Control Barrier Function Contracts for Vehicular Mission Planning Under Signal Temporal Logic Specifications

Muhammad Waqas¹, Nikhil Vijay Naik¹, Petros Ioannou¹, and Pierluigi Nuzzo¹

Abstract—We present a compositional control synthesis method based on assume-guarantee contracts with application to correct-by-construction design of vehicular mission plans. In our approach, a mission-level specification expressed in a fragment of signal temporal logic (STL) is decomposed into predicates defined on non-overlapping time intervals. The STL predicates are then mapped to an aggregation of contracts associated with continuously differentiable time-varying control barrier functions. The barrier functions are used to constrain the lower-level control synthesis problem, which is solved via quadratic programming. Our approach can avoid the conservatism of previous methods for task-driven control based on under-approximations. We illustrate its effectiveness on a case study motivated by vehicular mission planning under safety constraints as well as constraints imposed by traffic regulations under vehicle-to-vehicle and vehicle-toinfrastructure communication.

Index Terms—Signal temporal logic, control synthesis, contract-based design, control barrier functions.

I. Introduction

The necessity of ensuring mission safety of autonomous cyber-physical systems such as vehicles immersed in an urban setting [1], [2] has motivated the development of correct-by-construction, algorithmic control synthesis methods (see, e.g., [3], [4]) to ensure that a safety-critical system fulfills its mission requirements while avoiding potentially hazardous configurations.

A major challenge to control synthesis stems from the heterogeneity of formalisms needed to design and analyze complex cyber-physical systems [5]. Some of the efforts in the literature leverage symbolic approaches to effectively synthesize provably correct high-level task planners. However, by relying on discrete abstractions of the design space, these methods may be prone to scalability issues when applied to complex continuous systems. On the other hand, low-level feedback control synthesis methods have shown to be effective in enforcing invariance and simple reachability properties on continuous systems. They have, however, difficulty in capturing more complicated mission constraints, including logical constraints, often inducing discontinuities in the target safe sets. More recently, the representation of the mission specification in an expressive logic language, such as signal temporal logic (STL), together with mixed integer linear encodings

of the STL formulas [6] have been proposed to perform discrete-time trajectory planning in a model predictive control fashion for a wider class of objectives, including time-sensitive constraints. However, efficiently encompassing mission-level (logical) and control-level (dynamical) constraints within a unifying framework remains a challenge.

Compositional and hierarchical methods show the promise of harnessing the complexity due to the scale and heterogeneity of the control design problem, e.g., via a layered approach that can capture different kinds of constraints at different layers, without inducing excessive conservatism in the solutions. In this context, assume-guarantee (A/G) contracts have been employed [7], [8] to support compositional synthesis under temporal logic specifications. A/G reasoning has also been explored to argue about the correct composition of lane keeping and cruise control for vehicular planning [9]. However, a full-fledged A/G contract framework that can effectively bridge high-level planning and continuous-time feedback control is an open research problem.

This paper addresses the above challenges by exploring a formalization of control barrier functions in terms of assume-guarantee contracts capable of bridging high-level task planning and low-level feedback control. Central to our approach is the characterization of time-varying safe sets via a composition of continuously differentiable time-varying control barrier function (\mathcal{C}^1 TV-CBF) contracts that can capture time-varying constraints including jump discontinuities. By building on this abstraction, we introduce a control synthesis algorithm that maps a mission-level specification expressed in a fragment of STL to an aggregation of contracts associated with \mathcal{C}^1 TV-CBFs. The barrier functions are used to constrain the lower-level control synthesis problem, which is solved via quadratic programming.

Our method is reminiscent of previous approaches to STL control synthesis using CBFs [10], in that we associate candidate CBFs with atomic STL predicates in the specification. However, our approach can mitigate the potential conservatism induced by previous methods, based on concatenating multiple CBFs via a pointwise minimum operator and approximating the result via a smooth function, which may lead to overly defensive behaviors.

Our synthesis algorithm is also inspired by funnel-based control synthesis [11], where funnels associated with controllers from a predefined library are sequentially composed.

In a funnel-based approach, the current funnel is required to be a subset of the upcoming funnel at the time of switching (see Fig. 1). Our approach is, instead, based on the composition of time-varying safe sets, without *a priori* constraining

Fig. 1: In a funnel-based approach funnels are composable at time $t=t_1$ only under scenario (a) $C_1(t_1)\subseteq C_2(t_1)$. Our approach is based on the composition of time-varying safe sets expressed by contracts. Contracts compatibility requires $C_1(t_1)\cap C_2(t_1)\neq\emptyset$ holds, as in scenario (b).

the architecture of the controller that will be engaged. We can then relax the requirement that the current set be a subset of the upcoming one by relying on a time-varying version of a finite-time convergence CBF contract [12]. Our contributions can be summarized as follows:

- We formalize a notion of *time-varying finite-time convergence control barrier function* (TV-FCBF) as a contract providing an effective interface between task planning and feedback control synthesis.
- We determine necessary and sufficient conditions for the composition of two TV-FCBF contracts to generate a consistent contract, for which a controller is guaranteed to exist. Our compositional approach can capture timevarying constraints with jump discontinuities while avoiding the conservatism often induced by smooth underapproximations of the resulting safe sets.
- We introduce an algorithm to map an STL mission specification into an aggregation of CBF contracts from which a feedback controller can be designed by formulating and solving a quadratic program.

We demonstrate the effectiveness of the proposed approach on a case study of vehicular motion planning under safety and regulatory constraints like traffic signals and variable speed limit under vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communication.

II. BACKGROUND

We present a review of A/G contracts, followed by an overview of CBFs and STL.

1) A/G Contracts: A contract \mathcal{C} for a component M is a triple (V, A, G), where V is a set of variables, and A and G are sets of behaviors over V. A, termed the assumptions, encode the assumptions made by M on its operational environment. G is the set of guarantees, i.e., the collection of behaviors promised by M provided that the environment satisfies A. We say that M satisfies \mathcal{C} when all the behaviors of M composed with A are contained in G. A contract is consistent if there exists a valid implementation M, i.e., $G \cup \overline{A}$ is nonempty. It is said to be compatible, if there exists a valid environment E, i.e., A is nonempty. We can compare two contracts \mathcal{C}_1 and

 \mathcal{C}_2 through the *refinement* operation, which is a preorder on contracts. We say that \mathcal{C}_1 refines \mathcal{C}_2 and write $\mathcal{C}_1 \leq \mathcal{C}_2$ if and only if \mathcal{C}_1 has weaker assumptions and stronger guarantees. The *conjunction* of two contracts \mathcal{C}_1 and \mathcal{C}_2 is defined as the contract serving as the greatest lower bound which refines both. This can be used to represent a combination of requirements that must be satisfied simultaneously. The *composition* of contracts is, instead, used to derive a more complex contract that must be satisfied by a composition of components, each satisfying its local contract. A detailed exposition of all the terms summarized above may be found in the references [13], [14].

2) Control Barrier Functions: We assume that a dynamical system, e.g., describing the ego vehicle, is governed by the dynamics

$$\dot{\mathbf{x}} = f(\mathbf{x}) + g(\mathbf{x})u,\tag{1}$$

where f,g are locally Lipschitz-continuous functions of the system states $\mathbf{x} \in D \subseteq \mathbb{R}^n$, $u \in U \subseteq \mathbb{R}^m$ is the input vector, and U is the set of allowable inputs. CBFs are used to provide safety guarantees for such systems.

Definition 1 (Control Barrier Function [3]). Let $h(\mathbf{x}) : \mathbb{R}^n \to \mathbb{R}$ be a continuously-differentiable function and let $C \subseteq D \subseteq \mathbb{R}^n$ be a compact superlevel set of $h(\mathbf{x})$ such that $C = \{\mathbf{x} \in D : h(\mathbf{x}) \geq 0\}$. We say that h is a Control Barrier Function (CBF) if there exists an extended \mathcal{K}_{∞} class function α such that, for all $\mathbf{x} \in D$, the following holds:

$$\sup_{u \in U} \left[L_f h(\mathbf{x}) + L_g h(\mathbf{x}) u \right] \ge -\alpha(h(\mathbf{x})). \tag{2}$$

 $L_f h(\mathbf{x}) = \frac{dh(\mathbf{x})}{dt} f(\mathbf{x})$ and $L_g h(\mathbf{x}) = \frac{dh(\mathbf{x})}{dt} g(\mathbf{x})$ are the appropriate Lie derivatives. C is the safe set corresponding to the CBF [3].

It can be proven [3], [15] that any controller $u \in \mathcal{U}_{safe} = \{u \in U : L_f h(\mathbf{x}) + L_g h(\mathbf{x}) u \geq -\alpha(h(\mathbf{x}))\}$ ensures that, if the system starts in C, i.e., $\mathbf{x}(t_0) \in C$, then it will stay in C. The existence of a CBF is then equivalent to ensuring the forward-invariance property of the safe set C, hence rendering the system evolution safe, given safety conditions on its initial states. The notion of finite-time convergence CBF (FCBF) has been proposed for time-invariant CBFs of relative degree 1 [12] to ensure finite-time guarantees of convergence to the safe set. In this paper, we extend the concept of FCBF to time-varying CBF of relative degree 1 and formalize them as A/G contracts.

3) Signal Temporal Logic: We represent the mission specification using STL [16], which offers a rigorous formalism for the specification and analysis of temporal properties of real-valued dense-time signals. In STL, Boolean predicates ϕ_h are evaluated over real-valued predicate functions $h(\mathbf{x}) : \mathbb{R}^n \to \mathbb{R}$. ϕ_h evaluates to true if and only if the function $h(\mathbf{x}) \geq 0$, and false otherwise. The recursive construction of generic STL formulae may be found in [16]. In our work, we consider the

following fragment of STL, consisting of formulas defined using the following grammar:

$$\psi := \top \mid \phi_h \mid \neg \phi_h \mid \mathcal{G}_{\Gamma} \phi_h \mid \mathcal{F}_{\Gamma} \phi_h \mid \neg \psi \mid \psi_1 \wedge \psi_2 \qquad (3)$$

where ϕ_h is an STL predicate, ψ, ψ_1, ψ_2 are STL formulas.

 \mathcal{G} and \mathcal{F} are the *globally* and *eventually* temporal operators, respectively. Γ is a time interval capturing the horizon of these temporal operations. In this paper, we will consider an STL fragment which does not consider the nesting of temporal operations. Thus, the horizon of our STL formulas is union of all Γ over which the operators are defined. If there exists $\mathbf{x} \in \mathbb{R}^n$ such that formula ψ holds at time $t \in \Gamma$, then we write $(\mathbf{x}, t) \models \psi$. The formula is satisfied if $(\mathbf{x}, 0) \models \psi$.

III. CONTROL BARRIER FUNCTION A/G CONTRACTS

We begin by extending classical results from finite-time convergence CBFs [12] to a new class of CBFs, which we call time-varying finite-time convergence CBFs (FCBFs). We show that FCBFs can be formalized as A/G contracts. Their composition leads, in general, to piecewise continuously differentiable (\mathcal{C}^1) TV-CBF contracts for which a controller is guaranteed to exist.

Definition 2 (Time-Varying Finite-Time Convergence CBF (TV-FCBF)). Let $h(t, \mathbf{x}) : \mathbb{R}_{\geq 0} \times \mathbb{R}^n \to \mathbb{R}$ be a continuously differentiable function. Let $C(t) \subseteq D \subseteq \mathbb{R}^n$ be the compact superlevel set of $h(t, \mathbf{x})$. If for the system in (1) there exist $0 \leq \rho < 1$ and $\gamma > 0$ such that, $\forall t \geq 0, \forall \mathbf{x} \in D$, we have

$$\sup_{u \in U} \left[\frac{\partial}{\partial t} h(t, \mathbf{x}) + L_f h(t, \mathbf{x}) + L_g h(t, \mathbf{x}) u + \gamma \operatorname{sign}(h(t, \mathbf{x})) |h(t, \mathbf{x})|^{\rho} \right] \ge 0,$$

then $h(t, \mathbf{x})$ is a Time-Varying Finite-Time Convergence CBF.

When $h(t, \mathbf{x}) = h(\mathbf{x})$ the TV-FCBF reduces to a FCBF [12]. For a given $h(t, \mathbf{x})$, the set of safe inputs is

$$\mathcal{U}_{safe}(t) = \{ u \in U : \frac{\partial}{\partial t} h(t, \mathbf{x}) + L_f h(t, \mathbf{x}) + L_g h(t, \mathbf{x}) u + \gamma \operatorname{sign}(h(t, \mathbf{x})) |h(t, \mathbf{x})|^{\rho} \ge 0 \}.$$

The following theorem discusses the finite-time convergence property of a TV-FCBF.

Theorem 1. Given that the C(t) be the superlevel set of the continuously differentiable function $h(t, \mathbf{x}) : \mathbb{R}_{\geq 0} \times \mathbb{R}^n \to \mathbb{R}$ as in Definition 2, with corresponding $0 \leq \rho < 1$ and $\gamma > 0$, and the initial state be $\mathbf{x}(t_0) = \mathbf{x}_0 \in C(t_0)$, any controller $u \in \mathcal{U}_{safe}(t)$ renders C(t) forward-invariant $\forall t > t_0$. Moreover, if $\mathbf{x}_0 \in D \setminus C(t_0)$ then $u \in \mathcal{U}_{safe}(t)$ drives \mathbf{x} to C(t) within a finite time $T = \frac{1}{\gamma(1-\rho)}|h(t_0, \mathbf{x}_0)|^{1-\rho}$.

Proof. The proof follows the same line of reasoning as previous results [12]. Consider the candidate Lyapunov function $V(t, \mathbf{x}) = \max(0, -h(t, \mathbf{x}))$. When $\mathbf{x}_0 \in C(t_0)$, then $h(t_0, \mathbf{x}) \geq 0$ and $V(t, \mathbf{x}) = 0$ hold. By the comparison lemma [17], we obtain $V(t, \mathbf{x}) = 0$ for all $t > t_0$, hence $\mathbf{x}(t) \in C(t) \ \forall t > t_0$. When $\mathbf{x}_0 \in D \setminus C(t_0)$, then we have

 $V(t_0,\mathbf{x}_0)>0$ and $\dot{V}(t,\mathbf{x})\leq -\gamma V^{\rho}(t,\mathbf{x}) \ \forall t\geq t_0$. Again, by the comparison lemma [17], \mathbf{x} will converge to C(t) within the finite time $T=\frac{1}{\gamma(1-\rho)}|h(t_0,\mathbf{x_0})|^{1-\rho}$, i.e., $\mathbf{x}(t)\in C(t)$ $\forall t\geq t_0+T$.

We also say that $C_h(t) = \{ \mathbf{x} \in D : h(t, \mathbf{x}) \ge 0 \}$ is the safe set for the barrier function $h(t, \mathbf{x})$.

TV-FCBFs can mitigate the conservatism of concatenating multiple CBFs via a min operator and taking a smooth approximation of the result, as illustrated by the following example.

Example 1. For a simple vehicle model, $\dot{\mathbf{x}} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \mathbf{x} + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \mathbf{x}$

 $egin{bmatrix} 0 \ 1 \end{bmatrix} u$, where $u \in \mathbb{R}$ is the input acceleration and $\mathbf{x} =$

 $\begin{bmatrix} X & V \end{bmatrix}^T$, with $X \in \mathbb{R}$ and $V \in \mathbb{R}_{\geq 0}$ being the position and the velocity of the vehicle, let us consider the STL formula $\bigwedge_{i>1}^N \mathcal{G}_{[t_{i-1},t_i)}\phi_i$,

where the predicates $\phi_i := V_{max,i} - V$ are defined over N non-overlapping adjacent intervals, that is $\Gamma_i = [t_{i-1}, t_i)$ and $\Gamma_i \cap \Gamma_{i+1} = \emptyset$ for $1 \le i \le N$.

The formula ϕ_i prescribes a maximum speed limit in i^{th} time interval Γ_i .

A method to synthesize a controller satisfying this formula would associate a CBF $h_i(\mathbf{x}) := V_{max,i} - V$ with each predicate ϕ_i and combine them via a smooth under-approximation of the pointwise \min operator [10]. However, this procedure would result into an overly conservative requirement, always yielding a speed limit that is stricter than $\min_{1 \le i \le N} (V_{max,i} - V)$. We show that a combination of TV-CBF and TV-FCBF formalized as contracts can mitigate this conservatism.

The notion of invariance can be formalized as a *contract*. The contract algebra can then be used to reason about the composition of invariance properties and derive conditions for control synthesis.

Definition 3 (TV-CBF Contract). A TV-CBF contract $C_h = (V, A_h, G_h)$ is defined as follows:

$$V = \{t, \mathbf{x} = (x_1, \dots, x_n)\},$$

$$A_h := \mathbf{x}(t_0) \in C_h(t_0),$$

$$G_h := \forall t > t_0 : \mathbf{x}(t) \in C_h(t),$$

$$(4)$$

where $C_h(t)$ is the superlevel set corresponding to $h(t, \mathbf{x})$ and t_0 is the initial time.

Definition 4 (TV-FCBF Contract). A TV-FCBF contract $C_h = (V, A_h, G_h)$ is defined as follows:

$$A_h := \exists \ t_{conv} > 0 : \forall \ t \in [t_0, t_0 + t_{conv}) : \mathbf{x}(t) \notin C_h(t) \land \mathbf{x}(t_0 + t_{conv}) \in C_h(t_0 + t_{conv})$$

$$G_h := \forall \ t > t_{conv} + t_0 : \mathbf{x}(t) \in C_h(t).$$

If a CBF contract holds, then there exists a controller which ensures the forward-invariance of $C_h(t)$. Else, if a FCBF contract holds, there exists a controller which brings

the system to the safe set $C_h(t)$ after time t_{conv} . We say that contract \mathcal{C}_h is *imposed on interval* $\Gamma = [t_0, t_f]$, when t_0 is the initial time and the safe set is $C_h(t)$ for all $t \in \Gamma$. In the following, we also assume that contracts are non-vacuous, that is, their assumptions are satisfiable. Using the above notions, we can combine contracts over neighboring intervals as stated by the following results, whose proofs can be found in an extended version of this paper [?].

Theorem 2. The composition of the TV-CBF contracts $\mathcal{C}_h \otimes \mathcal{C}_g$ imposed on $\Gamma_1 = [t_0, t_1]$ and $\Gamma_2 = [t_1, t_2]$, respectively, is compatible if and only if $C_h(t_1) \cap C_g(t_1) \neq \emptyset$. Moreover, $\mathcal{C}_h \otimes \mathcal{C}_g$ is compatible for all $\mathbf{x}(t_0) \in C_h(t_0)$ if and only if $C_h(t_1) \subseteq C_g(t_1)$ holds.

Intuitively, contracts \mathcal{C}_h and \mathcal{C}_g imposed on adjacent intervals can be composed, that is, *at least one* trajectory $\mathbf{x}(t)$ satisfying the guarantees of \mathcal{C}_h also satisfies the assumptions of \mathcal{C}_g , if and only if their safe sets overlap at the switching point of their intervals. On the other hand, if we require that that *every* trajectory $\mathbf{x}(t)$ remains in the respective safe sets throughout $\Gamma_1 \cup \Gamma_2$, then the current safe must be a subset of the upcoming safe set at the time of switching. The latter, stronger condition is equivalent to the condition for sequential composition of funnels [11] illustrated in Figure 1(a). We now present the corresponding result for FCBF contracts.

Theorem 3. The composition of CBF contract \mathcal{C}_h imposed on $\Gamma_1 = [t_0, t_1]$ and the FCBF contract \mathcal{C}_g imposed on $\Gamma_2 = [\tau_g, t_2]$ is compatible if and only if: (1) $C_h(t_1) \cap C_g(t_1) \neq \emptyset$, (2) $\tau_g + t_{conv,g} \leq t_1$ hold.

In other words, we can guarantee that every trajectory $\mathbf{x}(t)$ remains in the respective safe sets of contracts \mathcal{C}_h and \mathcal{C}_g throughout $\Gamma_1 \cup \Gamma_2$, by simply requiring that $C_h(t)$ overlaps with $C_g(t)$ at the time of switching provided that $\mathbf{x}(t)$ converges to $C_g(t)$ before Γ_1 has finished. Because $t_{conv,g} \leq T_g$ by Theorem 1, if $\tau_g + T_g \leq t_1$, then condition (2) in Theorem 3 will also hold. We leverage this observation and the above theorems, combined with Definition 2 to compute the set of safe inputs satisfying compositions of contracts imposed on neighboring time intervals.

Theorem 4. Let $C_h = \bigotimes_{i=1}^{\mathcal{N}} C_{h,i}$ be imposed on neighboring intervals $\{\Gamma_1, \Gamma_2, \ldots, \Gamma_{\mathcal{N}}\}$ for $\Gamma_i = [t_{i-1}, t_i]$. Let $C_{h,i}$ be either a TV-CBF contract imposed over the interval Γ_i or $C_{h,i} = C_{h,i1} \otimes C_{h,i2}$ where $C_{h,i1}$ is a TV-CBF contract imposed over interval Γ_i and $C_{h,i2} = C_{h,i+1}$ is a TV-FCBF contract imposed over $[\tau_i, t_i]$ for $t_{i-1} < \tau_i < t_i$. If $\mathbf{x}(t_0) \in C_{h_1}(t_0)$, then any controller $u \in \mathcal{U}_{safe,h}(t)$ will satisfy C_h where

$$\mathcal{U}_{safe,h}(t) = \begin{cases} \mathcal{U}_{safe,i}(t) & (t_{i-1} < t \le \tau_i) \lor \\ & C_i(t_i) \subseteq C_{i+1}(t_i) \end{cases}$$

$$\mathcal{U}_{safe,h}(t) \cap (\tau_i < t < t_i) \land \\ \mathcal{U}_{safe,i+1}(t) \quad C_i(t_i) \not\subseteq C_{i+1}(t_i) \land \\ & C_i(t_i) \cap C_{i+1}(t_i) \neq \emptyset \end{cases}$$

$$\mathcal{U}_{safe,i}(t) = \{ u \in U : \frac{\partial}{\partial t} h_i(t, \mathbf{x}) + L_f h_i(t, \mathbf{x}) + L_g h_i(t, \mathbf{x}) u + \alpha(h_i(t, \mathbf{x})) \ge 0 \}$$

$$\mathcal{U}_{safe,i+1}(t) = \{ u \in U : \frac{\partial}{\partial t} h_{i+1}(t, \mathbf{x}) + L_f h_{i+1}(t, \mathbf{x}) + L_g h_{i+1}(t, \mathbf{x}) u + \gamma_{i+1} \operatorname{sign}(h_{i+1}(t, \mathbf{x})) \cdot |h_{i+1}(t, \mathbf{x})|^{\rho_{i+1}} \ge 0 \},$$

provided that

$$T_{i+1} = \frac{|h_{i+1}(\tau_i, \mathbf{x}(\tau_i))|^{1-\rho_{i+1}}}{\gamma_{i+1} \cdot (1-\rho_{i+1})} < t_i - \tau_i \le t_i - t_{i-1}.$$

For a given set of STL tasks as in (3), we propose a control synthesis algorithm by formalizing them in terms of contracts imposed on neighboring intervals.

IV. SYNTHESIS ALGORITHM

We propose a two-step control synthesis algorithm. In the pre-processing step, the high-level planner provides a set of STL tasks $\{\psi_1 = \mathcal{T}_{\Gamma_1}(h_1(\mathbf{x}) \geq 0), \ldots, \psi_{\mathcal{N}} = \mathcal{T}_{\Gamma_{\mathcal{N}}}(h_{\mathcal{N}}(\mathbf{x}) \geq 0)\}$, with $\mathcal{T} \in \{\mathcal{G}, \mathcal{F}\}$, defined over the time intervals $\{\Gamma_1, \ldots, \Gamma_{\mathcal{N}}\}$. Predicates of the form $\mathcal{F}_{\Gamma_i}(h_i(\mathbf{x}) \geq 0)$ are converted to $\mathcal{G}_{[t_s,t_s+\epsilon]}h_i(\mathbf{x}) \geq 0$, where $[t_s,t_s+\epsilon] \subset \Gamma_i$ is a user-specified "time of satisfaction." We then divide the set of STL tasks into the minimum of STL formulas G_1, \ldots, G_k such that each G_j is a conjunction of predicates $\mathcal{G}_{\Gamma_i}\phi_{h,i}$ that are defined over neighboring intervals like Theorem 4. For example, if the top-level STL specification $\Psi_{STL} = \mathcal{G}_{[0,T_{max})}(h(\mathbf{x}) \geq 0) \wedge \bigwedge_{i=1}^N \mathcal{G}_{[t_{i-1},t_i)}(h_i(\mathbf{x}) \geq 0)$, we can identify and separate the task predicates into the STL formulae $G_1 = \mathcal{G}_{[0,T_{max})}(h(\mathbf{x}) \geq 0)$, $G_2 = \bigwedge_{i=1}^N \mathcal{G}_{[t_{i-1},t_i)}(h_i(\mathbf{x}) \geq 0)$ such that $\Psi_{STL} = G_1 \wedge G_2$.

Next, we proceed to the synthesis step. Each $\mathcal{G}_{\Gamma_i}\phi_{h,i}$ in the formula \mathbf{G}_j corresponds to the predicate function $h_i(\mathbf{x})$. Because any $\mathbf{x}(t)$ in the safe set $C_i(t) = \{\mathbf{x} \in D : h_i(t,\mathbf{x}) \geq 0\}$ satisfies $\mathcal{G}_{\Gamma_i}\phi_{h,i}$, safe control synthesis for \mathbf{G}_j reduces to finding a controller that satisfies a contract of the form $\mathcal{C}_j = \bigotimes_{i=1}^{|\mathbf{G}_j|} \mathcal{C}_{h,i}$. Consequently, we use Theorem 4 to construct the safe input set $\mathcal{U}_{safe,j}(t)$ by conditioning over two possibilities: (1) $C_i(t_i) \subseteq C_{i+1}(t_i)$ or (2) $C_i(t_i) \cap C_{i+1}(t_i) \neq \emptyset$ and $T_{i+1} \leq t_i - t_{i-1}$. To synthesize a controller simultaneously satisfying contracts $\mathcal{C}_1, \ldots, \mathcal{C}_k$ corresponding to $\mathcal{G}_1, \ldots, \mathcal{G}_k$, we resort to the notion of contract conjunction (see Section II-1). Satisfying $\bigwedge_{j=1}^k \mathcal{C}_j$ corresponds to finding a controller in the safe set $\mathcal{U}_{safe,f}(t) = \bigcap_{j=1}^k \mathcal{U}_{safe,j}(t)$. Finally, the safe control actions at each time step can be obtained by solving a quadratic program of the form $u_{safe} = \underset{u \in \mathcal{U}_{safe}(t)}{\operatorname{erg}} \|u - u_{nom}\|_2^2$, where

 u_{nom} is a nominal PID or any other feedback controller. The procedure is summarized in Algorithm 1.

V. CASE STUDY

We illustrate our algorithm on a vehicular planning problem under safety and regulatory constraints. We use a non-linear model for the ego vehicle. Let X_f , V_f , X_l , and V_l be the longitudinal position, velocity of the ego vehicle and the

lead vehicle respectively. Let $X_l > X_f$, and let $X_r = X_l - X_f > 0$ be the relative distance and $V_r = V_l - V_f$ the relative velocity between the ego and the lead vehicle. Let $F_r = c_0 + c_1 V_f + c_2 V_f^2$ be the sum of all frictional and aerodynamic forces on the ego vehicle, where c_0 , c_1 , and c_2 are parameters. Let $u \in U$ be the input wheel force. Let $\mathbf{x} = \begin{pmatrix} X_f & V_f & X_l \end{pmatrix}^T$, $f(\mathbf{x}) = \begin{pmatrix} V_f & -\frac{1}{m}F_r & V_l \end{pmatrix}^T$, and $g(\mathbf{x}) = \begin{pmatrix} 0 & \frac{1}{m} & 0 \end{pmatrix}^T$, then the longitudinal dynamics of the system are given by $\dot{\mathbf{x}} = f(\mathbf{x}) + g(\mathbf{x})u$.

STL Specifications. The mission includes safety and regulatory requirements as follows. In the following, $t_{\mathcal{N}_v}$ is the time horizon of the mission.

- 1) The ego vehicle must maintain a safe distance from the lead vehicle. Let $\phi_1(t)$ be the spacing error between the ego vehicle and the lead vehicle, defined by $\phi_1 := X_r hV_f S_0 \frac{V_f^2 V_l^2}{2a_{max}}$. h is a constant time-headway, i.e., the time required by the ego vehicle to cover the distance X_r , S_0 is the relative distance between ego and lead vehicle when they are at the rest position. The absolute value of maximum braking capability is denoted by $a_{max} > 0$. We therefore require that $\mathcal{G}_{[0,H_{max})}\phi_1 \geq 0$ hold.
- 2) Let $\Gamma_v = [t_0, t_{\mathcal{N}_v}]$ be the time interval which is

divided into \mathcal{N}_i consecutive time intervals such that $\Gamma_v = \bigcup_{i \in \mathcal{N}_v} [t_{i-1}, t_i)$, for $t_{i-1} < t_i$. Let speed limit $V_{max}(t)$ be a discrete-valued function of time and it can be described in a piecewise manner as $V_{max}(t) = V_{max,i} \ \forall t \in \Gamma_{vi} = [t_{i-1}, t_i), \ \forall i \in \{1, \dots, \mathcal{N}_v\}$. We define $\phi_v := V_{max}(t) - V_f$ and $\mathcal{G}_{[t_0, t_{\mathcal{N}_v})}\phi_v$. If $\phi_{v,i} := V_{max,i} - V_f$, then $\mathcal{G}_{[0,t_{\mathcal{N}_v})}\phi_v = \bigwedge_{i \in \mathcal{N}_v} \mathcal{G}_{\Gamma_i}\phi_{v,i}$. Let the maximum achievable velocity by the ego vehicle be V_{MAX} and $T_{conv,v}$ be the maximum time it takes for the ego vehicle to come to a complete stop from the maximum velocity. Then, $T_{conv,v}$ is the convergence time for ϕ_v , with $T_{conv,v} < t_i - t_{i-1}$ for all $i \in \mathcal{N}_v$.

- 3) The ego vehicle must follow the traffic signals. Let $\phi_{pos,i} = P_i - X_f - \beta V_f - S_{stop}$, where P_i is the position of the i^{th} traffic signal, $\beta > 0$, and S_{stop} is the distance from the stop line when $V_f = 0$. Let the state of the traffic signal be denoted by $s_i \in \{\text{Red}, \text{Yellow}, \text{Green}\}.$ Let g_{ij} , y_{ij} , and r_{ij} encode the times when the i^{th} signal turns green, yellow, and red for the j^{th} time, respectively, that is, $s_i = \text{Green}, \forall t \in \Gamma_{ij,g} = [g_{ij}, y_{ij}),$ s_i = Yellow $\forall t \in \Gamma_{ij,y} = [y_{ij}, r_{ij}), \text{ and } s_{ij} = \texttt{Red}$ $\forall t \in \Gamma_{ij,r} = [r_{ij}, g_{i,j+1}).$ Let $s_i \neq \text{Red},$ $\forall t \in \Gamma_{ij,\bar{r}} = [g_{ij},r_{ij})$. During the red signal, $\phi_{pos,i} \wedge (t \in \Gamma_{ij,r}) \implies \mathcal{G}_{\Gamma_{ij,r}} \phi_{pos,i} \geq 0 \text{ holds.}$ Similarly during the yellow and green traffic signal $\phi_{pos,i} \wedge (\Gamma_{ij,\bar{r}}) \implies$ $\mathcal{G}_{\Gamma_{ij,\bar{r}}}\phi_{pos,i+1} \geq 0$ holds This can be summarized in the form of $\phi_{r,i}$ = $\neg (\phi_{pos,i} \land \neg [(\mathcal{G}_{\Gamma_{ij,r}}\phi_{pos,i}) \land (\mathcal{G}_{\Gamma_{ij,\bar{r}}}\phi_{pos,i+1})]).$ We want $\phi_{r,i}$ to hold globally, i.e., $\mathcal{G}_{[0,t_{\mathcal{N}_v})}\phi_{r,i}$. If the duration of the yellow light $Y_{ij} = r_{ij} - y_{ij}$ then $Y_{ij} \geq T_{conv,v}$.
- 4) The lead vehicle communicates its velocity V_l and acceleration a_l to the ego vehicle. The ego vehicle knows the timing cycle of the traffic signals through V2I communication.

We now translate the requirements into a conjunction of CBF contracts. We first divide the STL predicates into different STL formulae satisfying the three conditions in Algorithm 1. Using Algorithm 1, we then synthesize the controller that guarantees the forward-invariance properties for the composite piecewise \mathcal{C}^1 TV-CBF contracts.

Mapping STL Predicates to Contracts. The STL specification before pre-processing is

$$\phi_{m} = \bigwedge_{i=1}^{N} \bigwedge_{j \in \mathbb{N}} \bigwedge_{k=1}^{N_{v}} \neg \left(\phi_{pos,i} \wedge \neg \left[\left(\mathcal{G}_{[r_{ij},g_{i,j+1})}(\phi_{pos,i} \wedge \phi_{1}) \right) \right. \right. \\ \left. \wedge \left(\mathcal{G}_{[g_{ij},r_{ij})}(\phi_{pos,i+1} \wedge \phi_{1}) \right) \right] \right) \wedge \mathcal{G}_{[t_{k-1},t_{k})} \phi_{v,k}$$

where i indicates that $P_{i-1} < X_f \le P_i$, N denotes the total number of traffic signals, j denotes the cycle number of the i^{th} traffic signal. The predicates in the STL specification can be allocated to the following three STL formulae: $\mathsf{G}_1 = \bigwedge \mathcal{G}_{[0,t_{\mathcal{N}_v})} \phi_1 \ge 0$, $\mathsf{G}_2 = \bigwedge_{k=1}^{\mathcal{N}_v} \mathcal{G}_{[t_{i-1},t_i)} \phi_{v,k} \ge 0$, and $\mathsf{G}_3 = \bigwedge_{i=1}^{\mathcal{N}_v} \bigwedge_{j=\in\mathbb{N}}^{\mathcal{G}} \mathcal{G}_{[g_{ij},g_{i,j+1})} \phi_{r,ij} \ge 0$, where the

STL predicates in each group are defined on non-overlapping intervals.

We first consider G_1 . Since $\phi_1(\mathbf{x}) = h_1(\mathbf{x})$ is C^1 and there is only one STL predicate over the whole horizon, we generate the CBF contract C_1 with the corresponding safe set C_1 .

 G_2 can be associated to a CBF contract $\mathsf{C}_2 = \bigotimes_{i=1}^{\mathcal{N}_v} \mathsf{C}_{h_v,i}$, where $\mathsf{C}_{h_v,i}$ can either be a CBF contract over interval Γ_i or $\mathsf{C}_{h_v,i} = \mathsf{C}_{h_v,i1} \otimes \mathsf{C}_{h_v,i2}$ where $\mathsf{C}_{h_v,i1}$ is a CBF contract for $h_{v,i}$ and $\mathsf{C}_{h,i2}$ is a FCBF for $h_{v,i+1}$ imposed over the intervals Γ_i and $[t_i - T_{conv,v}, t_i)$, respectively. We set $\phi_{v,i}(\mathbf{x}) = h_{v,i}(\mathbf{x}) = V_{max,i} - V_f$ and $h_v(t,\mathbf{x}) = h_{vi}(t,\mathbf{x})$ for $t \in \Gamma_i \ \forall i \in \mathcal{N}_v$. Note that, all the predicate functions are piecewise- \mathcal{C}^1 .

Similarly to \mathcal{C}_2 we can form \mathcal{C}_3 for \mathcal{G}_3 , encodes the traffic signals' constraints for the scenario when the ego vehicle is approaching the i^{th} traffic signal. The corresponding safe sets $C_{pos,i}(t) = \{\mathbf{x} \in \mathbb{R}^n : h_{pos,i}(t,\mathbf{x}) \geq 0\}$ when $P_{i-1} < X_f \leq P_i$, are defined by

$$h_{pos,i}(t, \mathbf{x}) = \begin{cases} h_{\texttt{Green}, \texttt{ij}}(\mathbf{x}) & \text{if } g_{ij} \le t < r_{ij} \\ h_{\texttt{Red}, \texttt{ij}}(\mathbf{x}) & \text{if } r_{ij} \le t < g_{i,j+1} \end{cases}$$
(7)
$$h_{\texttt{Green}, \texttt{ij}}(\mathbf{x}) = \phi_{pos,i+1}, \ h_{\texttt{Red}, \texttt{ij}}(\mathbf{x}) = \phi_{pos,i}.$$

At $t = r_{ij}$, we only require that $C_{pos,i}(t = r_{ij}) \cap C_{pos,i}(t = r_{ij}) \neq \emptyset$ rather than $C_{pos,i}(t = r_{ij}) \subseteq C_{pos,i}(t = r_{ij})$.

Control Synthesis. We derive the set of constraints that will be used to find the control law guaranteeing the satisfaction of contracts \mathcal{C}_1 , \mathcal{C}_2 , and \mathcal{C}_3 . By Definition 1 and the related treatment, the set of inputs ensuring the satisfaction of \mathcal{C}_1 is given by $\mathcal{U}_{safe,h_1} = \{u \in U : u \leq \frac{ma_{max}}{ha_{max}+V_f}(h_1+V_r+\frac{V_l}{a_{max}}a_l)+F_r\}$, where a_l is the acceleration of the lead vehicle received by V2V communication.

Let $t_{i-1,0}$ be the time at which the ego vehicle crosses the $(i-1)^{th}$ traffic signal, serving as the initial condition as the vehicle approaches the i^{th} traffic signal. Let $\mathcal{U}_{\texttt{Green},ij}(t)$ denote the set of safe inputs when $s_i \neq \texttt{Red}$, i.e., when $t \in \Gamma_{ij,g} = \left[\max(g_{ij},t_{i-1,0}),r_{ij}\right)$, and $\mathcal{U}_{\texttt{Red},ij}(t)$ the set of safe inputs when $s_i = \texttt{Red}$, i.e., over $\Gamma_{ij,r}$. For all $j \in \mathbb{N}$, for all $t \in \Gamma_{ij,g}$, if $\max(y_{ij},t_{i-1,0}) \leq t < r_{ij}$, according to the Theorem 4, the set of safe inputs is

$$\begin{split} \mathcal{U}_{\texttt{Green}, \texttt{i}}(t) &= \begin{cases} \mathcal{U}_{\texttt{Green}, \texttt{ij}}(t) & g_{ij} \leq t \leq y_{ij} \\ \mathcal{U}_{\texttt{Green}, \texttt{ij}}(t) \cap \mathcal{U}_{\texttt{Red}, \texttt{ij}}(t) & y_{ij} < t < r_{ij} \end{cases} \\ \mathcal{U}_{\texttt{Green}, \texttt{ij}}(t) &= \{ u \in \mathcal{U} : u \leq \frac{m}{\beta} (h_{\texttt{Green}, \texttt{ij}} - V_f) + F_r \} \\ \mathcal{U}_{\texttt{Red}, \texttt{ij}}(t) &= \{ u \in \mathcal{U} : u \leq \frac{m}{\beta} (\gamma_{r,j+1} \text{sign}(h_{\texttt{Red}, \texttt{ij}}) \\ & \cdot |h_{\texttt{Red}, \texttt{i}}|^{\rho_{r,j+1}}) + F_r. \end{cases} \end{split}$$

We have $\gamma_{r,j+1} = \frac{|h_{\mathtt{Red},\mathtt{ij}}(t_{sj},\mathbf{x}(t_{sj}))|^{1-\rho_{j+1}}}{(Y_{ij})\cdot(1-\rho_{j+1})},$ for $t_{sj} = \max(y_{ij},t_{i-1,0}).$

The set inputs $\mathcal{U}_{h_v}(t)$ ensuring the satisfaction of \mathcal{C}_{h_v} can be finally calculated using Theorem 4 $\forall j \in \mathcal{N}_v$, $\forall t \in \Gamma_{vj}$,

leading to

$$\begin{split} \mathcal{U}_{h_v}(t) &= \begin{cases} \mathcal{U}_{h_v,j}(t) & t_{j-1} < t \leq t_j - T_{conv,v} \\ \mathcal{U}_{h_v,j}(t) \cap \mathcal{U}_{h_v,j+1}(t) & t_j - T_{conv,v} < t < t_j \end{cases} \\ \mathcal{U}_{h_v,j}(t) &= \{ u \in \mathcal{U} : u \leq \frac{m}{\beta} h_{v,h} + F_r \} \\ \mathcal{U}_{h_v,j+1}(t) &= \big\{ u \in \mathcal{U} : u \leq \frac{m}{\beta} (\gamma_{v,j+1} \mathrm{sign}(h_{v,j+1}) \\ & \cdot |h_{v,j+1}|^{\rho_{v,j+1}}) + F_r \big\}. \end{split}$$

We have $\gamma_{v,j+1} = \frac{|h_{v,j+1}(t_{sj},\mathbf{x}(t_j-T_{conv,v}))|^{1-\rho_{v,j+1}}}{(T_{conv,v})\cdot(1-\rho_{v,j+1})}$, ensuring that the system converges from $C_{v,j}$ to $C_{v,j+1}$ within $T_{conv,v}$. By combining all the constraints above, we get $\mathcal{U}_{safe}(t) = \mathcal{U}_{h_1}\cap\mathcal{U}_{h_{pos}(t)}\cap\mathcal{U}_{h_v}(t)$. A PID controller is chosen as a nominal controller $u_{nom} = m\left(k_1V_r + k_2\phi_1 + k_3\int_0^t\phi_1\,dx\right) + F_r$ to achieve the goal that $V_f \to V_l$ and $\phi_1 \to 0$, where k_1,k_2 , and k_3 are the PID gains. The $u \in \mathcal{U}_{safe}$ is obtained by solving quadratic programs as in (6).

VI. SIMULATIONS AND RESULTS

We simulate a road scenario with the ego and lead vehicles. The traffic is regulated by ten traffic signals. The distance between any two consecutive traffic signals is not equal. The timing cycle of different traffic signals is also different. The speed limits changes every 50 s, which is possibly unrealistic but helps validate our methodology in extreme conditions. The variable speed limit $V_{max}(t)$ has three values: $30\ m/s$, $25\ m/s$, and $10\ m/s$. We consider the worst-case scenario in which the lead vehicle may violate the rules. We use $g=9.8\ \frac{m}{s^2}$, $m=1650\ Kg$, $c_0=0.1\ N$, $c_1=5\ \frac{N}{m/s}$, $c_2=0.25\ \frac{N}{m/s^2}$, $a_{max}=0.4g\ \frac{m}{s^2}$, and $\rho_{r,j+1}=0.9$ and $\rho_{v,j+1}=0.91$ for all $j\in\mathbb{N}$. Y_{ij} is the convergence time for \mathcal{C}_2 while 5 s is the convergence time within each interval Γ_{vj} in G_2 .

Fig. 2a shows that $\mathcal{G}_{[0,t_{\mathcal{N}_v})}h_1(\mathbf{x}) \geq 0$ holds, i.e., the ego vehicle maintains a safe distance from the lead vehicle during the entire trip. The relative speed profile of the ego vehicle, the lead vehicle, and the variable speed limit $V_{max}(t)$ are shown in Fig. 2b. The Fig. 2b showing that $V_f \leq V_{max}(t)$ always holds.

Finally, as shown in Fig. 3, the ego vehicle complies with traffic signals. The height of the horizontal lines represents the relative position of the traffic signals with respect to the origin. The colors represent the states of the traffic signals with respect to time. The signals are not synchronized. The ego vehicle never crosses a traffic signal when the state is Red. Moreover, since $h_{pos}(t,\mathbf{x})$ is always non-negative in Fig. 2c, the traffic signal contract is satisfied. Fig. 2d provides the control input u as a function of time.

VII. CONCLUSIONS

We presented a compositional control synthesis method mapping a mission-level STL specification to an aggregation of contracts defined via piecewise continuously differentiable time-varying control barrier functions. The barrier functions are used to constrain the lower-level control synthesis problem,

(a) $\mathcal{G}_{[0,t_{\mathcal{N}_v})}h_1(x)\geq 0$. The ego vehicle always maintains a safe distance from the lead vehicle.

(b) $\mathcal{G}_{[0,\mathcal{N}_v)}h_v(t,\mathbf{x})\geq 0$. Speed profile of the lead vehicle (V_l) and ego vehicle (V_f) , and speed limit $V_{max}(t)$.

(c) $\mathcal{G}_{[0,\mathcal{N}_v)}h_{pos}(t,\mathbf{x})\geq 0$. The ego vehicle obeys the traffic signals.

(d) Normalized input u.

Fig. 2: Simulation results: all safety and regulatory constraints are satisfied by the controlled vehicle.

Fig. 3: Position of the ego vehicle X_f vs. time. The horizontal lines show the position of traffic signals while colors show the states at a given time.

which is solved via quadratic programming. We illustrated the effectiveness of the proposed algorithm on a case study motivated by vehicular mission planning under safety constraints as well as constraints imposed by traffic regulations. Future work includes investigating extensions of the synthesis approach to more expressive fragments of STL as well as multi-agent planning.
