$
y_2 = -\frac{\mu_2}{2\lambda}.\tag{14}
$$

Consequently, for $\mu_2 = 0$ this equilibrium lies at $y_2 = 0$, corresponding to the degenerate point of C_2 . This gives rise to the (singular) Hopf bifurcation [\[25\]](#page-25-22).

As advertised in the introduction, we study the Hopf bifurcation and periodic orbits of [\(9\)](#page-5-4) by first proving existence of a slow manifold Z_{2,r_2} (following [\[14,](#page-25-30) Section 3]), analytic in the space variables and smooth in ϵ and μ_2 , as a perturbation of C_2 in a fixed neighborhood of $y_2 = 0$. Then upon straightening out this one-dimensional manifold we ensure that polar coordinates in the normal directions are well-defined. This allows us to set up a return map, defined in a full neighborhood, which we describe using Melnikov theory.

2.1. Existence of an analytic slow manifold. For any $\nu > 0$, $k \in \mathbb{N}$, let

$$
\Omega^k(\nu) := \left\{ h = \sum_{n=0}^{\infty} h_n(\cdot)^n : \overline{B_{\nu}} \to \mathbb{C}^k \,|\, h_n \in \mathbb{R}^k, \|h\| < \infty \right\},\,
$$

with $\overline{B_{\nu}}$ being the closure of the open disc $B_{\nu} \subset \mathbb{C}$ of radius ν centered at the origin, and where

$$
\|\sum_{n=0}^{\infty} h_n(\cdot)^n\| := \sum_{n=0}^{\infty} |h_n| \nu^n.
$$
 (15)

In other words, $\Omega^k(\nu)$ consists of absolutely convergent power series on $\overline{B_\nu}$. Consequently, if $h \in \Omega^k(\nu)$ then the resulting function $h: B_{\nu} \to \mathbb{C}^k$ is real analytic. Moreover, any real analytic function, having

an absolutely convergent power series at the origin with radius of convergence $\rho > \nu$, belongs to $\Omega^k(\nu).$

Suppose that $h^m = \sum_{n=0}^{\infty} h_n^m(\cdot)^n \in \Omega^k(\nu)$ is a Cauchy sequence for $m \in \mathbb{N}$. Then by definition [\(15\)](#page-6-3) it follows that $\{h_n^m \nu^n\}_{n=0}^{\infty}$ is a Cauchy sequence in l_1 and therefore converges. Consequently, $\|\cdot\|$ is a Banach norm on $\Omega^k(\nu)$.

In the following, it will be convinient to write $u := (x_2, z_2) \in \mathbb{R}^2$.

Proposition 2.2. Consider ([9](#page-5-4)) with ([13](#page-6-2)) and F_2 , G_2 and H_2 all smooth functions, specifically analytic in x_2, y_2, z_2 . Fix $k \in \mathbb{N}$. Then there are constants $\delta > 0$ and $\nu > 0$, both sufficiently small, such that the following holds: There exists a locally invariant one-dimensional manifold Z_{2,r_2} of ([9](#page-5-4)) of the graph form:

$$
u=m(y_2,r_2,\mu_2),
$$

where $(r_2, \mu_2) \mapsto m(\cdot, r_2, \mu_2) \in \Omega^2(\nu)$ is C^k for $0 \le r_2 \ll 1$, $\mu_2 \in [-\delta, \delta]$, satisfying $m(y_2, 0, \mu_2) =$ $(-y_2^2, y_2)$ such that $Z_{2,0}$ is a submanifold of C_2 .

Proof. The proof follows [\[14\]](#page-25-30), see specifically [\[14,](#page-25-30) Lemma 3.25], on a related problem. Firstly, seeing that the linearization around C_2 has two eigenvalues that are bounded away from $0 \in \mathbb{C}$, it is standard (see e.g. [\[14,](#page-25-30) [36\]](#page-25-31)) that there is a formally invariant manifold

$$
u = \sum_{n=0}^{\infty} r_2^n h_n(y_2, \mu_2),
$$

with the right hand side to be understood as a formal power series. Each h_n is smooth, specifically $h_0(y_2, \mu_2) = (-y_2^2, y_2)$. Now define \tilde{u} by

$$
u = h_0(y_2, \mu_2) + r_2 h_1(y_2, \mu_2) + \tilde{u},
$$

Then upon dividing the right hand side by λ and setting

$$
v = y_2 + \frac{1}{2\lambda}\mu_2,
$$

we obtain

$$
\dot{\tilde{u}} = (A(v, \mu_2) + \mathcal{O}(r_2, \tilde{u})) \tilde{u} + \mathcal{O}(r_2^2),
$$

$$
\dot{v} = r_2 (v + \mathcal{O}(r_2, \tilde{u})),
$$

where

$$
A(v, \mu_2) = \lambda^{-1} \begin{pmatrix} 0 & -1 \\ 1 & 2v - \frac{1}{\lambda} \mu_2 \end{pmatrix},
$$

Now drop the tilde on u and let

$$
u=r_2\tilde{u}.
$$

This gives

$$
\dot{\tilde{u}} = A(v, \mu_2)\tilde{u} + r_2 R_2(\tilde{u}, v, r_2, \mu_2), \n\dot{v} = r_2(v + r_2 P_2(\tilde{u}, v, r_2, \mu_2)),
$$
\n(16)

For simplicity, we again drop the tilde on u. R_2 and P_2 are analytic functions in the phase space variables u, v , depending smoothly on $r_2, \mu_2 \sim 0$.

Notice that the eigenvalues of $A(v, \mu_2)$ are $\pm \lambda^{-1}i + \mathcal{O}(v, \mu_2)$. Consequently, for all μ_2 sufficiently small, we have that

$$
(qI - A(0, \mu_2))^{-1}
$$

exists for all $q \in \mathbb{R}$.

Lemma 2.3. Fix $\mu_2 \in [-\delta, \delta]$ with $\delta > 0$ sufficiently small. Then there exists a constant $C > 0$ such that

$$
||(qI - A(0, \mu_2))^{-1}|| \le \frac{C}{|q|+1},
$$

for all $q \in \mathbb{R}$ and all $\mu_2 \in [-\delta, \delta]$.

Proof. Clearly,

$$
|| (qI - A(0, \mu_2))^{-1} || \leq \tilde{C} |\chi(\mu_2) - q|^{-1},
$$

where $\chi(\mu_2)$ and $\bar{\chi}(\mu_2)$ are the imaginary eigenvalues of $A(0,\mu_2)$ and where $\tilde{C} > 0$ is a positive constant. We then use that $\chi(\mu_2)$ is close to the imaginary axis and uniformly bounded away from the origin to obtain the result.

In the following, we will suppress the dependency of μ_2 . We then write [\(16\)](#page-7-0) as a first order system in the following form:

$$
r_2 v \frac{du}{dv} - A(0)u = (A(v) - A(0))u + r_2 R_2(u, v, r_2)
$$

$$
- r_2^2 P_2(u, v, r_2) \frac{du}{dv}.
$$
(17)

We will prove the existence of the invariant manifold by solving this equation through a fixed-point argument on a closed subset of $\Omega^2(\nu)$.

Now, consider first

$$
r_2 v \frac{du}{dv} - A(0)u = F(v),\tag{18}
$$

with $F := \sum_{n=0}^{\infty} F_n(\cdot)^n \in \Omega^2(\nu)$. Then we have the following:

Lemma 2.4. Let $0 \le r_2 \ll 1$ and define the linear operator $T_n : \mathbb{R}^2 \to \mathbb{R}^2$ by

$$
T_k(F_k) = (r_2kI - A(0))^{-1}F_k, \quad F_k \in \mathbb{R}^2.
$$

Then

$$
||T_k|| \le \frac{C}{r_2 k + 1},\tag{19}
$$

with $C > 0$ from Lemma [2.3](#page-7-1) and

$$
u(v) = T(F)(v) := \sum_{n=0}^{\infty} T_n(F_n)v^n,
$$
\n(20)

is the unique real-analytic solution of ([18](#page-8-0)) in $\Omega^2(\nu)$. The operator $T : \Omega^2(\nu) \to \Omega^2(\nu)$ defined by ([20](#page-8-1)) is linear and continuous:

$$
||T(F)|| \le C||F||,\tag{21}
$$

for all $F \in \Omega(\nu)$.

Proof. Straightforward. [\(19\)](#page-8-2) follows from Lemma [2.3](#page-7-1) which gives [\(21\)](#page-8-3) upon using [\(20\)](#page-8-1).

The following is also important.

Lemma 2.5. Suppose that $P \in \Omega^1(\nu)$, $F \in \Omega^2(\nu)$. Then $T(r_2PF') \in \Omega^2(\nu)$ and

$$
||T(r_2PF')|| \leq C\nu^{-1}||P|| ||F||.
$$

Proof. Write $P(v) = \sum_{n=0}^{\infty} P_n v^n$ for $F(v) = \sum_{n=0}^{\infty} F_n v^n$. Then $F' = \sum_{n=0}^{\infty} (n+1) F_{n+1}(\cdot)^n : B_{\nu} \to \mathbb{C}$. Moreover, by Cauchy's product rule

$$
T(r_2PF')(v) = r_2 \sum_{n=0}^{\infty} T_n \left(\sum_{l=0}^{n+1} P_{n+1-l}lF_l \right) v^n,
$$

such that

$$
||T(r_2PF')(v)|| \leq \sum_{n=0}^{\infty} ||T_n||r_2(n+1) \sum_{l=0}^{n+1} |P_{n+1-l}||F_l|\nu^k
$$

\n
$$
\leq C \sum_{n=0}^{\infty} \sum_{l=0}^{n+1} |P_{n+1-l}||F_l|\nu^n
$$

\n
$$
\leq C\nu^{-1} \sum_{n=0}^{\infty} |P_n|\nu^n \sum_{n=0}^{\infty} |F_n|\nu^n
$$

\n
$$
= C\nu^{-1}||P|| ||F||. \tag{22}
$$

To solve [\(17\)](#page-8-4), we therefore write it as a fixed-point equation:

$$
u=\mathcal{L}(u),
$$

where $\mathcal L$ is the nonlinear operator defined by

$$
\mathcal{L}: u \mapsto T\left((A(v) - A(0))u + r_2 R_2(u, v, r_2) - r_2^2 P_2(u, v, r_2) \frac{du}{dv} \right). \tag{23}
$$

Consider the closed subset $\Omega_1^2(\nu, \sigma) \subset \Omega^2(\nu)$ defined by $||m|| \leq \sigma$, $m \in \Omega^2(\nu)$.

Lemma 2.6. There exist constants $\nu > 0$, $\sigma > 0$ and $r_{20} > 0$ such that \mathcal{L} is contraction on $\Omega_1^2(\nu, \sigma)$ for all $0 < r_2 \leq r_{20}$.

Proof. First, we show that $\mathcal{L}: \Omega_1^2(\nu, \sigma) \to \Omega_1^2(\nu, \sigma)$ is well-defined for $\nu > 0$ and $\sigma > 0$ small enough. For this, we use the linearity of T and estimate each of the resulting terms. Notice that R_2 and P_2 are analytic functions with radius of convergence $\rho \geq c > 0$ (uniformly in $r_2, \mu_2 \sim 0$). Consequently, upon composition with $u \in \Omega_1^2(\nu, \sigma)$ the resulting functions belong to $\Omega^2(\nu)$, $\Omega^1(\nu)$, respectively, for $\nu > 0$ and $\sigma > 0$ small enough, and are uniformly bounded there. We therefore have

$$
\|\mathcal{L}(u)\| \le C_1 \nu \sigma + C_2 r_2 + C_3 r_2 \nu^{-1} \sigma,
$$
\n(24)

for $C_1, C_2, C_3 > 0$ large enough and all $\nu, \sigma, r_2 > 0$ sufficiently small, upon estimating each of the resulting terms. In particular, the last term in the estimate [\(24\)](#page-9-0) comes from estimating

$$
T\left(r_2^2P_2(u,v,r_2)\frac{du}{dv}\right),\,
$$

using Lemma [2.5.](#page-8-5)

Next, for the Lipschitz constant of \mathcal{L} , we proceed in an analogously way, writing

$$
\mathcal{L}(u_1) - \mathcal{L}(u_2) = T((A(v) - A(0))(u_1 - u_2)) + T(r_2(R_2(u_1, v, r_2) - R_2(u_2, v, r_2))
$$

$$
- T\left(r_2^2 P_2(u_1, v, r_2)\frac{d}{dv}(u_1 - u_2)\right)
$$

$$
+ T\left(r_2^2 (P_2(u_2, v, r_2) - P_2(u_1, v, r_2))\frac{du_2}{dv}\right).
$$

We then write $V_2(u_1, v, r_2) - V_2(u_2, v, r_2) = \int_0^1 DV_2(u_1(1-s) + u_2s, v, r_2)ds(u_1 - u_2)$ for $V = R, P$. This leads to the following estimate

$$
\|\mathcal{L}(u_1) - \mathcal{L}(u_2)\| \le (C_4\nu + C_5r_2) \|u_1 - u_2\|,
$$

for some $C_4, C_5 > 0$ large enough and all $\nu, \sigma, r_2 > 0$ sufficiently small, using also Lemma [2.5.](#page-8-5) This completes the proof. \Box

By Banach's fixed point theorem, we obtain a unique fixed-point of $\mathcal{L}: \Omega_1^2(\nu, \sigma) \to \Omega_1^2(\nu, \sigma)$. This fixed point $\tilde{u} = \tilde{m}(\cdot, r_2, \mu_2) \in \Omega_1^2(\nu, \sigma)$ gives our desired locally invariant manifold of [\(16\)](#page-7-0). Transforming the result back to the (x_2, y_2, z_2) -variables gives the desired statement of Proposition [3.3](#page-16-0) for $k = 0$. To obtain the C^k-smoothness of $\tilde{m}(\cdot, r_2, \mu_2)$ with respect to r_2, μ_2 , we proceed in the usual way by differentiating [\(17\)](#page-8-4). This produces variational equations for the partial derivatives of \tilde{m} and these equations can then be solved successively (by the method of induction) up to some fixed order $k \in \mathbb{N}$ using the same approach as for $k = 0$. We skip further details because it is standard.

 \Box

The invariant manifold Z_{2,r_2} is a slow manifold extending uniformly with respect to r_2 across the degenerate set $y_2 = 0$, $\mu_2 = 0$. It is a subset of the stable (unstable) set of [\(14\)](#page-6-4) for $\lambda < 0$ ($\lambda > 0$, respectively).

2.2. Melnikov theory. We now straighten out the slow manifold of Proposition [2.2](#page-7-2) by writing:

$$
\begin{pmatrix} x_2 \\ z_2 \end{pmatrix} = m(y_2, r_2, \mu_2) + \tilde{u}.
$$
 (25)

Then the invariant manifold corresponds to $\tilde{u} = 0$ and consequently:

$$
\dot{\tilde{u}} = B(\tilde{u}, y_2)\tilde{u} + r_2 R_2(\tilde{u}, y_2, r_2, \mu_2)\tilde{u},
$$

\n
$$
\dot{y}_2 = r_2 \left(\frac{1}{2}\mu_2 + \lambda y_2 + P_2(\tilde{u}, y_2, r_2, \mu_2)\right),
$$
\n(26)

where $P_2(0, y_2, 0, \mu_2) = 0$ and

$$
B(\tilde{u}, y_2) = \begin{pmatrix} 0 & -1 \\ 1 & 2y_2 + \tilde{u}_2 \end{pmatrix},
$$

for $\tilde{u} = (\tilde{u}_1, \tilde{u}_2)$. For $r_2 = y_2 = 0$, we have $m(0, 0, \mu_2) = 0$ and hence \tilde{u} reduces to (x_2, z_2) in this case. We now again drop the tildes. The u-plane is therefore for $r_2 = 0$ also filled with the periodic orbits $\phi_h(t) = (x_{2h}(t), z_{2h}(t))$, intersecting the negative x_2 -axis in $(-h, 0)$ with $h > 0$. Moreover, due to the invariance of $u = 0$, the return map from $u_1 < 0, u_2 = 0$ to itself, mapping $(-h, 0, y_{20})$ to $(u_1(T), 0, y_2(T))$, with $T = T(h, y_2, r_2, \mu_2)$ being the transition time, is well-defined for all $h > 0$, $0 \leq r_2 \ll 1, \mu_2 \in [-\delta, \delta].$ In fact, polar coordinates in the u-plane is well-defined for all $y_2 \in [-\nu, \nu],$ $\mu_2 \in [-\delta, \delta]$, and as a result we obtain:

Lemma 2.7. The return map has a smooth extension to $h = 0$ with $T(0, y_2, r_2, \mu_2) = 2\pi + \mathcal{O}(y_2, r_2)$.

We now obtain fixed points of the return map using Melnikov theory to perturb away from the family of period orbits $u = \phi_h(t)$, $h > 0$, within $y_2 = 0$ for $\mu_2 = r_2 = 0$. For this purpose, let

$$
A_h(t) := \begin{pmatrix} 0 & -1 \\ 1 & 2z_{2h}(t) \end{pmatrix},
$$

denote the linearization around $u = \phi_h(t)$, $y_2 = r_2 = 0$. We then write

$$
u = \phi_h(t) + \tilde{u}, \quad y_2 = \tilde{y}_2. \tag{27}
$$

and let $\tilde{u}(t, h, y_2, r_2, \mu_2), \tilde{y}_2(t, h, y_2, r_2, \mu_2)$ denote the solutions of the resulting differential equations:

$$
\dot{\tilde{u}} = A_h(t)\tilde{u} + \left\{ B(\phi_h(t) + \tilde{u}, \tilde{y}_2)(\phi_h(t) + \tilde{u}) - A_h(t)\tilde{\phi}_h(t) - A_h(t)\tilde{u} \right\} \n+ r_2 R_2(\phi_h(t) + \tilde{u}, \tilde{y}_2, r_2, \mu_2)(\phi_h(t) + \tilde{u}) \right\},
$$
\n
$$
\dot{\tilde{y}}_2 = r_2 \left(\frac{1}{2}\mu_2 + \lambda \tilde{y}_2 + P_2(\phi_h(t) + \tilde{u}, \tilde{y}_2, r_2, \mu_2) \right),
$$

with initial conditions $\tilde{u}(0) = 0, \tilde{y}_2(0) = y_2$. We have

$$
\tilde{u}(t,0,y_2,r_2,\mu_2)\equiv 0,
$$

due to $\phi_0(t) \equiv 0$ and the invariance of $u = 0$ for [\(26\)](#page-10-1). Let $\Phi_h(t, s)$ denote the state-transition matrix associated with $A_h(t)$. Then by variation of constants we have that

$$
\tilde{u}(T, h, y_2, r_2, \mu_2) = \int_0^T \Phi_h(T, t) \{\cdots\} dt,
$$

$$
\tilde{y}_2(T, h, y_2, r_2, \mu_2) = y_2 + \int_0^T r_2(\cdots) dt,
$$

where

$$
\{\cdots\} = B(\phi_h(t) + \tilde{u}(t, h, y_2, r_2, \mu_2), \tilde{y}_2)(\phi_h + \tilde{u}(t, h, y_2, r_2, \mu_2)) - A_h(t)\tilde{\phi}_h(t) - A_h(t)\tilde{u}(t, h, y_2, r_2, \mu_2) + r_2R_2(\phi_h(t) + \tilde{u}(t, h, y_2, r_2, \mu_2), \tilde{y}_2(t, h, y_2, r_2, \mu_2), r_2, \mu_2) \times (\phi_h(t) + \tilde{u}(t, h, y_2, r_2, \mu_2)), (\cdots) = \frac{1}{2}\mu_2 + \lambda \tilde{y}_2(t, h, y_2, r_2, \mu_2) + P_2(\phi_h(t) + \tilde{u}(t, h, y_2, r_2, \mu_2), \tilde{y}_2(t, h, y_2, r_2, \mu_2), r_2, \mu_2).
$$

Recall that $T(h, y_2, r_2, \mu_2)$ denotes the transition time, with $T_0(h) := T(h, 0, 0, 0)$ being the period of the periodic orbits $\phi_h(t) = (x_{2h}(t), z_{2h}(t))$. Since the eigenvalues of $B(0,0)$ are $\pm i$, we have

$$
\phi_h(t) = -h \begin{pmatrix} \cos t + \mathcal{O}(h) \\ \sin t + \mathcal{O}(h) \end{pmatrix},\tag{28}
$$

for $h \to 0^+$. Moreover:

$$
T_0(0) := \lim_{h \to 0^+} T_0(h) = 2\pi,
$$
\n(29)

 $\big).$

see also Lemma [2.7.](#page-10-2) We then consider the adjoint system:

$$
\dot{\psi} = -A_h(t)^T \psi,
$$

and let $\psi_h(t)$ denote the solution with $\psi_h(T) = (1, 0)$. Then a simple calculation shows the following: Lemma 2.8.

$\psi_h(t) = -h^{-1} e^{\int_t^T 2z_{2h}(s)ds} \left(\begin{array}{c} z'_{2h}(t) \\ z'_{2h}(t) \end{array} \right)$

Moreover,

$$
\psi_h(T) \cdot \tilde{u}(T, h, y_2, r_2, \mu_2) = \int_0^T \psi_h(t) \cdot \{\cdots\} dt.
$$
\n(30)

 $-x'_{2h}(t)$

Proof. This is standard and follows from the theory of adjoint equations, see [\[41\]](#page-25-32). In particular, for [\(30\)](#page-11-0) we use $\psi_h(T)^T \Phi_h(T,s) = \psi_h(s)^T$.

We therefore define the Melnikov functions

$$
\Delta_1(h, y_2, r_2, \mu_2) = [x_{2h}(T) - h] + \int_0^T \psi_h(t) \cdot \{\cdots\} dt,
$$

$$
\Delta_2(h, y_2, r_2, \mu_2) = \int_0^T (\cdots) dt.
$$

so that roots of $\Delta := (\Delta_1, \Delta_2)$ for $h > 0$ (using [\(27\)](#page-10-3)) correspond to fixed points of the return map and periodic orbits. We have:

Lemma 2.9. Δ also extends smoothly to $h = 0$, with $\Delta_1(0, y_2, r_2, \mu_2) \equiv 0$ and $\Delta(h, 0, 0, 0) \equiv 0$ for all $h \geq 0$.

Proof. The extension of Δ follows from the invariance of $u = 0$ of [\(26\)](#page-10-1) and the fact that T extends smoothly to $h = 0$, recall Lemma [2.7.](#page-10-2) The invariance of $u = 0$ and the fact that $\phi_0(t) \equiv 0$ also gives ${\{\cdots\}}=0$ for $h=0$ and therefore $\Delta_1(0, y_2, r_2, \mu_2)\equiv 0$. Finally, $\Delta(h, 0, 0, 0)=0$ since $u=(x_2, z_2)=0$. $\phi_h(t)$ is a solution of [\(10\)](#page-5-2) within $y_2 = 0$ and $r_2 = 0$.

Following this lemma, the function

$$
\widehat{\Delta} := (h^{-1} \Delta_1, \Delta_2),
$$

is well-defined and smooth on $h \geq 0$. Moreover:

Lemma 2.10. $\widehat{\Delta}(h, 0, 0, 0) \equiv 0$ and

$$
\widehat{\Delta}_{y_2}'(h,0,0,0) = \begin{pmatrix} -2\int_0^{T_0(h)} e^{\int_t^T 2z_{2h}(s)ds} (h^{-1}z_{2h})(t)^2 dt \\ * \end{pmatrix},
$$
\n(31)

$$
\widehat{\Delta}_{\mu_2}'(h,0,0,0) = \begin{pmatrix} 0\\ \frac{1}{2}T_0(h) \end{pmatrix},\tag{32}
$$

for all $h \geq 0$, with $*$ denoting a quantity that is not important.

Proof. $\Delta(h, 0, 0, 0) \equiv 0$ follows from Lemma [2.9](#page-11-1) and [\(32\)](#page-11-2) is obvious. To show [\(31\)](#page-11-3), we compute for $h > 0$:

$$
\frac{\partial \Delta_1}{\partial y_2}(h,0,0,0) = \int_0^{T_0} \psi_h(t) \cdot \begin{pmatrix} 0 & 0 \\ 0 & 2 \end{pmatrix} \phi_h(t) dt
$$

= $2h^{-1} \int_0^T e^{\int_t^T 2z_{2h}(s)ds} x'_{2h}(t) z_{2h}(t) dt$
= $-2h^{-1} \int_0^T e^{\int_t^T 2z_{2h}(s)ds} z_{2h}(t)^2 dt$.

 $h^{-1}z_{2h}$ extends to all $h \ge 0$ by [\(28\)](#page-11-4), which then completes the proof.

The Jacobian matrix

$$
\widehat{\Delta}_{(y_2,\mu_2)}(h,0,0,0) := \left(\widehat{\Delta}_{y_2}'(h,0,0,0) \quad \widehat{\Delta}_{\mu_2}'(h,0,0,0)\right),
$$

is therefore regular for all $h > 0$, regardless of what $*$ is, also for $h = 0$ due to [\(28\)](#page-11-4) and [\(29\)](#page-11-5):

$$
\widehat{\Delta}_{y_2}'(\mathbf{0}) = \begin{pmatrix} -2\pi \\ * \end{pmatrix}, \quad \widehat{\Delta}_{\mu_2}'(\mathbf{0}) = \begin{pmatrix} 0 \\ \pi \end{pmatrix}.
$$

Proposition 2.11. Fix any $h_1 > 0$. Then there exist smooth functions $\overline{y}_2(h, r_2), \overline{\mu}_2(h, r_2)$ with $\overline{y}_2(h,0) = 0, \ \overline{\mu}_2(h,0) = 0$ such that $\Delta(h, \overline{y}_2(h,r_2), r_2, \overline{\mu}_2(h,r_2)) = 0$ for all $h \in [0,h_1]$ and all $0 \le r_2 \ll 1$.

Proof. Follows from the implicit function theorem. \Box

Corollary 2.12. Let $\mu_H(r_2) := r_2\overline{\mu}_2(0,r_2)$. Then ([9](#page-5-4)) undergoes a Hopf bifurcation at $\mu = \mu_H(r_2)$ for $0 < r_2 \ll 1$.

Proof. The statement follows directly from Proposition [2.11.](#page-12-2) \Box

Remark 2.13. We do not aim to describe the stability of the cycles. This is more difficult. However, sufficiently close to the Hopf bifurcation, one can describe stability in terms of the signs of λ and $\frac{\partial^2 \overline{\mu}_2}{\partial h^2}(0,r_2)$; here the latter quantity relates directly to the first Lyapunov coefficient of the Hopf (within a center manifold). In particular, if $\lambda > 0$ then $\mu_2 \ge \mu_H(r_2)$ means that the equilibrium is on the attracting/repelling side of Z_{2,r_2} , respectively. Therefore sufficiently close to the equilibrium, the limit (Hopf) cycles are unstable/stable if $\frac{\partial^2 \overline{\mu}_2}{\partial h^2}(0,r_2) \geqslant$ for $\lambda > 0$. If $\lambda < 0$, then the inequalities for μ_2 regarding the "normal stability" of ([14](#page-6-4)) become $\mu_2 \leq \mu_H(r_2)$ and the Hopf cycles are unstable/stable if $\frac{\partial^2 \overline{\mu}_2}{\partial h^2}(0,r_2) \leq 0$ in this case.

It is possible to compute a leading order expression for $\frac{\partial^2 \overline{\mu}_2}{\partial h^2}(0,r_2)$ but we chose not to include the complicated expression in the present paper.

Obviously, one could just compute the Lyapunov coefficient by applying the center manifold reduction. But – due the zero-Hopf bifurcation for $r_2 = 0$ – this approach does not quarantee that this quantity describe the stability of limit cycles in a uniform neighborhood (i.e. one that does not shrink in the (x_2, y_2, z_2) -space as $\epsilon \to 0$. Our Melnikov approach using Proposition [3.3](#page-16-0) in the analytic setting does imply such uniformity.

The family of periodic orbits of [\(9\)](#page-5-4) are small periodic orbits (with amplitude of order $o(1)$) of [\(3\)](#page-2-2) upon blowing down using [\(7\)](#page-4-0). By working in the chart $\bar{x} = -1$ in the following section, we are able to extend these cycles to "intermediate" cycles that include $\mathcal{O}(1)$ canards.

3. Existence of intermediate periodic orbits

Our strategy for extending the small periodic orbits to intermediate ones, that connect to cycles of size $\mathcal{O}(1)$, follows the approach for proving canard cycles in \mathbb{R}^2 : Working in the entry chart $\bar{x} = -1$, we fix a section along $z_1 = 0$, in a neighborhood of $(r_1, y_1, \epsilon_1) = 0$ with $\mu \sim 0$, and flow the points forward and backward and then measure their separation on a section $\{z_2 = 0\}$ in the scaling chart $\bar{\epsilon} = 1$ transverse to $\gamma_{2,0}(0)$, recall [\(11\)](#page-5-3). Based upon expansions from the solution of a Shilnikov problem [\[15\]](#page-25-27), we define appropriate scalings that allow us to solve for roots of the separation function by applying the implicit function theorem.

3.1. Analysis in the $\bar{x} = -1$ -chart. We first consider the $\bar{x} = -1$ -chart. Inserting [\(6\)](#page-4-1) into ([\(3\)](#page-2-2), $\dot{\epsilon} =$ 0) gives

$$
\begin{aligned}\n\dot{\epsilon}_1 &= \epsilon_1^2 \left[y_1 - (\mu + 1)z_1 + r_1 F_1(\epsilon_1, r_1, y_1, z_1, \mu) \right], \\
\dot{r}_1 &= -\frac{1}{2} r_1 \epsilon_1 \left[y_1 - (\mu + 1)z_1 + r_1 F_1(\epsilon_1, r_1, y_1, z_1, \mu) \right], \\
\dot{y}_1 &= \epsilon_1 \left(\frac{1}{2} \mu + r_1 G_1(\epsilon_1, r_1, y_1, z_1, \mu) \right) + \frac{1}{2} \epsilon_1 y_1 \left[y_1 - (\mu + 1)z_1 + r_1 F_1(\epsilon_1, r_1, y_1, z_1, \mu) \right], \\
\dot{z}_1 &= -1 + z_1^2 + r_1 z_1 H_1(\epsilon_1, r_1, y_1, z_1, \mu) + \frac{1}{2} \epsilon_1 z_1 \left[y_1 - (\mu + 1)z_1 + r_1 F_1(\epsilon_1, r_1, y_1, z_1, \mu) \right],\n\end{aligned} \tag{33}
$$

where $F_1 = r_1^{-2}F$, $G_1 = r_1^{-2}G$, and $H_1 = r_1^{-2}H$, each being smooth, also upon extending to $r_1 = 0$. The points $(0, 0, y_1, -1)$ are partially attracting, whereas $(0, 0, y_1, 1)$ are partially repelling. In particular, in each case the linearization has a single nonzero eigenvalue (positive/negative, respectively). Consequently, by center manifold theory we have the following.

Lemma 3.1. Fix any $k \in \mathbb{N}$. Then there exists a constant $\sigma > 0$ sufficiently small such that the following holds: There exist two three-dimensional center manifolds $M_{1,a}$ and $M_{1,r}$ of the sets $(0, 0, y_1, -1)$ and $(0, 0, y_1, 1), y_1 \in [-\sigma, \sigma]$, having the following graph representations:

$$
M_{1,a}: z_1 = m_{1,a}(\epsilon_1, r_1, y_1, \mu),
$$

$$
M_{1,r}: z_1 = m_{1,r}(\epsilon_1, r_1, y_1, \mu),
$$

for $0 \leq r_1, \epsilon_1, |y_1|, |\mu| \leq \sigma$. The functions $m_{1,a}$ and $m_{1,r}$ are C^k -smooth functions on the specified domain and satisfy $m_{1,a}(0,0,y_1,\mu) \equiv -1, m_{1,r}(0,0,y_1,\mu) \equiv 1$ for all $y_1,\mu \in [-\sigma,\sigma]$ as well as

$$
m_{1,a}(\epsilon_1, 0, \pm \mu, \mu) \equiv -1, m_{1,r}(\epsilon_1, 0, \pm \mu, \mu) \equiv 1.
$$
\n(34)

The properties in [\(34\)](#page-13-1) are consequences of the invariant sets $\gamma_{2,0}(\mu)$ in the $\bar{\epsilon} = 1$ -chart, recall [\(12\)](#page-6-5), which in the present chart become $r_1 = 0, y_1 = \pm \mu, z_1 = \pm 1$ and $\epsilon_1 \geq 0$; we denote these sets by $\gamma_{1,0,a}(\mu)$ and $\gamma_{1,0,r}(\mu)$, respectively. We illustrate the dynamics in the $\bar{x} = -1$ -chart in Fig. [3.](#page-13-2)

FIGURE 3. Dynamics in the entry chart $\bar{x} = -1$. In (a): for $\mu = 0$. In (b): for $\mu = \mu_0(r_1, 0)$. μ_0 is defined later, but essentially $\mu_0(\tilde{r}_1, 0)$ with $\tilde{r}_1 > 0$ is so that for $r_1 = \tilde{r}_1$, $\mu = \mu(\tilde{r}_1, 0)$ there is fast jump connecting γ_0 to itself.

As is standard, the center manifolds $M_{1,a}$, $M_{1,r}$ provide extensions of the family of Fenichel slow manifolds $\{(S_{a,\epsilon}, \epsilon) : \epsilon \in [0, \epsilon_0)\}\$ as $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ as foliations (through $r_1^2 \epsilon_1 = \epsilon = \text{const.}$) of the center manifolds [\[18\]](#page-25-10).

On $M_{1,a}$ and $M_{1,r}$ we have the following desingularized reduced problems

$$
\epsilon'_{1} = \epsilon_{1},
$$

\n
$$
r'_{1} = -\frac{1}{2}r_{1},
$$

\n
$$
y'_{1} = \frac{\frac{1}{2}\mu + \mathcal{O}(r_{1})}{y_{1} + (\mu + 1) + \mathcal{O}(\epsilon_{1}, r_{1})} + \frac{1}{2}y_{1},
$$
\n(35)

and

$$
\epsilon'_{1} = -\epsilon_{1},
$$

\n
$$
r'_{1} = \frac{1}{2}r_{1},
$$

\n
$$
y'_{1} = \frac{\frac{1}{2}\mu + \mathcal{O}(r_{1})}{-y_{1} + (\mu + 1) + \mathcal{O}(\epsilon_{1}, r_{1})} - \frac{1}{2}y_{1},
$$
\n(36)

obtained by dividing the right hand sides by $\pm \epsilon_1 [y_1 - (\mu + 1)z_1 + r_1F_1(\epsilon_1, r_1, y_1, z_1, \mu)]$ and then substituting $z_1 = m_{1,a}(\cdots)$ and $z_1 = m_{1,r}(\cdots)$, respectively. Notice that the square brackets $\pm [y_1 - (\mu+1)z_1 + r_1F_1(\epsilon_1, r_1, y_1, z_1, \mu)]$ are positive near $M_{1,a}$ and $M_{1,r}$, respectively, and for $\epsilon_1 > 0$ the divisions therefore correspond to time transformations.

The system [\(35\)](#page-14-0) has a hyperbolic equilibrium at $(0, 0, -\mu)$ with eigenvalues $-1/2, 1, \lambda(\mu)$ where

$$
\lambda(\mu) = \frac{1}{2}(1 - \mu). \tag{37}
$$

Similarly, [\(36\)](#page-14-1) has a hyperbolic equilibrium at $(0, 0, \mu)$ with eigenvalues $\frac{1}{2}, -1, -\lambda(\mu)$. There are therefore strong resonances of both systems when $\mu = 0$.

In the following, we now describe two transition mappings $P_{1,a}$ and $P_{1,r}$ from $\{z_1 = 0\}$ to $\{\epsilon_1 = \epsilon_{11}\}\$ obtained by applying the forward and backward flow, respectively. See illustration in Fig. [3.](#page-13-2) We will describe each mapping in appropriate "normal form coordinates". Since the two mappings are similar, we focus on $P_{1,a}$.

Lemma 3.2. Consider ([33](#page-13-3)) near $M_{1,a}$ and fix any $k \in \mathbb{N}$. Then for $\sigma > 0$ small enough, there exists a regular transformation of time and a C^k -smooth diffeomorphism $(y_1, z_1) \mapsto (y_{1,a}, z_{1,a})$, $y_1, z_1 + 1 \in$ $[-\sigma, \sigma]$, depending C^k -smoothly on (ϵ_1, r_1, μ) for $0 \leq r_1, \epsilon_1, |\mu| \leq \sigma$, such that

$$
y_{1,a} = h_{1,a}^0(\epsilon_1, r_1, y_1, \mu) + \epsilon_1 h_{1,a}^1(\epsilon_1, r_1, y_1, z_1, \mu),
$$

\n
$$
z_{1,a} = z_1 - m_{1,a}(\epsilon_1, r_1, y_1, \mu),
$$
\n(38)

where

$$
h_{1,a}^{0}(\epsilon_1, 0, -\mu, \mu) \equiv 0, \quad \frac{\partial h_{1,a}^{0}}{\partial y_1}(\mathbf{0}) = 1, \quad \frac{\partial h_{1,a}^{0}}{\partial \mu}(\mathbf{0}) = 1,\tag{39}
$$

and ([33](#page-13-3)) becomes

$$
\begin{aligned}\n\dot{\epsilon}_1 &= \epsilon_1^2, \\
\dot{r}_1 &= -\frac{1}{2}r_1\epsilon_1, \\
\dot{y}_{1,a} &= ((\lambda(\mu) + r_1L_0(r_1, y_{1,a}, \mu))y_{1,a} + r_1\epsilon_1L_1(\epsilon_1, r_1, y_{1,a}, \mu))\epsilon_1, \\
\dot{z}_{1,a} &= (-2 + L_2(r_1, y_{1,a}, z_{1,a}, \epsilon_1, \mu))z_{1,a},\n\end{aligned} \tag{40}
$$

with L_0, L_1, L_2 each C^k -smooth and $L_2(0) = 0$.

Proof. We first divide the right hand side by

$$
y_1 - (\mu + 1)z_1 + r_1F_1(\epsilon_1, r_1, y_1, z_1, \mu),
$$

which is positive near $M_{1,a}$. This defines our regular transformation of time. Consequently,

$$
\begin{aligned}\n\dot{\epsilon}_1 &= \epsilon_1^2, \\
\dot{r}_1 &= -\frac{1}{2}r_1\epsilon_1, \\
\dot{y}_1 &= \frac{\epsilon_1\left(\frac{1}{2}\mu + r_1G_1(\epsilon_1, r_1, y_1, z_1, \mu)\right)}{y_1 - (\mu + 1)z_1 + r_1F_1(\epsilon_1, r_1, y_1, z_1, \mu)} + \frac{1}{2}\epsilon_1 y_1, \\
\dot{z}_1 &= \frac{-1 + z_1^2 + r_1 z_1 H_1(\epsilon_1, r_1, y_1, z_1, \mu)}{y_1 - (\mu + 1)z_1 + r_1F_1(\epsilon_1, r_1, y_1, z_1, \mu)} + \frac{1}{2}\epsilon_1 z_1,\n\end{aligned}
$$

We then rectify $M_{1,a}$ to $z_{1,a} = 0$ by $z_1 = m_{1,a}(\epsilon_1, r_1, y_1, \mu) + z_{1,a}$ and subsequently straighten out the associated stable fibers of $M_{1,a}$ by a near-identity transformation $(\epsilon_1, r_1, y_1, z_{1,a}, \mu) \mapsto \tilde{y}_1$ such that $(\epsilon_1, r_1, \tilde{y}_1)'$ becomes independent on $z_{1,a}$ [\[32,](#page-25-33) [31\]](#page-25-6). Then

$$
\begin{aligned}\n\dot{\epsilon}_1 &= \epsilon_1^2, \\
\dot{r}_1 &= -\frac{1}{2}r_1\epsilon_1, \\
\dot{\tilde{y}}_1 &= \epsilon_1 \left(\frac{\frac{1}{2}\mu + \mathcal{O}(r_1)}{\tilde{y}_1 + (\mu + 1) + \mathcal{O}(\epsilon_1, r_1)} + \frac{1}{2}\tilde{y}_1 \right), \\
\dot{z}_{1,a} &= (-2 + \mathcal{O}(\epsilon_1, r_1, \tilde{y}_1, z_{1,a}, \mu))z_{1,a}.\n\end{aligned}
$$

By construction $r_1, \epsilon_1, \tilde{y}_1$ decouples. For $\epsilon_1 = 0$ it easy to see that $\tilde{y}_1 = y_1$. This shows the form of [\(38\)](#page-14-2) with the z₁-dependency of $y_{1,a}$ only entering the $\mathcal{O}(\epsilon_1)$ -term. Indeed, in the remainder of the proof we only transform \tilde{y}_1 in order to normalize the reduced problem on $z_{1,a} = 0$:

$$
\epsilon'_{1} = \epsilon_{1},
$$

\n
$$
r'_{1} = -\frac{1}{2}r_{1},
$$

\n
$$
y'_{1} = \frac{\frac{1}{2}\mu + \mathcal{O}(r_{1})}{y_{1} + (\mu + 1) + \mathcal{O}(\epsilon_{1}, r_{1})} + \frac{1}{2}y_{1},
$$
\n(41)

after dividing the right hand side by ϵ_1 . We have here dropped the tilde on y_1 and the system then coincides (by construction) with [\(35\)](#page-14-0).

Put $y_1 = -\mu + \tilde{y}_1$. Then

$$
\epsilon_1' = \epsilon_1,
$$

\n
$$
r_1' = -\frac{1}{2}r_1,
$$

\n
$$
y_1' = \lambda(\mu)y_1 + L_1(\epsilon_1, r_1, y_1, \mu),
$$
\n(42)

after dropping the tildes, with $L_1(\cdot,\mu)$ being of second order. First consider the $r_1 = 0$ subsystem:

$$
\epsilon_1' = \epsilon_1,
$$

\n
$$
y_1' = \lambda(\mu)y_1 + L_1(\epsilon_1, 0, y_1, \mu),
$$
\n(43)

having eigenvalues 1, $\lambda(\mu) = \frac{1}{2}(1 - \mu)$. Due to the invariance of $\epsilon_1 = 0$, there are no resonant monomials for $\mu \sim 0$ and

$$
\epsilon'_1 = \epsilon_1,
$$

$$
y'_1 = \lambda(\mu)y_1,
$$

is a formal normal form. Following [\[29\]](#page-25-29) and [\[17,](#page-25-34) Theorem 2.15 and section 2.7], the system [\(43\)](#page-15-0) can therefore be linearized by a C^{∞} -transformation of the form $(\epsilon_1, y_1, \mu) \mapsto \tilde{y}_1 = h_{1,a}(\epsilon_1, y_1, \mu)$ with $h_{1,a}(0,0,\mu) = 0$, $\frac{\partial h_{1,a}}{\partial y_1}(0,0,\mu) = 1$.. Applying this transformation to [\(42\)](#page-15-1), leaving r_1 untouched, it follows that we can take L_1 to be of the form $L_1 = r_1 \tilde{L}_1$. Then within $\epsilon_1 = 0$, we have a saddle for $\mu \sim 0$ and we can straighten out the unstable manifold by an r₁-dependent transformation of y_1 :

$$
(r_1, y_1) \mapsto y_{1,a}. \text{ This gives } \widetilde{L} = y_{1,a}\widetilde{L}_0 + \epsilon_1 \widetilde{L}_1:
$$

\n
$$
\epsilon'_1 = \epsilon_1,
$$

\n
$$
r'_1 = -\frac{1}{2}r_1,
$$

\n
$$
y'_{1,a} = (\lambda(\mu) + r_1 L_0(r_1, y_{1,a}, \mu))y_{1,a} + r_1 \epsilon_1 L_1(\epsilon_1, r_1, y_{1,a}, \mu),
$$
\n(44)

upon dropping the tildes. This completes the proof. \Box

Since the flow is regular on sets that are uniformly bounded away from $M_{1,a}$ and $M_{1,r}$, we can actually extend the transformation leading to [\(40\)](#page-14-3) to $z_1 \in [-1-\sigma, 0]$, say, by the flow-box theorem. We therefore describe $P_{1,a}$ using the coordinates of [\(40\)](#page-14-3) from $\{z_{1,a} = -\widetilde{m}_{1,a}(\epsilon_1, r_1, y_{1,a}, \mu)\}\)$ to $\{\epsilon_1 = \epsilon_{11}\}.$ Here $\widetilde{m}_{1,a}(\epsilon_1, r_1, y_{1,a}, \mu) := m_{1,a}(r_1, y_1(\epsilon_1, r_1, y_{1,a}, \mu), \epsilon_1, \mu)$ with the smooth function $y_1(\epsilon_1, r_1, y_{1,a}, \mu)$ being obtained (by the implicit function theorem) from [\(38\)](#page-14-2) with $z_1 = 0$:

$$
y_{1,a} = h_{1,a}^0(\epsilon_1, r_1, y_1, \mu) + \epsilon_1 h_{1,a}^1(\epsilon_1, r_1, y_1, 0, \mu).
$$

For simplicity, we denote the transformed mapping

$$
P_{1,a}(\epsilon_1,r_1,y_{1,a},\mu) = \begin{pmatrix} \epsilon_{11} \\ \sqrt{\epsilon_1 \epsilon_{11}^{-1}} r_1 \\ * \\ * \end{pmatrix},
$$

by the same symbol. Notice that the r_1 - and ϵ_1 -components of the mapping are just consequences of the conservation of $\epsilon = r_1^2 \epsilon_1$.

We describe $P_{1,a}$ in Proposition [3.4,](#page-17-0) but in preparation we first state a result on the *Shilnikov* problem associated with the $(\epsilon_1, r_1, y_{1,a})$ -subsystem, written in the desingularized form [\(44\)](#page-16-1). For this, it will be convinient to work with functions $(u, v) \in U \times V \mapsto f(u, v) \in \mathbb{R}^l$, $U \subset \mathbb{R}^n$, $V \subset \mathbb{R}^m$, $l, n, m \in \mathbb{N}$, that are C^k -smooth, $k \in \mathbb{N}$, with respect to the $v \in V$, depending continuously on $u \in U$. We write the function space of such functions by $C(u^0v^k)$ and let

$$
||f||_{u^0v^k} := \sup_{(u,v)\in U\times V, 0\leq |i|\leq k} |D^if(u,v)|,
$$

with D^i being the partial derivative with respect to v of order $i = (i_1, \ldots, i_m) \in \mathbb{N}_0^m$, denote the associated Banach norm. Notice that by $C(u^0v^k)$ and $\|\cdot\|_{u^0v^k}$ we suppress l, n, m, U and V; it should be clear from the context what these are. On the other hand, we use $||f||_{C^k} := \sup_{u \in U, 0 \leq |i| \leq k} |D^i f(u)|$ to denote the usual C^k -norm of a C^k -smooth function $f: U \to \mathbb{R}^l$.

Proposition 3.3. Fix $k \in \mathbb{N}$, $\alpha \in (0, \frac{1}{2})$ and consider ([44](#page-16-1)). Then there exist constants $\tau_0 > 0$, $K > 0$ and $C > 0$ such that the following holds for all $\delta > 0$ small enough: There exists a C^k smooth function $\underline{y}_{1,a}(t,\tau,\epsilon_{11},r_{10},y_{11},\mu)$, defined on the set given by: $(t,\tau): 0 \le t \le \tau, \tau > \tau_0$ and $0 \leq \epsilon_{11}, r_{10}, |y_{11}|, |\mu| \leq K\delta$, such that $y_{1,a}(t) = \underline{y}_{1,a}(t, \tau, \epsilon_{11}, r_{10}, y_{11}, \mu)$ solves the Shilnikov problem defined by

$$
\epsilon_1(\tau) = \epsilon_{11}, \quad r_1(0) = r_{10}, \quad y_{1,a}(\tau) = y_{11}.
$$

Moreover, $\underline{y}_{1,a}$ has the following expansion:

$$
\underline{y}_{1,a}(t,\tau,\epsilon_{11},r_{10},y_{11},\mu) = e^{\lambda(\mu)(t-\tau)}(y_{11} + \phi(t,\tau,\epsilon_{11},r_{10},y_{11},\mu)),
$$

where $\|\phi\|_{C^k} \leq C$; specifically

$$
\|\phi\|_{(t,\tau,\epsilon_{11},r_{10})^0(y_{11},\mu)^k} \le \delta, \quad \phi(t,\tau,\epsilon_{11},0,0,\mu) \equiv 0. \tag{45}
$$

Finally, define

$$
\phi_{\infty}(t, \epsilon_{11}, r_{10}, y_{11}, \mu) := \left(e^{-\int_t^{\infty} r_1(s)L_0(r_1(s), 0, \mu)ds} - 1\right) y_{11},
$$

for all $t > 0$ with $r_1(t) = e^{-\frac{1}{2}t}r_{10}$. Then $\phi_{\infty} \in C^k$ and

$$
\|\phi(t,\tau,\cdot)-\phi_{\infty}(t,\cdot)\|_{(\epsilon_{11},r_{10})^0(y_{11},\mu)^k} \leq C\delta e^{-\alpha\tau},\tag{46}
$$

for all $\tau > \tau_0$.

Proof. The proof follows [\[15\]](#page-25-27) and we therefore delay the details to Appendix [A.](#page-27-0)

Proposition 3.4. Fix $k \in \mathbb{N}$ and any $\delta > 0$. Then there exist constants $c > 0$, $\chi > 0$ and $0 < \epsilon_{10} \ll$ ϵ_{11} , $r_{10} > 0$ such that the following holds: The transition map $P_{1a}(\cdot, \mu)$ of ([40](#page-14-3)) is well-defined on a region $V_{1,a}(\chi)$ defined by

$$
|y_{1,a}| \le \chi(\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu)}, \epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}],
$$
\n(47)

and on this region, the mapping takes the following form

$$
P_{1,a}(\epsilon_1,r_1,y_{1,a},\mu) = \begin{pmatrix} \epsilon_{11} \\ \sqrt{\epsilon_1 \epsilon_{11}^{-1}} r_1 \\ (\epsilon_1^{-1} \epsilon_{11})^{\lambda(\mu)} y_{1,a} + \psi_{1,a}(\epsilon_1,r_1,(\epsilon_1^{-1} \epsilon_{11})^{\lambda(\mu)} y_{1,a},\mu) \\ \mathcal{O}(e^{-c/\epsilon_1}) \end{pmatrix}
$$

Here $\psi_{1,a}$ is a $C(\epsilon_1^0(r_1,u,\mu)^k)$ -function on the set $\epsilon_1 \in [0,\epsilon_{10}], r_1 \in [0,r_{10}], 0 \leq |u|, |\mu| \leq \chi$ with

$$
\|\psi_{1,a}\|_{(\epsilon_1,r_1)^0(u,\mu)^k} \le \delta, \quad \psi_{1,a}(\epsilon_1,0,0,\mu) \equiv 0. \tag{48}
$$

The $\mathcal{O}(e^{-c/\epsilon_1})$ remainder term in the $z_{1,a}$ -component is also a $C(\epsilon_1{}^0(r_1,y_{1,a},\mu)^k)$ -function with the order being unchanged upon differentiation up to order k with respect to $(r_1, y_{1,a}, \mu)$ for $(\epsilon_1, r_1, y_{1,a}) \in$ $V_{1,a}(\chi)$.

Proof. Since $(\epsilon_1, r_1, y_{1,a})$ -decouples, we use Proposition [3.3](#page-16-0) with τ defined by $\epsilon_{11} = e^{\tau} \epsilon_1$. Let

$$
y_{1,a} = \underline{y}_{1,a}(0,\tau,\epsilon_{11},r_1,y_{11},\mu) = e^{-\lambda(\mu)\tau}[y_{11} + \phi(0,\tau,\epsilon_{11},r_1,y_{11},\mu)].
$$
\n(49)

The $y_{1,a}$ -component of the transition map is then defined implicitly by this equation as $y_{1,a} \mapsto y_{11}$. Consider therefore $F(u_0, \tau, y_{11}, \mu) = 0$ with

$$
F(u_0, \tau, r_1, y_{11}, \mu) := u_0 - (y_{11} + \phi(0, \tau, \epsilon_{11}, r_1, y_{11}, \mu)),
$$

for $\epsilon_{11} > 0$ fixed, defined by setting the square bracket in [\(49\)](#page-17-1) equal to u_0 . Then by Proposition [3.3](#page-16-0) and the implicit function theorem, we obtain a locally unique solution

$$
y_{11} = u_0 + \psi_{1,a}(\tau, r_1, u_0, \mu), \tag{50}
$$

of $F = 0$ with $\widetilde{\psi}_{1,a} \in C^k$ defined on $\tau > \tau_0$, $0 \leq |u|, r_1, \epsilon_{11}, |\mu| \leq \chi$ with $\tau_0^{-1} > 0$ and $\chi > 0$ small enough. With $\epsilon_{11} > 0$ fixed in the folllowing we suppress its dependency from $\widetilde{\psi}_{1,a}$. Inserting $u_0 = e^{\lambda(\mu)\tau} y_{1,a} = (\epsilon_{11}\epsilon_1^{-1})^{\lambda(\mu)} y_{1,a}$ into the right hand side of [\(50\)](#page-17-2) and defining

$$
\psi_{1,a}(\epsilon_1,r_1,u_0,\mu) := \widetilde{\psi}_{1,a}(\log(\epsilon_1^{-1}\epsilon_{11}),r_1,u_0,\mu)
$$

give the desired expression for the $y_{1,a}$ -component of $P_{1,a}$ on the set $V_{1,a}(\chi)$. The function $\psi_{1,a}$ extends to a $C(\epsilon_1{}^0(r_1, u_0, \mu)^k)$ -function on the closed interval $\epsilon_1 \in [0, \epsilon_{10}]$ due to [\(46\)](#page-16-2). The bound in $C((\epsilon_1, r_1)^0(r_1, u_0, \mu)^k)$ in [\(48\)](#page-17-3) follows from [\(45\)](#page-16-3). Finally, the equality in (48) follows from the invariance of $r_1 = y_{1,a} = 0$ for [\(44\)](#page-16-1) (due to the existence of [\(12\)](#page-6-5)), see also the second equality in [\(45\)](#page-16-3).

We subsequently use the transition time $\tau = \log(\epsilon_1^{-1} \epsilon_{11})$ to exponentially estimate the $z_{1,a}$ component of $P_{1,a}$. This is standard and can be done in C^k with respect to $(r_1, y_{1,a}, \mu)$ through variational equations. This completes the proof.

 \Box

We can do precisely the same thing for $P_{1,r}$ by working in backward time. We therefore state the following results without proof.

Lemma 3.5. Consider ([33](#page-13-3)) near $M_{1,r}$ and fix any $k \in \mathbb{N}$. Then for $\sigma > 0$ small enough, there exists a regular transformation of time and a C^k -smooth diffeomorphism $(y_1, z_1) \mapsto (y_{1,r}, z_{1,r})$, $y_1, z_1 - 1 \in$ $[-\sigma, \sigma]$, depending C^k-smoothly on (ϵ_1, r_1, μ) for $0 \leq r_1, \epsilon_1, |\mu| \leq \sigma$, such that

$$
y_{1,r} = h_{1,r}^0(\epsilon_1, r_1, y_1, \mu) + \epsilon_1 h_{1,r}^1(\epsilon_1, r_1, y_1, z_1, \mu),
$$

\n
$$
z_{1,r} = z_1 - m_{1,r}(\epsilon_1, r_1, y_1, \mu),
$$
\n(51)

where

$$
h_{1,r}^{0}(\epsilon_1, 0, \mu, \mu) \equiv 0, \quad \frac{\partial h_{1,r}^{0}}{\partial y_1}(\mathbf{0}) = 1, \quad \frac{\partial h_{1,r}^{0}}{\partial \mu}(\mathbf{0}) = -1,\tag{52}
$$

.

and ([33](#page-13-3)) becomes

$$
\dot{r}_1 = \frac{1}{2} r_1 \epsilon_1,
$$
\n
$$
\dot{y}_{1,r} = ((-\lambda(\mu) + r_1 L_0(r_1, y_{1,a}, \mu)) y_{1,a} + r_1 \epsilon_1 L_1(\epsilon_1, r_1, y_{1,a}, \mu)) \epsilon_1,
$$
\n
$$
\dot{z}_{1,r} = (2 + L_2(r_1, y_{1,a}, z_{1,a}, \epsilon_1, \mu)) z_{1,r},
$$
\n
$$
\dot{\epsilon}_1 = -\epsilon_1^2,
$$
\n(53)

with L_0 , L_1 , L_2 each C^k -smooth and $L_2(0) = 0$.

We can as above extend the normal form transformation to $z_1 \in [0, 1 + \sigma]$, say, by the flow-box theorem.

Let $\widetilde{m}_{1,r}(\epsilon_1, r_1, y_{1,r}, \mu) = m_{1,r}(r_1, y_1(\epsilon_1, r_1, y_{1,r}, \mu), \epsilon_1, \mu)$ with the smooth function $y_1(\epsilon_1, r_1, y_{1,r}, \mu)$ being obtained (by the implicit function theorem) from [\(51\)](#page-17-4) with $z_1 = 0$:

$$
{1,r}=h{1,r}^{0}(\epsilon _{1},r_{1},y_{1},\mu)+\epsilon _{1}h_{1,r}^{1}(\epsilon _{1},r_{1},y_{1},0,\mu).
$$

Proposition 3.6. Fix $k \in \mathbb{N}$ and any $\delta > 0$. Then there exist constants $c > 0$, $\chi > 0$ and $0 <$ $\epsilon_{10} \ll \epsilon_{11}$, $r_{10} > 0$ such that the following holds: The transition map $P_{1,r}(\cdot,\mu)$ of ([53](#page-18-1)) from $\{z_{1,r} =$ $-\widetilde{m}_{1,r}(\epsilon_1,r_1,y_{1,r},\mu)$ to $\{\epsilon_1=\epsilon_{11}\}\$ is well-defined on a region $V_{1,r}(\chi)$ defined by

$$
|y_{1,r}| \le \chi(\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu)}, \epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}],
$$
\n(54)

and on this region, the mapping takes the following form

 \overline{y}

$$
P_{1,r}(\epsilon_1,r_1,y_{1,r},\mu) = \begin{pmatrix} \sqrt{\epsilon_1 \epsilon_{11}^{-1}} r_1 \\ (\epsilon_{11} \epsilon_1^{-1})^{\lambda(\mu)} y_{1,r} + \psi_{1,r}(\epsilon_1,r_1,(\epsilon_1^{-1} \epsilon_{11})^{\lambda(\mu)} y_{1,a},\mu) \\ \mathcal{O}(e^{-c/\epsilon_1}) \\ \epsilon_{11} \end{pmatrix}.
$$

Here $\psi_{1,r}$ is a $C(\epsilon_1^0(r_1,u,\mu)^k)$ -function on the set $\epsilon_1 \in [0,\epsilon_{10}], r_1 \in [0,r_{10}], 0 \leq |u|, |\mu| \leq \chi$ with

$$
\|\psi_{1,r}\|_{(\epsilon_1,r_1)^0(u,\mu)^k} \le \delta, \quad \psi_{1,r}(\epsilon_1,0,0,\mu) \equiv 0. \tag{55}
$$

The $\mathcal{O}(e^{-c/\epsilon_1})$ remainder term in the $z_{1,r}$ -component is also a $C((\epsilon_1,r_1)^0(y_{1,r},\mu)^k)$ -function with the order being unchanged upon differentiation up to order k with respect to $(y_{1,r}, \mu)$ in $V_{1,r}(\chi)$.

Remark 3.7. Notice that if we define $\hat{y}_{1,a}$ and $\hat{y}_{1,r}$ by

$$
y_{1,i} = (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu)} \hat{y}_{1,i}, \quad i = a, r \tag{56}
$$

for $\epsilon_1 \in (0, \epsilon_{10}]$ then $V_{1,i}$ and $V_{1,r}$ are "blown up" to $\hat{y}_{1,i} \in [-\chi, \chi], i = a, r$, and the $y_{1,i}$ -components of $P_{1,i}$

$$
\hat{y}_{1,i} + \psi_{1,i}(r_1, \epsilon_1, \hat{y}_{1,i}, \mu),
$$

become regular as functions of $(r_1, \hat{y}_{1,i}, \mu)$ for $i = a, r$. We will use a similar – but slightly different scaling – later on. The reason why ([56](#page-18-2)) will not work directly, is that we also have to transform μ appropriately in order to relate $y_{1,a}$ and $y_{1,r}$ (through their relationship to y_1) in such a way that the application of $P_{1,a}$ and $P_{1,r}$ correspond to flowing the same point forward and backward in time.

3.2. Analysis in the $\bar{\epsilon} = 1$ -chart. Having now followed points on $\{z_1 = 0\}$ forwards and backwards until the section $\{\epsilon_1 = \epsilon_{11}\}\$, we proceed to extend these further into the scaling chart. Here the equations are given by [\(9\)](#page-5-4). Notice specifically, that $\epsilon_1 = \epsilon_{11} > 0$ in the $\bar{x} = -1$ -chart corresponds to $x_2 = -\epsilon_{11}^{-1}$ in the scaling chart.

Let $P_{2,a}$ and $P_{2,r}$ denote the mappings from $\{x_2 = -\epsilon_{11}^{-1}\}\$ to $\{z_2 = 0\}$ near $\gamma_{2,0}(0)$, obtained by the first intersection upon application of the forward respectively backward flow of [\(9\)](#page-5-4). Each of these mappings are regular, i.e. smooth diffeomorphisms.

Through the flow of [\(9\)](#page-5-4) we can also extend the center manifolds $M_{2,a}$ and $M_{2,r}$, being the coordinate transformations of $M_{1,a}$ and $M_{1,r}$, respectively, using [\(8\)](#page-4-2). The manifolds $M_{2,a}$ and $M_{2,r}$ within the (x_2, y_2, z_2, r_2) -space are foliated by constant values of $r_2 \sim 0$. Let $M_{2,a}(r_2)$ and $M_{2,r}(r_2)$ denote the corresponding leafs of this foliation projecting onto the (x_2, y_2, z_2) -space. It is standard, see [\[44\]](#page-25-14), that $M_{2,a}(0)$ and $M_{2,r}(0)$ intersect transversally along $\gamma_{2,0}(\mu)$ for all $\mu \sim 0$. This gives rise to a connecting orbit $\gamma_{2,r_2}(\mu) = M_{2,a}(r_2) \cap M_{2,r}(r_2)$ for all $0 < r_2 = \sqrt{\epsilon} \ll 1$, see [\[44\]](#page-25-14). In this way, one may obtain the perturbed (maximal) strong canard $\gamma_{\epsilon}(\mu)$ with $\lim_{\epsilon \to 0} \gamma_{\epsilon}(\mu) \to \gamma_0(\mu)$, see [\[44\]](#page-25-14).

3.3. Putting it all together. We summarize the local findings in charts into a global diagram in Fig. [4.](#page-19-1) Notice that the strong canard orbit γ_0 (in orange) is a heteroclinic orbit of partially hyperbolic points on the blowup sphere. For $\mu = 0$, there is a fast jump (in black) that together with γ_0 gives rise to heteroclinic cycle. It is the perturbation of this cycle, that produce the intermediate periodic orbits that connect to the small ones (as perturbations of the green orbits, recall Fig. [2\)](#page-6-1) and canard cycles.

FIGURE 4. Dynamics for the blown up system for $\mu = 0$. The blue and red surfaces are the attracting and repelling critical manifolds. Upon blowup these manifolds extend onto the blowup sphere as normally hyperbolic invariant sets (the red and blue curves, respectively, on the sphere). The weak canard is in purple. In the case of the folded saddle-node for $\mu = 0$, it extends onto the blowup sphere as a critical manifold for $\mu = 0$. The associated reduced problem has a stable node (indicated by the purple arrows and the black dot inside the sphere), which undergoes a Hopf bifurcation of the layer problem. This Hopf bifurcation is degenerate (the layer problem is Hamiltonian) and there is a family of periodic orbits (one example is shown in green). This family is bounded by the strong canard γ_0 (in orange). On the blowup sphere, γ_0 and the fast connection in black from the repelling set (in red) to the attracting set (in blue), produces a heteroclinic cycle.

We now define $\Delta_a(\epsilon_1, r_1, y_{1,a}, \mu)$ in the following way:

$$
\Delta_a(\epsilon_1, r_1, y_{1,a}, \mu) = \left(\Pi \circ P_{2,a} \circ \widehat{C}_{21} \circ P_{1,a}\right)(\epsilon_1, r_1, y_{1,a}, \mu),
$$

with Π the projection onto the (x_2, y_2) -plane and where \hat{C}_{21} is the change of coordinates from $(\epsilon_1, r_1, y_{1,a}, z_{1,a})$ to (x_2, y_2, z_2, r_2) defined by [\(38\)](#page-14-2) and [\(8\)](#page-4-2). Δ_a therefore describes the transition map from $\{z_1 = 0\}$ in chart $\bar{x} = -1$, using the coordinates $(\epsilon_1, r_1, y_{1,a})$, to $\{z_2 = 0\}$ in chart $\bar{\epsilon} = 1$, $\lim_{\epsilon \to 0} \lim_{\epsilon \to 0} \frac{z_1 - \sigma_f}{z_2 - \sigma_f}$ in chart $x = -1$, using the coordinates $(\epsilon_1, \epsilon_1, \epsilon_1, \epsilon_1, \epsilon_2, \epsilon_3)$ for $r_2 = \sqrt{\epsilon} = r_1 \sqrt{\epsilon_1}$. We define Δ_r completely analogously:

$$
\Delta_r(\epsilon_1, r_1, y_{1,r}, \mu) = \left(\Pi \circ P_{2,r} \circ \widehat{C}_{21} \circ P_{1,r}\right)(\epsilon_1, r_1, y_{1,r}, \mu).
$$

If $(\epsilon_1, r_1, y_{1,a}) \in V_{1,a}(\chi)$ and $(\epsilon_1, r_1, y_{1,r}) \in V_{1,r}(\chi)$, under the coordinate transformations [\(38\)](#page-14-2) and [\(51\)](#page-17-4) for $z_1 = 0$, correspond to the same point $(\epsilon_1, r_1, y_1, 0)$ on the section $\{z_1 = 0\}$ in the $\bar{x} = -1$ -chart, then $\Delta_a(\epsilon_1, r_1, y_{1,a}, \mu) = \Delta_r(\epsilon_1, r_1, y_{1,r}, \mu)$ for $r_1 \geq 0, \epsilon_1 > 0$ clearly implies existence of a closed orbit of $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ system through the point given by $(\epsilon_1, r_1, y_1, 0) \in \{z_1 = 0\}$ in the $\bar{x} = -1$ -chart.

Solving [\(38\)](#page-14-2) and [\(51\)](#page-17-4) with $z_1 = 0$ for y_1 , we find that

$$
y_1 = h_{1,a}(\epsilon_1, r_1, y_{1,a}, \mu),
$$

and

$$
y_1 = h_{1,r}(\epsilon_1, r_1, y_{1,r}, \mu),
$$

by applying the inverse/implicit function theorem. Here $\bar{h}_{1,i}$ have the same smoothness properties as $h_{1,i}, \overline{h}_{1,i}(\epsilon_1, \mathbf{0}) \equiv 0, i = a, r$, and

$$
\frac{\partial \overline{h}_{1,a}}{\partial y_{1,a}}(\mathbf{0}) = 1, \quad \frac{\partial \overline{h}_{1,a}}{\partial \mu}(\mathbf{0}) = -1,\tag{57}
$$

$$
\frac{\partial \overline{h}_{1,r}}{\partial y_{1,r}}(\mathbf{0}) = 1, \quad \frac{\partial \overline{h}_{1,r}}{\partial \mu}(\mathbf{0}) = 1.
$$
\n(58)

Equating these expressions for y_1 , we obtain the following equation

$$
L(\epsilon_1, r_1, y_{1,a}, y_{1,r}, \mu) := h_{1,a}(\epsilon_1, r_1, y_{1,a}, \mu) - h_{1,r}(\epsilon_1, r_1, y_{1,r}, \mu) = 0,
$$
\n(59)

relating $y_{1,a}$ and $y_{1,r}$, as desired. We can use the implicit function theorem to solve this equation for $y_{1,r}$ as function of $(\epsilon_1, r_1, y_{1,a}, \mu)$. Subsequently, since we are interested in applying both $P_{1,a}$ and $P_{1,r}$, we need to ensure that the image of the region $V_{1,a}(\chi)$ (or an appropriate subset hereof) under the associated mapping $(\epsilon_1, r_1, y_{1,a}) \mapsto (\epsilon_1, r_1, y_{1,r})$ defined by [\(59\)](#page-20-0), will be contained within $V_{1,r}(\chi)$. For this, we therefore first adjust μ .

Lemma 3.8. There exists a continuous function $\mu_0(\epsilon_1, r_1)$ with $\mu_0(\epsilon_1, 0) \equiv 0$ such that $L(\epsilon_1, r_1, 0, 0, \mu_0(\epsilon_1, r_1)) =$ 0 for all $\epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}].$

Proof. Simple application of the implicit function theorem using $L(\epsilon_1, \mathbf{0}) = 0$ and $L'_{\mu}(\mathbf{0}) = -2$. \Box

Remark 3.9. Clearly, $\mu_0 \in C(\epsilon_0^0 r_1^k)$ but we will not use the smoothness in r_1 in the proof Theo-rem [1.1](#page-3-1). This relates to the fact that the statement is only that $\bar{\mu}(h,\epsilon)$ is continuous. In the author's opinion, the smoothness properties of this function with respect to h is more involved and certainly more difficult to state. The interpretation of μ_0 within $\epsilon_1 = 0$ is illustrated in Fig. [3](#page-13-2)(b).

Following on from this, we then obtain:

Lemma 3.10. The equation

$$
L(\epsilon_1, r_1, y_{1,a}, y_{1,r}, \mu_0(\epsilon_1, r_1) + \tilde{\mu}) = 0,
$$

has a locally unique solution of the form

$$
y_{1,r} = h_{ra}(\epsilon_1, r_1, y_{1,a}, \tilde{\mu}), \tag{60}
$$

with $h_{ra} \in C((\epsilon_1, r_1)^0(y_{1,a}, \tilde{\mu})^k)$ and

$$
h_{ra}(\epsilon_1, r_1, 0, 0) \equiv 0, \quad \frac{\partial h_{ra}}{\partial y_{1,a}}(\mathbf{0}) = 1, \quad \frac{\partial h_{ra}}{\partial \tilde{\mu}}(\mathbf{0}) = -2.
$$
 (61)

Proof. Follows from the implicit function theorem, using

$$
L(\epsilon_1, r_1, 0, 0, \mu_0(\epsilon_1, r_2)) = 0, \quad L'_{y_{1,r}}(\epsilon_1, r_1, 0, 0, \mu_0(\epsilon_1, r_1)) \approx 1.
$$

Due to [\(61\)](#page-20-1) and the mean value theorem, $h_{ra}(\epsilon_1, r_1, y_{1,a}, \tilde{\mu}) = y_{1,a}(\cdots) + \tilde{\mu}(\cdots)$ which leads to the following.

Lemma 3.11. Let $\sigma > 0$, $0 < \chi_i < \chi$ for $i = a, r$. Define the scaled quantities $\hat{y}_{1,a}, \hat{y}_{1,a}, \hat{\mu}$ by

$$
y_{1,a} = (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0)} \hat{y}_{1,a}, \quad y_{1,r} = (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0)} \hat{y}_{1,r}, \quad \mu = \mu_0(\epsilon_1, r_1) + (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0)} \hat{\mu}, \tag{62}
$$

for $\epsilon_1 > 0$. Then we have the following.

(1) For $\epsilon_{10} > 0$ small enough, with $y_{1,i}$ given by ([62](#page-20-2)) for

$$
\hat{y}_{1,a} \in [-\chi_a, \chi_a], \quad \hat{y}_{1,r} \in [-\chi_r, \chi_r], \quad \hat{\mu} \in [-\sigma, \sigma], \tag{63}
$$

we have $(\epsilon_1, r_1, y_{1,i}) \in V_{1,i}(\chi)$, $i = a, r$ for all $\epsilon_1 \in (0, \epsilon_{10}).$

 \Box

 (2) (60) (60) (60) becomes

 $\hat{y}_{1,r} = \hat{h}_{ra}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) := (\epsilon_1 \epsilon_{11}^{-1})^{-\lambda(\mu_0)} h_{ra}(\epsilon_1, r_1, (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0)} \hat{y}_{1,a}, (\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0)} \hat{\mu}),$

for $\epsilon_1 \in (0, \epsilon_{10}]$. \hat{h}_{ra} has a $C((\epsilon_1, r_1)^0(\hat{y}_{1,a}, \hat{\mu})^{k-1})$ -extension to the closed interval $\epsilon_1 \in [0, \epsilon_{10}]$ with $\hat{h}_{ra}(\epsilon_1, r_1, 0, 0) \equiv 0.$

(3) $\hat{h}_{ra}(0, r_1, \cdot, \cdot)$ is linear and for $r_1 = 0$:

$$
\hat{h}_{ra}(0,0,\hat{y}_{1,a},\hat{\mu}) = \hat{y}_{1,a} - 2\hat{\mu}.
$$

(4) For $\sigma > 0$, $r_{10} > 0$ and $\epsilon_{10} > 0$ all small enough, we have that:

$$
\hat{h}_{ra}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) \in (-\chi, \chi),
$$

for all
$$
\epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}], \hat{y}_{1,a} \in [-\chi_a, \chi_a], \hat{\mu} \in [-\sigma, \sigma].
$$

Proof. Recall from [\(47\)](#page-17-5) and [\(54\)](#page-18-3) that $(\epsilon_1, r_1, y_{1,i}) \in V_{1,i}(\chi)$ with $\epsilon_1 > 0$ if and only if

$$
(\epsilon_1^{-1}\epsilon_{11})^{\lambda(\mu)}|y_{1,i}| \le \chi. \tag{64}
$$

Now, by [\(37\)](#page-14-4) and [\(62\)](#page-20-2) for $|\hat{y}_{1,i}| \leq \chi_i$ the left hand side of [\(64\)](#page-21-0) becomes

$$
(\epsilon_1 \epsilon_{11}^{-1})^{(\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0(\epsilon_1, r_1))}\hat{\mu}}|\hat{y}_{1,i}| \leq e^{(\epsilon_1 \epsilon_{11}^{-1})^{\lambda(\mu_0(\epsilon_1, r_1))}\hat{\mu}\log(\epsilon_1 \epsilon_{11}^{-1})}\chi_i = (1 + \mathcal{O}(\epsilon_1^{\lambda(\mu_0)} \log \epsilon_1))\chi_i,\tag{65}
$$

and the item [1](#page-20-4) therefore follows. Items [2](#page-21-1) and [3](#page-21-2) follow from Lemma [3.10;](#page-20-5) notice we lose one degree of smoothness due to the application of the mean value theorem. Finally, item [4](#page-21-3) follows from [2](#page-21-1) and [3](#page-21-2) using $0 < \chi_a < \chi$ and $\epsilon_{10} > 0$ small enough.

The implications of item [1.](#page-20-4) are the following: Let

$$
P_{1,i}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) := P_{1,i}(\epsilon_1, r_1, y_{1,a}, \mu), \tag{66}
$$

for $i = a, r$ and with $y_{1,a}, y_{1,r}$ and μ on the right hand side given by the expressions in [\(62\)](#page-20-2). Then we have:

Lemma 3.12. Fix $\delta > 0$ small enough. Then for $r_{10} > 0$, $\epsilon_{10} > 0$ sufficiently small,

$$
\widehat{P}_{1,i} \in C((\epsilon_1, r_1)^0(\hat{y}_{1,a}, \hat{\mu})^k),
$$

 $i = a, r, \text{ defined for } \hat{y}_{1,a} \in [-\chi_a, \chi_r], \hat{y}_{1,r} \in [-\chi_r, \chi_r], \hat{\mu} \in [-\sigma, \sigma], \epsilon_1 \in [0, \epsilon_{10}], \; r_1 \in [0, r_{10}].$ In particular, the $y_{1,i}$ component of $\widehat{P}_{1,i}$ takes the following form:

$$
\hat{y}_{1,i} + \psi_{1,i}(\epsilon_1, r_1, \hat{y}_{1,i}, \hat{\mu}), \tag{67}
$$

where

$$
\|\hat{\psi}_{1,i}\|_{(\epsilon_1,r_1)^0(\hat{y}_{1,i},\hat{\mu})^k} \le \delta, \quad \hat{\psi}_{1,i}(\epsilon_1,0,0,\hat{\mu}) \equiv 0. \tag{68}
$$

Proof. We insert [\(62\)](#page-20-2) into the $y_{1,i}$ -component of $P_{1,i}$. Proceeding as in [\(65\)](#page-21-4) for the expansion in ϵ_1 we obtain [\(67\)](#page-21-5). [\(68\)](#page-21-6) follows from [\(48\)](#page-17-3) and [\(55\)](#page-18-4). \square

Moreover, by item [4.](#page-21-3) we have that the composed mapping

$$
(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) \mapsto \widehat{P}_{1,r}(\epsilon_1, r_1, \hat{h}_{ra}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}), \hat{\mu}), \tag{69}
$$

is a $C((\epsilon_1, r_1)^0(\hat{y}_{1,a}, \hat{\mu})^{k-1})$ -function defined for $y_{1,a} \in [-\chi_a, \chi_a]$ and $\hat{\mu} \in [-\sigma, \sigma]$ and all $r_1 \in [0, r_{10}]$, $\epsilon_1 \in [0, \epsilon_{10}]$ for $\sigma > 0$ and $\epsilon_{10} > 0$ small enough.

We now return to the problem of solving $\Delta_a = \Delta_r$ for closed orbits. Define

$$
\Delta_i(\epsilon_1, r_1, \hat{y}_{1,i}, \hat{\mu}) = \Delta_i(\epsilon_1, r_1, y_{1,i}, \mu), \quad i = a, r
$$

with $y_{1,i}$ and μ on the right hand side given by the expressions [\(62\)](#page-20-2). By the properties of $\hat{P}_{1,i}$ and the regularity of C_{21} and $P_{2,i}$, we have $\hat{\Delta}_i \in C((\epsilon_1, r_1)^0(\hat{y}_{1,i}, \hat{\mu})^k)$ for $i = a, r$. Finally, let

$$
\widehat{\Delta}(\epsilon_1, r_1, \hat{y}_{1,a}, \widehat{\mu}) := \widehat{\Delta}_r \left(\epsilon_1, r_1, \hat{h}_{ra}(\epsilon_1, r_1, \hat{y}_{1,a}, \widehat{\mu}), \widehat{\mu} \right) - \widehat{\Delta}_a \left(\epsilon_1, r_1, \hat{y}_{1,a}, \widehat{\mu} \right), \tag{70}
$$

for $\epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}], \hat{y}_{1,a} \in [-\chi_a, \chi_a], \hat{\mu} \in [-\sigma, \sigma]$. By Lemma [3.11](#page-20-6) item [2,](#page-21-1) we finally have that $\widehat{\Delta} \in C((\epsilon_1, r_1)^0(\hat{y}_{1,a}, \hat{\mu})^{k-1}).$

Clearly,

$$
\widehat{\Delta}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) = \mathbf{0},\tag{71}
$$

defines closed orbits for $\epsilon_1 > 0$, $r_1 \geq 0$ sufficiently small. We therefore proceed to solve this equation. We will do so by solving for $\hat{y}_{1,a}$, $\hat{\mu}$ as functions of ϵ_1 and r_1 using the implicit function theorem. Henceforth we therefore take $k \geq 2$.

Lemma 3.13.

$$
\widehat{\Delta}(\mathbf{0}) = \mathbf{0}.\tag{72}
$$

Moreover, there exists two nonzero tangent vectors

$$
v_i = (*, *, 0) \in T_{\gamma_{2,0}(0) \cap \{z_2 = 0\}} M_{2,i}(0),
$$

 $i = a, r$, such that:

$$
\frac{\partial \widehat{\Delta}}{\partial \widehat{y}_{1,a}}(\mathbf{0}) = \Pi v_r - \Pi v_a,
$$

$$
\frac{\partial \widehat{\Delta}}{\partial \widehat{\mu}}(\mathbf{0}) = -2\Pi v_r.
$$
 (73)

Proof. First, [\(72\)](#page-22-0) follows from the connection $\gamma_{2,0}(0)$. Next, for the proof of the the partial derivatives, we first focus on the partial derivatives of $\hat{\Delta}_a$. For this we differentiate $\hat{P}_{1,a}$. Following Lemma [3.12,](#page-21-7) see [\(68\)](#page-21-6), we have $\frac{\partial P_{1,a}}{\partial \hat{\mu}}(0) = 0$, and hence $\frac{\partial \hat{\Delta}_a}{\partial \hat{\mu}}(0) = 0$. Next, by [\(67\)](#page-21-5)

$$
\frac{\partial \widehat{P}_{1,a}}{\partial \widehat{y}_{1,a}}(\mathbf{0}) = \begin{pmatrix} 0 \\ 0 \\ 1 + \mathcal{O}(\delta) \\ 0 \end{pmatrix}.
$$
\n(74)

Since $\widehat{P}_{1,a}(\mathbf{0}) = (\epsilon_{11}, 0, 0, 0) \in M_{1,a}$, the vector (74) gives a tangent vector to $M_{2,a}(0)$ at $x_2 = -\epsilon_{11}^{-1}$ upon application of the tangent map $T_{(\epsilon_{11},0,0,0)}\hat{C}_{21}$ of the change of coordinates \hat{C}_{21} . Consequently, by applying $TP_{2,a}$ we have

$$
\frac{\partial \widehat{\Delta}_a}{\partial \hat{y}_{1,a}}(\mathbf{0}) = \Pi v_a,
$$

for some nonzero tangent vector $v_a \in T_{\gamma_{2,0}(0) \cap \{z_2=0\}} M_{2,a}(0)$.

 $\widehat{\Delta}_{r}$ can be handled similarly:

$$
\frac{\partial \widehat{\Delta}_r}{\partial \hat{y}_{1,r}}(\mathbf{0}) = \Pi v_r, \quad \frac{\partial \widehat{\Delta}_r}{\partial \hat{\mu}}(\mathbf{0}) = \mathbf{0}
$$

for some nonzero tangent vector $v_r \in T_{\gamma_{2,0}(0)\cap\{z_2=0\}}M_{2,r}(0)$. The partial derivative [\(73\)](#page-22-2) with respect to $\hat{\mu}$ then follows from Lemma [3.11,](#page-20-6) see item [3,](#page-21-2) and the chain rule.

Since the intersection of $M_{a,2}(0)$ and $M_{r,2}(0)$ is transverse along γ_2 , the vectors v_i , $i = a, r$, as well as Πv_i , $i = a, r$, are linearly independent and consequently,

$$
\det\left(\frac{\partial\widehat{\Delta}}{\partial(\hat{y}_{1,a},\hat{\mu})}(\mathbf{0})\right) = \det\left(\Pi v_r - \Pi v_a \quad -2\Pi v_r\right) = 2\det\left(\Pi v_a \quad \Pi v_r\right) \neq 0.
$$

In this way, by the implicit function theorem we can solve $\hat{\Delta}(\epsilon_1, r_1, \hat{y}_{1,a}, \hat{\mu}) = 0$ locally for $(\hat{y}_{1,a}, \hat{\mu})$ as continuous functions of (ϵ_1, r_1) . In this way, we conclude the following.

Proposition 3.14. There exist continuous functions $\bar{y}(\epsilon_1, r_1)$, $\bar{\mu}(\epsilon_1, r_1)$, $\epsilon_1 \in [0, \epsilon_{10}], r_1 \in [0, r_{10}]$ for $\epsilon_{10} > 0$ and $r_{10} > 0$ small enough, with $\bar{y}(0,0) = \bar{\mu}(0,0) = 0$ such that there is a periodic orbit of $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ $((3), \dot{\epsilon} = 0)$ through any point $(\epsilon_1, r_1, \bar{y}(\epsilon_1, r_1), 0)$ in chart $\bar{x} = -1$ for $\mu = \bar{\mu}(\epsilon_1, r_1)$ for all $\epsilon_1 \in (0, \epsilon_{10}], r_1 \in [0, r_{10}].$

Proof. After having solved $\hat{\Delta} = 0$ for $\hat{y}_{1,a}$ and $\hat{\mu}$ as continuous functions (ϵ_1, r_1) by the implicit function theorem using Lemma [3.13,](#page-22-3) we complete the result by mapping the solution back to the (y_1, μ) -variables.

 \Box

24 KRISTIANSEN, K. U.

4. Completing the proof of Theorem [1.1](#page-3-1)

To complete the proof of Theorem [1.1,](#page-3-1) we first collect our results thus far: First, by Proposition [2.11](#page-12-2) we have for any $h_1 > 0$ a family of periodic orbits $\Gamma_{2,h,\epsilon}^{\text{small}}$, $h \in (0,h_1]$, of [\(9\)](#page-5-4) with $\mu = r_2\overline{\mu}_2(h,\epsilon)$ for all $r_2 = \sqrt{\epsilon} > 0$ small enough, parametrized in the \tilde{u} -variables, see [\(25\)](#page-10-4), by their intersection $\tilde{u} = (-h, 0)$, $y_2 = \overline{y}_2(h, r_2)$ with $\tilde{u}_2 = 0$.

Lemma 4.1. Consider ([9](#page-5-4)) for parameter values $\mu \in [-\delta, \delta]$, and let D be any compact domain in the phase (x_2, z_2) -plane. Then there is an $h_1 > 0$ such that any periodic orbit of this system for $r_2 > 0$ small enough, that is contained within the set defined by $(x_2, z_2) \in D$, $y_2 \in [-\delta, \delta]$ and intersects $\tilde{u}_1 < 0$, $\tilde{u}_2 = 0$ in a single point, belongs to the family $\Gamma_{2,h,\epsilon}^{\text{small}}$, $h \in (0,h_1]$.

Proof. The statement is clearly true for $\mu = r_2\mu_2$ with $\mu_2 \in [-\delta, \delta]$ for $\delta > 0$ small enough, since the family Γ_{2,h,r_2} , $h \in (0,h_1]$, is obtained by the implicit function theorem. Next, we realize that there are no periodic orbits for any $|\mu_2| > \delta$ and $r_2 > 0$ small enough since in this case, the equilibrium [\(14\)](#page-6-4) is hyperbolic; specifically, C_2 is normally hyperbolic in a neighborhood of [\(14\)](#page-6-4). Finally, for $r_2c \leq |\mu| \leq \delta$ with $c > 0$ large enough, \dot{y}_2 has a single sign in the set $(x_2, z_2) \in D$, $y_2 \in [-\delta, \delta]$, completing the proof. \square

Clearly, the family $\Gamma_{2,h,\epsilon}^{\text{small}}$, $h \in (0,h_1]$, becomes a family of "small" periodic orbits $\Gamma_{h,\epsilon}^{\text{small}}$ of [\(3\)](#page-2-2) upon blowing down, intersecting $z = 0$ in $x \sim \sqrt{\epsilon}h$, $y = r_2\overline{y}_2(h, \sqrt{\epsilon})$, $h \in (0, h_1]$. (Here we have used \sim in the expression for x since this only holds to leading order; the family is parametrized by $\tilde{u}_1 = h$ and x_2 and \tilde{u}_1 differ by $\mathcal{O}(\sqrt{\epsilon})$ in the relevant domain.)

Next, we turn to the intermediate periodic orbits obtained from Proposition [3.14.](#page-22-4) Here we obtain rext, we turn to the intermediate periodic orbits obtained from Froposition 3.14. Here we obtain
a family of periodic orbits $\Gamma_{h,\epsilon}^{\text{inter}}$, $h \in [\sqrt{\epsilon}/\sqrt{\epsilon_{11}}, r_{10}]$, of [\(3\)](#page-2-2) with $\mu = \overline{\mu}(h^{-2}\epsilon, h)$ for all $\epsilon > 0$ small enough, parametrized by their intersecting $(x, z) = (-h, 0)$ and $y = h\overline{y}(h^{-2}\epsilon, h)$. This follows from Proposition [3.14](#page-22-4) and [\(6\)](#page-4-1), specifically $\epsilon = r_1^2 \epsilon_1$ and $r_1 = h$. Now, $r_1 = h = \sqrt{\epsilon}/\sqrt{\epsilon_{11}}$ corresponds to $\frac{1}{\sqrt{\epsilon_{11}}}$ corresponds to $\epsilon_1 = \epsilon_{11}$ or $x_2 = -1/\epsilon_{11}$ upon change of coordinates [\(8\)](#page-4-2). Consequently, upon taking $h_1 > -1/\sqrt{\epsilon_{11}}$ the branch $\Gamma_{2,h,\epsilon}^{\text{inter}}$, i.e. $\Gamma_{h,\epsilon}^{\text{inter}}$ written in the coordinates of the $\bar{\epsilon} = 1$ -chart, overlap with $\Gamma_{2,h,\epsilon}^{\text{small}}$ for all $0 < \epsilon \ll 1$. By Lemma [4.1,](#page-23-2) where they overlap, they coincide for all $0 < \epsilon \ll 1$. In this way, we obtain the desired family by gluing the two branches together in the domain where they overlap.

5. Discussion

Our main theorem generalizes the birth of canard cycles in \mathbb{R}^2 , see e.g. [\[38\]](#page-25-12), to \mathbb{R}^3 through the folded saddle-node of type II and the strong canard. In contrast to the result in [\[38\]](#page-25-12), our results are – however – only local. (The local neighborhood is independent of ϵ). Nevertheless, it is also possible to use our method to obtain more global results. We have illustrated a situation in Fig. [5\(](#page-24-10)a) of an S-shaped critical manifold (as in the Koper model [\[27,](#page-25-26) [33\]](#page-25-24)). Here we can also follow the forward and backward flow of the set of points on the section (in orange) that is indicated in the figure using the normal forms and the solutions of the Shilnikov problem, see Lemma [3.2](#page-14-5) and Proposition [3.3.](#page-16-0) In contrast to $P_{2,i}$, $i = a, r$, above, we would just define transition maps from $r_1 = r_{10}$ fixed to $\epsilon_1 = \epsilon_{11}$. Otherwise, the proof for the existence of closed orbits, would proceed analogously, using that the center manifolds $M_{a,r}$ intersect transversally along the strong canard $\gamma_0(\mu)$. (Notice that in general these cycles occur for $\mu = \mathcal{O}(1)$, i.e. at an order one distance from the folded saddle-node.) The same holds for the perturbation of the singular cycles in Fig. [5\(](#page-24-10)b). (Having said that, the transition from (a) to (b) is more complicated.) These extensions could even be done in the smooth setting. The cycles in Fig. [5\(](#page-24-10)c) mark the end of canard cycles and in \mathbb{R}^2 this is where classical relaxation oscillations appear. However, in contrast to \mathbb{R}^2 the folded singularity p can be of different types, e.g. folded nodes or folded saddles (since we are away from the folded saddle-node in general). In future work, we will describe the transition to relaxation oscillations in \mathbb{R}^3 .

We proved our main result in the analytic setting. In particular, we used analyticity to prove existence of a slow manifold, that is not normally hyperbolicity but acts as the center of (normal) oscillations. This in connection with Melnikov theory, enabled an extension of the Hopf cycles. Although results on normally elliptic slow manifolds [\[4,](#page-24-11) [10,](#page-24-12) [14,](#page-25-30) [36\]](#page-25-31) are almost exclusively in the analytic setting, it seems plausible (following the work of [\[7,](#page-24-8) [8\]](#page-24-9), discussed in Section [1.2\)](#page-3-0) that the result could be extended to the smooth setting.

Finally, we note that our main result does not rely upon analyticity with respect to ϵ , only in the space variables. This suggests that our results may also apply to systems that have been reduced from a slow manifold reduction from a higher dimension. Indeed, slow manifolds in analytic systems have been shown to be analytic in space variables (and only Gevrey in ϵ), see e.g. [\[14\]](#page-25-30) and references herein.

FIGURE 5. Canard cycles in \mathbb{R}^3 in the case of a S-shaped critical manifold. In (a): canard cycle without head (following the terminology from \mathbb{R}^2 , see [\[38\]](#page-25-12)), (b): canard cycles with head and (c): the end of the canard cycles, where transition to classical relaxation oscillations appear.

APPENDIX A. PROOF OF PROPOSITION [3.3](#page-16-0)

We consider [\(44\)](#page-16-1), repeated here for convinience:

$$
\epsilon_1' = \epsilon_1,
$$

\n
$$
r_1' = -\frac{1}{2}r_1,
$$

\n
$$
y_{1,a}' = (\lambda(\mu) + r_1 L_0(r_1, y_{1,a}, \mu))y_{1,a} + r_1 \epsilon_1 L_1(\epsilon_1, r_1, y_{1,a}, \mu),
$$
\n(75)

with

$$
r_1(t) = e^{-\frac{1}{2}t}r_{10}, \quad \epsilon_1(t) = e^{(t-\tau)}\epsilon_{11},
$$

and $y_{1,a}(\tau) = y_{11}$. We write

$$
y_{1,a}(t) = e^{\lambda(\mu)(t-\tau)} e^{\int_{\tau}^{t} r_1(s)L_0(r_1(s),0,\mu)ds} (y_{11} + u(t)), \qquad (76)
$$

with $u(\tau) = 0$. Here

$$
\left| \int_{\tau}^{t} r_1(s) L_0(r_1(s), 0, \mu) ds \right| \leq 2r_{10}C_1,
$$

for $0 \leq t \leq \tau$ using $\int_0^{\tau} e^{-\frac{1}{2}s} ds \leq 2$ and $|L_0(r_1, 0, \mu)| \leq C_1$ for some $C_1 > 0$. Then from [\(75\)](#page-27-1) and variation of constants, we have

$$
u(t) = \int_{\tau}^{t} r_1(s)e^{\lambda(\mu)(s-\tau)}e^{\int_{\tau}^{s} r_1(v)L_0(r_1(v),0,\mu)dv} \overline{L}_0(r_1(s), y_{1,a}(s), \mu) (y_{11} + u(s))^2 ds
$$

+
$$
\int_{\tau}^{t} r_1(s)\epsilon_1(s)e^{-\lambda(\mu)(s-\tau)}e^{-\int_{\tau}^{s} r_1(s)L_0(r_1(s),0,\mu)ds}L_1(r_1(s),\epsilon_1(s), y_{1,a}(s), \mu) ds,
$$
\n(77)

with the smooth function \overline{L}_0 defined by

$$
L_0(r_1, y_{1,a}, \mu) = L_0(r_1, 0, \mu) + \overline{L}_0(r_1, y_{1,a}, \mu) y_{1,a},
$$

and the mean value theorem. Let $\alpha > 0$. We then consider the closed subset

$$
\Gamma_{\alpha}(\delta) = \{ u \in C_{\alpha}([0, \tau]; \mathbb{R}) \mid \|u\| \le \delta, u(\tau) = 0 \},\tag{78}
$$

of the Banach space $C_{\alpha}([0, \tau]; \mathbb{R})$ equipped with the norm

$$
||u||:=\sup_{t\in[0,\tau]}e^{\alpha\tau}|u(t)|.
$$

 $y_{1,a}(t)$ in [\(76\)](#page-27-2) is bounded by $2(\chi + \delta)$ for $|y_{11}| \leq \chi, u \in \Gamma_\alpha(\delta)$ and all $r_{10} > 0$ small enough. Let $\Theta(u)(t)$, with $y_{1,a}$ given by [\(76\)](#page-27-2), denote the right hand side of [\(77\)](#page-27-3). We then show that Θ is

a contraction on $\Gamma_{\alpha}(\delta)$, upon choosing the constants appropriately.

For this purpose, we first emphasize that $\Theta(u)(\tau) = 0$. Moreover, by [\(37\)](#page-14-4), we have $|\lambda(\mu) - \frac{1}{2}| \leq \frac{1}{2}\chi$ for all $|\mu| \leq \chi$. Then for $|\mu| \leq \chi$, $|y_{11}| \leq \chi$, we estimate

$$
|\Theta(u)(t)| \le 2C_1 r_{10}(\chi + \delta)^2 \int_0^\tau e^{-\frac{1}{2}s} e^{\lambda(\mu)(s-\tau)} ds + 2C_1 r_{10} \epsilon_{11} \int_0^\tau e^{-\frac{1}{2}s} e^{(s-\tau)} e^{-\lambda(\mu)(s-\tau)} ds
$$

$$
\le 2C_1 \tau e^{(\chi - \frac{1}{2})\tau} r_{10} \left((\chi + \delta)^2 + \epsilon_{11} \right), \tag{79}
$$

for $0 \le t \le \tau$, $r_{10} > 0$ small enough, using $|\overline{L}_0(r_1, y_{1,a}, \mu)|, |\overline{L}_1(r_1, \epsilon, y_{1,a}, \mu)| \le C_1$ for some $C_1 > 0$. Moreover, seeing that \overline{L}_0 and L_2 are smooth functions, there is a $C_2 > 0$ such that

$$
|\overline{L}_0(r_1(t), y_{1,a}(t), \mu)(y_{11} + u(t))^2 - \overline{L}_0(r_1(t), \tilde{y}_{1,a}(t), \mu)(y_{11} + \tilde{u}(t))^2| \le C_2|u(t) - \tilde{u}(t)|,
$$

and

$$
|L_1(r_1(t), \epsilon_1(t), y_{1,a}(t), \mu) - L_1(r_1(t), \epsilon_1(t), \tilde{y}_{1,a}(t), \mu)| \leq C_2 |u(t) - \tilde{u}(t)|,
$$

for all $0 \le t \le \tau$, $\tau > \tau_0$, $u, \tilde{u} \in \Gamma_\alpha(\delta)$ and $C_2 > 0$. This leads to

$$
\|\Theta(u) - \Theta(\tilde{u})\| \le 2\tau C_2 e^{(\chi - \frac{1}{2})\tau} r_{10} (1 + \epsilon_{11}) \|u - \tilde{u}\|,
$$

for any $\tilde{u}, u \in \Gamma_{\alpha}(\delta)$.

We fix $\alpha \in (0, \frac{1}{2})$. From the preceding estimates, it then follows that

$$
\Theta: \Gamma_{\alpha}(\delta) \to \Gamma_{\alpha}(\delta),
$$

is well-defined and a contraction for $\delta > 0$, $r_{10} > 0$, $\epsilon_{11} > 0$ and $\chi > 0$ small enough.

We denote the unique fixed-point – existence of which follows from Banach's fixed point theorem – by $\underline{u}(t, \tau, \epsilon_{11}, r_{10}, y_{11}, \mu)$. From [\(79\)](#page-27-4), we find that there is a $C_3 > 0$ such that

$$
|\underline{u}(t,\tau,\epsilon_{11},r_{10},y_{11},\mu)| \leq e^{-\alpha \tau} C_3 r_{10},
$$

for all $0 \le t \le \tau$, $\tau > \tau_0$. Writing

$$
\begin{aligned} \phi(t,\tau,\epsilon_{11},r_{10},y_{11},\mu) &:= \left(e^{\int_{\tau}^{t} r_{1}(s) L_{0}(r_{1}(s),0,\mu) ds} - 1\right) y_{11} \\ &+ e^{\int_{\tau}^{t} r_{1}(s) L_{0}(r_{1}(s),0,\mu) ds} \underline{u}(t,\tau,\epsilon_{11},r_{10},y_{11},\mu), \end{aligned}
$$

gives Proposition [3.3](#page-16-0) for $k = 0$. Now, regarding the C^k -smoothness of ϕ , we can proceed completely analogously by setting up fixed-point equations for the partial derivatives of \underline{u} . We leave out further details, and refer instead to [\[15\]](#page-25-27).
