

THE ROPELENGTH CONJECTURE OF ALTERNATING KNOTS

YUANAN DIAO

ABSTRACT. A long standing conjecture states that the ropelength of any alternating knot is at least proportional to its crossing number. In this paper we prove that this conjecture is true. That is, there exists a constant $b_0 > 0$ such that $R(K) \geq b_0 Cr(K)$ for any alternating knot K , where $R(K)$ is the ropelength of K and $Cr(K)$ is the crossing number of K . In this paper, we prove that this conjecture is true.

1. INTRODUCTION

The ropelength of a knot K is defined as the minimum length among all knots in the ambient class of K with unit thickness [3, 10, 13]. A fundamental question in geometric knot theory asks how the ropelength $R(K)$ of a knot K is related to $Cr(K)$, the crossing number of K [1, 2, 3, 5, 8]. In the particular case that K is an alternating knot, a long standing conjecture, well known at least to researchers who study the ropelength problem, states that the ropelength of K is at least proportional to $Cr(K)$. We prove that this conjecture is true. More specifically, we prove that there exists a constant $b_0 > 0$ such that $R(K) > b_0 Cr(K)$ for any alternating knot K . In fact, $b_0 > 1/59.5$.

2. REVERSE PARALLEL LINKS OF ALTERNATING KNOTS

Let K be a knot in \mathbf{S}^3 . The regular neighborhood of K on any orientable surface M embedded in \mathbf{S}^3 on which K lies is an annulus. The link formed by the boundaries K' , K'' of such an annulus is called a *reverse parallel link* of K if K' , K'' are assigned opposite orientations. A reverse parallel link of K is characterized by the linking number between K' and K'' . That is, two reverse parallel links of K are ambient isotopic if and only if they have the same linking number.

Lemma 2.1. *For any alternating knot K , there exist two ambient isotopic classes $\mathcal{L}_1, \mathcal{L}_2$ of reverse parallel links of K such that if L is a reverse parallel link of K and $L \notin \mathcal{L}_1, \mathcal{L}_2$, then*

$$\text{breadth}_v(P_L(v, z)) \geq 2Cr(K) + 2,$$

where $P_L(v, z)$ is the HOMFLY-PT polynomial of L [12] and $Cr(K)$ is the crossing number of K .

Key words and phrases. knots, links, alternating knots and links, braid index, ropelength.

Proof. Let $F_K(v, z)$ be the Kauffman polynomial of K . Let $\tilde{P}_L(v, z)$ and $\tilde{F}_K(v, z)$ be the polynomials $P_L(v, z)$ and $F_K(v, z)$ respectively with their coefficients reduced mod 2. By [15, Congruence Theorem and Proposition 2(5)], we have

$$(2.1) \quad \frac{v^{-1} - v}{z} \tilde{P}_L(v, z) - 1 = v^{-2f} \left(1 + \frac{v^{-2} + v^2}{z^2}\right) \tilde{F}_K(v^{-2}, z^2),$$

or equivalently

$$(2.2) \quad \frac{v^{-1} - v}{z} \tilde{P}_L(v, z) = v^{-2f} \left(1 + \frac{v^{-2} + v^2}{z^2}\right) \tilde{F}_K(v^{-2}, z^2) + 1,$$

where f is the linking number of L . By [4, Proposition, line 15, page 62], we have $\text{breadth}_v(\tilde{F}_K(v, z)) \geq \text{Cr}(K)$ since K is alternating. Thus we have

$$\text{breadth}_v \left(v^{-2f} \left(1 + \frac{v^{-2} + v^2}{z^2}\right) \tilde{F}_K(v^{-2}, z^2) \right) \geq 2\text{Cr}(K) + 4.$$

Let 2α and 2β be the lowest and highest v powers of the polynomial $(1 + \frac{v^{-2} + v^2}{z^2}) \tilde{F}_K(v^{-2}, z^2)$ respectively and let \mathcal{L}_1 and \mathcal{L}_2 be the two ambient isotopic classes of reverse parallel links of K corresponding to $f = \alpha$ and $f = \beta$. Then for any $L \notin \mathcal{L}_1, \mathcal{L}_2$, the lowest and highest v powers of the polynomial $v^{-2f} (1 + \frac{v^{-2} + v^2}{z^2}) \tilde{F}_K(v^{-2}, z^2)$ are not zero. It follows that

$$\begin{aligned} & \text{breadth}_v(P_L(v, z)) + 2 \\ &= \text{breadth}_v \left(\frac{v^{-1} - v}{z} P_L(v, z) \right) \\ &\geq \text{breadth}_v \left(\frac{v^{-1} - v}{z} \tilde{P}_L(v, z) \right) \\ &= \text{breadth}_v \left(v^{-2f} \left(1 + \frac{v^{-2} + v^2}{z^2}\right) \tilde{F}_K(v^{-2}, z^2) + 1 \right) \\ &\geq \text{breadth}_v \left(v^{-2f} \left(1 + \frac{v^{-2} + v^2}{z^2}\right) \tilde{F}_K(v^{-2}, z^2) \right) \\ &\geq 2Cr(K) + 4. \end{aligned}$$

Thus $\text{breadth}_v(P_L(v, z)) \geq 2\text{Cr}(K) + 2$ as claimed. \square

Remark 2.2. Since $Cr(K) \geq 3$ for any non-trivial knot K , $\beta - \alpha \geq Cr(K) + 2 \geq 5$. It follows that the linking numbers of any two links $L_1 \in \mathcal{L}_1$ and $L_2 \in \mathcal{L}_2$ differ by at least 5.

3. THE ROPELENGTHS OF ALTERNATING KNOTS

Theorem 3.1. *There exists a constant $b_0 > 1/59.5$ such that for any alternating knot K , $R(K) \geq b_0 Cr(K)$.*

Proof. Let K_c be a knot on the cubic lattice that is ambient isotopic to K and has the minimum length among all lattice knots in the ambient isotopic class of K . Let $\ell(K_c)$ be the length of K_c , then we have $R(K) > \frac{1}{14} \ell(K_c)$ as a consequence from the proof of [9, Lemma 1].

Now, the set $\{\mathbf{x} + t(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}) : \mathbf{x} \in K_c, 0 \leq t \leq 1\}$ is an embedding of the annulus $\{1 \leq x^2 + y^2 \leq 2 : x, y \in \mathbb{R}\}$ into \mathbb{R}^3 with K_c and $K'_c = (\frac{1}{2}, \frac{1}{2}, \frac{1}{2}) + K_c$ as its boundary curves. Assigning K_c and K'_c opposite orientations yields a reverse parallel link L_c of K . Let \mathbb{K}_c and \mathbb{K}'_c be the lattice knots obtained from K_c and K'_c by scaling up with a scaling factor of 2, and let \mathbb{L}_c be the link formed by them. Notice that $\ell(\mathbb{L}_c) = 4\ell(K_c)$.

Call a line segment between two adjacent lattice points an *edge* and consider an edge e on K_c with the following properties: (i) e is perpendicular to the z -axis and has the maximum z -coordinate among all such edges; (ii) if e is parallel to the x -axis (y -axis) then it has maximum x -coordinate (y -coordinate) among all such edges that also satisfy condition (i). Notice that e correspond to two straight segments l_1 and l_2 each consisting of two edges in \mathbb{K}_c and \mathbb{K}'_c respectively. If we replace the edge on l_1 by the lattice path as shown in Figure 1 (the choice of e ensures that this path does not creates self-intersections), then we obtain another reverse parallel link \mathbb{L}'_c whose linking number differ by one from that of \mathbb{L}_c . By Lemma 2.1 and Remark 2.2, either $\text{breadth}_v(P_{\mathbb{L}'_c}) \geq 2\text{Cr}(K) + 2$ or $\text{breadth}_v(P_{\mathbb{L}_c}) \geq 2\text{Cr}(K) + 2$. Say the former is true (which is the worse case since $\ell(\mathbb{L}'_c) = \ell(\mathbb{L}_c) + 8$). By the MFW inequality [11, 14], we have

$$\mathbf{b}(\mathbb{L}'_c) \geq \text{breadth}_v(P_{\mathbb{L}'_c})/2 + 1 \geq \text{Cr}(K) + 2,$$

where $\mathbf{b}(\mathbb{L}'_c)$ is the braid index of \mathbb{L}'_c . On the other hand, by [6, Theorem 3.1], we have $\ell(\mathbb{L}'_c) = 4\ell(K_c) + 8 \geq \mathbf{b}(\mathbb{L}'_c)$. It follows that $4\ell(K_c) + 6 \geq \text{Cr}(K)$. Since $\ell(K_c) \geq 24$ for any non-trivial knot K_c on the cubic lattice [7], $4\ell(K_c) + 6 \leq 4.25\ell(K_c)$. It follows that $\ell(K_c) \geq \frac{1}{4.25}\text{Cr}(K)$ hence $R(K) > \frac{1}{14}\ell(K_c) \geq \frac{1}{59.5}\text{Cr}(K)$. This completes the proof. \square

FIGURE 1. Left: the line segments $l_1 \in \mathbb{K}_c$ and $l_2 \in \mathbb{K}'_c$ corresponding to e . The two edges marked by thin lines are used to indicate the grid lines, they are not part of the link; Right: An edge on l_1 is replaced by the path showing.

Remark 3.2. The construction in the proof of [9, Lemma 1] can in fact be improved to yield a better bound $R(K) > \frac{1}{12}\ell(K_c)$. This would allow us to improve the estimation of the constant b_0 to be at least $1/51$.

Remark 3.3. The application of the Congruence Theorem in [15], unfortunately, fails in the case of an alternating link. Thus the ropelength conjecture remains open in general for alternating links.

Acknowledgement. The author sincerely thanks the anonymous referee of an earlier version of this paper for bringing the results of [4, 15] to the attention of the author.
