Spectral hypergraph sparsification via chaining

James R. Lee[∗]

Abstract

In a hypergraph on n vertices where D is the maximum size of a hyperedge, there is a weighted hypergraph spectral ε -sparsifier with at most $O(\varepsilon^{-2} \log(D) \cdot n \log n)$ hyperedges. This improves over the bound of Kapralov, Krauthgamer, Tardos and Yoshida (2021) who achieve $O(\varepsilon^{-4}n(\log n)^3)$, as well as the bound $O(\varepsilon^{-2}D^3n \log n)$ obtained by Bansal, Svensson, and Trevisan (2019). The same sparsification result was obtained independently by Jambulapati, Liu, and Sidford (2022).

Contents

1 Introduction

Consider a weighted hypergraph $H = (V, E, w)$ with $w \in \mathbb{R}^E_+$ and the corresponding energy: For $x \in \mathbb{R}^V$,

$$
Q_H(x) := \sum_{e \in E} w_e \max_{\{u,v\} \in {e \choose 2}} (x_u - x_v)^2
$$

The problem of minimizing the energy Q_H over various convex bodies occurs in many applied contexts, especially in machine learning; we refer to the discussion in [\[KKTY21a\]](#page-25-0).

[∗]Computer Science & Engineering, University of Washington. jrl@cs.washington.edu

In the graph case—when all the hyperedges have cardinality 2—this corresponds to the quadratic form associated to the weighted Laplacian and carries a physical interpretation as the potential energy of a family of springs indexed by $\{u, v\} \in E$ whose respective endpoints are pinned at x_u and x_v . Let us mention the appealing analog for hypergraphs: If we stretch a rubber band around vertices pinned at locations $\{x_u : u \in e\}$, then $\max_{\{u,v\} \in {e \choose 2}} (x_u - x_v)^2$ is proportional 2)
1 to its potential energy. Here the weight w_e represents the elasticity of the band.

For hypergraphs, the edge set E could have cardinality as large $2^{|V|}$, and one can ask if there is a substantially smaller hypergraph that approximates the energy for every configuration of vertices. Soma and Yoshida [\[SY19\]](#page-26-0) formalized the following notion of spectral sparsification for hypergraphs, generalizing the well-studied notion for graphs [\[ST11\]](#page-25-1). Say that a weighted hypergraph $\tilde{H} = (V, \tilde{E}, \tilde{w})$ is a *spectral* ε -*sparsifier* for H if $\tilde{E} \subseteq E$, and

$$
|Q_H(x) - Q_{\tilde{H}}(x)| \le \varepsilon Q_H(x), \qquad \forall x \in \mathbb{R}^V.
$$
 (1.1)

We will use $n := |V|$ throughout. The authors [\[SY19\]](#page-26-0) showed that one can always find a spectral ε -sparsifier \tilde{H} with $|\tilde{E}| \le O(n^3/\varepsilon^2)$. In [\[BST19\]](#page-24-0), the authors established a bound of $O(\varepsilon^{-2}D^3n \log n)$, where $D := \max\{|e| : e \in E\}$ is often called the *rank of H*, and subsequently the authors of [\[KKTY21b\]](#page-25-2) achieved an upper bound of $nD(\varepsilon^{-1}\log n)^{O(1)}$.

Finally, in a recent and remarkable breakthrough, the authors of [\[KKTY21a\]](#page-25-0) show that one can obtain a spectral sparsifier with at most $O(n(\log n)^3 / \varepsilon^4)$ hyperedges, bypassing the polynomial dependence on the rank, and coming within $poly(\varepsilon^{-1} \log n)$ factors of the optimal bound. By refining their approach via Talagrand's powerful generic chaining theory, we obtain the following improvement.

Theorem 1.1. For any *n*-vertex weighted hypergraph $H = (V, E, w)$ and $\varepsilon > 0$, there is a spectral ε -sparsifier $H = (V, \tilde{E}, \tilde{w})$ for H with

$$
|\tilde{E}| \leq O\left(\frac{\log D}{\varepsilon^2}n\log n\right)\,,
$$

where $D := \max_{e \in E} |e|$.

As in many prior works, [Theorem 1.1](#page-1-0) is proved by defining a distribution on E and then sampling edges independently from this distribution. For approaches based on independent sampling, the bound of [Theorem 1.1](#page-1-0) is tight up to a constant factor for every fixed D . In particular, this generalizes the analysis of independent random sampling for graph sparsifiers [\[SS11\]](#page-25-3) where $D = 2$.

It should be noted that for *cut sparsifiers*, the log D factor can be removed [\[CKN20\]](#page-25-4). This corresponds to the weaker notion where we only require that [\(1.1\)](#page-1-1) holds for $x \in \{-1,1\}^V$. Whether the $\log D$ factor can be removed in general remains an intriguing open question.

Our proof of [Theorem 1.1](#page-1-0) entails an algorithm for constructing the sparsifier H whose running time is polynomial in the size of the input. But our sampling analysis can also be applied directly to the faster algorithm presented in [\[KKTY21a\]](#page-25-0) whose running time is $|E|D \text{ poly}(\log |E|) + \text{poly}(n)$.

[Theorem 1.1](#page-1-0) was proved independently and concurrently by Jambulapati, Liu, and Sidford [\[JLS22\]](#page-25-5), via a closely related approach. While their main chaining result is somewhat less general than the one proved here (see (1.5) below), they also present a near-linear time algorithm for generating suitable sampling probabilities $\{\mu_e : e \in E\}$. This improves the running time to $|E|D$ poly(log $|E|$).

1.1 The random selector method and chaining for subgaussian processes

Suppose we have a probability distribution $\mu \in \mathbb{R}_+^E$ on hyperedges in *H*. We sample hyperedges $\tilde{E} = \{e_1, e_2, \dots, e_M\}$ independently according to μ , and define the random weighted hypergraph $\tilde{H} = (V, \tilde{E}, \tilde{\omega})$ so that

$$
Q_{\tilde{H}}(x) = \frac{1}{M} \sum_{k=1}^{M} \frac{w_{e_k}}{\mu_{e_k}} Q_{e_k}(x),
$$

where we define

$$
Q_e(x) := \max_{\{i,j\} \in {e \choose 2}} (x_i - x_j)^2 ,
$$

and the edge weights

$$
\tilde{w}_e := \frac{\#\{k \in [M] : e_k = e\}}{M} \cdot \frac{w_e}{\mu_e} \,. \tag{1.2}
$$

In particular, this gives $\mathbb{E}[Q_{\tilde{H}}(x)] = Q_H(x)$ for all $x \in \mathbb{R}^V$.

Now in order to find a spectral ε -sparsifier, we want to choose M sufficiently large so that

$$
\mathbb{E} \max_{x: Q_H(x) \leq 1} |Q_H(x) - Q_{\tilde{H}}(x)| \leq \varepsilon.
$$

To control concentration of $Q_{\tilde{H}}(x)$ around its mean, it suffices to bound the average maximal fluctuations. Thus by a standard sort of reduction (see [Section 3.1](#page-19-0) and also [\[Tal14,](#page-26-1) Lem 9.1.11] for a general formulation), it suffices to prove that for any *fixed* hyperedges $e_1, \ldots, e_M \in E$,

$$
\mathbb{E} \max_{x:Q_H(x)\leq 1} \sum_{k=1}^M \varepsilon_k \frac{w_{e_k}}{\mu_{e_k}} Q_{e_k}(x) \leq O(\varepsilon M), \tag{1.3}
$$

.

where $\varepsilon_1, \ldots, \varepsilon_M \in \{-1, 1\}$ are i.i.d. random signs.

Thus our task is now to control the left-hand side of [\(1.3\)](#page-2-1). If we define the random variable

$$
V_x := \sum_{k=1}^M \varepsilon_k \frac{w_{e_k}}{\mu_{e_k}} Q_{e_k}(x),
$$

then $\{V_x : x \in \mathbb{R}^n\}$ is a subgaussian process (defined in [\(2.1\)](#page-5-3)) with respect to the (semi)metric

$$
d(x, \hat{x}) := \left(\sum_{k=1}^{M} \left(\frac{w_{e_k}}{\mu_{e_k}} \right)^2 |Q_{e_k}(x) - Q_{e_k}(\hat{x})|^2 \right)^{1/2}
$$

There are well-developed tools for studying quantities like $\mathbb{E} \max\{V_x : Q_H(x) \leq 1\}$, but they rely on an understanding of the geometry of the space (\mathbb{R}^n , *d*), and a correct choice of distribution μ is essential for making this geometry well-behaved.

Importance sampling. For spectral graph sparsification, one chooses the sampling probability μ_e to be proportional to the effective resistance across e [\[SS11\]](#page-25-3). In order to extend this to hypergraphs, the authors of [\[BST19\]](#page-24-0) define sampling probabilities $\{\mu_e : e \in E\}$ derived from the graph $G = (V, F)$, where $F := \bigcup_{e \in E}$ \int_{a}^{b} $\frac{e}{2}$) is a union of cliques on every hyperedge. They take

$$
\mu_e \propto \sum_{\{u,v\} \in {e \choose 2}} R_{uv},
$$

where R_{uv} denotes the effective resistance between a pair of vertices u , v in G .

To remove the polynomial dependence on D, the authors of [\[KKTY21a\]](#page-25-0) choose a *weighted graph* $G = (V, F, c)$ and define

$$
\mu_e \propto w_e \max\left\{\mathsf{R}_{uv} : \{u,v\} \in \binom{e}{2}\right\}.
$$

Now R_{uv} is the effective resistance in *G*, where edges $\{u, v\} \in F$ have conductance c_{uv} .

Let L_G denote the corresponding (weighted) graph Laplacian, and use L_G^+ to denote its pseudoinverse. Define $T := \{v \in \mathbb{R}^n : Q_H(L_G^{+/2}v) \leq 1\}$. This construction of the sampling probabilities allows us to write

$$
\mathbb{E} \max_{Q_H(x)\leq 1} V_x = \mathbb{E} \max_{v\in T} \sum_{k=1}^M \varepsilon_k \max_{\{i,j\}\in e_k} \langle v, y_{ij}^{e_k} \rangle^2, \tag{1.4}
$$

for a family of vectors $\{y_{ij}^{e_k}\}$ that depends on our choice of edge conductances $c \in \mathbb{R}_+^F$ in G .

A central component of this approach is the existence of conductances that ensure two key properties:

- 1. $T \subseteq B_2^n$ $Z_2^n := \{x \in \mathbb{R}^n : ||x|| \le 1\},\$
- 2. $\|y_{ij}^{e_k}\| \le O(\sqrt{n})$ for all $k = 1, ..., M$ and $\{i, j\} \in {e_k \choose 2}$ $\binom{2}{2}$.

We return to a discussion of these properties in a moment.

Chaining bounds. Note that the right-hand side of [\(1.4\)](#page-3-0) can be written as

$$
\mathbb{E} \max_{v \in T} \sum_{k=1}^{M} \varepsilon_k N_k(v)^2,
$$

where N_k is an ℓ_{∞} norm on a subset of the coordinates of Av , and A is a matrix whose rows are the vectors $\{y_{ij}^{e_k}\}.$ Thus in [Section 2,](#page-5-1) we apply aspects of the generic chaining theory (see the extensive reference [\[Tal14\]](#page-26-1)) to the analysis of such expected maxima.

For readers familiar with the theory, let us note that a bound of $|\tilde{E}| \le O(\varepsilon^{-2}n(\log n)^3)$ in [Theorem 1.1](#page-1-0) follows from applying Dudley's entropy bound (cf. [\(2.4\)](#page-6-0)) in a straightforward way. A bound of $|\tilde{E}| \le O(\varepsilon^{-2} n (\log n)^2)$ follows from a deeper inequality of Talagrand (see [Theorem 2.2](#page-6-1) and [Section 2.2\)](#page-7-0) that exploits property (1) above, that T is a subset of the Euclidean unit ball.

Finally, in order to achieve $|\tilde{E}| \le O(\varepsilon^{-2} \log(D) \cdot n \log n)$, we need to exploit further structure of the norms $\{N_k\}$ in a novel way. Our approach is modeled after Rudelson's geometric argument [\[Rud99a\]](#page-25-6) which, roughly speaking, handles the case where each N_k is a 1-dimensional norm, as well as Talagrand's method of chaining via growth functionals (see [Section 2.3](#page-8-0) and [Section 2.4\)](#page-10-0).

To state this bound, let us consider arbitrary norms N_1, \ldots, N_M on \mathbb{R}^n . Define:

$$
\kappa := \mathbb{E} \max_{k \in [M]} N_k(g),
$$

$$
\lambda := \max_{k \in [M]} \left(\mathbb{E}[N_k(g)^2] \right)^{1/2},
$$

where g is a standard *n*-dimensional Gaussian. In [Section 2.4,](#page-10-0) we prove that for any $T \subseteq B_2^n$ $\frac{n}{2}$,

$$
\mathbb{E}\sup_{x\in T}\sum_{k=1}^{M}\varepsilon_k N_k(x)^2 \leq O\left(\lambda\sqrt{\log n} + \kappa\right) \cdot \sup_{x\in T}\left(\sum_{k=1}^{M} N_k(x)^2\right)^{1/2} \tag{1.5}
$$

When $M = m$, each N_k is a 1-dimensional norm $N_k(x) := |\langle x, a_k \rangle|$ for some $a_k \in \mathbb{R}^n$, and $T = B_2^n$ $n \over 2$, this lemma recovers Rudelson's concentration bound for Bernoulli sums of rank-1 matrices [\[Rud99b\]](#page-25-7) (as mentioned there, the inequality we state next is a consequence of the noncommutative Khintchine inequalities [\[LPP91\]](#page-25-8)).

Observe that $N_k(x)^2 = \langle x, a_k \rangle^2 = \langle x, a_k a_k^* x \rangle$, and using $\|\cdot\|_{op}$ to denote the operator norm, the preceding bound asserts that

$$
\mathbb{E}\left\|\sum_{k=1}^m \varepsilon_k a_k a_k^*\right\|_{op} = \mathbb{E}\max_{x\in B_2^n}\left\langle x, \left(\sum_{k=1}^m \varepsilon_k a_k a_k^*\right)x\right\rangle \le O(\sqrt{\log(m+n)})\max_{k\in[m]}\|a_k\| \cdot \left\|\sum_{k=1}^m a_k a_k^*\right\|_{op}^{1/2},
$$

where we use $\lambda \le O(1) \max_{k \in [m]} ||a_k||$ and $\kappa \le O(\sqrt{\log m}) \max_{k \in [m]} ||a_k||$.

When applying [\(1.5\)](#page-4-0) to hypergraph sparsification, one picks up an additional $\sqrt{\log D}$ factor because each N_k is an ℓ_{∞} norm on a subset of at most D coordinates.

Remark 1.2. As far as we know, it is an open problem to replicate consequences of the noncommutative Khintchine bound for higher-rank matrices using chaining, i.e., in the setting where $N_k(x) = ||A_k x||$ for matrices A_1, \ldots, A_M .

Choosing good conductances. In order to satisfy properties (1) and (2) above, one chooses nonnegative numbers

$$
\left\{c_{ij}^{e} \geq 0: \{i,j\} \in \binom{e}{2}, e \in E\right\}
$$
\n
$$
\sum_{\{i,j\} \in \binom{e}{2}} c_{ij}^{e} = w_e, \qquad \forall e \in E.
$$
\n(1.6)

for which

Define the edge conductances $c_{ij} := \sum$ $_{e \in E: \{i,j\} \in \binom{e}{2}} c_{ij}^e$. As argued in [Section 3.2,](#page-22-0) any such choice satisfies property (1).

Let R_{ij} denote the effective resistance between $\{i, j\} \in F$ in the weighted graph $G = (V, F, c)$. To satisfy property (2), it suffices that for all hyperedges $e \in E$, the effective resistances R_{ij} are the same for all pairs $\{i, j\} \in {e \choose 2}$ $\binom{e}{2}$ with $c_{ij}^e > 0$. (This continues to hold even if the resistances are only comparable up to universal constant factors.)

Let J denote the all-ones matrix and consider maximizing the quantity

$$
\log \det(L_G + J)
$$

over all choices of (c_{ij}^e) satisfying [\(1.6\)](#page-4-1). This quantity is a concave function of the conductances (c_{ij}^e) and the KKT conditions for the maximizer establish the desired property for the effective resistances. See [Section 3.3.](#page-23-0)

This is essentially a reformulation and simplification of the method used in [\[KKTY21a\]](#page-25-0) for establishing the existence of nice conductances $c : F \to \mathbb{R}_+$. It is also reminiscent of Barthe's method for analyzing the Gaussian maximizers of the Brascamp-Lieb (and reverse Brascamp-Lieb) inequalities [\[Bar98\]](#page-24-1) (see also the treatment in [\[HM13\]](#page-25-9)).

1.2 Notation

For two expressions A and B, we will use the equivalent notations $A \leq B$ and $A \leq O(B)$ to denote that there is a constant $C > 0$ such that $A \leq CB$. If A and B depend on some parameters $\alpha_1, \alpha_2, \ldots$, we use the notation $A \leq_{\alpha_1,\alpha_2,...} B$ to denote that there is a number $C = C(\alpha_1, \alpha_2,...)$ such that $A \leq CB$. We use $A \leq B$ to denote the conjunction of $A \leq B$ and $B \leq A$.

A number of vector and matrix norms will appear in what follows. When $x \in \mathbb{R}^n$ is a vector, $\|x\|$ will always refer to the standard Euclidean norm of x. For a positive integer $M \ge 1$, we will sometimes use the notation $[M] := \{1, 2, \ldots, M\}.$

2 Extrema of random processes

2.1 Background on generic chaining

A space (T, d) is called a *K*-quasimetric if satisfies

- 1. $d(x, y) = d(y, x)$ for all $x, y \in T$.
- 2. $d(x, x) = 0$ for all $x \in T$.
- 3. There is a constant $K > 0$ such that

$$
d(x,y)\leq K\left(d(x,z)+d(z,y)\right)\,,\qquad \forall x,y,z\in T\,.
$$

Say that (T, d) is a *quasimetric space* if (T, d) is a *K*-quasimetric for some $K > 0$.

Consider a distance *d* on *T*. A random process $\{V_x : x \in T\}$ is said to be *subgaussian with respect to d* if there is a number $\alpha > 0$ such that

$$
\mathbb{P}\left(|V_x - V_y| > t\right) \le \exp\left(-\alpha \frac{t^2}{d(x, y)^2}\right), \qquad t > 0.
$$
\n(2.1)

The generic chaining functional. For a quasimetric space (T, d) , let us recall Talagrand's generic chaining functional [\[Tal14,](#page-26-1) Def. 2.2.19]. Define $N_h \coloneqq 2^{2^h}.$ Then

$$
\gamma_2(T, d) := \inf_{\{\mathcal{A}_h\}} \sup_{x \in T} \sum_{h=0}^{\infty} 2^{h/2} \operatorname{diam}_d(\mathcal{A}_h(x)), \tag{2.2}
$$

where the infimum runs over all sequences $\{\mathcal{A}_h : h \geq 0\}$ of partitions of T satisfying $|\mathcal{A}_h| \leq N_h$ for each $h \geq 0$. Note that we use the notation $\mathcal{A}_h(x)$ for the unique set of \mathcal{A}_h that contains x, and diam $_d(S) := \sup_{x,y \in S} d(x,y)$ for $S \subseteq T$. The next theorem constitutes the generic chaining upper bound; see [\[Tal14,](#page-26-1) Thm 2.2.18].

Theorem 2.1. If $\{V_x : x \in T\}$ is a centered subgaussian process satisfying [\(2.1\)](#page-5-3) with respect to a K*quasimetric* (T, d) *, then*

$$
\mathbb{E}\sup_{x\in T}V_x\lesssim_{K,\alpha}\gamma_2(T,d).
$$
\n(2.3)

Define the entropy numbers $e_h(T, d) := \inf \{ \sup_{t \in T} d(t, T_h) : T_h \subseteq T, |T_h| \leq 2^{2^h} \}.$ This is the infimum of numbers $r > 0$ such that T can be covered by at most 2^{2^h} balls of radius r . A classical way of controlling $\gamma_2(T, d)$ is given by Dudley's entropy bound (see, e.g., [\[Tal14,](#page-26-1) Prop 2.2.10]):

$$
\gamma_2(T, d) \le \sum_{h \ge 0} 2^{h/2} e_h(T, d).
$$
 (2.4)

.

But often additional structure of the space (T, d) allows one to improve on [\(2.4\)](#page-6-0). The next lemma is a consequence of [\[Tal14,](#page-26-1) Thm 4.1.11 & (4.23)]. It actually holds whenever T is the unit ball of a uniformly 2-convex Banach space and d is induced by some (possibly different) norm.

Theorem 2.2. *Suppose that* $T = B_2^n$ 2 *is the unit Euclidean ball in* ℝ^𝑛 *and* k · k^𝑋 *is a norm on* ^ℝ^𝑛 *. Then,*

$$
\gamma_2(T, \|\cdot\|_X) \le \left(\sum_{h\ge 0} \left(2^{h/2} e_h(T, \|\cdot\|_X)\right)^2\right)^{1/2}
$$

In order to bound the entropy numbers $e_h(B_2^n)$ $\frac{n}{2}$, $\|\cdot\|_X$), we will use the following classical fact; see, e.g., [\[LT11,](#page-25-10) (3.15)].

Lemma 2.3 (Dual Sudakov inequality). Let B_2^n $^{\emph{n}}_2$ denote the unit Euclidean ball, and suppose that $\|\cdot\|_{\mathcal{X}}$ is *a norm on* ℝ^𝑛 *. Then*

$$
e_h(B_2^n,\|\cdot\|_X)\lesssim 2^{-h/2}\,\mathbb{E}\,\|g\|_X,
$$

where q is a standard n-dimensional Gaussian.

Corollary 2.4. *Suppose* $\|\cdot\|_X$ *is a norm on* \mathbb{R}^n *, and furthermore that* $\|\cdot\|_X \le L \|\cdot\|$ *for some* $L \ge 1$ *. Then,*

$$
\gamma_2(B_2^n, \|\cdot\|_X) \lesssim L + \sqrt{\log n} \mathbb{E} \|g\|_X,
$$

where q is a standard n-dimensional Gaussian.

Proof. A straightforward volume argument shows that any set of δ -separated points in (B_2^n) $\frac{n}{2}$, $\|\cdot\|$) must have cardinality at most $(4/\delta)^n$, and therefore

$$
e_h(T, ||\cdot||) \leq 4 \cdot N_h^{-1/n} = 4 \cdot 2^{-2^h/n}.
$$

By assumption, we have $e_h(B_2^n)$ $\binom{n}{2}, \|\cdot\|_X \leq L \cdot e_h(B_2^n)$ $\frac{n}{2}$, $\|\cdot\|$), and therefore

$$
e_h(B_2^n, \|\cdot\|_X) \le 4L \cdot (2^{-2^h/n}).
$$

Denote $S := \sup_{h \geq 0} 2^{h/2} e_h(T, \|\cdot\|_X)$. Applying [Theorem 2.2](#page-6-1) yields, for any $h_0 \geq 0$,

$$
\gamma_2(T, d) \leq S\sqrt{h_0} + 4L\left(\sum_{h \geq h_0} (2^{h/2}2^{-2^h/n})^2\right)^{1/2}.
$$

Choosing $h_0 \geq 2 \log n$ bounds the latter sum by $O(1)$, yielding

$$
\gamma_2(T, d) \lesssim S \sqrt{\log n} + L \, .
$$

To conclude, use [Lemma 2.3](#page-6-2) to bound S. \Box

2.2 Warm up

The next lemma will allow us to establish the existence of hypergraph spectral sparsifiers with at most $O(\varepsilon^{-2}n(\log n)^2)$ hyperedges. It also provides a nice warm up for the more delicate arguments in [Section 2.4.](#page-10-0)

Let $A : \mathbb{R}^n \to \mathbb{R}^m$ denote a linear operator. We use the notation

$$
||A||_{2\to\infty} := \max_{||x|| \leq 1} ||Ax||_{\infty}.
$$

This is equal to the maximum ℓ_2 norm of a row of A. Define the norm

 $||x||_A := ||Ax||_{\infty}$

and let us observe the following.

Lemma 2.5. *If g is a standard n-dimensional Gaussian, it holds that*

$$
\mathbb{E} \, \|g\|_A \lesssim \|A\|_{2\to\infty} \sqrt{\log m} \, .
$$

In particular, [Lemma 2.3](#page-6-2) gives

$$
e_h(B_2^n, \|\cdot\|_A) \lesssim 2^{-h/2} \sqrt{\log m} \|A\|_{2\to\infty}.
$$

Proof. If a_1, \ldots, a_m are the rows of A and g is an n -dimensional Gaussian, then

$$
\mathbb{E} \left\| Ag \right\|_{\infty} = \mathbb{E} \max_{i \in [m]} |\langle g, a_i \rangle| \lesssim \max_{i \in [m]} \|a_i\| \sqrt{\log m} = \|A\|_{2 \to \infty} \sqrt{\log m} .
$$

Additionally, let $\varphi_1, \varphi_2, \ldots, \varphi_M : \mathbb{R}^m \to \mathbb{R}$ be arbitrary functions.

Lemma 2.6. *For any subset* $T \subseteq B_2^n$ 2 *, it holds that*

$$
\mathbb{E}\sup_{x\in T}\sum_{j=1}^M \varepsilon_j\varphi_j(Ax)^2 \lesssim \sqrt{\log m \log n} \|A\|_{2\to\infty} \cdot \sup_{\substack{j\in [M],\\ \|z-z'\|_{\infty}\le 1}} |\varphi_j(z)-\varphi_j(z')|\cdot \sup_{x\in T} \left(\sum_{j=1}^M \varphi_j(Ax)^2\right)^{1/2},
$$

where $\varepsilon_1, \ldots, \varepsilon_M$ are *i.i.d.* Bernoulli ± 1 *random variables.*

Proof. Define

$$
\alpha := \max_{j \in [M]} \sup_{\|z - z'\|_{\infty} \leq 1} |\varphi_j(z) - \varphi_j(z')|, \tag{2.5}
$$

$$
\beta := \sup_{x \in T} \left(\sum_{j=1}^{M} \varphi_j(Ax)^2 \right)^{1/2},
$$
\n
$$
V_x := \sum_{j=1}^{M} \varepsilon_j \varphi_j(Ax)^2,
$$
\n(2.6)

 $j=1$

and note that $\{V_x : x \in \mathbb{R}^n\}$ is a subgaussian process with respect to the distance

$$
d(x, \hat{x}) := \left(\sum_{j=1}^{M} |\varphi_j(Ax)^2 - \varphi_j(A\hat{x})^2|^2\right)^{1/2}
$$

Thus in light of (2.3) , it suffices to prove that

$$
\gamma_2(T, d) \lesssim \sqrt{\log m \log n} \|A\|_{2 \to \infty} \cdot \alpha \beta. \tag{2.7}
$$

.

Note that for $x, \hat{x} \in T$,

$$
d(x, \hat{x})^2 = \sum_{j=1}^{M} (\varphi_j(Ax) - \varphi_j(A\hat{x}))^2 (\varphi_j(Ax) + \varphi_j(A\hat{x}))^2
$$

\n
$$
\leq 2 \sum_{j=1}^{M} (\varphi_j(Ax) - \varphi_j(A\hat{x}))^2 (\varphi_j(Ax)^2 + \varphi_j(A\hat{x})^2)
$$

\n
$$
\leq 2\alpha^2 \|A(x - \hat{x})\|_{\infty}^2 \sum_{j=1}^{M} (\varphi_j(Ax)^2 + \varphi_j(A\hat{x})^2)
$$

\n
$$
\leq 4\alpha^2 \beta^2 \|x - \hat{x}\|_A^2.
$$
\n(2.8)

In particular, we have

$$
\gamma_2(T, d) \leq 2\alpha\beta \cdot \gamma_2(T, \|\cdot\|_A) \leq 2\alpha\beta \cdot \gamma_2(B_2^n, \|\cdot\|_A),\tag{2.9}
$$

where the last inequality uses $T \subseteq B_2^n$ $\frac{n}{2}$.

We can thus apply [Lemma 2.5](#page-7-3) and [Corollary 2.4](#page-6-4) with $\|\cdot\|_X = \|\cdot\|_A$ and $L := \|A\|_{2\to\infty}$ to conclude that

$$
\gamma_2(B_2^n, \|\cdot\|_A) \lesssim \|A\|_{2\to\infty} \sqrt{\log m \log n}.
$$

Combining this with (2.9) completes our verification of (2.7) .

In [Section 2.4,](#page-10-0) we will obtain an improved bound by using convexity in a stronger way. In particular, we will assume that each of the functions φ_j in [Lemma 2.6](#page-7-4) is a norm on \mathbb{R}^m .

2.3 Growth functionals

Talagrand introduced a powerful way to control $\gamma_2(T, d)$ via the existence of certain growth functionals. For $x \in T$ and $\rho > 0$, define the ball

$$
B_d(x,\rho) := \{ y \in T : d(x,y) \le \rho \}.
$$
 (2.10)

Definition 2.7 (Separated sets). Let (T, d) denote a metric space and consider numbers $a > 0, r \ge 4$. Say that subsets $H_1, \ldots, H_m \subseteq T$ *are* (a, r) *-separated* if

$$
H_{\ell} \subseteq B_d(x_{\ell},a/r), \quad \ell=1,\ldots,m,
$$

where $x_1, \ldots, x_m \in T$ are points satisfying

$$
a \leq d(x_{\ell}, x_{\ell'}) \leq ar, \quad \forall \ell \neq \ell'.
$$
\n
$$
(2.11)
$$

Definition 2.8 (The growth condition). Consider nonnegative functionals $\{F_h : h \geq 0\}$ defined on subsets of a metric space (T, d) and which satisfy the following two conditions for every $h \ge 0$:

$$
F_h(S) \le F_h(S'), \qquad \forall S \subseteq S' \subseteq T,
$$

$$
F_{h+1}(S) \le F_h(S), \qquad \forall S \subseteq T.
$$

Say that such functionals satisfy the *growth condition with parameters* $r \geq 4$ *and* $c^* > 0$ if for any integer $h \ge 0$ and $a > 0$, the following holds true with $m = N_{h+1}$: For each collection of subsets $H_1, \ldots, H_m \subseteq T$ that are (a, r) -separated, we have

$$
F_h\left(\bigcup_{\ell\leq m} H_{\ell}\right) \geq c^* a 2^{h/2} + \min_{\ell\leq m} F_{h+1}(H_{\ell}).
$$
\n(2.12)

Theorem 2.9 ([\[Tal14,](#page-26-1) Thm 2.3.16]). Let (T, d) be a K-quasimetric space and consider a sequence of *functionals* ${F_h}$ *satisfying the growth condition (cf. [Definition 2.8\)](#page-9-0)* with parameters $r \geq 4$ and $c^* > 0$. *Then,*

$$
\gamma_2(T,d)\lesssim_K \frac{r}{c^*}F_0(T)+r\cdot\text{diam}_d(T)\,.
$$

Remark 2.10 (Packing/covering duality)**.** For the reader encountering [Definition 2.8](#page-9-0) and [Theorem 2.9](#page-9-1) for the first time, the role of the functionals ${F_h}$ might appear mysterious. Some intuition can be gained by considering the duality between covering and packing: A set S in some metric space can be covered by m balls of radius $r > 0$ if it is impossible to find m points in S that are pairwise separated by distance r .

The quantity $\gamma_2(T, d)$ (cf. [\(2.2\)](#page-5-4)) is a sort of multiscale covering functional. The growth functionals ${F_h}$ measure the "size" of packings of various cardinalities, and [\(2.12\)](#page-9-2) asserts a form of packing impossibility. This makes [Theorem 2.9](#page-9-1) a multiscale analog of the simple packing/covering argument recalled above.

Those familiar with convex optimization and duality may find the approach of [\[BDOS21\]](#page-24-2) instructive in this regard. It is shown that the corresponding *fractional* multiscale covering and packing values are equal by convex duality, and then a rounding argument establishes that the integral versions are equivalent up to constant factors.

We will use the following corollary of [Theorem 2.9](#page-9-1) that simplifies the construction of functionals if we have a bound on the growth rate of nets in (T, d) .

Corollary 2.11. Let (T, d) be a K-quasimetric and assume there are numbers $k, L \geq 1$ and $r \geq 4$ such that *that for every* $a > 0$ *,* \mathbf{L}

$$
H_1, \ldots, H_m \subseteq T \text{ are } (a, r)\text{-separated} \implies m \leqslant \left(\frac{L}{a}\right)^k. \tag{2.13}
$$

Let h_0 *be the largest integer* $h \geq 0$ *such that*

$$
2^{2^h} \leq 2^{k(h-1)/2} \,. \tag{2.14}
$$

Consider a sequence of functionals {𝐹0, 𝐹1, . . . , 𝐹ℎ⁰ } *satisfying the growth condition* [\(2.12\)](#page-9-2) *with parameters* 𝑟 *and* 𝑐 ∗ > 0*. Then,*

$$
\gamma_2(T, d) \leq K \frac{r}{c^*} F_0(T) + r \left(\text{diam}_d(T) + L \right). \tag{2.15}
$$

Proof. Define the numbers

$$
c_j := c^* L \cdot 2^{-2^j / k} 2^{(j-1)/2}
$$

$$
C_0 := \sum_{j=h_0+1}^{\infty} c_j,
$$

and note that $C_0 \le c^*L$, since [\(2.14\)](#page-9-3) is violated for every $h \ge h_0 + 1$.

Define a new family of functionals $\{\tilde{F}_h : h \geq 0\}$ so that for every $S \subseteq T$,

$$
\tilde{F}_h(S) := F_h(S) + C_0, \qquad h = 0, 1, ..., h_0,
$$
\n
$$
\tilde{F}_h(S) := F_{h_0}(S) + C_0 - \sum_{j=h_0+1}^h c_j, \qquad h > h_0.
$$

By construction, these satisfy the growth condition [Definition 2.8](#page-9-0) since for $h \ge h_0$, if $H_1, \ldots, H_m \subseteq$ *T* are (a, r) -separated sets with $m = 2^{2^{h+1}}$, then

$$
\tilde{F}_{h+1}\left(\bigcup_{\ell\leq m}H_\ell\right)\geq c_{h+1}+\tilde{F}_h\left(\bigcup_{\ell\leq m}H_\ell\right)\geq c_{h+1}+\min_{\ell\leq m}\tilde{F}_h\left(H_\ell\right)\geq c^*a2^{h/2}+\min_{\ell\leq m}\tilde{F}_h\left(H_\ell\right),
$$

where the last inequality uses the fact that $a \leq L2^{-2^{h+1}/k}$ from [\(2.13\)](#page-9-4). Moreover, we have

 $\tilde{F}_0(T) = F_0(T) + C_0 \leq F_0(T) + O(c^*L)$,

and therefore we can apply [Theorem 2.9](#page-9-1) to $\{\tilde{F}_h\}$ to complete the proof.

2.4 Further exploiting convexity

We will now use the growth functional approach (cf. [Section 2.3\)](#page-8-0) to prove a more elaborate upper bound under the additional assumption that our summands are derived from norms. This will allow us in [Section 3](#page-18-0) to find spectral ε -sparsifiers with $O\left(\frac{\log D}{\varepsilon^2}\right)$ $\frac{18D}{\epsilon^2} n \log n$ hyperedges.

Let N_1, N_2, \ldots, N_M be norms on ℝⁿ and define

$$
\begin{aligned} \kappa &:= \mathbb{E} \max_{j \in [M]} N_j(g) \,, \\ \lambda &:= \max_{j \in [M]} \left(\mathbb{E}[N_j(g)^2] \right)^{1/2} \,, \end{aligned}
$$

where q is a standard n -dimensional Gaussian.

Lemma 2.12. *For any* $T \subseteq B_2^n$ 2 *, it holds that*

$$
\mathbb{E}\sup_{x\in T}\sum_{j=1}^M \varepsilon_j N_j(x)^2 \lesssim \left(\lambda \sqrt{\log n} + \kappa\right) \cdot \sup_{x\in T} \left(\sum_{j=1}^M N_j(x)^2\right)^{1/2},
$$

where $\varepsilon_1, \ldots, \varepsilon_M$ *are i.i.d. Bernoulli* ± 1 *random variables.*

Before proving the lemma, let us illustrate a corollary that we will use to construct hypergraph sparsifiers. Consider a linear operator $A:\mathbb{R}^n\to\mathbb{R}^m$, and suppose that each N_i is a (weighted) ℓ_∞ norm on some subset $S_i \subseteq [m]$ of the coordinates:

$$
N_i(z) = \max_{j \in S_i} w_j |(Az)_j|, \qquad w \in [0, 1]^{S_i}.
$$
 (2.16)

Let a_1, \ldots, a_m denote the rows of A, and observe that $(Ag)_j = \langle a_j, g \rangle$ is a normal random variable with variance $||a_j||^2$, and therefore

$$
\mathbb{E}[N_i(g)]^2 = \max_{j \in S_i} w_j^2 |\langle a_j, g \rangle|^2 \lesssim \max_{j \in S_i} ||a_j||^2 \cdot \sqrt{\log |S_i|}.
$$

Similarly, we have

$$
\kappa = \mathbb{E} \max_{i \in [M]} \max_{j \in S_i} w_j^2 |\langle a_j, g \rangle|^2 \leq \mathbb{E} \max_{i \in [m]} |\langle a_i, g \rangle|^2 \leq ||A||_{2 \to \infty} \sqrt{\log m}.
$$

Corollary 2.13. *If the norms* N_1, \ldots, N_M *are of the form* [\(2.16\)](#page-11-0) *for some* $A : \mathbb{R}^n \to \mathbb{R}^m$ *and subsets* $S_1, \ldots, S_M \subseteq [m]$ with $\max_{i \in [M]} |S_i| \le D$, then for any $T \subseteq B_2^n$ 2 *, it holds that*

$$
\mathbb{E}\sup_{x\in T}\sum_{j=1}^M \varepsilon_j N_j(x)^2 \lesssim ||A||_{2\to\infty}\sqrt{\log(m+n)\log D}\cdot \sup_{x\in T}\left(\sum_{j=1}^M N_j(x)^2\right)^{1/2},
$$

where $\varepsilon_1, \ldots, \varepsilon_M$ *are i.i.d.* Bernoulli ± 1 *random variables.*

The proof of [Lemma 2.12](#page-10-1) is modeled after arguments of Rudelson [\[Rud99a\]](#page-25-6) and Talagrand; see [\[Tal14,](#page-26-1) §16.7] and the historical notes in [\[Tal14,](#page-26-1) §16.10]. A version of the latter argument first appeared in [\[Rud99a\]](#page-25-6), as a simplification of Rudelson's original construction of an explicit majorizing measure. In the proof of [\[Tal14,](#page-26-1) Prop 16.7.4], one encounters growth functionals of the form $F(S) = 1 - inf\{\|u\| : u \in conv(S)\}\$, where $\|\cdot\|$ is a uniformly 2-convex norm. We recall this definition.

Definition 2.14 (Uniform p -convexity). A Banach space Z is called *uniformly* p -convex if there is a number $\eta > 0$ such that for all $x, y \in \mathbb{Z}$ with $||x||_{\mathbb{Z}}$, $||y||_{\mathbb{Z}} \leq 1$,

$$
\left\|\frac{x+y}{2}\right\|_Z \le 1 - \eta \|x-y\|_Z^p
$$

.

We remark that the statement of [Lemma 2.12](#page-10-1) actually holds when T is a subset of the unit ball of any uniformly 2-convex norm on \mathbb{R}^n (with an implicit constant that depends on η).

We will instead employ functionals of the form

$$
F(S) = 2 - \inf \left\{ ||u||^2 + \sum_{j=1}^{M} N_j(u)^2 : u \in conv(S) \right\}.
$$

Problematically, the norm $u \mapsto$ $\overline{1}$ $||u||^2 + \sum_{j=1}^{M} N_j(u)^2\bigg)^{1/2}$ is potentially very far from uniformly 2-convex, thus we have to be careful in using only 2-convexity of the Euclidean norm, along with 2-convexity of the "outer" ℓ_2 norm of the N_j 's. This requires application of the inequality $|N_i(x) - N_i(\hat{x})| \le N_i(x - \hat{x})$ only at judiciously chosen points in the argument. We offer some further explanation in [Remark 2.21](#page-17-0) after the proof.

Proof of [Lemma 2.12.](#page-10-1) For a set $S \subseteq \mathbb{R}^n$, let conv(S) denote the closed convex hull of S. Note that by convexity,

$$
\sup_{x \in T} \left(\sum_{j=1}^{M} N_j(x)^2 \right)^{1/2} = \sup_{x \in \text{conv}(T)} \left(\sum_{j=1}^{M} N_j(x)^2 \right)^{1/2}.
$$

Therefore we may replace T by $\text{conv}(T)$ and henceforth assume that T is compact and convex.

By scaling $\{N_i\}$, we may assume that

$$
\sup_{x \in T} \sum_{j=1}^{M} N_j(x)^2 = 1.
$$
 (2.17)

Define $V_x := \sum_{j=1}^M \varepsilon_j N_j(x)^2$. Then $\{V_x : x \in \mathbb{R}^n\}$ is a subgaussian process with respect to the metric

$$
\tilde{d}(x,\hat{x}) := \left(\sum_{j=1}^{M} |N_j(x)^2 - N_j(\hat{x})^2|^2\right)^{1/2},
$$

therefore from [\(2.3\)](#page-6-3), we have

$$
\mathbb{E}\sup_{x\in T}V_x\lesssim \gamma_2(T,\tilde{d}).\tag{2.18}
$$

Passing to a nicer distance. Define the related distance

$$
d(x,\hat{x}) := \left(\sum_{j=1}^{M} N_j(x-\hat{x})^2 (N_j(x)^2 + N_j(\hat{x})^2)\right)^{1/2},
$$

and note that for all $x, \hat{x} \in \mathbb{R}^n$,

$$
\tilde{d}(x,\hat{x})^2 = \sum_{j=1}^M (N_j(x) - N_j(\hat{x}))^2 (N_j(x) + N_j(\hat{x}))^2
$$

\$\leq 2 \sum_{j=1}^M N_j(x - \hat{x})^2 (N_j(x)^2 + N_j(\hat{x})^2) = 2 d(x, \hat{x})^2.

We will observe momentarily that

$$
d(x, \hat{x}) \leq 2\sqrt{2} \left(d(x, y) + d(y, \hat{x}) \right), \qquad \forall x, \hat{x}, y \in \mathbb{R}^n.
$$
 (2.19)

Since $\tilde{d} \leq \sqrt{2}d$ and d is a quasimetric, [\(2.3\)](#page-6-3) gives

$$
\mathbb{E}\sup_{x\in T}V_x\lesssim \gamma_2(T,d)\,,
$$

and thus our goal is to establish that

$$
\gamma_2(T, d) \le \lambda \sqrt{\log n} + \kappa \,. \tag{2.20}
$$

Lemma 2.15. *For any metric space* (X, D) *and* $x_0 \in X$ *, it holds that the distance*

 $\tilde{D}(x, \hat{x}) \coloneqq D(x, \hat{x}) (D(x, x_0) + D(\hat{x}, x_0))$

is a 2*-quasimetric.*

Proof. Define $\psi(x) := D(x, x_0)$ and consider $x, \hat{x}, y \in X$. Then,

$$
\tilde{D}(x,\hat{x}) \le (D(x,y) + D(\hat{x},y)) (\psi(x) + \psi(\hat{x}))
$$
\n
$$
\le D(x,y) (\psi(x) + \psi(y) + D(\hat{x},y)) + D(\hat{x},y) (\psi(\hat{x}) + \psi(y) + D(x,y))
$$
\n
$$
\le \tilde{D}(x,y) + \tilde{D}(\hat{x},y) + 2D(x,y)D(\hat{x},y).
$$

Now use $2D(x, y)D(\hat{x}, y) \le D(x, y)^2 + D(\hat{x}, y)^2 \le \tilde{D}(x, y) + \tilde{D}(\hat{x}, y)$, completing the proof. \square

Applying the preceding lemma with $D(x, \hat{x}) = N_i(x - \hat{x})$ and $x_0 = 0$ shows that the distance $(x, \hat{x}) \mapsto N_j(x - \hat{x})(N_j(x) + N_j(\hat{x})^2)^{1/2}$ is a 2 $\sqrt{2}$ -quasimetric for each $j = 1, ..., M$, and therefore d is a 2 $\sqrt{2}$ -quasimetric on \mathbb{R}^n , verifying [\(2.19\)](#page-12-0).

Balls in (\mathbb{R}^n , *d*) are approximately convex. Recall the definition of the balls $B_d(x, \rho)$ from [\(2.10\)](#page-8-3). **Lemma 2.16.** *For any* $x \in \mathbb{R}^n$ *and* $\rho > 0$ *, it holds that*

$$
conv(B_d(x,\rho)) \subseteq B_d(x,4\rho).
$$

Proof. For $y \in B_d(x, \rho)$, we have

$$
\left(\sum_{j=1}^{M} N_j(x-y)^2 N_j(x)^2\right)^{1/2} \le \rho \,, \tag{2.21}
$$

as well as

$$
\sqrt{\rho} \ge d(x, y)^{1/2} = \left(\sum_{j=1}^{M} N_j (x - y)^2 (N_j (x)^2 + N_j (y)^2)\right)^{1/4} \ge \left(\frac{1}{2} \sum_{j=1}^{M} N_j (x - y)^4\right)^{1/4},\tag{2.22}
$$

where the final inequality uses $N_j(x - y) \le N_j(x) + N_j(y)$. Since the left-hand side of [\(2.21\)](#page-13-0) and the right-hand side of (2.22) are both convex functions of y , these inequalities remain true for all $y \in \text{conv}(B_d(x, \rho)).$

In particular, for any $y \in \text{conv}(B_d(x, \rho))$, we can use $a^2 + b^2 \leq 4a^2 + 2(a - b)^2$ to write

$$
d(x, y) \le \left(\sum_{j=1}^{M} N_j (x - y)^2 (4N_j (x)^2 + 2(N_j (x) - N_j (y))^2)\right)^{1/2}
$$

$$
\le 2\left(\sum_{j=1}^{M} N_j (x - y)^2 N_j (x)^2\right)^{1/2} + \sqrt{2}\left(\sum_{j=1}^{M} N_j (x - y)^4\right)^{1/2} \le 4\rho.
$$

Covering estimates. Define now the following norms on ℝⁿ:

$$
||x||_N := \max_{j \in [M]} N_j(x),
$$

$$
||x||_{\mathcal{E}(u)} := \left(\sum_{j=1}^M N_j(x)^2 N_j(u)^2\right)^{1/2}, \quad u \in \mathbb{R}^n.
$$

Lemma 2.17. *For all* $x, \hat{x}, u \in \mathbb{R}^n$,

$$
d(x,\hat{x})^2 \leq 2 \|x-\hat{x}\|_{\mathcal{N}}^2 \left(\sum_{j=1}^M (N_j(x)-N_j(u))^2 + \sum_{j=1}^M (N_j(\hat{x})-N_j(u))^2 \right) + 4 \|x-\hat{x}\|_{\mathcal{E}(u)}^2.
$$

Proof. Use the inequalities

$$
N_j(x)^2 \le 2(N_j(x) - N_j(u))^2 + 2N_j(u)^2, \qquad x, u \in \mathbb{R}^n
$$

to write

$$
\sum_{j=1}^{M} N_j (x - \hat{x})^2 N_j (x)^2 \le 2||x - \hat{x}||_N^2 \sum_{j=1}^{M} (N_j (x) - N_j (u))^2 + 2 \sum_{j=1}^{M} N_j (x - \hat{x})^2 N_j (u)^2
$$

= 2||x - \hat{x}||_N^2 \sum_{j=1}^{M} (N_j (x) - N_j (u))^2 + 2||x - \hat{x}||_{\mathcal{E}(u)}^2.

Lemma 2.18. *It holds that*

$$
e_h(B_2^n, \|\cdot\|_N) \lesssim 2^{-h/2}\kappa ,
$$

$$
e_h(B_2^n, \|\cdot\|_{\mathcal{E}(u)}) \lesssim 2^{-h/2}\lambda , \quad \forall u \in T.
$$

Proof. Both inequalities follow readily from [Lemma 2.3:](#page-6-2) If g is a standard n -dimensional Gaussian, then

$$
e_h(B_2^n, \|\cdot\|_N) \le 2^{-h/2} \mathbb{E} \|g\|_N = 2^{-h/2} \kappa,
$$

by the definition of κ . For the second inequality,

$$
e_h(B_2^n,\|\cdot\|_{\mathcal{E}(u)})\lesssim 2^{-h/2}\,\mathbb{E}\,\|g\|_{\mathcal{E}(u)}\,.
$$

Now use convexity of the square to bound

$$
\left(\mathbb{E} \|\mathcal{g}\|_{\mathcal{E}(u)}\right)^2 \leq \mathbb{E} \|\mathcal{g}\|_{\mathcal{E}(u)}^2 = \sum_{j=1}^M N_j(u)^2 \mathbb{E}[N_j(g)^2] \leq \lambda^2,
$$

where the final line uses the definition of λ and $\sum_{j=1}^{M} N_j(u)^2 \leq 1$ by [\(2.17\)](#page-12-1), because $u \in T$.

We also need a basic estimate that we will use to apply [Corollary 2.11.](#page-9-5) Observe that for x , $\hat{x} \in T$,

$$
d(x, \hat{x}) \stackrel{(2.17)}{\leq} \sqrt{2} \|x - \hat{x}\|_{\mathcal{N}} \leq \sqrt{2} \left(\|x\|_{\mathcal{N}} + \|\hat{x}\|_{\mathcal{N}} \right) \leq 2\sqrt{2}, \tag{2.23}
$$

where the last inequality uses $||x||_N \le (\sum_{j=1}^M N_j(x)^2)^{1/2} \le 1$ for $x \in T$, by [\(2.17\)](#page-12-1).

Lemma 2.19. For any $a > 0$, if $x_1, \ldots, x_K \in T$ satisfy $d(x_i, x_j) \ge a$ for $i \ne j$, then, $K \leq \left(\frac{6}{a}\right)^n$.

Proof. As noted above, we have $||x||_N \le 1$ for $x \in T$, and [\(2.23\)](#page-14-0) gives $||x_i - x_j||_N \ge a/\sqrt{2}$ for $i \ne j$. Therefore by a simple volume argument (valid for any norm on \mathbb{R}^n):

$$
K \leq \left(1+\frac{2\sqrt{2}}{a}\right)^n \leq \left(\frac{6}{a}\right)^n,
$$

where the last inequality follows because if $K \geq 2$, then [\(2.23\)](#page-14-0) implies $a \leq 2\sqrt{3}$ $\overline{2}$.

The growth functionals. Define a norm on \mathbb{R}^n by

$$
\|u\| := \left(\|u\|^2 + \sum_{j=1}^{M} N_j(u)^2\right)^{1/2}.
$$
\n(2.24)

Denote $r := 64$. Let h_0 be the largest integer so that $2^{2^{h_0}} \le 2^{n(h-1)/2}$, and note that $h_0 \le O(\log n)$. Define

$$
F_h(S) := 2 - \inf \left\{ ||u||^2 : u \in conv(S) \right\} + \frac{\max(h_0 + 1 - h, 0)}{\log n}, \qquad h = 0, 1, ..., h_0.
$$
 (2.25)

Recall that $T \subseteq B_2^n$ n_2^n and, along with [\(2.17\)](#page-12-1), this gives $\max_{u \in T} ||u||^2 \le 2$. Since $h_0 \le O(\log n)$, we have $F_0(T) \leqslant O(1)$.

From [\(2.23\)](#page-14-0), we have diam_d(T) \leq O(1). Note also that from [Lemma 2.19,](#page-15-0) it holds that the packing assumption [\(2.13\)](#page-9-4) is satisfied with $L \le O(1)$ and $k = n$. Therefore if we can verify that our functionals satisfy the growth conditions [\(2.12\)](#page-9-2) for $h = 0, 1, \ldots, h_0$, then we will conclude from [\(2.15\)](#page-9-6) that

$$
\gamma_2(T, d) \lesssim \frac{1}{c^*} + 1 \,. \tag{2.26}
$$

Consideration of (a, r) -separated sets. Define $K := N_{h+1}$ and consider points $\{x_1, \ldots, x_K\} \subseteq T$ such that $d(x_\ell, x_{\ell'}) \ge a$ whenever $\ell \ne \ell'$, along with sets $H_\ell \subseteq T \cap B_d(x_\ell, a/r)$ for $\ell = 1, ..., K$.

Let z_0 be a minimizer of $||u||^2$ over $u \in \text{conv}(\bigcup_{\ell \leq K} H_\ell)$, and note that $z_0 \in T$ since T is closed and convex. Define $\theta_0 := ||z_0||^2$ and

$$
\theta := \max_{\ell \leq K} \min \left\{ ||u||^2 : u \in \text{conv}(H_\ell) \right\},\
$$

and for each $\ell \in [K]$, let $z_{\ell} \in \text{conv}(H_{\ell})$ be such that $||z_{\ell}||^2 \le \theta$.

Note that $conv(H_\ell) \subseteq conv(B_d(x_\ell, a/r)) \subseteq B_d(x_\ell, 4a/r)$, where the latter inclusion follows from [Lemma 2.16.](#page-13-2) Since $z_\ell \in \text{conv}(H_\ell)$, we have $d(x_\ell, z_\ell) \leq 4a/r$ for all $\ell \in \{1, ..., K\}$. In particular for $\ell, \ell' \in \{1, \ldots, K\}$ with $\ell \neq \ell'$, we can use the quasimetric inequalities [\(2.19\)](#page-12-0) to write

$$
a \le d(x_{\ell}, x_{\ell'}) \le 2\sqrt{2} \left(d(x_{\ell}, z_{\ell}) + d(z_{\ell}, x_{\ell'}) \right)
$$

$$
\le 2\sqrt{2} \frac{4a}{r} + 8 \left(d(z_{\ell}, z_{\ell'}) + d(z_{\ell'}, x_{\ell'}) \right) \le (8 + 2\sqrt{2}) \frac{4a}{r} + 8 d(z_{\ell}, z_{\ell'}).
$$

Using our choice $r = 64$, we conclude that that for $l \neq l'$,

$$
d(z_{\ell}, z_{\ell'}) \geqslant \frac{a}{32} \,. \tag{2.27}
$$

Observe that

$$
F_h\left(\bigcup_{\ell\leq m}H_\ell\right)-\min_{\ell\leq K}F_{h+1}(H_\ell)=(2-\theta_0)-(2-\theta)+\frac{1}{\log n}=\theta-\theta_0+\frac{1}{\log n}\,,
$$

thus to verify that the growth condition [Definition 2.8](#page-9-0) holds for $\{F_h\}$, our goal is to show that

$$
\theta - \theta_0 + \frac{1}{\log n} \ge \frac{2^{h/2}a}{\kappa + \lambda \sqrt{\log n}}, \qquad h = 0, 1, \dots, h_0.
$$
 (2.28)

This will confirm the growth condition with c^* \asymp $\overline{1}$ $\lambda \sqrt{\log n} + \kappa$ \setminus^{-1} , and therefore [\(2.26\)](#page-15-1) yields our desired goal [\(2.20\)](#page-12-2).

The next lemma exploits 2-uniform convexity of the ℓ_2 distance. Note that the claimed inequality would fail (in general) if the left-hand side were replaced by the larger quantity $|||z_0 - z_\ell|||^2$, as $|||\cdot|||$ is not necessarily 2-convex.

Lemma 2.20. *For every* $\ell = 1, \ldots, K$ *, it holds that*

$$
||z_0 - z_{\ell}||^2 + \sum_{j=1}^{M} (N_j(z_0) - N_j(z_{\ell}))^2 \le 2(\theta - \theta_0).
$$

Proof. Let us use

$$
\left(\frac{a-b}{2}\right)^2 = \frac{1}{2}a^2 + \frac{1}{2}b^2 - \left(\frac{a+b}{2}\right)^2.
$$

to write

$$
\left\|\frac{z_0 - z_\ell}{2}\right\|^2 + \sum_{j=1}^M \left(\frac{N_j(z_0) - N_j(z_\ell)}{2}\right)^2 = \frac{1}{2} \left(\|z_\ell\|^2 + \sum_{j=1}^M N_j(z_\ell)^2\right) + \frac{1}{2} \left(\|z_0\|^2 + \sum_{j=1}^M N_j(z_0)^2\right) - \left\|\frac{z_0 + z_\ell}{2}\right\|^2 - \sum_{j=1}^M \left(\frac{N_j(z_0) + N_j(z_\ell)}{2}\right)^2.
$$

By convexity of the norm N_j , we have $\frac{1}{2}(N_j(z_0) + N_j(z_\ell)) \ge N_j(\frac{z_0 + z_\ell}{2})$, so the preceding identity gives

$$
\left\| \frac{z_0 - z_\ell}{2} \right\|^2 + \sum_{j=1}^M \left(\frac{N_j(z_0) - N_j(z_\ell)}{2} \right)^2 \le \frac{1}{2} \| |z_\ell\|^2 + \frac{1}{2} \| |z_0\|^2 - \left(\frac{z_0 + z_\ell}{2} \right)^2
$$

$$
\le \| |z_\ell\|^2 - \left(\frac{z_0 + z_\ell}{2} \right)^2
$$

$$
\le \theta - \theta_0,
$$

where the inequality $\left\| \frac{z_0 + z_{\ell}}{2} \right\|$ $\Vert^2 \ge \theta_0$ follows from $\frac{z_0 + z_\ell}{2} \in \text{conv}(\bigcup_{\ell \le K} H_\ell)$, since $z_0 \in \text{conv}(\bigcup_{\ell \le K} H_\ell)$ and $z_\ell \in \text{conv}(H_\ell)$.

Define $\rho := \theta - \theta_0$. One consequence of [Lemma 2.20](#page-16-0) is that

$$
z_1,\ldots,z_K\in z_0+\sqrt{2\rho}B_2^n
$$

.

We can cover $z_0 + \sqrt{2\rho} B_2^n$ $\frac{n}{2}$ by N_h sets that have $\|\cdot\|_N$ -diameter bounded by 2 $e_h(\sqrt{2\rho}B_2^n)$ $\frac{n}{2}$, $\|\cdot\|_{\mathcal{N}}$). Since we have $K = N_{h+1} = N_h^2$ points z_1, \ldots, z_K , at least N_h of them $z_{i_1}, \ldots, z_{i_{N_h}}$ must lie in the same set of the cover. And by definition, these points cannot all have pairwise $\|\cdot\|_{\mathcal{E}(z_0)}^2$ distance greater than $e_h(\sqrt{2\rho}B_2^n)$ $\|u\|_{\mathcal{E}(z_0)}$). Therefore we must have at least two points z_ℓ and $z_{\ell'}$ with $\ell \neq \ell'$ and $\ell, \ell' \geq 1$, and such that

$$
||z_{\ell} - z_{\ell'}||_N \le 2e_h(\sqrt{2\rho}B_2^n, ||\cdot||_N) \le 2^{-h/2}\kappa\sqrt{\rho},
$$

$$
||z_{\ell} - z_{\ell'}||_{\mathcal{E}(z_0)} \le e_h(\sqrt{2\rho}B_2^n, ||\cdot||_{\mathcal{E}(z_0)}) \le 2^{-h/2}\lambda\sqrt{\rho},
$$

where the latter two estimates follow from [Lemma 2.5](#page-7-3) and [Lemma 2.18,](#page-14-1) respectively.

Let us also note a second consequence of [Lemma 2.20,](#page-16-0) that

$$
\sum_{j=1}^{M} (N_j(z_0) - N_j(z_{\ell}))^2 + \sum_{j=1}^{M} (N_j(z_0) - N_j(z_{\ell'}))^2 \le 4\rho.
$$

Using the three preceding inequalities in [Lemma 2.17](#page-14-2) yields

$$
a^2 \stackrel{(2.27)}{\lesssim} d(z_\ell, z_{\ell'})^2 \lesssim 2^{-h} \rho^2 \kappa^2 + 2^{-h} \rho \lambda^2 \le \max \left(2^{-h} \kappa^2 \rho^2, 2^{-h} \lambda^2 \rho \right).
$$

This implies

$$
\rho \gtrsim \min\left(\frac{2^{h/2}a}{\kappa}, \frac{2^h a^2}{\lambda^2}\right).
$$

Since it holds that

$$
\frac{2^h a^2}{\lambda^2} + \frac{1}{\log n} \ge \frac{2^{h/2} a}{\lambda \sqrt{\log n}}
$$

,

.

we conclude that

$$
\rho+\frac{1}{\log n}\gtrsim \min\left(\frac{2^{h/2}a}{\kappa},\frac{2^{h/2}a}{\lambda\sqrt{\log n}}\right)\gtrsim \frac{2^{h/2}a}{\lambda\sqrt{\log n}+\kappa}
$$

Recalling that $\rho = \theta - \theta_0$, we have established [\(2.28\)](#page-16-2), completing the proof.

Remark 2.21 (Discussion of the implicit partitioning)**.** It is often more intuitive to think about bounding $\gamma_2(T, d)$ by explicitly constructing the sequence of partitions { \mathcal{A}_h } (recall [\(2.2\)](#page-5-4)). This is a technical process that is aided significantly by [Theorem 2.9,](#page-9-1) whose proof involves the construction of partitions from growth functionals.

Recall the norm $\|\cdot\|$ from [\(2.24\)](#page-15-2) and for a subset $S \subseteq B_2^n$ $n/2$, define the quantity

$$
\varphi(S) := 2 - \min \{ ||x||^2 : x \in \text{conv}(S) \}.
$$

Then $\varphi(S)$ can be considered as an approximate measure of the "size" of S, where sets of larger $\varphi(S)$ value tend to have a larger $\mathbb{E} \sup_{x \in S} \sum_{j=1}^{M} \varepsilon_j N_j(x)^2$ value.

Recall that $r := 64$. Consider a ball $B_d(x_0, \eta)$, and let $z_0 \in B_d(x_0, 4\eta)$ be such that $\varphi(B_d(x_0, \eta)) =$ 2 – $|||z_0|||^2$. Let us think of z_0 as the "analytic center" of the ball $B_d(x_0, \eta)$. (We have to take $z_0 \in B_d(x_0, 4\eta)$ because the ball $B_d(x_0, \eta)$ is only approximately convex.)

Define the distance

$$
\Delta(x, y) := \left(||x - y||^2 + \sum_{j=1}^{M} (N_j(x) - N_j(y))^2 \right)^{1/2}, \qquad x, y \in \mathbb{R}^n.
$$

For $x \in B_d(x_0, \eta)$, let $\hat{x} \in B_d(x, 4\eta/r^2)$ denote a point satisfying $\varphi(B_d(x, \eta/r^2)) = 2 - ||x||^2$. Then [Lemma 2.20](#page-16-0) gives

$$
\Delta(z_0, \hat{x})^2 \le \varphi\left(B_d(x_0, \eta)\right) - \varphi\left(B_d(x, \eta/r^2)\right). \tag{2.29}
$$

In other words, either the φ -value of $B_d(x, \eta/r^2)$ is significantly smaller than that of $B_d(x_0, \eta)$, or \hat{x} is close (in the distance Δ) to the analytic center z_0 .

The second part of the argument involves bounding the number of centers that can be within a certain distance of z_0 . Consider now any points $x_1, \ldots, x_M \in B_d(x_0, \eta)$ with $d(x_i, x_j) > \eta/r$ for $i \neq j$. [Lemma 2.17](#page-14-2) and the covering estimates on $e_h(B_2^n)$ $\binom{n}{2}$, $\|\cdot\|_{\mathcal{E}(z_0)}$ and $e_h(B_2^n)$ $\frac{n}{2}$, $\|\cdot\|_{\mathcal{N}}$) together give that for some constant $C > 0$,

$$
\#\left\{i\geqslant 1:\Delta(z_0,\hat{x}_i)^2\leqslant\rho\right\}\leqslant\exp\left(\frac{C}{\eta^2}\left(\kappa^2\rho^2+\lambda^2\rho\right)\right).
$$
\n(2.30)

Now [\(2.29\)](#page-18-1) and [\(2.30\)](#page-18-2) imply that for any $\delta > 0$,

$$
\#\left\{i\geqslant 1:\varphi\left(B_d(x_i,\eta/r^2)\right)\geqslant\varphi\left(B_d(x_0,\eta)\right)-\delta\right\}\leqslant\exp\left(\frac{C}{\eta^2}\left(\kappa^2\delta^2+\lambda^2\delta\right)\right).
$$
 (2.31)

This is the key tradeoff occuring in the argument: A bound on the number of pairwise separated "children" $B_d(x_i, \eta/r^2)$ of $B_d(x_0, \eta)$ that do not experience a significant reduction in their φ -value.

Employing this bound repeatedly, in a sufficiently careful manner, allows one to construct a sequence of partitions $\{\mathcal{A}_h\}$ that yields the desired upper bound on $\gamma_2(T, d)$. The role of [Theorem 2.9](#page-9-1) is to automate this process.

3 Hypergraph sparsification

Suppose $H = (V, E, w)$ is a weighted hypergraph and denote $n := |V|$. For a single hyperedge $e \in E$, let us recall the definitions

$$
Q_e(x) := \max_{\{u,v\} \in {e \choose 2}} (x_u - x_v)^2,
$$

as well as the energy

$$
Q_H(x) := \sum_{e \in E} w_e Q_e(x).
$$

3.1 Sampling

Suppose we have a probability distribution $\mu \in \mathbb{R}_+^E$ on hyperedges in H. Let us sample hyperedges $\tilde{E} = \{e_1, e_2, \ldots, e_M\}$ independently according to μ . The weighted hypergraph $\tilde{H} = (\tilde{V}, \tilde{E}, \tilde{\omega})$ is defined so that

$$
Q_{\tilde{H}}(x) = \frac{1}{M} \sum_{k=1}^{M} \frac{w_{e_k}}{\mu_{e_k}} Q_{e_k}(x),
$$

In particular, $\mathbb{E}[Q_{\tilde{H}}(x)] = Q_H(x)$ for all $x \in \mathbb{R}^V$. Recall that the hyperedge weights in \tilde{H} are given by [\(1.2\)](#page-2-2). To help us choose the distribution μ , we now introduce a Laplacian on an auxiliary graph.

An auxiliary Laplacian. Define the edge set $F := \bigcup_{e \in E}$ \int_{a}^{b} $\binom{e}{2}$, and let $G = (V, F, c)$ be a weighted graph, where we will choose the edge conductances $c \in \mathbb{R}_+^F$ later. Denote by $L_G : \mathbb{R}^V \to \mathbb{R}^V$ the weighted Laplacian

$$
L_G := \sum_{\{i,j\} \in F} c_{ij} (\chi_i - \chi_j) (\chi_i - \chi_j)^*,
$$
 (3.1)

where χ_1, \ldots, χ_n is the standard basis of \mathbb{R}^n . Let L_G^+ denote its Moore-Penrose pseudoinverse and define

$$
R_{ij} := ||L_G^{+/2}(\chi_i - \chi_j)||^2, \qquad \{i, j\} \in F,
$$

\n
$$
R_{\text{max}}(e) := \max \{R_{ij} : \{i, j\} \in {e \choose 2}\}, \qquad e \in E,
$$

\n
$$
Z := \sum_{e \in E} w_e R_{\text{max}}(e),
$$

\n
$$
\mu_e := \frac{w_e R_{\text{max}}(e)}{Z}, \qquad e \in E.
$$
\n(3.2)

Lemma 3.1. *Suppose it holds that*

$$
||x||^2 \le Q_H(L_G^{+/2}x), \qquad \forall x \in \mathbb{R}^n.
$$

Then for any $\varepsilon \in (0, 1)$ *, there is a number*

$$
M_0 \lesssim \frac{\log D}{\varepsilon^2} Z \log n
$$

such that for $M \geq M_0$, with probability at least 1/2, the hypergraph \tilde{H} is a spectral ε -sparsifier for H.

Proof. By convexity,

$$
\mathbb{E} \max_{\tilde{H} \, v: Q_H(v) \leq 1} \left| Q_H(v) - Q_{\tilde{H}}(v) \right| \leq \mathbb{E} \max_{\tilde{H}, \hat{H} \, v: Q_H(v) \leq 1} \left| Q_{\tilde{H}}(v) - Q_{\hat{H}}(v) \right|, \tag{3.4}
$$

where \hat{H} is an independent copy of \tilde{H} .

The latter quantity can be written as

$$
\underset{\tilde{e},\hat{e}}{\mathbb{E}}\max_{v:Q_H(v)\leq 1}\left|\frac{1}{M}\sum_{i=1}^M\frac{w_{\tilde{e}_i}}{\mu_{\tilde{e}_i}}Q_{\tilde{e}_i}(v)-\frac{1}{M}\sum_{i=1}^M\frac{w_{\hat{e}_i}}{\mu_{\hat{e}_i}}Q_{\hat{e}_i}(v)\right|
$$

$$
= \mathbb{E} \mathop{\mathbb{E}}_{\varepsilon} \mathop{\mathbb{E}}_{\tilde{\varepsilon},\hat{\varepsilon}} \max_{v:Q_H(v)\leq 1} \left| \frac{1}{M} \sum_{i=1}^M \varepsilon_i \left(\frac{w_{\tilde{e}_i}}{\mu_{\tilde{e}_i}} Q_{\tilde{e}_i}(v) - \frac{w_{\hat{e}_i}}{\mu_{\hat{e}_i}} Q_{\hat{e}_i}(v) \right) \right| \tag{3.5}
$$

$$
\leq 2 \mathop{\mathbb{E}}_{\tilde{H}} \mathop{\mathbb{E}}_{\varepsilon} \max_{v:Q_H(v)\leq 1} \left| \frac{1}{M} \sum_{i=1}^{M} \varepsilon_i \frac{w_{e_i}}{\mu_{e_i}} Q_{e_i}(v) \right|, \tag{3.6}
$$

where $\varepsilon_1, \ldots, \varepsilon_M$ are i.i.d. Bernoulli ±1 random variables. Note that we can introduce signs in [\(3.5\)](#page-20-0) because the distribution of $\frac{w_{\tilde{e}_i}}{\mu_{\tilde{e}_i}}Q_{\tilde{e}_i}(v) - \frac{w_{\tilde{e}_i}}{\mu_{\tilde{e}_i}}Q_{\hat{e}_i}(v)$ is symmetric.

For $e \in E$ and $\{i, j\} \in {e \choose 2}$ $\binom{e}{2}$, define the vectors

$$
y_{ij} := L_G^{+/2}(\chi_i - \chi_j)
$$

$$
y_{ij}^e := \sqrt{\frac{w_e}{\mu_e}} y_{ij} = \sqrt{\frac{Z}{R_{\text{max}}(e)}} y_{ij}.
$$

Then we have

$$
\frac{w_e}{\mu_e} Q_e(L_G^{+/2}x) = \frac{w_e}{\mu_e} \max_{\{i,j\} \in {e \choose 2}} |\langle L_G^{+/2}x, \chi_i - \chi_j \rangle|^2 = \max_{\{i,j\} \in {e \choose 2}} \langle x, y_{ij}^e \rangle^2.
$$
(3.7)

Define the values

$$
S_{ij} := \max_{e \in E: \{i,j\} \in \binom{e}{2}} \|y_{ij}^e\|, \quad \{i,j\} \in F,
$$

and the linear map $A: \mathbb{R}^n \to \mathbb{R}^F$ by $(Ax)_{\{i,j\}} := S_{ij}\langle x, y_{ij}/||y_{ij}||$.

For $k = 1, ..., M$, define the weighted ℓ_{∞} norms

$$
N_k(z) := \max\left\{ \left| (Az)_{\{i,j\}} \right| \frac{ \| y_{ij}^{e_k} \|}{S_{ij}} : \{i,j\} \in \binom{e_k}{2}, S_{ij} > 0 \right\}.
$$

It holds that

$$
N_k(x) = \max_{\{i,j\} \in e_k} |\langle x, y_{ij}^{e_k} \rangle|,
$$

so from [\(3.7\)](#page-20-1), we have

$$
Q_{\tilde{H}}(L_G^{+/2}x) = \frac{1}{M} \sum_{i=1}^{M} N_i(x)^2, \qquad (3.8)
$$

$$
\frac{1}{M} \sum_{i=1}^{M} \varepsilon_i \frac{w_{e_i}}{\mu_{e_i}} Q_{e_i} (L_G^{+/2} x) = \frac{1}{M} \sum_{i=1}^{M} \varepsilon_i N_i(x)^2.
$$
 (3.9)

Thus we can write the quantity (3.6) as

$$
2\mathop{\mathbb{E}}_{\tilde{H}}\mathop{\mathbb{E}}_{\varepsilon} \max_{x: Q_H(L_G^{+/2}x) \leq 1} \left| \frac{1}{M} \sum_{i=1}^M \varepsilon_i N_i(x)^2 \right| \leq 4\mathop{\mathbb{E}}_{\tilde{H}} \mathop{\mathbb{E}}_{x: Q_H(L_G^{+/2}x) \leq 1} \frac{1}{M} \sum_{i=1}^M \varepsilon_i N_i(x)^2,
$$

Define $T := \{x \in \mathbb{R}^n : Q_H(L_G^{+/2}x) \leq 1\}$ and note that from [\(3.3\)](#page-19-1), we have $T \subseteq B_2^n$ $\frac{n}{2}$. Now apply [Corollary 2.13](#page-11-1) to bound

$$
\mathbb{E} \max_{\varepsilon} \frac{1}{x \in T} \frac{M}{M} \sum_{i=1}^{M} \varepsilon_i N_i(x)^2 \le \frac{\|A\|_{2 \to \infty} \sqrt{\log n \log D}}{M^{1/2}} \max_{x \in T} \left(\frac{1}{M} \sum_{i=1}^{M} N_i(x)^2 \right)^{1/2}.
$$
 (3.10)

Note also that

$$
\max_{x \in T} \frac{1}{M} \sum_{i=1}^{M} N_i(x)^2 = \max_{v: Q_H(v) \leq 1} \frac{1}{M} \sum_{i=1}^{M} N_i \left(L_G^{1/2} v \right)^2 = \max_{v: Q_H(v) \leq 1} Q_{\tilde{H}}(v).
$$

where the first equality follows from the fact that $Q_H(x) = Q_H(\hat{x})$ when $x - \hat{x} \in \text{ker}(L_G)$, and the second inequality uses this and an application of [\(3.8\)](#page-20-3) with $x = L_G^{1/2}v$.

Recalling our starting point [\(3.4\)](#page-19-2), it follows that for some universal constant $C > 0$,

$$
\begin{aligned} \tau &:= \underset{\tilde{H}}{\mathbb{E}}\max_{v: Q_H(v) \leq 1}\left|Q_H(v) - Q_{\tilde{H}}(v)\right| \leq C\frac{\|A\|_{2\to\infty}\sqrt{\log n\log D}}{M^{1/2}}\underset{\tilde{H}}{\mathbb{E}}\left(\max_{v: Q_H(v) \leq 1}Q_{\tilde{H}}(v)\right)^{1/2}\\ &\leq C\frac{\|A\|_{2\to\infty}\sqrt{\log n\log D}}{M^{1/2}}\left(\underset{\tilde{H}}{\mathbb{E}}\max_{v: Q_H(v) \leq 1}Q_{\tilde{H}}(v)\right)^{1/2}, \end{aligned}
$$

where the last inequality is by concavity of the square root.

Observe that

$$
\max_{v:Q_H(v)\leq 1} Q_{\tilde{H}}(v) \leq \max_{v:Q_H(v)\leq 1} (|Q_H(v) - Q_{\tilde{H}}(v)| + Q_H(v)) \leq 1 + \max_{v:Q_H(v)\leq 1} |Q_H(v) - Q_{\tilde{H}}(v)|,
$$

and therefore we have

$$
\tau \leq C \frac{\|A\|_{2\to\infty} \sqrt{\log n \log D}}{M^{1/2}} (1+\tau)^{1/2} .
$$

It follows that if $M \geqslant (2C||A||_{2\to\infty}\sqrt{\log n\log D})^2$, then $\tau \leqslant 4C \frac{||A||_{2\to\infty}\sqrt{\log n\log D}}{M^{1/2}}$ $\frac{\sqrt{108 \pi \log B}}{M^{1/2}}$. For $0 < \varepsilon < 1$, choosing

$$
M := \frac{4C^2 \log D}{\varepsilon^2} ||A||_{2 \to \infty}^2 \log n
$$

gives

$$
\mathop{\mathbb{E}}_{\tilde{H}} \max_{v: Q_H(v) \leq 1} |Q_H(v) - Q_{\tilde{H}}(v)| = \tau \leq \varepsilon.
$$

The proof is complete once we observe that

$$
||A||_{2\to\infty}^2 = \max_{\{i,j\}\in F} S_{ij}^2 = \max_{e \in E, \{i,j\}\in {e \choose 2}} ||y_{ij}^e||^2 = Z \max_{\{i,j\}\in {e \choose 2}} \frac{R_{ij}}{R_{\max}(e)} \le Z.
$$

3.2 Choosing conductances

We are therefore left to find edge conductances in the graph $G = (V, F, c)$ so that [\(3.3\)](#page-19-1) holds and Z is small. To this end, let us choose nonnegative numbers

$$
\left\{c_{ij}^{e} \geq 0 : \{i, j\} \in \binom{e}{2}, e \in E\right\}
$$
\n
$$
\sum_{\{i, j\} \in \binom{e}{2}} c_{ij}^{e} = w_e, \quad \forall e \in E.
$$
\n(3.11)

such that

For
$$
\{i, j\} \in F
$$
, we then define our edge conductance

$$
c_{ij} := \sum_{e \in E: \{i,j\} \in {e \choose 2}} c_{ij}^e.
$$
 (3.12)

In this case,

$$
||L_G^{1/2}v||^2 = \langle v, L_G v \rangle = \sum_{\{i,j\} \in F} c_{ij}(v_i - v_j)^2
$$

=
$$
\sum_{e \in E} \sum_{\{i,j\} \in {e \choose 2}} c_{ij}^e (v_i - v_j)^2
$$

$$
\leqslant \sum_{e \in E} \sum_{\{i,j\} \in {e \choose 2}} c_{ij}^e \max_{\{i,j\} \in {e \choose 2}} (v_i - v_j)^2
$$

$$
\leqslant \sum_{e \in E} w_e \max_{\{i,j\} \in {e \choose 2}} (v_i - v_j)^2 = Q_H(v).
$$

Taking $v = L_G^{+/2}x$ gives

$$
||x||^2 \leq Q_H(L_G^{+/2}x),
$$

verifying [\(3.3\)](#page-19-1).

Lemma 3.2 (Foster's Network Theorem). *It holds that* $\sum_{\{i,j\} \in F} c_{ij} R_{ij} \leq n - 1$.

Proof. Recall that
$$
R_{ij} = \langle \chi_i - \chi_j, L_G^+(\chi_i - \chi_j) \rangle
$$
 and $L_G = \sum_{\{i,j\} \in F} c_{ij} (\chi_i - \chi_j) (\chi_i - \chi_j)^*$. It follows that\n
$$
\sum_{\{i,j\} \in F} c_{ij} R_{ij} = \sum_{\{i,j\} \in F} tr(c_{ij} (\chi_i - \chi_j) (\chi_i - \chi_j)^* L_G^+) = tr(L_G L_G^+) \le n - 1,
$$

since rank $(L_G) \leq n - 1$.

Define

$$
K := \max_{e \in E} \max_{\{i,j\} \in {e \choose 2}} \frac{\mathsf{R}_{\max}(e)}{\mathsf{R}_{ij}} \mathbb{1}_{\{c_{ij}^e > 0\}}
$$
(3.13)

so that

$$
Z = \sum_{e \in E} w_e \mathsf{R}_{\text{max}}(e) = \sum_{e \in E} \sum_{\{i,j\} \in \binom{e}{2}} c_{ij}^e \mathsf{R}_{\text{max}}(e) \leq K \sum_{e \in E} \sum_{\{i,j\} \in \binom{e}{2}} c_{ij}^e \mathsf{R}_{ij} \leq K(n-1)\,,
$$

where the last inequality uses [\(3.12\)](#page-22-2) and [Lemma 3.2.](#page-22-3) In conjunction with [Lemma 3.1,](#page-19-3) we have proved the following.

Lemma 3.3. *Suppose there is a choice of conductances so that* [\(3.11\)](#page-22-1) *holds. Then for any* $\varepsilon > 0$ *, there is a* spectral ϵ -sparsifier for H with at most $O(K\frac{\log D}{\varepsilon^2})$ $\frac{g}{\epsilon^2}$ n $\log n$) hyperedges, where K is defined in [\(3.13\)](#page-22-4).

3.3 Balanced effective resistances

We will exhibit conductances satisfying (3.11) and (3.13) with $K \le 1$. To this end, we may assume that the weighted hypergraph $H = (V, E, w)$ has strictly positive edge weights and that the (unweighted) graph $G_0 = (V, F)$ is connected.

Define $\hat{F} := \{(e, \{i, j\}) : e \in E, \{i, j\} \in {e \choose 2} \}$ $\{e\}\{e_j\}$, and consider vectors $\left(c_{ij}^e : e \in E, \{i,j\} \in \binom{e}{2}\right)$ $\binom{e}{2}$ $\in \mathbb{R}$ ^{\hat{F}}. Define the convex set

$$
\mathsf{K} := \mathbb{R}^{\hat{F}}_{+} \cap \left\{ \sum_{\{i,j\} \in {e \choose 2}} c_{ij}^{e} = w_{e} : e \in E \right\}.
$$

We use S_{+}^n and S_{++}^n for the cones of positive semidefinite (resp., positive definite) $n \times n$ matrices. Define $c_{ij} := \sum$ $e:\{i,j\}\in\binom{e}{2}$ C_{ij}^e and denote the linear function $L_G: \mathbb{R}_+^{\tilde{F}} \to \mathcal{S}_+^n$ by

$$
L_G\left((c_{ij})\right) := \sum_{\{i,j\} \in F} c_{ij}(\chi_i - \chi_j)(\chi_i - \chi_j)^*.
$$

Let *be the all-ones matrix and consider the objective*

$$
\Phi\left((c_{ij})\right) := -\log \det \left(L_G\left((c_{ij})\right) + J\right) \, .
$$

Note that $X \mapsto -\log \det(X)$ is a convex function on the cone S_{+}^{n} of $n \times n$ positive semidefinite matrices (see, e.g., [\[BV04,](#page-25-11) §3.1]) and takes the value $+\infty$ on $S^n_+ \setminus S^n_{++}$. Consider finally the convex optimization problem:

$$
\min\left\{\Phi\left((c_{ij})\right) : (c_{ij}^e) \in \mathsf{K}\right\}.
$$
\n(3.14)

Since G_0 is connected, it holds that if $(c_{ij}) \in \mathbb{R}^F_{++}$, then ker (L_G) is the span of $(1, 1, ..., 1)$, and therefore $L_G((c_{ij})) + J \in S_{++}^n$. Therefore Φ is finite on the strictly positive orthant \mathbb{R}_{++}^F .

Lemma 3.4. *The value of* [\(3.14\)](#page-23-1) *is finite and there is a feasible point in the relative interior of* K*.*

Proof. It is straightforward to check that the maximum of eigenvalue of L_G is bounded by 2Σ $\{i,j\}\in\binom{e}{2}$ $c_{ij} = 2 \sum_{e \in E} w_e$, hence the value of [\(3.14\)](#page-23-1) is finite. Moreover, the vector defined by $\frac{1}{2}$ $c_{ij}^e := \frac{1}{\sqrt{\frac{e}{n}}}$ $\vert \begin{pmatrix} e \\ 2 \end{pmatrix} \vert$ w_e is feasible and lies in ℝ \hat{F}_+ since the weights w_e are strictly positive. \Box

We can write the corresponding Lagrangian as

$$
g\left((c_{ij}^e); \alpha, \beta\right) = -\log \det \left(L_G\left((c_{ij})\right) + J\right) + \sum_{e \in E} \alpha_e \left(\sum_{\{i,j\} \in {e \choose 2}} c_{ij}^e - w_e\right) - \sum_{e \in E} \sum_{\{i,j\} \in {e \choose 2}} \beta_{ij}^e c_{ij}^e
$$

[Lemma 3.4](#page-23-2) allows one to conclude that there are vectors $(\hat{c}^e_{ij}), \hat{\alpha}, \hat{\beta}$ with $\hat{\beta} \geqslant 0$ and such that the KKT conditions hold; see [\[Roc70,](#page-25-12) Thm 28.2]. In particular, for all $e \in E$ and $\{i, j\} \in \binom{e}{2}$ $_2^e$), we have

$$
\partial_{c_{ij}^e} g\left((\hat{c}_{ij}^e); \hat{\alpha}, \hat{\beta}\right) = 0 \tag{3.15}
$$

$$
\hat{\beta}_{ij}^e > 0 \implies \hat{c}_{ij}^e = 0. \tag{3.16}
$$

By the rank-one update formula for the determinant, we have

$$
\partial_{c_{ij}^e} \log \det(L_G + J) = \langle \chi_i - \chi_j, (L_G + J)^{-1}(\chi_i - \chi_j) \rangle.
$$

Define $\hat{L}_G := L_G((\hat{c}_{ij}))$. Define $\hat{\mathsf{R}}_{ij} := \langle \chi_i - \chi_j, \hat{L}_G^+(\chi_i - \chi_j) \rangle$. Taking the derivative of g with respect to each c_{ij}^e and using [\(3.15\)](#page-24-3) gives

$$
\hat{\mathsf{R}}_{ij} = \langle \chi_i - \chi_j, (\hat{L}_G + J)^{-1}(\chi_i - \chi_j) \rangle = \hat{\alpha}_e - \hat{\beta}_{ij}^e, \qquad \forall e \in E, \{i, j\} \in \binom{e}{2},
$$

where the first equality uses the fact that the eigenvectors of L_G and J are orthogonal and $\chi_i - \chi_j \in$ ker J.

Note that since $\hat{\beta} \ge 0$ coordinate-wise, this implies that

$$
\widehat{\mathsf{R}}_{\max}(e) := \max_{\{i,j\} \in \binom{e}{2}} \widehat{\mathsf{R}}_{ij} \leq \widehat{\alpha}_e.
$$

Moreover, if $\hat{c}^e_{ij}>0$, then $\hat{\beta}^e_{ij}=0$ (cf. [\(3.16\)](#page-24-4)), and in that case $\hat{\sf R}_{ij}=\hat{\alpha}_e=\hat{\sf R}_{\rm max}(e)$.

We conclude that the edge conductances \hat{c}^e_{ij} yield $K \leq 1$ in [\(3.13\)](#page-22-4), and therefore [Lemma 3.3](#page-23-3) gives a sparsifier with $O(\frac{\log D}{\varepsilon^2})$ $\frac{gD}{\epsilon^2}$ n log n) edges, completing the proof of [Theorem 1.1.](#page-1-0)
