A Locally Adaptive Shrinkage Approach to False Selection Rate Control in High-Dimensional Classification

Bowen Gang¹, Yuantao Shi², and Wenguang Sun³

Abstract

The uncertainty quantification and error control of classifiers are crucial in many high-consequence decision-making scenarios. We propose a selective classification framework that provides an "indecision" option for any observations that cannot be classified with confidence. The false selection rate (FSR), defined as the expected fraction of erroneous classifications among all definitive classifications, provides a useful error rate notion that trades off a fraction of indecisions for fewer classification errors. We develop a new class of locally adaptive shrinkage and selection (LASS) rules for FSR control in the context of high-dimensional linear discriminant analysis (LDA). LASS is easy-to-analyze and has robust performance across sparse and dense regimes. Theoretical guarantees on FSR control are established without strong assumptions on sparsity as required by existing theories in high-dimensional LDA. The empirical performances of LASS are investigated using both simulated and real data.

Key words and phrases: Classification with confidence, False discovery rate, Linear discriminant analysis, Risk control, Shrinkage estimation.

1 Introduction

Linear discriminant analysis (LDA) has been widely used in classification problems. We focus on the basic setup, which assumes that the observations are p-dimensional vectorvalued features that are drawn with equal probability from one of the two multivariate normal distributions:

$$
\mathcal{N}(\boldsymbol{\mu}_1, \Sigma)
$$
 (class 1) and $\mathcal{N}(\boldsymbol{\mu}_2, \Sigma)$ (class 2). (1.1)

Let $W \in \mathcal{R}^p$ be a new observation. Denote $\mu = \frac{\mu_1 + \mu_2}{2}$ $\frac{+\boldsymbol{\mu}_2}{2}$ and $\boldsymbol{d} = \boldsymbol{\mu}_1 - \boldsymbol{\mu}_2$. The procedure that achieves the minimal misclassification risk is Fisher's linear discriminant rule:

$$
\delta^{F} = \mathbb{I}\left\{ (\boldsymbol{W} - \boldsymbol{\mu})^{\top} \Sigma^{-1} \boldsymbol{d} < 0 \right\} + 2 \cdot \mathbb{I}\left\{ (\boldsymbol{W} - \boldsymbol{\mu})^{\top} \Sigma^{-1} \boldsymbol{d} \ge 0 \right\},\tag{1.2}
$$

which assigns W to class c if $\delta^F = c$, $c = 1, 2$. When μ_1 , μ_2 and Σ are unknown, the common practice is to construct a data-driven LDA rule by obtaining suitable estimates of the unknown quantities in (1.2) . In the high-dimensional setting, naive sample estimates become highly unstable, and a plethora of regularized LDA rules have been proposed and shown to achieve substantial improvements in prediction accuracy [\(Friedman, 1989;](#page-31-0) [Tib](#page-33-0)[shirani et al., 2003;](#page-33-0) [Witten and Tibshirani, 2009;](#page-33-1) [Cai and Liu, 2011;](#page-30-0) [Shao et al., 2011;](#page-33-2) [Mai](#page-32-0) [et al., 2012;](#page-32-0) [Cai and Zhang, 2019;](#page-31-1) among others). However, it still remains unknown how to assess the uncertainties and control the decision errors in high-dimensional LDA. This article proposes a selective classification approach to controlling the false selection rate (FSR). We develop a new class of data-driven LDA rules based on locally adaptive shrinkage and selection (LASS), and illustrate how LASS can be deployed in decision-making scenarios to control the FSR at a user-specified level.

1.1 Selective classification and false selection rate

Uncertainty quantification and error control are crucial in many sensitive decision-making scenarios. The decision errors, which can be very expensive to correct, are often unavoidable due to the intrinsic ambiguity of a classification problem. Consider the ideal setting where the multivariate normal parameters μ_1 , μ_2 and Σ are known. Then among all classification rules, the LDA rule [\(1.2\)](#page-1-0) achieves the minimum classification risk $1 - \Phi$ $\sqrt{1}$ 2 √ $\overline{\bm{d}^{\top} \Sigma^{-1} \bm{d}}$, where $\Phi(\cdot)$ is the cumulative distribution function (CDF) of a standard normal variable. However, this minimum risk can still be unacceptably high when the signal to noise ratio √ $d^T\Sigma^{-1}d$ is low. The issue is exacerbated in practice, particularly in high-dimensional settings, where we must employ "plug-in" rules learned from limited training data.

In contrast with conventional classification algorithms which are forced to make classifications on all new observations, a useful strategy for uncertainty quantification involves providing an indecision option (also referred to as abstention or reject option) for any observations which cannot be classified with confidence. The observations with indecisions can then be separately evaluated. This strategy is attractive in practice when the cost of handling indecisions is less than that of fixing a classification error. To see how it aligns with the social and policy objectives, consider a high-consequence classification scenario where one needs to assess the likelihood of a defendant becoming a recidivist. Obviously the social cost of incorrectly classifying a low-risk individual as a recidivist is much higher than that of an indecision $- -$ it is worthy of waiting and collecting additional contextual knowledge of the convicted individual to mitigate the ambiguity. Likewise, in medical screening, a misclassification can result in either missed medical care or unnecessary treatments, both of which can be much more expensive than turning the patient over for a more careful examination/evaluation.

Suppose we observe labeled training data \mathcal{D}^{train} . The goal is to predict the classes for m new observations $\mathcal{D}^{test} = \{ \boldsymbol{W}_j : 1 \leq j \leq m \}$. This article considers a selective classification framework that only makes definitive decisions on a selected subset of \mathcal{D}^{test} , while

the remaining subjects will receive indecisions (i.e. be rejected for further investigation). The reject/indecision option, which is much less expensive to handle, is considered as a wasted opportunity rather than a severe error. We propose to control the false selection rate (FSR), which is the expected fraction of erroneous classifications among all definitive classifications. Selective classification with FSR control provides an effective approach to uncertainty quantification and error control. We demonstrate that with the reject/indecision option, the FSR can be controlled at a user-specified level. When the signal to noise ratio is low, the degree of ambiguity in the classification task can be, in a sense, captured by the fraction of indecisions in \mathcal{D}^{test} . Hence, a more powerful data-driven rule, subject to the FSR constraint, translates to a smaller fraction of indecisions, which means that less wasted efforts are needed to perform separate evaluations.

1.2 FSR control via locally adaptive shrinkage and selection

The task of controlling the FSR in high-dimensional LDA is challenging; we start by discussing several limitations of existing works.

First, the methodology and theory of many high-dimensional LDA rules (e.g. [Cai and](#page-30-0) [Liu, 2011;](#page-30-0) [Shao et al., 2011;](#page-33-2) [Mai et al., 2012;](#page-32-0) [Cai and Zhang, 2019\)](#page-31-1) critically depend on strong sparsity assumptions, which may not hold in practice. The sparsity assumption is counter-intuitive from the perspective of classification error control. Consider the simple case where all non-zero coordinates in $\mathbf{d} = \mathbf{\mu}_1 - \mathbf{\mu}_2$ take the same value. Then a larger l_0 norm of **d** (i.e. non-sparse setting) virtually implies that the two classes are better separated, and hence, the control of classification risk should become easier. However, many state-of-the-art LDA rules lack theoretical justifications and often do poorly in the supposedly easier non-sparse setting (Section [5\)](#page-21-0). Second, the analysis of the error rate of a classifier often requires a precise quantification of the quality of its outputs, which is in general intractable due to the complexity of contemporary LDA rules. Finally, most learning algorithms are driven by the need of improving prediction performance instead of

avoiding high-consequence decision errors. It is unclear how to tailor existing algorithms to trade off a fraction of indecisions for fewer classification errors, and further, how to calibrate suitable data-driven thresholds to control the FSR at a user-specified level.

This article develops a class of FSR rules via a locally adaptive shrinkage and selection (LASS) algorithm. LASS consists of three steps: first estimating a score according to the LDA rule [\(1.2\)](#page-1-0), second ordering all individuals according to the estimated scores, and finally choosing upper and lower data-adaptive thresholds to select individuals into the two classes, with the unselected ones assigned to the *indecision* group. We prove theories to establish the asymptotic validity of LASS for FSR control under mild conditions. A key innovation in our method is the construction of intuitive and easy-to-analyze shrinkage factors that are capable of reducing uncertainties without strong assumptions on sparsity. LASS provides a principled and theoretically solid LDA rule that has comparable performance with state-ofthe-art classification rules (e.g. [Cai and Liu, 2011;](#page-30-0) [Shao et al., 2011;](#page-33-2) [Cai and Zhang, 2019\)](#page-31-1) in the sparse setting and substantially better performance under the non-sparse setting. The theoretical adaptiveness of LASS to the unknown sparsity and its robust numerical performance across sparse and dense settings are attractive for practitioners – particularly in real world applications we only "bet on sparsity"; this working assumption (of sparsity) can distort the hardness of the problem, and hence, lead to wrong choices of method.

1.3 Our contributions

Our work makes several contributions. First, selective classification via FSR control provides a useful approach to risk-sensitive decision-making scenarios, where classification errors have high impacts on one's social, economic or health status. Second, we develop a novel shrinkage rule for estimating the linear discriminant score, which is effective for reducing the uncertainties in high dimensions. The estimator is intuitive, assumption-lean, easy-to-analyze and enjoys strong theoretical properties. Third, we derive data-adaptive decision boundaries based on the shrunken LDA rule to select and classify the observations.

Theoretical guarantees on FSR control are established under much weaker conditions compared to existing theories on sparse LDA.

1.4 Related works

We discuss several related lines of research to further explain the merits of LASS and place our contributions in context.

Under the high-dimensional sparse setting, [Bickel and Levina](#page-30-1) [\(2004\)](#page-30-1) demonstrated that the naive Fisher's rule can perform no better than random guess. A plethora of regularized LDA rules have been proposed to exploit the sparse structure in the data; a few representative works include the shrunken centroid method [\(Tibshirani et al., 2003\)](#page-33-0), the LPD and AdaLDA rules [\(Cai and Liu, 2011;](#page-30-0) [Cai and Zhang, 2019\)](#page-31-1), and other penalized or thresholding methods [\(Shao et al., 2011;](#page-33-2) [Mai et al., 2012\)](#page-32-0). However, as we demonstrate in our numerical studies, these methods do not work well under the non-sparse setting. LASS, which employs an adaptive shrinkage rule with robust performance *across sparse and dense* regimes, is provably valid for error rate control.

Exemplified by the James-Stein estimator [\(James and Stein, 1992\)](#page-32-1) and Tweedie's formula (e.g. [Brown and Greenshtein, 2009;](#page-30-2) [Efron, 2011;](#page-31-2) [Koenker and Mizera, 2014\)](#page-32-2), shrinkage is a powerful and ubiquitous idea in compound estimation. Under the independence assumption (i.e. Σ is a diagonal matrix), the implementation of the LDA rule [\(1.2\)](#page-1-0) boils down to the compound estimation of μ and \dot{d} . [Efron](#page-31-3) [\(2009\)](#page-32-3), [Greenshtein and Park](#page-32-3) (2009) and [Dicker and Zhao](#page-31-4) [\(2016\)](#page-31-4) proposed empirical Bayes (EB) methods (Tweedie's formula and g-estimation) to construct "plug-in" LDA rules. EB shrinkage can effectively reduce the uncertainty in high dimensions without the sparsity assumption. However, there are several drawbacks. First, existing EB rules ignore the correlations, which may lead to suboptimal shrinkage factors and hence inferior LDA rules. By contrast, LASS performs shrinkage in a coordinate-wise shrinkage manner, which enjoys strong numerical and theoretical properties under dependence. Second, in contrast with EB "plug-in" rules that

are rather complicated to analyze, the uncertainty quantification of LASS is simple, which enables the development of data-driven rules and theory on FSR control.

1.5 Organization and notations

The article is organized as follows. Section [2](#page-6-0) presents the problem formulation and derives the oracle rule for FSR control. The data-driven LASS is developed in Section [3](#page-11-0) with its theoretical properties established in Section [4.](#page-17-0) The results are presented in Section [5.](#page-21-0) Proofs are relegated to the Supplementary Material.

Summary of notation. Denote $\mu = \frac{\mu_1 + \mu_2}{2}$ $\frac{1+\bm{\mu}_2}{2}, \bm{d} = (d_1, ..., d_p)^\top = \bm{\mu}_1 - \bm{\mu}_2, \bar{\bm{X}} = (\bar{X}_1, \dots, \bar{X}_p)^\top =$ $(1/n_1)\sum_{i=1}^{n_1} X_i$ and $\bar{Y}=(\bar{Y}_1,\ldots,\bar{Y}_p)^\top=(1/n_2)\sum_{i=1}^{n_2} Y_i$. I_p denotes the $p\times p$ identity matrix. For matrix A and $1 \leq w \leq \infty$, the matrix l_w norm is defined as $||A||_w = \sup_{|\mathbf{x}|_w \leq 1} |A\mathbf{x}|_w$. The largest/smallest eigenvalue of A is denoted $\lambda_{max}(A)/\lambda_{min}(A)$.

2 Problem Formulation

This section first introduces a generalized discriminant rule, then defines the false selection rate, and finally outlines the roadmap for methodological developments.

2.1 The generalized discriminant rule

Let W be a new observation and $S := S(W)$ be a generic score, with larger (smaller) S indicating a higher chance of being in class 2 (class 1). Suppose we need to classify m new observations $\{W_j : 1 \le j \le m\}$, which are drawn with equal probability from [\(1.1\)](#page-1-1). It is natural to consider the following generalized discriminant rule $\boldsymbol{\delta} = (\delta_j : 1 \leq j \leq m)$, where

$$
\delta_j = \mathbb{I}\left\{S(W_j) < t_l\right\} + 2 \cdot \mathbb{I}\left\{S(W_j) \ge t_u\right\}, \quad 1 \le j \le m. \tag{2.1}
$$

In the above, t_l and t_u represent the lower and upper thresholds, respectively, with the requirement that $t_l \leq t_u$. A key difference between the two discriminant rules [\(2.1\)](#page-6-1) and [\(1.2\)](#page-1-0) is that (1.2) uses $t_l = t_u = 0$ whereas the generalized rule [\(2.1\)](#page-6-1) allows $t_l < t_u$. The interval (t_l, t_u) is called an *ambiguity region*. The true class of any observation falling within this region cannot be determined with confidence. The values of t_l and t_u will be determined according to user-specified error rates, which will be discussed in the next subsection. It follows that δ_j defined in [\(2.1\)](#page-6-1) can take three possible values in the action space $\mathcal{A} = \{0, 1, 2\}$, with $\delta_j = k$ indicating that we classify \mathbf{W}_j to class k, $k = 1, 2$, while $\delta_j = 0$ indicating that we make an indecision or rejection option [\(Herbei and Wegkamp,](#page-32-4) [2006;](#page-32-4) [Sun and Wei, 2011;](#page-33-3) [Lei, 2014\)](#page-32-5). Denote $\{\theta_j : 1 \le j \le m\} \in \{1,2\}^m$ the unknown true classes. Consider the example of medical screening, where $\theta_j = 1$ ($\theta_j = 2$) indicates that the patient is healthy (sick). Then a patient with $\delta_j = 1$ will not receive the treatment, with $\delta_j = 2$ will receive the treatment, with $\delta_j = 0$ will be followed up for further evaluation.

2.2 False selection rate

In risk-sensitive applications, we view misclassifications as severe errors, the fraction of which should be controlled at a low level. Under the selective inference framework [\(Ben](#page-30-3)[jamini, 2010\)](#page-30-3), the error rate is defined to assess the quality of the selected subset, in which observations receive definitive classifications. By contrast, the indecisions are viewed as wasted opportunities and used to describe the power notion.

For the binary setting, we may encounter two types of misclassifications: $(\theta = 1, \delta = 2)$ and $(\theta = 2, \delta = 1)$. If the two directions are symmetric, it is natural to consider the false selection rate (FSR) without distinguishing the two types:

$$
\text{FSR} = \mathbb{E}\left[\frac{\sum_{j=1}^{m} \mathbb{I}\left(\theta_j \neq \delta_j, \delta_j \neq 0\right)}{\left\{\sum_{j=1}^{m} \mathbb{I}(\delta_j \neq 0)\right\} \vee 1}\right],\tag{2.2}
$$

where $x \vee y = \max(x, y)$. The FSR was recently considered in [Rava et al.](#page-32-6) [\(2021\)](#page-32-6) in a

different context (fairness in machine learning), and is analogous to the false discovery rate [\(Benjamini and Hochberg, 1995\)](#page-30-4) in one-class classification problems (outlier detection) [\(Bates et al., 2021;](#page-30-5) [Angelopoulos et al., 2021\)](#page-30-6). The FSR reduces to the misclassification rate $\frac{1}{m} \mathbb{E} \{ \sum_{j=1}^m (\theta_j \neq \delta_j) \}$ if indecisions are not allowed (i.e. $\delta_j \neq 0$ for every $1 \leq j \leq m$).

In the asymmetric situation we may define the class-specific FSR:

$$
\text{FSR}^c = \mathbb{E}\left[\frac{\sum_{j=1}^m \mathbb{I}(\delta_j = c, \theta_j \neq c)}{\left\{\sum_{j=1}^m \mathbb{I}(\delta_j = c)\right\} \vee 1}\right], \quad c = 1, 2. \tag{2.3}
$$

This provides a useful error notion in applications where one type of error is more sensitive than the other and it is desirable to set different tolerance levels for the two types of errors^1 errors^1 . To this end, we focus on the setup allowing class-specific constraints: $\text{FSR}^c \leq \alpha_c$, $c = 1, 2$. As a special case, one may set $\alpha_1 = \alpha_2 = \alpha$. If the class-specific constraints $FSR^c \leq \alpha$ are fulfilled for both $c = 1$ and $c = 2$, then it can be shown that the global constraint $FSR \leq \alpha$ defined in [\(2.2\)](#page-7-0) is also fulfilled.

The selective classification framework enables one to control the FSR at a user-specified level, which can be impossible without the indecision option. However, the price we need to pay is the wasted opportunity for performing separate evaluations on the indecisions. The user-specified error bounds α_c reflect our tolerance levels of the associated risks. To simultaneously quantify the degree to which the decisions can be trusted and minimize the wasted efforts, we consider a constrained optimization problem. Let $\text{ECC} = \mathbb{E} \left\{ \sum_{j=1}^{m} \mathbb{I}(\theta_j = \delta_j) \right\}$ denote the expected number of correct classifications. The goal is to

maximize the ECC subject to
$$
FSR^c \leq \alpha_c, c = 1, 2.
$$
 (2.4)

¹The class-specific FSR^c is connected to but fundamentally different from the Neyman-Pearson classification framework [\(Scott and Nowak, 2005;](#page-33-4) [Rigollet and Tong, 2011\)](#page-33-5) for asymmetric error control. The class-specific FSR^c , as a concept under the selective inference framework, is analogous to the FDR in multiple testing, whereas Neyman-Pearson classification operates under the classical Type I/II error paradigm in single hypothesis testing. Moreover, the two lines of research focus on substantially different issues.

2.3 Oracle rules for FSR control

In this subsection we derive a class of oracle FSR rules. To motivate our methodology, consider an asymptotically equivalent error rate (Appendix [C\)](#page-54-0), the marginal FSR

$$
\text{mFSR}^c = \frac{\mathbb{E}\left\{\sum_{j=1}^m \mathbb{I}(\delta_j = c, \theta_j \neq c)\right\}}{\mathbb{E}\left\{\sum_{j=1}^m \mathbb{I}(\delta_j = c)\right\}}.
$$
\n(2.5)

We aim to develop a selective classification rule that solves the following constrained optimization problem: maximize the ECC subject to $mFSR^c \leq \alpha_c$, $c=1, 2$. Next we prove an intuitive result that the optimal mFSR rule is a thresholding rule based on the optimal LDA function $S_j^{\pi} \equiv (\boldsymbol{W}_j - \boldsymbol{\mu})^{\top} \Sigma^{-1} \boldsymbol{d}$ (or its monotone transformations).

Consider a generalized discriminant rule $\boldsymbol{\delta}(t_1, t_2) = (\delta_j : 1 \le j \le m)$ of the form [\(2.1\)](#page-6-1): $\delta_j = \mathbb{I} (1 - T^j < t_1) + 2\mathbb{I} (T^j < t_2), 1 \le j \le m$, where

$$
T^j \coloneqq T(\boldsymbol{W}_j) = \mathbb{P}(\theta_j = 1 | \boldsymbol{W}_j) = \frac{\exp(S_j^{\pi})}{\exp(S_j^{\pi}) + 1},
$$

and $t_1, t_2 \in (0, 1)$ are the lower and upper thresholds satisfying $t_1 < 1 - t_2$. As T^j is a monotone transformation of S_j^{π} , generalized LDA rules based on T_j^j and S_j^{π} , with suitably adjusted thresholds, are equivalent. We use T^j instead of S_j^{π} to facilitate the development of a step-wise algorithm, which is described at the end of this section.

Let $Q^{c}(t_c)$ be the mFSR^c of $\boldsymbol{\delta}(t_1,t_2)$, $c=1,2$. Define the oracle thresholds t_{OR}^{c} $\sup\left\{t:Q^c(t)\leq\alpha_c\right\},c=1,2.$ To avoid assigning an individual to multiple classes, we assume that α_1 and α_2 have been chosen such that both t_{OR}^1 and t_{OR}^2 are less than or equal to 0.5^{[2](#page-9-0)}. Define the oracle mFSR procedure $\boldsymbol{\delta}_{OR} = (\delta_{OR}^j : 1 \le j \le m)$, where

$$
\delta_{OR}^j = \mathbb{I}\left(1 - T^j < t_{OR}^1\right) + 2 \cdot \mathbb{I}\left(T^j < t_{OR}^2\right). \tag{2.6}
$$

²This is an assumption to facilitate theoretical development. If there is overlapping selection in practice, we can simply classify the individual to the class with larger class probability $P(\theta_j = c | \mathbf{W}_j)$, $c = 1, 2$.

The next theorem shows that δ_{OR} is optimal.

Theorem 1. Let $\mathcal{D}_{\alpha_1,\alpha_2}$ be the collection of all classification rules such that for any $\delta \in$ $\mathcal{D}_{\alpha_1,\alpha_2}$, $mFSR_{\delta}^1 \leq \alpha_1$ and $mFSR_{\delta}^2 \leq \alpha_2$. Then $ECC_{\delta} \leq ECC_{\delta_{OR}}$ for any $\delta \in \mathcal{D}_{\alpha_1,\alpha_2}$.

The thresholds t_{OR}^1 and t_{OR}^2 in the oracle rule [\(2.6\)](#page-9-1) can be approximately calculated using the following step-wise algorithm. Denote $T^{(i)}$ the *i*th ordered statistic of $\{T^1, ..., T^m\}$.

Let
$$
k_1 = \min \left\{ 1 \le j \le m : \frac{1}{j+1} \sum_{i=0}^j \left\{ 1 - T^{(m-i)} \right\} \le \alpha_1 \right\}, k_2 = \max \left\{ 1 \le j \le m : \frac{1}{j} \sum_{i=1}^j T^{(i)} \le \alpha_2 \right\}.
$$
 (2.7)

As indicated by the theory in Section [4,](#page-17-0) t_{OR}^1 and t_{OR}^2 can be consistently estimated by $\hat{t}_{OR}^1 = \min\left(T^{(k_2)}, 0.5\right)$ and $\hat{t}_{OR}^2 = \min\left(1 - T^{(m-k_1)}, 0.5\right)$ under mild conditions. Here 0.5 is imposed to avoid overlapping selections. To see why the stepwise algorithm [\(2.7\)](#page-10-0) makes sense, note that the moving average $\frac{1}{r} \sum_{j=1}^{r} T^{(j)}$ provides an estimate of mFSR² when r observations with the smallest T^j are selected to class 2 (cf. [Sun and Cai](#page-33-6) [\(2007\)](#page-33-6)). Hence, it follows from [\(2.7\)](#page-10-0) that \hat{t}_{OR}^2 corresponds to the largest threshold such that the estimated FSR² is below α_2 . The explanation for \hat{t}^1_{OR} is similar.

Denote $\delta_{OR}^* = \left\{ \mathbb{I}(1 - T^j < \hat{t}_{OR}^1) + 2 \cdot \mathbb{I}(T^j < \hat{t}_{OR}^2) : 1 \leq j \leq m \right\}$. The next theorem shows that the stepwise algorithm [\(2.7\)](#page-10-0) is valid for both FSR and mFSR control.

Theorem 2. Consider the oracle setting where T^j are known, $j = 1, \dots, m$. Then we have $FSR^k(\delta_{OR}^*) \leq \alpha_k$, $mFSR^k(\delta_{OR}^*) \leq \alpha_k$, for $k = 1, 2$.

Remark 1. δ_{OR}^* is asymptotically optimal in the sense that $ECC_{\delta_{OR}^*}/ECC_{\delta_{OR}} \rightarrow 1$ as $m \to \infty$. This fact can be proved using similar arguments as those presented in the proof of Theorem [4.](#page-20-0)

2.4 Issues and roadmap

The FSR control in selective classification, which is closely related to the false discovery rate (FDR, [Benjamini and Hochberg, 1995\)](#page-30-4) control in multiple testing, presents unique chal-

lenges in high-dimensional inference. In multiple testing the null distribution of the p -values is assumed to be known precisely; hence FDR rules, such as the Benjamini-Hochberg's algorithm, can be derived to determine a proper p -value threshold that upper bounds the FDR. However, in classification the scores $(S_j^{\pi}$ or $T_j^j)$ must be estimated from the training data with noise. For state-of-the-art LDA rules in the high-dimensional setting [\(Cai and](#page-30-0) [Liu, 2011;](#page-30-0) [Shao et al., 2011;](#page-33-2) [Mai et al., 2012;](#page-32-0) [Dicker and Zhao, 2016;](#page-31-4) [Cai and Zhang, 2019\)](#page-31-1), the distributions of the estimated scores (and hence p -values) are in general unknown, rendering the uncertainty quantification and analysis of error rate intractable.

We take a different approach and develop a data-driven FSR rule in two steps. In the first step, we provide an efficient and robust score \hat{S}_j , which employs a new shrinkage rule that works well across sparse and dense regimes. In the second step, we develop a step-wise algorithm based on \hat{S}_j . Owing to the easy-to-analyze shrunken mechanism, we show that the uncertainties in the estimated score and its stochastic contribution to the errors by running the algorithm can be precisely quantified, establishing the theory on FSR control.

3 The Data-Driven LASS Procedure

The key step in estimating the score S_j^{π} is to develop a good estimate for $\mathbf{d} = \mathbf{\mu}_1 - \mathbf{\mu}_2$. In high-dimensional settings, most regularized LDA rules bet on the sparsity of d (e.g. [Tibshi](#page-33-0)[rani et al., 2003;](#page-33-0) [Shao et al., 2011\)](#page-33-2) to reduce the high variability in the sample estimates. However, the sparsity requirement, which may not hold in practice and often only serves as a working assumption, is counter-intuitive in the sense that the two classes are better separated as d has more nonzero elements. By contrast, [Efron](#page-31-3) (2009) ; [Greenshtein and](#page-32-3) [Park](#page-32-3) [\(2009\)](#page-32-3); [Dicker and Zhao](#page-31-4) [\(2016\)](#page-31-4) proposed LDA rules based on Tweedie-type shrinkage estimators of d , sidestepping the sparsity assumption. Existing non-sparse LDA rules have two limitations. First, Tweedie-type estimates are intractable to analyze, making it difficult to assess the uncertainties in classification. Moreover, Tweedie's formula requires

that the elements in d must be independent, which leads to efficiency loss when the dependence structure is highly informative [\(Cai and Liu, 2011;](#page-30-0) [Shao et al., 2011\)](#page-33-2). We propose an easy-to-analyze shrinkage estimator that overcomes the above limitations. The methodology and illustrative examples are provided in Sections [3.1](#page-12-0) and [3.2.](#page-14-0) The data-driven LASS procedure is presented in Section [3.3.](#page-17-1)

3.1 Methodology

Let \bar{X}_k and \bar{Y}_k be the kth coordinate of $\bar{\mathbf{X}}$ and $\bar{\mathbf{Y}}$, respectively. We consider a class of shrinkage estimators

$$
\hat{\mathbf{d}} = (\hat{d}_k : 1 \le k \le p) = \{ (\bar{X}_k - \bar{Y}_k) q_k : 1 \le k \le p \},\tag{3.1}
$$

where $q_k \in (0, 1)$ is a coordinate-wise shrinkage factor. To effectively reduce the uncertainties and quantify the associated misclassification risks, q_k needs to be designed carefully such that it converges to 1/0 at appropriate rates according to the strength of the signal. The proposed method chooses the following class of q_k :

$$
q_k := \frac{g_{1k} \left(|\bar{X}_k - \bar{Y}_k| \right)}{g_0 \left(|\bar{X}_k - \bar{Y}_k| \right) + g_{1k} \left(|\bar{X}_k - \bar{Y}_k| \right)},\tag{3.2}
$$

where g_0 and g_{1k} are respectively the density functions of $\mathcal{N}\left(0, \frac{n_1+n_2}{n_1n_2}\right)$ n_1n_2) and

$$
\mathcal{N}\left(\left\{(2+b)\sqrt{\hat{\sigma}_{kk}}+\sqrt{(2+b)^2\hat{\sigma}_{kk}+4}\right\}\sqrt{\frac{(n_1+n_2)}{2n_1n_2}\log p},\frac{n_1+n_2}{n_1n_2}\right),\right\}
$$

 $b > 0$ is a small constant, and $\hat{\sigma}_{kk}$ is the pooled sample variance of $\{X_{ik} : i = 1, ..., n_1\}$ and ${Y_{ik} : i = 1..., n_2}.$ The constant $b > 0$ is included in the definition only for theoretical considerations. In practice we can choose $b \approx 0$ or simply set $b = 0$. In all our simulations and data analyses, we report the results with $b = 0.1$, which are almost identical to the

results with $b = 0$.

The behavior of q_k is qualitatively different depending on the strength of d_k . The following proposition shows an intuitively appealing demarcation phenomenon of q_k , implying that the multiplicative shrinkage rule [\(3.1\)](#page-12-1) produces effects similar to that of hard thresholding rules: strong signals are kept and moderate/weak signals are suppressed.

Proposition 1. Consider q_k defined in [\(3.2\)](#page-12-2). Let $a_k = \left\{ (2 + b)\sqrt{\sigma_{kk}} + \sqrt{(2 + b)^2 \sigma_{kk} + 4} \right\}$ and ϵ an arbitrarily small constant. Define the following three groups:

$$
\mathcal{G}_1 = \left\{ 1 \le k \le p : |d_k| > (a_k/2 + \epsilon) \sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p} \right\} \text{ (strong signals)};
$$
\n
$$
\mathcal{G}_2 = \left\{ 1 \le k \le p : |d_k| = o(\sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p}} \right\} \text{ (weak signals)};
$$
\n
$$
\mathcal{G}_3 = \left\{ 1 \le k \le p : |d_k| < (a_k/2 - \epsilon) \sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p} \text{ and } k \notin \mathcal{G}_2 \right\} \text{ (moderate signals)}.
$$

Then there exists $\gamma > 0$ independent of p, n_1 and n_2 such that the following hold:

$$
(a). \ \ 1 - \mathbb{E}(q_k \mid k \in \mathcal{G}_1) = O(p^{-\gamma});
$$

(b).
$$
\mathbb{E}(q_k \mid k \in \mathcal{G}_3) = O(p^{-\gamma});
$$

(c). $\mathbb{E}(q_k | k \in \mathcal{G}_2) = O(p^{-(1+\gamma)}).$

We mention some merits of the proposed shrinkage rule. First, under the dense regime, the multiplicative factor q_k can produce significantly less noisy estimates than original observations while being capable of retaining more nonzero coordinates than thresholding rules. This leads to shrinkage rules (Section [3.2\)](#page-14-0) with robust and superior performance at different sparsity levels. Second, unlike LDA rules based on Tweedie's formula [\(Efron, 2009;](#page-31-3) [Dicker and Zhao, 2016\)](#page-31-4), the coordinate-wise shrinkage scheme in (3.2) does not require the independence between d_k . Finally, the multiplicative rule is easy to analyze and leads to provably valid rules for FSR control.

3.2 Adaptation to unknown sparsity: illustrations

We present numerical examples to provide insights on why the shrinkage rule (3.1) works well across the sparse and dense regimes.

We start with the sparse case. Suppose $n_1 = n_2 = n$. Let $n = 5$, $p = 625$, $d =$ (d_1, \ldots, d_p) , where $d_k = 2.5$ for $k \in \{1, \ldots, 50\}$ and $d_k = 0$ for $k \in \{51, \ldots, 625\}$. The observations are generated as $\mathbf{X}_i \sim \mathcal{N}(\mathbf{0}, \frac{1}{2})$ $\frac{1}{2}I_p$) and $\boldsymbol{Y}_i \sim \mathcal{N}(\boldsymbol{d}, \frac{1}{2}I_p), i = 1, \ldots, n$, where **0** is a p-dimensional vector of zeros and I_p a p-dimensional identity matrix. It follows that $\bar{X}_k-\bar{Y}_k \sim \mathcal{N}(d_k,1/n)$. We contrast the proposed shrinkage rule with hard/soft thresholding rules in Figure [1.](#page-15-0) Panels (a) and (b) plot d_k and observed $\bar{X}_k - \bar{Y}_k$, respectively, with coordinates corresponding to zero/nonzero d_k being marked in blue/red. Panel (c) plots the shrinkage estimates $(\bar{X}_k - \bar{Y}_k)q_k$, where q_k is defined in [\(3.2\)](#page-12-2) with $b = 0$. Panels (d)–(f) show the hard/soft thresholding estimates with different thresholds λ , where $\rho_h(t, \lambda, \sigma) \coloneqq$ $t\mathbb{I}(|t| > \lambda\sqrt{\sigma})$ and $\rho_s(t, \lambda, \sigma) \coloneqq \text{sgn}(t) \cdot \max(|t| - \lambda)$ √ $(\overline{\sigma},0)$ are the hard and soft thresholding functions, respectively.

We can see from Panel (c) that almost all blue points are pulled towards and centered around the line of zero by our proposed shrinkage rule. The multiplicative factor q_k is as effective as existing thresholding methods for noise reduction in the sense that the patterns in Panel (c) is qualitatively similar to those in Panels (d) to (f), except that in (d) and (e) too many blue points have survived whereas in (f) too many nonzero signals have been killed. Panel (c) shrinks most noisy entries to zero while being capable of preserving a significant portion of nonzero signals. The bottom row compares the shrinkage functions ρ_h and ρ_s with q_k by setting $\hat{\sigma}_{kk} = 0.5$ and $\lambda = 2.5$. We can see that our shrinkage function is continuous, nearly unbiased for large signals and yields similar effects as that of the hard-thresholding function. The proposed shrinkage rule is desirably tuning-free in the sense that one can simply set $b = 0$ in practice; this merit is justified in our theoretical analysis and corroborated by our numerical results. By contrast, the performance of existing thresholding rules depends critically on the value of λ , which is nontrivial to choose.

Figure 1: A comparison of our shrinkage rule [\(3.2\)](#page-12-2) with hard/soft thresholding rules in the sparse case. Panels (a), (b) and (c) respectively plot the true d_k , observed $\bar{X}_k - \bar{Y}_k$ and $(\bar{X}_k - \bar{Y}_k)q_k$. Panels (d)-(f) $[(g)-(i)]$ present results of hard-thresholding (soft-thresholding) rules. The effects of different shrinkage functions are provided at the bottom row.

Figure 2: Comparison of the proposed shrinkage rule with thresholding rules. The proposed shrinkage rule exhibits a curved pattern [Panel (c)], which is more effective in eliminating weak signals and keeping strong signals. Green lines are cubic polynomial fits of the points above the horizontal line of 0.2.

Next we turn to the dense case. The data are generated in a similar way as before except that we let $d_k = 2.5(k-1)/624$, $k = 1, ..., 625$, i.e. d_k increases linearly from 0 to 2.5. We mark the coordinates of **d** in three colors: red if d_k > ($\sqrt{0.5} + \sqrt{0.5 + 1} \sqrt{\log p/n} \approx 2.19$, black if $1.5 < d_k < ($ $\sqrt{0.5} + \sqrt{0.5 + 1} \sqrt{\log p/n}$ and blue otherwise^{[3](#page-16-0)}. We plot our shrinkage estimate and thresholding estimates in Figure [2.](#page-16-1) In this high-dimensional "dense" regime, the boundaries between weak, moderate and strong signals are blurred. Therefore the working assumptions (sparsity and dichotomy of \boldsymbol{d}) underpinning the use of thresholding rules can be problematic. In contrast with the (roughly) linear patterns of the surviving points in Panels (d) to (i), the curved pattern in Panel (c) provides differential amount of shrinkage for weak and strong signals, achieving a more desirable balance between reducing the uncertainties and maintaining useful signals.

³There are no clearcut boundaries; the colors in this example are only chosen for illustration purpose.

3.3 The Data-Driven LASS Procedure

We propose to estimate $S_j^{\pi} = (\boldsymbol{W}_j - \boldsymbol{\mu})^{\top} \Sigma^{-1} \boldsymbol{d}$ by

$$
\hat{S}_j = \left(\boldsymbol{W}_j - \frac{\bar{\boldsymbol{X}} + \bar{\boldsymbol{Y}}}{2}\right)^{\top} \hat{\boldsymbol{\Sigma}}^{-1} \hat{\boldsymbol{d}}.
$$
\n(3.3)

First, $\hat{\Sigma}^{-1}$ is the estimated precision matrix and $\hat{\boldsymbol{d}}$ is the proposed shrinkage estimate [\(3.1\)](#page-12-1). The estimation of the precision matrix has been intensively studied in the literature; see [Liu and Luo](#page-32-7) [\(2015\)](#page-32-7), [Cai et al.](#page-31-5) [\(2016\)](#page-31-5), [Loh and Tan](#page-32-8) [\(2018\)](#page-32-8), [Wang et al.](#page-33-7) [\(2013\)](#page-33-7), [Sun and](#page-33-8) [Zhang](#page-33-8) [\(2013\)](#page-33-8), [Yuan](#page-33-9) [\(2010\)](#page-33-9) for related works. In our numerical studies we use the ACLIME estimator proposed in [Cai et al.](#page-31-6) [\(2011\)](#page-31-6). Next, $\hat{\boldsymbol{d}} = ((\bar{X}_1 - \bar{Y}_1)q_1, \ldots, (\bar{X}_p - \bar{Y}_p)q_p)$, where q_k is as defined in [\(3.2\)](#page-12-2). Let $\hat{T}^j :=$ $\exp(\hat{S}_j)$ $1 + \exp(\hat{S}_j)$. Denote $\{\hat{T}^{(j)}: 1 \leq j \leq m\}$ the ordered statistics. Define

$$
k_1 = \min\left\{1 \le j \le m : \frac{1}{j+1} \sum_{i=0}^j (1 - \hat{T}^{(m-i)}) \le \alpha_1\right\}, \quad k_2 = \max\left\{1 \le j \le m : \frac{1}{j} \sum_{i=1}^j \hat{T}^{(i)} \le \alpha_2\right\}.
$$
\n(3.4)

The data-driven LASS procedure is given by $\hat{\boldsymbol{\delta}} = (\hat{\delta}_1, \dots \hat{\delta}_m)$, where

$$
\hat{\delta}_j = \mathbb{I}\left\{1 - \hat{T}^j < \min\left(1 - \hat{T}^{(m-k_1)}, 0.5\right)\right\} + 2 \cdot \mathbb{I}\left\{\hat{T}^j \le \min\left(\hat{T}^{(k_2)}, 0.5\right)\right\}.\tag{3.5}
$$

Remark 2. If we choose $\alpha_1 = \alpha_2 = 0.5$, then indecisions are not allowed by [\(3.5\)](#page-17-2). That is, LASS becomes a classical rule that makes definitive classifications on all individuals. We shall see that LASS is still superior in both theory and numerical performance compared to existing methods under this classical setup (Corollary [1](#page-20-1) in Section [4](#page-17-0) and Section [5.1\)](#page-21-1).

4 Theoretical Properties of LASS

This section studies theoretical properties for the data-driven LASS procedure. We focus on the regime of $\frac{n_1+n_2}{n_1n_2}$ log $p \to 0$, which requires that the dimension does not grow too fast relative to the sample size. We consider issues on FSR control and optimality in turn, and conclude the section with a discussion of connections to existing works.

We first state and explain a few conditions needed in our theoretical analysis.

(A1) The covariance matrix $\Sigma = (\sigma_{kl})_{1 \leq k,l \leq p}$ satisfies $0 < \epsilon_0 \leq \sigma_{kk} \leq 1/\epsilon_0$ for all $1 \leq k \leq p$, where ϵ_0 is a fixed positive constant.

(A1) is a standard condition in matrix analysis, and is satisfied when the covariance matrix is well-conditioned, as assumed in, for example, [Bickel and Levina](#page-30-7) [\(2008\)](#page-30-7).

(A2) The estimated precision matrix $\hat{\Sigma}^{-1}$ satisfies $\|\hat{\Sigma}^{-1} - \Sigma^{-1}\|_2^2 = o(1)$.

Consistent estimation of the precision matrix Σ^{-1} has been studied intensively. Effective estimators and sufficient conditions for consistent estimation have been discussed in a large body of works including [Bickel and Levina](#page-30-7) [\(2008\)](#page-30-7), [Yuan](#page-33-9) [\(2010\)](#page-33-9), [Liu and Luo](#page-32-7) [\(2015\)](#page-32-7)[,Cai](#page-31-5) [et al.](#page-31-5) [\(2016\)](#page-31-5) and [Avella-Medina et al.](#page-30-8) [\(2018\)](#page-30-8), among others.

(A3) $|\mathcal{G}_1| \geq 1$ and $|\mathcal{G}_3| = O(\frac{n_1 n_2}{n_1 + n_2})$ $\frac{n_1 n_2}{n_1 + n_2}$, where \mathcal{G}_1 and \mathcal{G}_3 are defined in Proposition [1](#page-13-0) and correspond to collections of strong and moderate coordinates of d , respectively.

In (A3), $|\mathcal{G}_1| \geq 1$ provides a sufficient condition under which LASS makes at least one definitive classification with high probability. As opposed to existing works that require the sparsity of both \mathcal{G}_1 and \mathcal{G}_3 , we do not impose an upper bound on $|\mathcal{G}_1|$. Our condition seems to be more sensible because having more strong signals $(d_k \in G_1)$ is helpful for distinguishing the two classes, and what really hurts the performance of LDA rules is an overwhelming number of nonzero elements of moderate strength $(d_k \in G_3)$. The condition $|\mathcal{G}_3| = O(\frac{n_1 n_2}{n_1 + n})$ $\frac{n_1 n_2}{n_1 + n_2}$ corresponds to a weaker notion of sparsity in the sense that the sparsity or approximate sparsity conditions in existing works (e.g. [Cai and Liu, 2011\)](#page-30-0) will be violated if $|\mathcal{G}_3| \gg \frac{n_1 n_2}{n_1+n_2}$. We stress that the conventional sparsity notion assumes that there are relatively few signals, while we require that there are relatively few signals of moderate strength will fall with the narrow range defined by \mathcal{G}_3 , which eliminates the need of the counter-intuitive sparsity condition on \mathcal{G}_1 as used in existing works. The superiority of LASS under the dense signal setting is illustrated in our numerical results (Section [5\)](#page-21-0).

The next theorem establishes the asymptotic validity of LASS for FSR control.

Theorem 3. Let δ be the data-driven LASS procedure defined in [\(3.5\)](#page-17-2). Under conditions (A1)-(A3), we have $mFSR_{\hat{\delta}}^c \leq \alpha_c + o(1)$ and $FSR_{\hat{\delta}}^c \leq \alpha_c + o(1)$ for $c = 1, 2$.

Remark [3](#page-19-0). Note that in Theorem 3 mFS R^c can be asymptotically smaller than α_c . This is because when the two classes are well separated, $\hat{T}^{(k_2)}$ and $1-\hat{T}^{(m-k_1)}$ can be greater than 0.5 (k_1 and k_2 are as defined in [\(3.4\)](#page-17-3)). Since the thresholds in [\(3.5\)](#page-17-2) are at most 0.5, $mFSR_{\hat{\delta}}^c$ may not attain the target level α_c . However, this should not be viewed as a drawback of our method. If both $\hat{T}^{(k_2)}$ and $1-\hat{T}^{(m-k_1)}$ are larger than 0.5, there will be no indecision and we are back in the classical setting.

Our conditions on error rate control are substantially different in nature compared to those required by state-of-the-art LDA rules. First, the sparsity of Σ^{-1} is not a necessary condition for our theory on FSR control^{[4](#page-19-1)}. Second, our theory needs neither sparsity nor consistent estimation of d . Finally, in contrast with existing works (e.g. [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0), [Shao et al.](#page-33-2) [\(2011\)](#page-33-2)), our theory has no restrictions on the norm of **d** or Σ^{-1} **d**. We stress that estimation and classification are fundamentally different tasks: the assumptions on the norm are natural for estimation problems, but counter-intuitive for classification problems – larger norms make the classification task easier and lead to lower error rates.

Next we investigate the asymptotic optimality of LASS. The next condition, which requires the elements in both \mathcal{G}_2 and \mathcal{G}_3 are sparse in L_2 , ensures that shrinking weak and moderate signals has negligible effects on the power.

$$
(A4) \sum_{k \notin \mathcal{G}_1} d_k^2 = o(1).
$$

The next theorem shows that the data-driven LASS achieves the performance of the oracle procedure [\(2.6\)](#page-9-1) asymptotically. As opposed to existing theories in sparse LDA, no conditions are imposed on the sparsity or norm of strong signals $(d_k \in \mathcal{G}_1)$.

⁴Note that even when the sparsity of Σ^{-1} is needed for consistent estimation, the sparsity conditions on Σ^{-1} and **d** usually correspond to fundamentally different notions in scientific studies. Our theory seems to be more sensible as it eliminates the need on the sparsity of d .

Theorem 4. Under conditions (A1)-(A4), we have $mFSR_{\hat{\delta}}^c \leq \alpha_c + o(1)$, $FSR_{\hat{\delta}}^c \leq \alpha_c + o(1)$ for $c = 1, 2$, and $ECC_{\hat{\boldsymbol{\delta}}}/ECC_{\boldsymbol{\delta}_{OR}} = 1 + o(1)$.

If we let $\alpha_1 = \alpha_2 = 0.5$, then the FSR control setup reduces to the classical setup where indecisions are not allowed. Let δ be a classification rule that only takes on value 1 or 2, define $L(\boldsymbol{\delta}) = \mathbb{P}\{\theta_j \neq \delta_j | (\boldsymbol{X}_i, 1 \leq i \leq n_1), (\boldsymbol{Y}_i, 1 \leq i \leq n_2)\}, R(\boldsymbol{\delta}) = \mathbb{E}\{L(\boldsymbol{\delta})\}, \text{ the }$ following corollary is a direct consequence of Theorem [4.](#page-20-0)

Corollary 1. (Risk consistency). Suppose we choose $\alpha_1 = \alpha_2 = 0.5$. Then under conditions (A1)-(A5), we have $R(\hat{\boldsymbol{\delta}}) - R(\boldsymbol{\delta}^F) \to 0$, where $\boldsymbol{\delta}^F$ is the oracle Fisher's rule.

We conclude this section with an example to contrast our thoery with existing theories in high-dimensional LDA, where the assumption on the sparsity of \boldsymbol{d} is commonly believed to be "indispensable". For example, [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0) requires $|\Sigma^{-1} \mathbf{d}|_0 =$ $o(\sqrt{(n_1+n_2)/\log p})$ to achieve risk consistency. This sparsity condition seems to be necessary if the scope of analysis is limited to the class of thresholding rules. It is not an artifact of the theoretical analysis, as we can see from the numerical results in Section [5.1.2](#page-24-0) where the disadanvantages of existing works are reflected. However, LASS still achieves risk consistency even when the condition in [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0) is violated. We illustrate this through the next example.

Example 1. Consider an asymptotic setup where $n_1 = n_2 = n$, $p = n^2$, $\Sigma = I_p$ and $\boldsymbol{\mu}_1 = (0, \ldots, 0)^\top$. Let $\boldsymbol{\mu}_2 = (1, \ldots, 1, 0, \ldots, 0)^\top$ be a vector with the first k entries being 1 and the rest 0. Let $k = n$ and $\Delta_p = d^T \Sigma^{-1} d$, then in this setting $\Delta_p = n$. It is clear that $|\mathbf{\Sigma}^{-1} \mathbf{d}|_0 = n$ and $|\mathbf{\Sigma}^{-1} \mathbf{d}|_1 = n$. Denote $\hat{\boldsymbol{\delta}}_{LPD}$ the LPD rule in [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0). To guarantee that $R(\hat{\boldsymbol{\delta}}_{LPD}) - R(\boldsymbol{\delta}^F) \to 0$, the theory in [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0) requires that $|\mathbf{\Sigma}^{-1}\mathbf{d}|_0 = o(\sqrt{n/\log p})$ or $\frac{|\mathbf{\Sigma}^{-1}\mathbf{d}|_1}{\Delta_p^{1/2}} + \frac{|\mathbf{\Sigma}^{-1}\mathbf{d}|_1^2}{\Delta_p^2} = o(\sqrt{n/\log p})$, both of which are violated. By contrast, note that all nonzero elements in d are in G_1 , the conditions of Corollary [1](#page-20-1) are satisfied for any $k \geq 1$, which guarantees that LASS achieves risk consistency across

sparse and dense settings. We shall see in simulation studies that the gap in numerical performance between LASS and LPD grows as k increases.

As opposed to existing works that produce approximately the same amount of shrinkage for elements in both \mathcal{G}_1 (strong) and \mathcal{G}_3 (moderate), LASS adopts an adaptive strategy that makes it possible to provide differential amounts of shrinkage for the elements in \mathcal{G}_1 and G_3 (Proposition 1 and Figure 2c). The resulting shrinkage rule is more effective in keeping strong signals and eliminating noisy elements; this explains the superiority of LASS in both theory and numerical performance.

5 Numerical Experiments

This section illustrates the numerical performance of LASS using both simulated and real data. The simulation considers two setups: the conventional setup that does not allow indecisions (Section [5.1\)](#page-21-1), and the selective classification setup that aims to control the FSR (Section [5.2\)](#page-24-1). Two real data sets are discussed in Sections [5.3](#page-27-0) and [5.4.](#page-29-0) In all analyses, LASS is implemented using $b = 0.1$ in [\(3.2\)](#page-12-2) and the ACLIME method [\(Cai et al., 2016\)](#page-31-5) is adopted for estimating Σ^{-1} . For the simulated data, we take $n_1 = n_2 = n$.

5.1 Simulation: the conventional setup

We start with the classical setting where no indecisions are allowed. We compare LASS with the following methods.

- Fisher's rule that uses true μ_1 , μ_2 and Σ^{-1} (denoted "Oracle"). This method serves as the optimal benchmark for all classification rules.
- The LPD rule proposed by [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0) (denoted "LPD"), which is implemented using the code provided on the authors' website.
- The AdaLDA rule proposed by [Cai and Zhang](#page-31-1) [\(2019\)](#page-31-1) (denoted "AdaLDA"), which is implemented using the code provided on the authors' website.
- Fisher's rule that uses sample estimates of μ_1, μ_2 and Σ^{-1} (denoted "Naive"). Specifically, S_j^{π} is estimated as $(W_j - \frac{\bar{\mathbf{x}} + \bar{\mathbf{y}}}{2})$ $\left(\frac{1}{2}\right)^{\top} \hat{\Sigma}^{-1}(\bar{\pmb{X}} - \bar{\pmb{Y}}),$ where $\hat{\Sigma}^{-1}$ is the Penrose inverse of the sample covariance matrix.
- The L_1 logistic regression method (denoted "Lasso"). We have followed the approach suggested by [Lei](#page-32-5) [\(2014\)](#page-32-5), where the tuning parameter is chosen by cross-validation.
- The empirical Bayes method proposed in [Efron](#page-31-3) [\(2009\)](#page-31-3) (denoted "Ebay"). We use the R-package Ebay to estimate d . Σ^{-1} is estimated by a diagonal matrix where diagonals are the inverses of sample variances.

We present numerical results in the next two subsections to show that LASS (a) is comparable to state-of-the-art methods in the sparse case, and (b) substantially outperforms competing methods in the dense case.

5.1.1 Sparse setting

Let $\mu_1 = (0, ..., 0)^T \in \mathbb{R}^p$, and μ_2 be a vector with the first 10 entries being 0.5, the next 10 being $0.1(\log p/n)^{1/2}$, and the rest being 0. Consider the following three correlation structures that are widely considered in the literature [\(Cai and Liu, 2011;](#page-30-0) [Cai and Zhang,](#page-31-1) [2019;](#page-31-1) [Avella-Medina et al., 2018\)](#page-30-8).

Model 1: Band graph. Let $\Sigma^{-1} = \Omega = (\omega_{ij})_{p \times p}$, where $\omega_{ii} = 1$, $\omega_{i,i+1} = \omega_{i+1,i} = 0.35$, $\omega_{i,i+2} = \omega_{i+2,i} = 0.175$, and $\omega_{ij} = 0$ if $|i - j| > 2$.

Model 2: AR(1) structure. Let $\Sigma^{-1} = \Omega = (\omega_{ij})_{p \times p}$, where $\omega_{ij} = 0.3^{|i-j|}$.

Model 3: Block structure. Let $\Sigma^{-1} = \Omega = (\mathbf{B} + \delta I_p)/(1 + \delta)$, where $b_{ij} = b_{ji} = 0.05$. Bernoulli(0.1) for $1 \le i \le p/2$, $i < j \le p$, $b_{ij} = b_{ji} = 0.05$ for $p/2 + 1 \le i < j \le p$, $b_{ii} = 1$ for $1 \le i \le p$, and $\delta = \max\{-\lambda_{min}(\mathbf{B}), 0\} + 0.1$.

The size of the training set is $n = 400$, with p varying from 500 to 1000. The misclassification rate is computed based on $m = 2000$ test points generated from $\mathcal{N}(\mu_1, \Sigma)$ or $\mathcal{N}(\boldsymbol{\mu}_2, \Sigma)$ with equal probability. We repeat the experiment for 100 times, and report the misclassification rates (in percentage) in Table [1.](#page-23-0)

\boldsymbol{p}	Oracle	Naive	LASS	LPD	$\rm AdaLDA$	LASSO	Ebay

Table 1: Comparison of average misclassification rate in percentage. The smallest error rate (next to that by the oracle) in each setting has been boldfaced.

We can see that the Naive method can be substantially improved by LPD, AdaLDA and LASSO, all of which make strong assumptions on the sparsity structure of the data generating model. Although no method dominates, LASS and AdaLDA seem to perform the best among all methods being considered. LASS is comparable to AdaLDA in terms of the overall effectiveness across the three settings. This is impressive since [Cai and](#page-31-1) [Zhang](#page-31-1) [\(2019\)](#page-31-1) showed AdaLDA is minimax optimal in sparse LDA. We shall see in the

next simulation that in the non-sparse setting, LASS substantially outperforms AdaLDA. Similar to LASS, the Ebay method adopts the shrinkage idea and does not make strong assumptions on the sparsity structure. We can see that Ebay performs reasonably well. However, Ebay relies on the independence assumption, has no theoretical guarantee on the convergence of error rate, and is less effective than LASS in all settings.

5.1.2 Dense setting

Consider the three models in the previous section. The choices of μ_1 and Σ are the same, while μ_2 contains more nonzero entries: the first $(p/4)$ entries are 0.4 and the rest are 0. The misclassification rates (in percentage) are summarized in Table [2.](#page-25-0) As expected, methods that rely heavily on the sparsity assumption of d , such as LPD and AdaLDA, do not perform well. We mention a few important patterns in the results.

- The performance of LPD and AdaLDA deteriorates as p increases. This is undesirable considering that the classification problem seems to have become easier, as is manifested in the improved performance of the oracle rule. In many settings LPD and AdaLDA can be worse than Naive.
- Ebay does relatively well when p is small but its performance also deteriorates as p increases. The misclassification rates can be much higher than the oracle benchmark.
- LASS and Lasso substantially outperform competing methods in most settings. The performance of both improves as p increases, exhibiting the same desirable trend as that of the oracle rule. LASS dominates Lasso, and the gap in error rate is substantial in several settings.

5.2 Simulation: FSR control

We now turn to the selective inference setup where the goal is to control the FSR. For Naive, Lasso and Ebay, we first form an estimate for the discriminant, denoted as \hat{S}_j , then

use $\hat{T}^j = \frac{\exp(\hat{S}_j)}{1 + \exp(\hat{S}_j)}$ $\frac{\exp(S_j)}{1+\exp(\hat{S}_j)}$ in [\(3.4\)](#page-17-3) and [\(3.5\)](#page-17-2), which serve as the *base algorithm* for FSR control. LPD and AdaLDA are omitted as they only produce the signs of the discriminants and it is unclear how to adjust the algorithms for FSR control.

Next we present results pertaining to FSR control in the sparse settings as considered in Section [5.1.1,](#page-22-0) but omit the results for the dense settings in Sections [5.1.2.](#page-24-0) The reason is that when the classification task becomes easy (as indicated by Table [2\)](#page-25-0): the misclassification rate is so low that the FSR framework is no longer needed.

Table 2: Comparison of average misclassification rate in percentage. The smallest error rate (next to that by the oracle) in each setting has been boldfaced.

Consider the models in Section [5.1.1.](#page-22-0) We fix $n = 400$ and vary p from 200 to 800. The target FSR^1 and FSR^2 levels are both set 0.1. The experiment is repeated for 100 times, and the average FSRs (displayed in the first two columns) and power (defined as ECC/m ;

Figure 3: Comparison of FSR and Power. Naive and Ebay fail to control the FSR. LASS controls FSR at the nominal level with the highest Power.

displayed in the last column) are reported in Figure [3.](#page-26-0) We mention the following patterns.

- Both Naive and Ebay fail to control the FSR. The Naive method becomes worse as p increases. This corroborates the analysis in [Bickel and Levina](#page-30-1) [\(2004\)](#page-30-1), which shows that LDA rules based on sample estimates suffer from high dimensionality.
- Both Lasso and LASS control the FSR at the nominal level, showing that our proposed data-driven algorithm [\(3.4\)](#page-17-3) is effective for FSR control when equipped with reasonably good estimates of the scores.
- LASS controls the FSR at the nominal level accurately across all settings. Lasso is conservative and has lower power.

5.3 Lung cancer data

We analyze the lung cancer data [\(Gordon et al., 2002,](#page-32-9) available at [https://leo.ugr.es/](https://leo.ugr.es/elvira/DBCRepository/LungCancer/LungCancer-Harvard2.html) [elvira/DBCRepository/LungCancer/LungCancer-BHarvard2.html](https://leo.ugr.es/elvira/DBCRepository/LungCancer/LungCancer-Harvard2.html)), a benchmark data set in high-dimensional classification problems. The data set collects expression levels for $p =$ 12, 533 genes on 181 tissue samples. Among the 181 samples, 31 are from malignant pleural mesothelioma (MPM) group and 150 are from adenocarcinoma (ADCA) group. The training set contains 16 samples from MPM and 16 samples from ADCA. The testing set contains 134 samples from MPM and 15 samples from ADCA.

We follow the same data pre-processing steps in [Cai and Liu](#page-30-0) [\(2011\)](#page-30-0). First, the sample variances of individual genes are obtained based on the training data. Next, we drop 195 genes whose sample variances are greater than 10^2 or less than 10^{-2} after rescaling by a factor of 10⁴ . Finally, to reduce the computational cost (which mainly comes from estimating the precision matrix), only top 200 genes (with the largest absolute values of the two sample t-statistics) are used for constructing different classification rules. Figure [4](#page-28-0) illustrates the scores $\hat{T}^j = \frac{\exp(\hat{S}_j)}{1 + \exp(\hat{S}_j)}$ $\frac{\exp(S_j)}{1+\exp(\hat{S}_j)}$ estimated by LASS, Naive, Ebay and Lasso. For better illustration, the first 134 testing points are from ADCA group and the next 15 are from MPM group.

To achieve better separation, the values of the first 134 points (the next 15 points) should be high (low). We can see that LASS shows perfect separation of the two classes. While Ebay provides a clearer separation than Naive and Lasso, it is less effective than LASS. For this particular data set, if we choose to control the FSR at level $\alpha = 0.1$, then LASS makes no indecision. Thus, it makes sense to compare the misclassification rates under the classical setup. The results are presented in Table [3,](#page-28-1) from which we can see that LASS has the best performance.

Figure 4: Comparison of estimated T: LASS separates the two classes almost perfectly. Ebay does better than Naive and Lasso but worse than LASS.

Table 3: $\#$ of misclassifications by each method

	LASS Naive	$ $ LPD	AdaLDA Lasso	Ebar
Misclassification $\mathbf{0}$ ($\mathbf{0\%}$) 5 (3.36%) 1 (0.67%) 1 (0.67%) 5 (3.36%) 3 (2.01%)				

	\overline{L} LASS \overline{L}	\vert Naive \vert LPD	\vert AdaLDA \vert Lasso \vert Ebay	
Misclassification 30.73% 40.24% 32.34% 30.28% 31.23% 31.57%				

Table 4: Misclassification rates of different methods

Table 5: FSR and power comparison.

	LASS	Naive	Lasso	Ebay
$\overline{\text{FSR}^1}$	$\overline{\bf 10.38\%}$	41.90%	17.81\%	32.01\%
$\sqrt{FSR^2}$	11.51%	38.75%	16.00%	30.88%
Power	20.60%	59.38\%	19.25\%	68.41\%

5.4 p53 Mutants Data

Finally we perform classification on p53 mutants data [\(Danziger et al., 2009\)](#page-31-7), which consist of 16,772 tissue samples, and for each sample a $p = 5,407$ -dimensional vector is measured. Among the 16,772 samples, 143 are determined as "active" and the rest are determined as "inactive". We randomly select 100 active samples and 100 inactive samples as our training data, then take the rest 43 active samples and 50 random inactive samples as our testing set. To make the classification problem more difficult, an independent $\mathcal{N}(0, 40)$ noise variable is added to each gene in both the training and testing sets.

We follow the previous pre-processing steps: (a) the training data are used to estimate the sample variances, (b) genes with variances greater than 10^2 or smaller than 10^{-2} are dropped, and (c) only top 100 genes with the largest t-statistics are used. The experiment is repeated 50 times with results summarized in Tables [4](#page-29-1) and [5.](#page-29-2)

Table [4](#page-29-1) contains the results under the conventional setup. LASS performs as well as the LPD and AdaLDA rules. But all methods have high misclassification rates. Hence we consider FSR control. We set the target FSR levels for both classes to be 0.1. In Table [5](#page-29-2) we compare the FSR and power of different methods. We can see that LASS effectively controls the FSR while Naive, Ebay and Lasso fail to do so.

Online Supplementary Material for "A Locally Adaptive Shrinkage Approach to False Selection Rate Control in High-Dimensional Classification"

This supplement contains the proofs of main theorems, propositions and corollaries (Section A), proofs of technical lemmas (Section B), and an argument establishing the asymptotic equivalence of FSR and mFSR (Section C).

A Proofs of main theorems, propositions and corollaries

We swap the proofs of Theorems [4](#page-20-0) and [3](#page-19-0) as the latter is simpler. Other proofs are arranged according to the orders in the text.

A.1 Proof of Theorem [1](#page-10-1)

We only need to show $\delta_{OR}^j = 2\mathbb{I}(T^j \lt t_{OR}^2)$ controls mFSR² at level α_2 and maximizes $\mathbb{E} \left\{ \sum_{i=1}^m \mathbb{I}(\theta_j = 2, \delta_j = 2) \right\}$. The same argument can be used to show that $\delta_{OR}^j = \mathbb{I}(1 - T^j <$ t_{OR}^1) controls mFSR¹ at level α_1 and maximizes $\mathbb{E}\left\{\sum_{i=1}^m \mathbb{I}(\theta_j=1,\delta_j=1)\right\}$. The theorem is proved when we combine these two statements.

The proof is divided into two parts. In part (a), we establish two properties of the classification rule $\delta^2(t) = \{2\mathbb{I}(T^j \lt t) : 1 \leq j \leq m\}$. We show that it produces mFSR² $\lt t$ for all $t \in (0,1)$ and that its mFSR² is monotonic in t. In part (b) we show that when the threshold is t_{OR}^2 , the classification rule has mFSR² = α_2 and maximizes $\mathbb{E} \left\{ \sum_{i=1}^m \mathbb{I}(\theta_j = 2, \delta_j = 2) \right\}$ amongst all valid classification rule with mFSR² $\lt \alpha_2$.

Part(a). Consider classification rule $\{2 \cdot \mathbb{I}(T^j \lt t) : 1 \leq j \leq m\}$. Let $Q^2(t) = \alpha_t$ be its

the mFSR² level. We first show that $\alpha_t < t$. Since $T^j = P(\theta_j = 1 | \boldsymbol{W}_j)$, then

$$
\mathbb{E}\left\{\sum_{j=1}^m \mathbb{I}(\theta_j=1,\delta_j=2)\right\} = \mathbb{E}_{\boldsymbol{W}}\left[\left\{\sum_{j=1}^m \mathbb{E}_{\boldsymbol{\theta}|\boldsymbol{W}}\mathbb{I}(\theta_j=1,\delta_j=2)\right\}\right] = \mathbb{E}_{\boldsymbol{W}}\left\{\sum_{i=1}^m T^j \mathbb{I}(\delta_j=2)\right\},\,
$$

where E is the expectation over (W, θ) , E_W is the expectation over W, and $E_{\theta|W}$ is the expectation over θ holding W fixed. Recall $Q_{OR}^2(t) = \alpha_t$ is the FSR² level of the classification rule $\{2 \cdot \mathbb{I}(T^j < t) : 1 \leq i \leq m\}$, we have

$$
\mathbb{E}_{\mathbf{W}}\left\{\sum_{j=1}^{m} (T^j - \alpha_t) \mathbb{I}(T^j < t)\right\} = 0. \tag{A.1}
$$

This implies that $\alpha_t < t$. To see this, if $\alpha_t \geq t$, then $(T^j - \alpha_t) \mathbb{I}(T^j < t) < 0$, which contradicts the right hand side.

Next, we show that $Q^2(t)$ is nondecreasing in t. That is, letting $Q^2(t_j) = \alpha_{t_j}$, if $t_1 < t_2$, then $\alpha_{t_1} \leq \alpha_{t_2}$. We argue by contradiction. Suppose that $t_1 < t_2$ but $\alpha_{t_1} > \alpha_{t_2}$. Then

$$
(T^{j} - \alpha_{t_2})\mathbb{I}(T^{j} < t_2) \tag{A.2}
$$
\n
$$
= (T^{j} - \alpha_{t_1})\mathbb{I}(T^{j} < t_1) + (\alpha_{t_1} - \alpha_{t_2})\mathbb{I}(T^{j} < t_1) + (T^{j} - \alpha_{t_2})\mathbb{I}(t_1 \le T^{j} < t_2)
$$
\n
$$
\ge (T^{j} - \alpha_{t_1})\mathbb{I}(T^{j} < t_1) + (\alpha_{t_1} - \alpha_{t_2})\mathbb{I}(T^{j} < t_1) + (T^{j} - \alpha_{t_1})\mathbb{I}(t_1 \le T^{j} < t_2).
$$

By [\(A.1\)](#page-35-0) we have $\mathbb{E}\left\{\sum_{j=1}^m(T^j-\alpha_{t_1})\mathbb{I}(T^j < t_1)\right\} = 0$, together with the fact that $\alpha_{t_1} < t_1$ we have $\mathbb{E}\left\{\sum_{j=1}^m(T^j-\alpha_{t_2})\mathbb{I}(T^j < t_2)\right\} > 0$, contradicting [\(A.1\)](#page-35-0).

Part(b). Define $t_{OR}^2 = \sup_t \{ t \in (0,1) : Q^2(t) \leq \alpha \}$. By part (a), $Q^2(t)$ is non-decreasing in t. By continuity, $Q^2(T) = \alpha_2$. Next, consider the oracle rule $\delta_{OR}^2 = (\delta_{OR}^{2,1}, \ldots, \delta_{OR}^{2,m}) =$ ${2\mathbb{I}(T^j < t_{OR}^2): 1 \leq j \leq m}$ and an arbitrary rule $\boldsymbol{\delta}_* = (\delta_*^1, \cdots, \delta_*^m)$ such that $mFSR_{\boldsymbol{\delta}_*}^2 \leq$ α_2 . Using the result in part (a), we have

$$
\mathbb{E}\left\{\sum_{j=1}^{m}(T^j-\alpha)\mathbb{I}(\delta_{OR}^{2,j}=2)\right\}=0 \text{ and } \mathbb{E}\left\{\sum_{j=1}^{m}(T^j-\alpha)\mathbb{I}(\delta^j*=2)\right\}\leq 0. \tag{A.3}
$$

Taking the difference of the two equations in [\(A.3\)](#page-35-1), we have

$$
\mathbb{E}\left\{\sum_{j=1}^{m} (T^j - \alpha) \mathbb{I}(\delta_{OR}^{2,j} = 2) - (T^j - \alpha) \mathbb{I}(\delta_*^j = 2)\right\} \ge 0.
$$
 (A.4)

Next consider the transformation $f(x) = (x - \alpha)/(1 - x)$. Note that $f'(x) = (1 - \alpha)/(1 - x)$ $(x)^2 > 0$, $f(x)$ is monotonically increasing, the order is preserved by this transformation: if $T^i < t_{OR}^2$ then $f(T^i) < f(t_{OR}^2)$. This means we can rewrite the oracle rule as

$$
\delta_{OR}^{2,i} = 2\mathbb{I}\left[\left\{ (T^i - \alpha)/(1 - T^i) \right\} < \lambda_{OR}^2 \right],
$$

where $\lambda_{OR}^2 = (t_{OR}^2 - \alpha)/(1 - t_{OR}^2)$. It will be useful to note that, from part (a), we have $\alpha_{t_2} < t_{OR}^2 < 1$, which implies that $\lambda_{OR}^2 > 0$. Note that

$$
\mathbb{E}\left[\sum_{j=1}^{m} \left\{\mathbb{I}(\delta_{OR}^{2,j} = 2) - \mathbb{I}(\delta_{*}^{j} = 2)\right\} \left\{(T^{j} - \alpha) - \lambda_{OR}^{2}(1 - T^{j})\right\}\right] \le 0
$$
 (A.5)

To see this, consider that if $\mathbb{I}(\delta^{2,j}_{OR} = 2) - \mathbb{I}(\delta^j_*) = 2 \neq 0$, then either (i) $\mathbb{I}(\delta^{2,j}_{OR} = 2) - \mathbb{I}(\delta^j_*) = 1$ $2) > 0$ or (ii) $\mathbb{I}(\delta_{OR}^{2,j} = 2) - \mathbb{I}(\delta_{*}^{j} = 2) < 0$ holds. If (i) holds, then $\delta_{OR}^{2,j} = 2$ and it follows that $\{(T^j-\alpha)/(1-T^j)\}\lt \lambda_{OR}^2$. If (ii) holds, then $\delta_{OR}^j\neq 2$ and $\{(T^j-\alpha)/(1-T^j)\}\geq \lambda_{OR}^2$. In both cases, we have

$$
\left\{ \mathbb{I}(\delta_{OR}^{2,j} = 2) - \mathbb{I}(\delta_*^j = 2) \right\} \left\{ (T^j - \alpha) - \lambda_{OR}^2 (1 - T^i) \right\} \le 0.
$$

Summing over all m terms and taking the expectation yields $(A.5)$.

Combining $(A.4)$ and $(A.5)$, we obtain

$$
0 \leq \lambda_{OR}^2 \mathbb{E}\left[\sum_{j=1}^m \left\{\mathbb{I}(\delta_{OR}^{2,j}=2) - \mathbb{I}(\delta_*^j=2)\right\}(1-T^j)\right]
$$

Finally, since $\lambda_{OR}^2 > 0$, it follows that

$$
\mathbb{E}\left[\sum_{i=1}^m \left\{\mathbb{I}(\delta_{OR}^j=2) - \mathbb{I}(\delta_*^j=2)\right\}(1-T^j)\right] \ge 0.
$$

 \Box

A.2 Proof of Theorem [2](#page-10-2)

As in the proof of Theorem [1,](#page-10-1) we will show $\delta^{*2}_{OR} = {\delta^{*2,j}_{OR}} = 2\mathbb{I}(T^j \langle \hat{t}_{OR}^2 \rangle, j = 1, \ldots, m\}$ controls mFSR² and FSR² at level α_2 . Let $\boldsymbol{\theta} = (\theta_1, \dots, \theta_m)$. Note that

$$
\text{FSR}^2 = \mathbb{E}\left[\frac{\sum_{j=1}^m \delta_{OR}^{*2,j} \mathbb{I}(\theta_j \neq 2)}{\left\{\sum_{j=1}^m \delta_{OR}^{*2,j}\right\} \vee 1}\right] = \mathbb{E}_{\pmb{\delta}_{OR}^{*2}} \mathbb{E}_{\pmb{\theta}|\pmb{\delta}_{OR}^{*2}}\left[\frac{\sum_{j=1}^m \delta_{OR}^{*2,j} \mathbb{I}(\theta_j \neq 2)}{\left\{\sum_{j=1}^m \delta_{OR}^{*2,j}\right\} \vee 1}\bigg|\pmb{\delta}_{OR}^{*2}\right].
$$

By definition of the rule δ^{*2}_{OR} , if $\sum_{j=1}^{m} \delta^{*2,j}_{OR} = k \ge 1$ then

$$
\mathbb{E}_{\theta|\delta_{OR}^{*2}}\sum_{j=1}^m \delta_{OR}^{*2,j}\mathbb{I}(\theta_j \neq 2) = \sum_{i=1}^m \mathbb{P}(\theta_j \neq 2)\delta_{OR}^{*2,j} \leq k\alpha_2.
$$

It follows that
$$
\mathbb{E}_{\boldsymbol{\theta}|\boldsymbol{\delta}_{OR}^{*2}}\left[\frac{\sum_{j=1}^{m}\delta_{OR}^{*2,j}\mathbb{I}(\theta_j \neq 2)}{\sum_{j=1}^{m}\delta_{OR}^{*2,j}\} \vee 1} \bigg|\boldsymbol{\delta}_{OR}^{*2}\right] \leq \alpha, \text{ and } \text{FSR}^2 \leq \alpha_2.
$$

Let $W = (\mathbf{W}_1, \dots, \mathbf{W}_m)$. For mFSR² we have

$$
\frac{\mathbb{E}\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\right)}{\mathbb{E}\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)} = \frac{\mathbb{E}_{\mathcal{W}}\mathbb{E}_{\theta|\mathcal{W}}\left\{\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\right\}}{\mathbb{E}\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)} \\
= \frac{\mathbb{E}_{\mathcal{W}}\mathbb{E}_{\theta|\mathcal{W}}\left\{\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\right)\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right\}}{\mathbb{E}\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)} \\
= \frac{\mathbb{E}_{\mathcal{W}}\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)\mathbb{E}_{\mathcal{W}}\left\{\mathbb{E}_{\theta|\mathcal{W}}\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\right)\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right\}}{\mathbb{E}_{\mathcal{W}}\left(\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)} \\
= \mathbb{E}_{\mathcal{W}}\left\{\mathbb{E}_{\theta|\mathcal{W}}\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)\right\}.
$$

The fourth equality holds because δ^{*2}_{OR} depends on θ only through W. Now given W and that $\sum_i \delta^{*2,j}_{OR} = k$, we have

$$
\mathbb{E}_{\mathcal{W}}\left\{E_{\theta|\mathcal{W}}\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\delta_{OR}^{*2,j}\Big|\sum_{j=1}^{m}\delta_{OR}^{*2,j}\right)\right\} = \mathbb{E}_{\mathcal{W}}\left\{\frac{\mathbb{E}_{\theta|\mathcal{W}}\left(\sum_{j=1}^{m}\mathbb{I}(\theta_{j}\neq 2)\right)\delta_{OR}^{*2,j}}{k}\right\}
$$
\n
$$
= \mathbb{E}_{\mathcal{W}}\left(\frac{\sum_{j=1}^{m}T^{j}\delta_{OR}^{*2,j}}{k}\right).
$$

By the definition of $\delta^{\ast 2}_{OR}$, we have

$$
\mathbb{E}_{\mathcal{W}}\left(\frac{\sum_{j=1}^{m}T^{j}\delta_{OR}^{2,j}}{k}\right) \leq \alpha_2.
$$

Hence δ_{OR}^{*2} satisfies mFSR² $\leq \alpha_2$.

A.3 Proof of Proposition [1](#page-13-0)

Let $q_k(x) := \tilde{g}_{1k}(|x|)/\{g_0(|x|) + \tilde{g}_{1k}(|x|)\}\$, where g_0 and \tilde{g}_{1k} are the density function of $\mathcal{N}\left(0, \frac{n_1+n_2}{n_1n_2}\right)$ n_1n_2 and $\mathcal{N}\left(\left\{(2+b)\sqrt{\sigma_{kk}}+\sqrt{(2+b)^2\sigma_{kk}+4}\right\}\sqrt{\frac{(n_1+n_2)}{2n_1n_2}\log p},\frac{n_1+n_2}{n_1n_2}\right)$ \setminus respectively. We will assume without loss of generality that $d_k > 0$.

 \Box

We shall first prove the result when the true variance σ_{kk} is known and then argue that with probability greater than $1 - pe^{-O(n)}$ the result still holds when σ_{kk} is replaced by $\hat{\sigma}_{kk}$. Let g_{2k} be the density function of $\mathcal{N}\left(d_k, \sigma_{kk} \frac{n_1+n_2}{n_1n_2}\right)$ n_1n_2). Assume d_k is strong, we investigate the asymptotic behavior of

$$
1 - \mathbb{E}\{q_k(X)|X \sim g_{2k}\} = \int_{-\infty}^{\infty} \frac{g_0(|x|)g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)} dx
$$
\n
$$
= \int_{-\infty}^{d_k - \frac{\epsilon}{4}} \sqrt{\frac{\binom{n_1 + n_2}{2n_1 n_2} \log p}{g_0(|x|) + \tilde{g}_{1k}(|x|)}} dx + \int_{d_k - \frac{\epsilon}{4}}^{\infty} \sqrt{\frac{\binom{n_1 + n_2}{2n_1 n_2} \log p}{g_0(|x|) + \tilde{g}_{1k}(|x|)}} dx
$$
\n(A.6)

Consider the first term, it is easy to see that

$$
\int_{-\infty}^{d_k - \frac{\epsilon}{4} \sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p}} \frac{g_0(|x|) g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)} dx \le \int_{-\infty}^{d_k - \frac{\epsilon}{4} \sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p}} g_{2k}(x) dx = O(p^{-\epsilon^2/(64\sigma_{kk})}).
$$

Since $d_k \in \mathcal{G}_1$, we have $x > (a_k/2 + 3\epsilon/4) \sqrt{\frac{(n_1+n_2)}{2n_1n_2} \log p}$ if $\left(d_k - (\epsilon/4) \sqrt{\frac{(n_1+n_2)}{2n_1n_2} \log p}, \infty\right)$ \setminus ; on this interval we have

$$
\frac{\tilde{g}_{1k}(|x|)}{g_0(|x|)} = \exp\left(\frac{2a_k|x|\sqrt{\frac{(n_1+n_2)}{2n_1n_2}\log p} - a_k^2 \frac{(n_1+n_2)}{2n_1n_2}\log p}{2\frac{n_1+n_2}{n_1n_2}}\right)
$$
\n
$$
\geq \exp\left(\frac{1}{2}a_k(a_k/2 + 3\epsilon/4)\log p - \frac{1}{4}a_k^2\log p\right)
$$
\n
$$
\geq \exp\left(\frac{3a_k\epsilon}{8}\log p\right)
$$
\n
$$
\geq p^{3a_k\epsilon/8}.
$$

It follows that

$$
\int_{(d_k - \epsilon/4)}^{\infty} \int_{\frac{(n_1 + n_2)}{2n_1 n_2} \log p}^{\infty} \frac{g_0(|x|) g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)} dx \le \sup_{x > (d_k - \epsilon/4)} \frac{1}{\sqrt{\frac{(n_1 + n_2)}{2n_1 n_2} \log p}} \frac{1}{1 + \tilde{g}_{1k}(x)/g_0(x)} \le p^{-3a_k \epsilon/8}.
$$

Using [\(A.6\)](#page-39-0), we have $\mathbb{E}(q_k|\theta_k=1) = O(p^{-\epsilon_1})$, where $\epsilon_1 > 0$ is some constant.

Next, when $d_k \in \mathcal{G}_3,$ we can similarly show that

$$
\mathbb{E}\{q_k(X)|X \sim g_{2k}\} = \left|1 - \int_{-\infty}^{\infty} \frac{g_0(|x|)g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)}dx\right| = O(p^{-\epsilon_2}).
$$

Finally, consider the the case when $d_k \in \mathcal{G}_2$. We have

$$
\int_{-\infty}^{\infty} \frac{g_0(|x|)g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)} dx = \int_{-\infty}^{\infty} \frac{g_{2k}(x)}{1 + \exp\left(\frac{2a_k\sqrt{\frac{(n_1+n_2)}{2n_1n_2}\log p|x|} - a_k^2 \frac{(n_1+n_2)}{2n_1n_2}\log p}{2\frac{n_1+n_2}{n_1n_2}}\right)} dx
$$

$$
= \int_{-\infty}^{\infty} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}}a_k|x|\sqrt{\frac{n_1n_2}{n_1+n_2}\log p} - \frac{a_k^2}{4}\log p\right)} dx.
$$

Let $\mathcal{A}_t = \left\{ x : -t/\sqrt{\frac{2n_1n_2}{n_1+n_2}} + d_k \leq x \leq t/\sqrt{\frac{2n_1n_2}{n_1+n_2}} + d_k \right\},\$

$$
\int_{-\infty}^{\infty} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}}a_k|x|\sqrt{\frac{n_1n_2}{n_1+n_2}\log p} - \frac{a_k^2}{4}\log p\right)} - g_{2k}(x)dx
$$

=
$$
\int_{x \in \mathcal{A}_t^c} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}}a_k|x|\sqrt{\frac{n_1n_2}{n_1+n_2}\log p} - \frac{a_k^2}{4}\log p\right)} - g_{2k}(x)dx
$$

+
$$
\int_{x \in \mathcal{A}_t} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}}a_k|x|\sqrt{\frac{n_1n_2}{n_1+n_2}\log p} - \frac{a_k^2}{4}\log p\right)} - g_{2k}(x)dx.
$$

Some algebra shows that

$$
\begin{split}\n&\left| \int_{x \in \mathcal{A}_{t}^{c}} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}} a_{k} |x| \sqrt{\frac{n_{1} n_{2}}{n_{1} + n_{2}} \log p} - \frac{a_{k}^{2}}{4} \log p\right)} - g_{2k}(x) dx \right| \\
&\leq \qquad \int_{x \in \mathcal{A}_{t}^{c}} \frac{g_{2k}(x) dx}{g_{2k}(x) dx} = O\left(e^{-\frac{t^{2}}{4 \sigma_{kk}}}\right), \text{ and} \\
&\left| \int_{x \in \mathcal{A}_{t}} \frac{g_{2k}(x)}{1 + \exp\left(\frac{1}{\sqrt{2}} a_{k} |x| \sqrt{\frac{n_{1} n_{2}}{n_{1} + n_{2}} \log p} - \frac{a_{k}^{2}}{4} \log p\right)} dx \right| \\
&\leq \qquad \left| \int_{x \in \mathcal{A}_{t}} \frac{\phi_{2k}(x)}{1 + \exp\left(\frac{1}{2} a_{k} t \sqrt{\log p} + o(\log p) - \frac{a_{k}^{2}}{4} \log p\right)} - g_{2k}(x) dx \right|.\n\end{split} \tag{A.8}
$$

Take $t = (2 + b/2) \sqrt{\sigma_{kk} \log p}$, we can see that $(A.7)$ is bounded by $o(1/p^{1+b})$. For $(A.8)$ to be bounded by $o(1/p^{1+a})$ for some constant $a > 0$, we need $a_k^2/4 - (1 + b/4)a_k\sqrt{\sigma_{kk}} >$ 1 + c for some constant c > 0. Some computation shows that $a_k > (2 + b/2)\sqrt{\sigma_{kk}}$ + $\sqrt{(2+b/2)^2 \sigma_{kk}+4}$ can satisfy both requirements. Since we take $a_k = (2+b)\sqrt{\sigma_{kk}} +$ $\sqrt{(2+b)^2 \sigma_{kk}+4}$ we have [\(A.8\)](#page-41-0) is bounded by:

$$
\left| \int_{x \in \mathcal{A}_t} \frac{g_{2k}(x)}{1 + o(1/p^{1+\epsilon_3})} - g_{2k}(x) dx \right| = O(1/p^{1+\epsilon_3}) \int g_{2k}(x) dx = O(1/p^{1+\epsilon_3}),
$$

where $\epsilon_3 > 0$ is some constant. Use the fact that $\int \phi_{2k} dx = 1$ we conclude that

$$
\mathbb{E}\{q_k(X)|X \sim g_{2k}\} = \left|1 - \int_{-\infty}^{\infty} \frac{g_0(|x|)g_{2k}(x)}{g_0(|x|) + \tilde{g}_{1k}(|x|)}dx\right| = O(1/p^{1+\epsilon_3}).
$$

Take $\gamma = \min(\epsilon_1, \epsilon_2, \epsilon_3)$, the results follow.

Define $\hat{a}_k = (2+b)$ √ $\overline{\hat{\sigma}_{kk}} + \sqrt{(2+b)^2 \hat{\sigma}_{kk} + 4}$. From the above proof, we can see that if we would like the results to hold when we replace a_k by \hat{a}_k , we need $x > (\hat{a}_k/2 + 3\epsilon'/4) \sqrt{\frac{(n_1+n_2)}{2n_1n_2} \log p}$ on the interval $(d_k - (\epsilon/4) \sqrt{\frac{(n_1+n_2)}{2n_1n_2} \log p}, \infty)$ when d_k is strong and $\hat{a}_k > (2 + b/2) \sqrt{\sigma_{kk}} +$ $\sqrt{(2+b/2)^2 \sigma_{kk}+4}$ when d_i is weak. Here ϵ' is some positive constant less than ϵ and

depends solely on ϵ . As a_k satisfies these two conditions, we can choose a constant d which depends solely on ϵ' and b such that \hat{a}_k satisfies these two conditions when $|\hat{a}_k - a_k| < d$. When the true variance is unknown, we use the pooled sample variance

$$
\hat{\sigma}_{kk} = \frac{n_1 - 1}{n_1 + n_2 - 2} \sum_{i=1}^{n_1} (X_{ik} - \bar{X}_{k})^2 + \frac{n_2 - 1}{n_1 + n_2 - 2} \sum_{i=1}^{n_2} (Y_{ik} - \bar{Y}_{k})^2
$$

to estimate σ_{kk} , and use \hat{a}_k to estimate a_k . Since \hat{a}_k is a continuous function of $\hat{\sigma}_{kk}$ and $\hat{a}_k = a_k$ when $\hat{\sigma}_{kk} = \sigma_{kk}$, we can choose a constant λ small enough such that $|\hat{a}_k - a_k| < d$ when $|\hat{\sigma}_{kk} - \sigma_{kk}| < \epsilon_0^{-1}\lambda$. (Recall that ϵ_0^{-1} is the upper bound of σ_{kk} .) The constant λ here depends solely on d and ϵ_0 , which are fixed and independent of n_1 , n_2 and p. Recall that since X_{ik} are *i.i.d* for $1 \leq i \leq n_1$ and Y_{ik} are *i.i.d* for $1 \leq i \leq n_2$, we have $(n_1 + n_2 - 2)\hat{\sigma}_{kk}/\sigma_{kk} \sim \chi^2_{n_1+n_2-2}$. Lemma 1 in [Foygel and Drton](#page-31-8) [\(2010\)](#page-31-8) and Lemma 4 in [Cai](#page-31-9) [\(2002\)](#page-31-9) proved the following concentration inequality for χ^2 random variable. For $n \geq 4\lambda^{-2} + 1$, we have

$$
P\left\{\chi_n^2 > n(1+\lambda)\right\} \leq \frac{1}{\lambda\sqrt{\pi n}} e^{-\frac{n}{2}(\lambda - \log(1+\lambda))};
$$

$$
P\left\{\chi_n^2 < n(1-\lambda)\right\} \leq \frac{1}{\lambda\sqrt{\pi(n-1)}} e^{-\frac{n-1}{2}(\lambda + \log(1-\lambda))}.
$$

Noting that λ is a constant independent of n_1 , n_2 and p, we apply the above results to conclude that

$$
P\left(\left|\frac{\hat{\sigma}_{kk}}{\sigma_{kk}}-1\right|<\lambda\right)
$$

\n
$$
\geq 1 - \frac{1}{\lambda\sqrt{\pi(n_1+n_2-2)}}e^{-\frac{n_1+n_2-2}{2}(\lambda-\log(1+\lambda))} - \frac{1}{\lambda\sqrt{\pi(n_1+n_2-3)}}e^{-\frac{n_1+n_2-3}{2}(\lambda+\log(1-\lambda))}
$$

\n
$$
= 1 - e^{-\frac{n_1+n_2-2}{2}(\lambda-\log(1+\lambda))+O(\log(n_1+n_2))} - e^{-\frac{n_1+n_2-3}{2}(\lambda+\log(1-\lambda))+O(\log(n_1+n_2))}.
$$

\n
$$
= 1 - e^{-O(n_1+n_2)}
$$

p $\left(\begin{array}{c}p\\1\end{array}\right)$ \setminus $\leq \sum_{i=1}^p P\left(|\hat{\sigma}_{kk} - \sigma_{kk}| > \epsilon_0^{-1}\lambda\right) \leq \sum_{i=1}^p P\left(|\hat{\sigma}_{kk} - \sigma_{kk}| > \sigma_{kk}\lambda\right),$ $|\hat{\sigma}_{kk} - \sigma_{kk}| > \epsilon_0^{-1} \lambda$ Since P $i=1$ we have with probability greater than $1 - pe^{-O(n_1+n_2)}$, $|\hat{\sigma}_{kk} - \sigma_{kk}| < \epsilon_0^{-1} \lambda$ for all $1 \le i \le p$. Combining with the fact that $\mathbb{E}(q_k)$ is bounded, the theorem follows. \Box

A.4 Proof of Theorem [4](#page-20-0)

Define $\text{ECC}_{\pmb{\delta}}^2 = \mathbb{E} \left\{ \sum_{j=1}^m \mathbb{I}(\delta_j = 2, \theta_j = 2) \right\}$. We will prove $\text{mFSR}_{\pmb{\delta}}^2 = \text{mFSR}_{\pmb{\delta}_{OR}}^2 + o(1)$ and $\text{ECC}^2_{\hat{\pmb{\delta}}} / \text{ECC}^2_{\pmb{\delta}_{OR}} = 1 + o(1)$. Then by the same argument one can show mFSR $^1_{\hat{\pmb{\delta}}}$ $mFSR_{\boldsymbol{\delta}_{OR}}^1 + o(1)$ and $\text{ECC}_{\boldsymbol{\hat{\delta}}/}\text{ECC}_{\boldsymbol{\delta}_{OR}}^1 = 1 + o(1)$, then the theorem follows.

We begin with a summary of notation used throughout the proof:

- $Q(t) = m^{-1} \left\{ \sum_{j=1}^{m} (T^j \alpha_2) \mathbb{I}(T^j < t) \right\}.$
- $\hat{Q}(t) = m^{-1} \left\{ \sum_{j=1}^{m} (\hat{T}^{j} \alpha_2) \mathbb{I}(\hat{T}^{j} < t) \right\}.$
- $Q_{\infty}(t) = \mathbb{E}\{(T-\alpha_2)\mathbb{I}(T < t)\}.$
- $t_{\infty} = \sup\{t : Q_{\infty}(t) \leq 0\}$ is the "ideal" threshold.

Note that T^j is a function of W_j only. Since each W_j are iid, it follows that T^j are also iid. Without loss of generality, assume the first s_1 signals are strong, the next s_2 signals are moderate and the rest are weak. We break the proof into 2 cases:

Case 1: $\sum_{k=1}^{s_1} d_k^2 < \infty$ as $n, p \to \infty$. Case 2: $\sum_{k=1}^{s_1} d_k^2 \to \infty$ as $n, p \to \infty$.

A.4.1 Proof of case 1

We first show that $mFSR_{\pmb{\delta}}^2 = mFSR_{\pmb{\delta}_{OR}}^2 + o(1)$. We define a continuous version of $\widehat{Q}(t)$ using the following procedure: If t_1 and t_2 are two adjacent points of discontinuity, on the interval $[t_1, t_2]$,

$$
\widehat{Q}_C(t) = \frac{t - t_2}{t_1 - t_2} \widehat{Q}(t_1) + \frac{t - t_1}{t_2 - t_1} \widehat{Q}(t_2).
$$

As t_{∞} is proved to be larger than α_1 in section [A.1,](#page-34-0) it is easy to verify that $\widehat{Q}_C(t)$ is continuous and monotone on the interval $[\alpha_1, 1)$. Hence, its inverse \widehat{Q}_C^{-1} is well–defined, continuous, and monotone on the interval $(\alpha, 1)$.

Next, we shall show the following two results in turn: (i) $\hat{Q}(t) \stackrel{p}{\rightarrow} Q_{\infty}(t)$ and (ii) $\widehat{Q}_C^{-1}(0) \stackrel{p}{\rightarrow} t_{\infty}$. We shall need the following two lemmas, which are proved later:

Lemma 1. $\mathbb{E}(\hat{T}-T)^2 \to 0$.

Lemma 2. Let $V_j = (T^j - \alpha_2) \mathbb{I}(T^j < t)$ and $\hat{V}_j = (\hat{T}^j - \alpha_2) \mathbb{I}(\hat{T}^j < t)$. Then $\mathbb{E}(\hat{V}_j - V_j)^2 =$ $o(1)$.

To show (i), note that $Q(t) \stackrel{p}{\rightarrow} Q_{\infty}(t)$ by the WLLN, so that we only need to establish that $\hat{Q}(t) \stackrel{p}{\to} Q(t)$. Let $S_m = \sum_{j=1}^m (\hat{V}_j - V_j)$. By Lemma [2](#page-44-0) and the Cauchy-Schwartz inequality, $\mathbb{E}\left\{ \left(\hat{V}_i - V_i \right) \left(\hat{V}_j - V_j \right) \right\} = o(1)$. It follows that

$$
Var(m^{-1}S_m) = m^{-2}Var(S_m) \le m^{-2} \sum_{j=1}^m \mathbb{E}\left\{ \left(\hat{V}_j - V_j\right)^2 \right\}
$$

$$
+ O\left(\frac{1}{m^2} \sum_{i,j:i \ne j} \mathbb{E}\left\{ \left(\hat{V}_i - V_i\right) \left(\hat{V}_j - V_j\right) \right\} \right)
$$

$$
= o(1).
$$

By Lemma [2,](#page-44-0) $\mathbb{E}(m^{-1}S_m) \to 0$, applying Chebyshev's inequality, we obtain $m^{-1}S_m =$ $\widehat{Q}(t) - Q(t) \stackrel{p}{\rightarrow} 0$. Hence (i) is proved.

Next, we show (ii). Since $\widehat{Q}_C(t)$ is continuous, for any $\varepsilon > 0$, we can find $\eta > 0$ such that $\left| \widehat{Q}_{C}^{-1}(0) - \widehat{Q}_{C}^{-1} \left\{ \widehat{Q}_{C} \left(t_{\infty} \right) \right\} \right|$ $<\varepsilon$ if $\left|\widehat{Q}_{C}\left(t_{\infty}\right)\right|<\eta$. It follows that

$$
P\left\{ \left| \widehat{Q}_C\left(t_\infty\right) \right| > \eta \right\} \ge P\left\{ \left| \widehat{Q}_C^{-1}(0) - \widehat{Q}_C^{-1}\left\{ \widehat{Q}_C\left(t_\infty\right) \right\} \right| > \varepsilon \right\}.
$$

Lemma [1](#page-44-1) and the WLLN imply that $\hat{Q}_C(t) \stackrel{p}{\to} Q_\infty(t)$. Note that $Q_\infty(t_\infty) = 0$. Then,

$$
P\left(\left|\widehat{Q}_C\left(t_\infty\right)\right|>\eta\right)\to 0.
$$

Hence, we have

$$
\widehat{Q}_C^{-1}(0) \xrightarrow{p} \widehat{Q}_C^{-1} \left\{ \widehat{Q}_C \left(t_\infty \right) \right\} = t_\infty, \tag{A.1}
$$

completing the proof of (ii). Notice that $Q_{\infty}(t)$ is continuous by construction, by (i) we also have $\widehat{Q}(t) \stackrel{p}{\rightarrow} \widehat{Q}_C(t)$.

We can similarly define the continuous version of $Q(t)$ as $Q_C(t)$ and the corresponding threshold as Q_C^{-1} $C^{-1}(0)$. Write $\hat{\boldsymbol{\delta}} = \hat{\boldsymbol{\delta}}^1 + \hat{\boldsymbol{\delta}}^2$, where $\hat{\boldsymbol{\delta}}^1$ is of the form $\mathbb{I} \left\{ 1 - \hat{T}^j \leq \beta_1 \right\}$ and $\hat{\boldsymbol{\delta}}^2$ is of the form $2\mathbb{I} \{\hat{T}^j \leq \beta_2\}$ for some $\beta_1, \beta_2 > 0$. Similarly, write $\boldsymbol{\delta} = \boldsymbol{\delta}^1 + \boldsymbol{\delta}^2$, where $\boldsymbol{\delta}^1$ is of the form $\mathbb{I} \{1 - T^j \le t_{OR}^1\}$ and δ_{OR}^2 is of the form $2\mathbb{I} \{T^j \le t_{OR}^2\}$ for some $\beta_1, \beta_2 > 0$. Then by construction, we have

$$
\hat{\boldsymbol{\delta}}^2 = \left[2\mathbb{I}\left\{\hat{T}^j \leq \widehat{Q}_C^{-1}(0)\right\} : 1 \leq j \leq m\right] \quad \text{and} \quad \boldsymbol{\delta}_{OR}^2 = \left[2\mathbb{I}\left\{T^j \leq Q_C^{-1}(0)\right\} : 1 \leq i \leq m\right].
$$

Also, following the previous arguments, we can show that

$$
Q_C^{-1}(0) \stackrel{p}{\to} t_\infty. \tag{A.2}
$$

According to $(A.1)$ and $(A.2)$, we have

$$
\widehat{Q}_C^{-1}(0) = Q_C^{-1}(0) + o_p(1). \tag{A.3}
$$

Note that the mFSR² level of $\pmb{\delta}_{OR}$ and $\hat{\pmb{\delta}}$ are

$$
\mathrm{mFSR}_{\pmb\delta_{OR}}^2 = \frac{P_{\theta_j=1}\left\{T^j \leq Q_C^{-1}(0)\right\}}{P\left\{T^j \leq Q_C^{-1}(0)\right\}} \quad \text{and} \quad \mathrm{mFSR}_{\pmb\delta}^2 = \frac{P_{\theta_j=1}\left\{\hat{T}^j \leq q_C^{-1}(0)\right\}}{P\left\{\hat{T}^j \leq q_C^{-1}(0)\right\}}.
$$

From Lemma [1,](#page-44-1) $\hat{T}^j \stackrel{p}{\rightarrow} T^j$, [\(A.2\)](#page-35-2), and by the continuous mapping theorem, mFSR $_{\hat{\boldsymbol{\delta}}}^2$ = $mFSR_{\delta_{OR}}^2 + o(1) = \alpha_2 + o(1)$. By the asymptotic equivalence between mFSR and FSR (Appendix [C\)](#page-54-0), the desired result follows.

Next we show that $\text{ECC}^2_{\hat{\boldsymbol{\delta}}}/\text{ECC}^2_{\boldsymbol{\delta}_{OR}} = 1 + o(1)$. By definition,

$$
\text{ECC}_{\hat{\pmb{\delta}}}^2 = \mathbb{E}\left\{ \sum_{j=1}^m \mathbb{I}(\hat{T}^j \le \hat{Q}_C^{-1}(0))(1-T^i) \right\} \quad \text{and} \quad \text{ECC}_{\pmb{\delta}_{OR}}^2 = \mathbb{E}\left\{ \sum_{j=1}^m \mathbb{I}(T^j \le Q_C^{-1}(0))(1-T^j) \right\}
$$

.

Using the fact that $\hat{T}^j \stackrel{p}{\rightarrow} T^j$ and $\hat{Q}_C^{-1}(0) \stackrel{p}{\rightarrow} Q_C^{-1}$ $_C^{-1}(0)$, the result follows.

A.4.2 Proof of case 2

From the proof of Lemma 1, we have:

$$
\mathbb{E}\left(S_j^{\pi} - \hat{S}_j\right)^2 = O(s_1 \frac{n_1 + n_2}{n_1 n_2}) + o\left(\sum_{k=1}^{s_1} d_k^2\right) + O\left(\sum_{k=1}^{s_1} d_k \frac{n_1 + n_2}{n_1 n_2}\right) + o(1). \tag{A.4}
$$

Since $\sum_{k=1}^{s_1} d_k^2 \geq c s_1 \frac{n_1+n_2}{n_1 n_2}$ $\frac{a_1+n_2}{n_1n_2}$ log p for some $c > 0$ and $\mathbb{E}(S_j^{\pi}) \propto \sum_{k=1}^{s_1} d_k^2$, by $(A.4)$

$$
\mathbb{E}\left(S_j^{\pi} - \hat{S}_j\right)^2 / \sum_{k=1}^{s_1} d_k^2 = O\left(\frac{1}{\log p}\right).
$$

It follows that $\mathbb{E}\sum_{k=1}^{s_1} \{q_k(\bar{X}_k - \bar{Y}_k)\}^2 \propto \mathbb{E}(|S_j^{\pi}|) \propto \sum_{k=1}^{s_1} d_k^2$. If $\sum_{k=1}^{s_k} d_i^2 \to \infty$, then $\hat{T}^{j} \to 0$ or $\hat{T}^{j} \to \infty$. In either case, we have perfect separation between the two classes asymptotically. The theorem follows. \Box

A.5 Proof of Theorem [3](#page-19-0)

Again, without loss of generality, assume the first s_1 signals are strong, the next s_2 signals are moderate and the rest are weak. Consider the same model as described in section 2, but replace μ_1 and μ_2 by $\tilde{\mu}_1 = (\mu_{11}, ..., \mu_{1s_1}, 0, ..., 0)^t$ and $\tilde{\mu}_2 = (\mu_{21}, ..., \mu_{2s_1}, 0, ..., 0)^t$ respectively. Let $\tilde{\bm{W}}_j = \bm{W}_j - \bm{\mu}_1 + \tilde{\bm{\mu}}_1$ when $\theta_j = 1$ and $\tilde{\bm{W}}_j = \bm{W}_j - \bm{\mu}_2 + \tilde{\bm{\mu}}_2$ when $\theta_j = 2$. It is then clear that

$$
\tilde{\boldsymbol{W}}_j \sim \mathbb{I}(\theta_j = 1) \mathcal{N}(\tilde{\boldsymbol{\mu}}_1, \boldsymbol{\Sigma}) + \mathbb{I}(\theta_j = 2) \mathcal{N}(\tilde{\boldsymbol{\mu}}_2, \boldsymbol{\Sigma}).
$$

Denote $\tilde{\boldsymbol{d}} = \tilde{\boldsymbol{\mu}}_1 - \tilde{\boldsymbol{\mu}}_2$, define

$$
Z_j := Z(\tilde{\boldsymbol{W}}_j) := \left(\tilde{\boldsymbol{W}}_j - \frac{\tilde{\boldsymbol{\mu}}_1 + \tilde{\boldsymbol{\mu}}_2}{2}\right)^{\top} \Sigma^{-1} \tilde{\boldsymbol{d}},
$$

 $Z_{OR}^{j} := Z_{OR}(\tilde{W}_{j}) = \exp(Z_{j})/(\exp(Z_{j})+1)$. Consider the decision rule:

$$
\delta_Z^j = 2\mathbb{I}\{Z_{OR}^j \le \min(Z_{OR}^{(k_4)}, 0.5)\} + \mathbb{I}\{1 - Z_{OR}^j \le \min(1 - Z_{OR}^{(m-k_3)}, 0.5)\},\
$$

where

$$
k_3 = \inf \left\{ j : \frac{1}{j+1} \sum_{i=0}^{j} (1 - Z_{OR}^{(m-i)}) \le \alpha_1 \right\}
$$
 and $k_4 = \sup \left\{ j : \frac{1}{j} \sum_{i=1}^{j} Z_{OR}^{(i)} \le \alpha_2 \right\}$.

By the proof of theorem 1 and theorem 3, $\boldsymbol{\delta}_Z = (\delta_Z^1, \dots, \delta_Z^m)$ controls mFSR¹ and mFSR² at level α_1 and α_2 respectively. Now notice that

$$
\mathbb{E}\left(Z_j - \hat{S}_j\right)^2
$$
\n
$$
= \mathbb{E}\left\{\left(\tilde{W}_j - \frac{\tilde{\mu}_1 + \tilde{\mu}_2}{2}\right)^{\top} \Sigma^{-1} \tilde{d} - \left(W_j - \frac{\bar{X} + \bar{Y}}{2}\right)^{\top} \hat{\Sigma}^{-1} \hat{d}\right\}^2
$$
\n
$$
= O\left[\mathbb{E}\left\{\left(W_i - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1} (\tilde{d} - \hat{d})\right\}^2 + \mathbb{E}\left\{\left(\tilde{W}_j - W_j + \frac{\bar{X} + \bar{Y}}{2} - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1} \hat{d}\right\}^2
$$
\n
$$
+ \mathbb{E}\left\{\left(W_i - \frac{\bar{X} + \bar{Y}}{2}\right)^{\top} (\Sigma - \hat{\Sigma}^{-1}) \hat{d}\right\}^2\right]
$$
\n
$$
= I + II + III
$$

For II , note that

$$
\mathbb{E}\left\{\left(\tilde{W}_{j}-W_{j}+\frac{\tilde{\mu}_{1}+\tilde{\mu}_{2}}{2}-\frac{\bar{X}+\bar{Y}}{2}\right)^{\top}\Sigma^{-1}\hat{d}\right\}^{2}
$$
\n
$$
=O\left[\mathbb{E}\left\{\hat{d}^{\top}(\Sigma^{-1})^{t}\frac{1}{4}\frac{n_{1}+n_{2}}{n_{1}n_{2}}\Sigma\Sigma^{-1}\hat{d}\right\}+\left\{\lambda_{max}(\Sigma^{-1})p^{-\gamma}\log p\right\}^{2}\right]
$$
\n
$$
=O\left[\mathbb{E}\left\{\hat{d}^{\top}(\Sigma^{-1})^{T}\frac{1}{4}\frac{n_{1}+n_{2}}{n_{1}n_{2}}\hat{d}\right\}+\left\{\lambda_{max}(\Sigma^{-1})p^{-\gamma}\log p\right\}^{2}\right]
$$
\n
$$
=O\left[\mathbb{E}\left(\frac{n_{1}+n_{2}}{n_{1}n_{2}}\lambda_{max}(\Sigma^{-1})||\hat{d}-\hat{d}||^{2}\right)+\mathbb{E}\left(\frac{n_{1}+n_{2}}{n_{1}n_{2}}\lambda_{max}(\Sigma^{-1})||\hat{d}||^{2}\right)+\left\{\lambda_{max}(\Sigma^{-1})p^{-\gamma}\log p\right\}^{2}\right]
$$
\n
$$
=O\left[\mathbb{E}\left(\frac{n_{1}+n_{2}}{n_{1}n_{2}}\lambda_{max}(\Sigma^{-1})(||\hat{d}-\hat{d}||^{2}+||\hat{d}||^{2})+\left\{\lambda_{max}(\Sigma^{-1})p^{-\gamma}\log p\right\}^{2}\right].
$$

By (A1) $\{\lambda_{max}(\Sigma^{-1})p^{-\gamma}\log p\}^2 \to 0$, use the same computation in the proof of lemma [1,](#page-44-1)

we have

have
\n
$$
\mathbb{E}\left(Z_j - \hat{S}_j\right)^2 = O\left(\mathbb{E}\sum_{k=1}^p \{q_k(\bar{X}_k - \bar{Y}_k) - \tilde{d}_k\}^2\right) + o(1),
$$
\n
$$
\mathbb{E}\sum_{k=1}^{s_1} \{q_k(\bar{X}_k - \bar{Y}_k) - \tilde{d}_k\}^2 = O(s_1 \frac{n_1 + n_2}{n_1 n_2}) + o(\sum_{k=1}^{s_1} d_k^2) + O(\sum_{k=1}^{s_1} d_k \frac{n_1 + n_2}{n_1 n_2}) + o(1).
$$

We know that

$$
\mathbb{E}\sum_{i=s_1+1}^{s_1+s_2} \left\{ q_k(\bar{X}_k - \bar{Y}_k) \right\}^2 = O(s_2)O(p^{-\gamma})O\left(\frac{n_1+n_2}{n_1n_2}\log p\right) = O(p^{-\gamma}\log p) \to 0,
$$

$$
\mathbb{E}\sum_{k=s_2+1}^{p} \left\{ q_k(\bar{X}_k - \bar{Y}_k) \right\}^2 = O(p)O(p^{-1-\gamma})O\left(\frac{n_1+n_2}{n_1n_2}\log p\right) \to 0.
$$

Thus,

$$
\mathbb{E}\left(Z_j - \hat{S}_j\right)^2 = O(s_1 \frac{n_1 + n_2}{n_1 n_2}) + o\left(\sum_{k=1}^{s_1} d_k^2\right) + O\left(\sum_{k=1}^{s_1} d_k \frac{n_1 + n_2}{n_1 n_2}\right) + o(1). \tag{A.5}
$$

Since $\sum_{k=1}^{s_1} d_k^2 \geq c s_1 \log p \frac{n_1+n_2}{n_1 n_2}$ $\frac{a_1+n_2}{n_1n_2}$ for some $c>0$ and $\mathbb{E}(Z_j) \propto \sum_{k=1}^{s_1} d_k^2$, by $(A.5)$

$$
\mathbb{E}\left(Z_j - \hat{S}_j\right)^2 / \sum_{k=1}^{s_1} d_k^2 = O\left(\frac{1}{\log p}\right)
$$

It follows that $\mathbb{E}\sum_{k=1}^{s_1} \{q_k(\bar{X}_k - \bar{Y}_k)\}^2 \propto \mathbb{E}(|Z_j|) \propto \sum_{k=1}^{s_1} d_k^2$. If $\sum_{k=1}^{s_1} d_k^2 \to \infty$, then $\hat{T}^{j} \rightarrow 0$ or $\hat{T}^{j} \rightarrow 1$. In either case, we have perfect separation between the two classes asymptotically. The theorem follows trivially. If $\sum_{k=1}^{s_1} d_k^2 < \infty$, then

$$
\left(\mathbb{E}\left|\hat{T}^{j}-Z_{OR}^{j}\right|\right)^{2}=e^{O(\sum_{k=1}^{s_{1}}d_{k}^{2})}\left\{O\left(s_{1}\frac{n_{1}+n_{2}}{n_{1}n_{2}}\right)+O(\sum_{k=1}^{s_{1}}d_{k}^{2}p^{-2\gamma})+O(p^{-\gamma}\log p)\right\}.
$$

 $\frac{a_1+n_2}{n_1n_2}$ and $\sum_{k=1}^{s_1} d_k^2 < \infty$, it follows that $e^{O(\sum_{k=1}^{s_1} d_k^2)} < \infty$ Since $\sum_{k=1}^{s_1} d_k^2 \geq c s_1 \log p \frac{n_1+n_2}{n_1 n_2}$ $+ O(\sum_{k=1}^{s_1} d_k^2 p^{-2\gamma}) + O(p^{-\gamma} \log p) \to 0.$ Thus, $\mathbb{E}(\hat{T}^j - Z^j_{OR})^2 \to 0.$ The and $O(s_1 \frac{n_1+n_2}{n_1n_2})$ n_1n_2 theorem follows by using the same argument presented in the proof of theorem [4.](#page-20-0) \Box

A.6 Proof of Corollary [1](#page-20-1)

Note that $\min\{T^j, 1 - T^j\} \leq 0.5$. Hence, if we choose $\alpha_1 = \alpha_2 = 0.5$, δ_{OR} makes no indecision. Since δ_{OR} has the highest ECC among all rules that controls mFSR¹ and mFSR² at level 0.5, and δ^F also controls mFSR¹ and mFSR² at level 0.5, it follows that $\text{ECC}_{\pmb{\delta}_{OR}} \geq \text{ECC}_{\pmb{\delta}^F}$. On the other hand, $\pmb{\delta}^F$ has the lowest risk among all rules that do not make indecision and risk equals to $1 - \text{ECC}/m$. It follows that $\text{ECC}_{\pmb{\delta}_{OR}} \leq \text{ECC}_{\pmb{\delta}^F}$. Hence, $\text{ECC}_{\delta_{OR}} = \text{ECC}_{\delta^F}$. By Theorem [4,](#page-20-0) we have $\text{ECC}_{\delta_{OR}} / \text{ECC}_{\hat{\delta}} \to 1$, it follows that $R(\hat{\boldsymbol{\delta}}) \rightarrow R(\boldsymbol{\delta}^F).$ \Box

B Proof of Technical Lemmas

Appendix B contains proofs of techincal lemmas. We will assume without loss of generality, the first s_1 signals are strong, the next s_2 signals are moderate and the rest are weak.

B.1 Proof of Lemma 1

Let
$$
\hat{\mathbf{d}} = (q_1(\bar{X}_1 - \bar{Y}_1), ..., q_p(\bar{X}_p - \bar{Y}_p)).
$$
 We have

$$
\mathbb{E} \|\hat{\boldsymbol{d}} - \boldsymbol{d}\|^2 = \sum_{k=1}^p \left\{ \mathbb{E} (q_k^2 (\bar{X}_k - \bar{Y}_k)^2) - 2d_k \mathbb{E} \{ q_k (\bar{X}_k - \bar{Y}_k) \} + d_k^2 \right\} \n= \sum_{k=1}^p \left\{ \text{Cov} \{ q_k^2, (\bar{X}_k - \bar{Y}_k)^2 \} + \mathbb{E} (q_k^2) \mathbb{E} (\bar{X}_k - \bar{Y}_k)^2 - 2d_k \left[\text{Cov} \{ q_k, (\bar{X}_k - \bar{Y}_k) \} + d_k \mathbb{E} q_k \right] + d_k^2 \right\}.
$$

Since q_k is bounded between 0 and 1, $\text{Var}(q_k^2)$ and $\text{Var}(q_i)$ are both bounded. For $1 \leq k \leq s_1$, note that $(\bar{X}_k - \bar{Y}_k) \sim N(d_k, \sigma_{kk} \frac{n_1+n_2}{n_1n_2})$ $\frac{a_1+n_2}{n_1n_2}$), and $d_k^2 < \infty$ we have $\text{Var}\{(\bar{X}_k - \bar{Y}_k)^2\} = O(\frac{n_1+n_2}{n_1n_2})$ $\frac{n_1+n_2}{n_1n_2}$. Use Cauchy-Schwarz inequality, for $1 \leq k \leq s_1$, each summand has absolute value bounded by

$$
O(\frac{n_1 + n_2}{n_1 n_2}) + \mathbb{E}\left\{q_k^2 \left(\frac{n_1 + n_2}{n_1 n_2}\sigma_{kk} + d_k^2\right)\right\} - 2d_k^2 \mathbb{E}(q_k) + d_k^2 - 2d_k \text{Cov}(q_k, \bar{X}_k - \bar{Y}_k)
$$

= $O(\frac{n_1 + n_2}{n_1 n_2}) + d_k^2 \mathbb{E}(q_k^2) + d_k^2 - 2d_k^2 \mathbb{E}(q_k) + O(d_k \frac{n_1 + n_2}{n_1 n_2}) + O(\frac{n_1 + n_2}{n_1 n_2})$
= $O(\frac{n_1 + n_2}{n_1 n_2}) + O(d_k \frac{n_1 + n_2}{n_1 n_2}) + O\left\{d_k^2(1 - \mathbb{E}(q_k))^2\right\} + O\left\{d_k^2(E(q_k^2) - (Eq_k)^2)\right\}$
= $O(\frac{n_1 + n_2}{n_1 n_2}) + O(d_k \frac{n_1 + n_2}{n_1 n_2}) + o(d_k^2).$

For $s_1 + 1 \leq i \leq p$,

$$
\mathbb{E}\{q_k(\bar{X}_k-\bar{Y}_k)-d_k\}^2\leq d_k^2.
$$

Hence, by (A4)

$$
\mathbb{E} \|\hat{\boldsymbol{d}} - \boldsymbol{d}\|^2 = O(s_1 \frac{n_1 + n_2}{n_1 n_2}) + o(\sum_{k=1}^{s_1} d_k^2) + O(\sum_{k=1}^{s_1} d_k \frac{n_1 + n_2}{n_1 n_2}) + o(1).
$$
 (B.6)

Since $s_1 \frac{n_1+n_2}{n_1 n_2}$ $\frac{a_1+n_2}{n_1n_2} = O(\sum_{k=1}^{s_1} d_k^2)$ and by assumption of case 1, $\sum_{k=1}^{s_1} d_k^2 = O(1)$ and $\sum_{k=1}^{s_1} d_k \frac{n_1+n_2}{n_1n_2}$ $\frac{n_1+n_2}{n_1 n_2} =$ $o(1)$ we have $\mathbb{E} \|\hat{\bm{d}} - \bm{d}\|^2 = o(1)$. Now, since $\bar{\bm{X}} + \bar{\bm{Y}}$ and $\bar{\bm{X}} - \bar{\bm{Y}}$ are independent, and using Basu's Theorem we know that $\bar{\pmb{X}} + \bar{\pmb{Y}}$ and $\hat{\sigma}_{kk}$ are independent, thus $\bar{\pmb{X}} + \bar{\pmb{Y}}$ and \hat{d} are

independent and we have

$$
\mathbb{E}(S_j^{\pi} - \hat{S}_j)^2
$$
\n
$$
= \mathbb{E}\left\{\left(W_j - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1}d - \left(W_j - \frac{\bar{X} + \bar{Y}}{2}\right)^{\top} \hat{\Sigma}^{-1}\hat{d}\right\}^2
$$
\n
$$
= \mathbb{E}\left\{\left(W_j - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1}(d - \hat{d}) + \left(\frac{\bar{X} + \bar{Y}}{2} - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1}\hat{d} + \left(W_j - \frac{\bar{X} + \bar{Y}}{2}\right)^{\top} (\Sigma^{-1} - \hat{\Sigma}^{-1})\hat{d}\right\}^2
$$
\n
$$
= O\left[\mathbb{E}\left\{\left(W_j - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1}(d - \hat{d})\right\}^2 + \mathbb{E}\left\{\left(\frac{\bar{X} + \bar{Y}}{2} - \frac{\mu_1 + \mu_2}{2}\right)^{\top} \Sigma^{-1}\hat{d}\right\}^2
$$
\n
$$
+ \mathbb{E}\left\{\left(W_j - \frac{\bar{X} + \bar{Y}}{2}\right)^{\top} (\Sigma - \hat{\Sigma}^{-1})\hat{d}\right\}^2\right]
$$
\n
$$
= I + II + III.
$$

For term I , as in case 1 we have $||\boldsymbol{d}||^2$ bounded:

$$
\mathbb{E}\left\{\left(\boldsymbol{W}_j-\frac{\boldsymbol{\mu}_1+\boldsymbol{\mu}_2}{2}\right)^{\top}\Sigma^{-1}(\boldsymbol{d}-\hat{\boldsymbol{d}})\right\}^2=O\left\{\mathbb{E}\left(\lambda_{max}(\Sigma^{-1})^2||\boldsymbol{d}-\hat{\boldsymbol{d}}||^2\right)\right\},\right.
$$

where $\lambda_{max}(\Sigma^{-1})$ is the largest eigenvalue of Σ^{-1} , which in our case is bounded by some constant.

For term II , we have

$$
\mathbb{E}\left\{\left(\frac{\bar{X}+\bar{Y}}{2}-\frac{\mu_1+\mu_2}{2}\right)^{\top}\Sigma^{-1}\hat{\boldsymbol{d}}\right\}^2
$$

= $O\left\{\mathbb{E}\left(\frac{n_1+n_2}{n_1n_2}\lambda_{max}(\Sigma^{-1})||\boldsymbol{d}-\hat{\boldsymbol{d}}||^2\right)+\mathbb{E}\left(\frac{n_1+n_2}{n_1n_2}\lambda_{max}(\Sigma^{-1})||\boldsymbol{d}||^2\right)\right\}$
= $O\left\{\frac{n_1+n_2}{n_1n_2}\mathbb{E}\left(\lambda_{max}(\Sigma^{-1})(||\boldsymbol{d}-\hat{\boldsymbol{d}}||^2+||\boldsymbol{d}||^2)\right)\right\}.$

For term III , we have

$$
\mathbb{E}\left\{\left(W_{j}-\frac{\bar{X}+\bar{Y}}{2}\right)^{\top}(\Sigma^{-1}-\hat{\Sigma}^{-1})\hat{d}\right\}^{2}
$$
\n
$$
=\mathbb{E}\left[\hat{d}^{\top}(\Sigma-\hat{\Sigma}^{-1})^{\top}\left\{\left(1+\frac{1}{4}\frac{n_{1}+n_{2}}{n_{1}n_{2}}\right)\Sigma^{-1}+\frac{1}{4}dd^{\top}\right\}(\Sigma^{-1}-\hat{\Sigma}^{-1})\hat{d}\right]
$$
\n
$$
\leq\mathbb{E}\left[\left\{\left(1+\frac{1}{4}\frac{n_{1}+n_{2}}{n_{1}n_{2}}\right)\frac{1}{\epsilon_{0}}+\frac{1}{4}\max\{d_{i}d_{j}, 1\leq i, j\leq p\}\right\}\hat{d}^{\top}(\Sigma^{-1}-\hat{\Sigma}^{-1})^{\top}(\Sigma^{-1}-\hat{\Sigma}^{-1})\hat{d}\right]
$$
\n
$$
=O\left[\mathbb{E}\left\{\left|\left|(\Sigma^{-1}-\hat{\Sigma}^{-1})\right|\right|_{2}^{2}\|\hat{d}\|^{2}\right\}\right]
$$
\n
$$
=O\left[\mathbb{E}\left\{\left|\left|(\Sigma^{-1}-\hat{\Sigma}^{-1})\right|\right|_{2}^{2}\|\hat{d}\|^{2}\right\}\right]
$$
\n
$$
=o(1).
$$

The last equality follows from assumption (A2) and the fact that $||\mathbf{d}||^2 < \infty$ in case 1. Hence,

$$
\mathbb{E}\left(S_j^{\pi} - \hat{S}_j\right)^2 = O\left\{\mathbb{E}\left(\|\hat{\boldsymbol{d}} - \boldsymbol{d}\|^2\right)\right\} + O\left(\frac{n_1 + n_2}{n_1 n_2}\right) + o(1) = o(1).
$$

Next we ask under what conditions do we have $\mathbb{E}\,\Big|\,$ $\hat{T}^j - T^j$ ² \rightarrow 0. Let $\delta > 0$ be some constant, applying Chebyshev's inequality, we have $P\left(|\hat{S}_j - S_j^\pi| > \delta\right) = O$ $\left\{\mathbb{E}\left(\left|S^{\pi}_{j}-\hat{S}_{j}\right|\right)^{2}\right\}$ \rightarrow 0. When $|\hat{S}_j - S_j^{\pi}| \le \delta$, apply Cauchy-Schwartz inequality, we have:

$$
\mathbb{E}_{\left|S_j^{\pi}-\hat{S}_j\right|<\delta} \left| \exp(\hat{S}_j) - \exp(S_j^{\pi}) \right|^2
$$
\n
$$
\leq \mathbb{E}e^{2S_j^{\pi} + 2\delta} \mathbb{E}\left(S_j^{\pi} - \hat{S}_j\right)^2
$$
\n
$$
= e^{O\left(\sum_{k=1}^{s_1} d_k^2\right)} \cdot o(1).
$$

Under the assumption of case 1 the above goes to 0. Therefore, as \hat{T}^j , T^j are bounded

above by 1, we have:

$$
\mathbb{E}(\hat{T}^j - T^j)^2 \le \mathbb{E} \left| \hat{T}^j - T^j \right|
$$

$$
\le 2P\left(\left| \hat{S}_j - S_j^{\pi} \right| > \delta \right) + E_{\left| \hat{S}_j - S_j^{\pi} \right| < \delta} \left| \exp(\hat{S}_j) - \exp(S_j^{\pi}) \right|.
$$

 \Box

The lemma follows.

B.2 Proof of Lemma 2

Using the definitions of \hat{V}_j and V_j , we can show that

$$
\frac{1}{2}\left(\hat{V}_j - V_j\right)^2 \leq \left(\hat{T}^j - T^j\right)^2 \mathbb{I}\left(\hat{T}^j \leq t, T^j \leq t\right) + \left(\hat{T}^j - \alpha_2\right)^2 \mathbb{I}\left(\hat{T}^j \leq t, T^j > t\right) + \left(T^j - \alpha_2\right)^2 \mathbb{I}\left(\hat{T}^j > t, T^j \leq t\right).
$$

Let us refer to the three summands on the right hand as (1) , (2) and (3) respectively. By Lemma 1, (1) = $o(1)$. Then let $\varepsilon > 0$, and consider that

$$
P\left(\hat{T}^j \le t, T^j > t\right)
$$

\n
$$
\le P\left(\hat{T}^j \le t, T^j \in (t, t + \varepsilon)\right) + P\left(\hat{T}^j \le t, T^j \ge t + \varepsilon\right)
$$

\n
$$
\le P\left\{T^j \in (t, t + \varepsilon)\right\} + P\left(\left|T^j - \hat{T}^j\right| > \varepsilon\right).
$$

The first term on the right hand is vanishingly small as $\varepsilon \to 0$ because T^j is a continuous random variable. The second term converges to 0 by Lemma 1. Noting that $0 \leq T^j \leq 1$, we conclude (2) = $o(1)$. In a similar fashion, we can show that (3) = $o(1)$, thus proving \Box the lemma.

C Asymptotic Equivalence of FSR and mFSR

We show FSR_{δ}^c and mFSR_{δ}^c are asymptotically equivalent. Let $\mathcal{X}_{\delta}^c = \frac{1}{m}$ $\frac{1}{m}\sum_{j=1}^m \mathbb{I}(\delta_j=c,\theta_j\neq$ c) and $\mathcal{Y}_{\delta}^{c} = \frac{1}{m}$ $\frac{1}{m}\sum_{j=1}^{m} \mathbb{I}(\delta_j = c)$. The goal is to show $|\text{FSR}_{\pmb{\delta}}^c - \text{mFSR}_{\pmb{\delta}}^c| = o(1)$.

$$
|\mathrm{FSR}_{\pmb\delta}^c - \mathrm{mFSR}_{\pmb\delta}^c| \leq \mathbb{E}\left\{\left|\frac{\mathcal{X}_{\pmb\delta}^c}{\mathcal{Y}_{\pmb\delta}^c} - \frac{\mathcal{X}_{\pmb\delta}^c}{\mathbb{E}\mathcal{Y}_{\pmb\delta}^c}\right| \mathbb{I}(\mathcal{Y}_{\pmb\delta}^c > 0)\right\} = \mathbb{E}\left\{\frac{\mathcal{X}_{\pmb\delta}^c}{\mathcal{Y}_{\pmb\delta}^c} \mathbb{I}(\mathcal{Y}_{\pmb\delta}^c > 0) \frac{|\mathcal{Y}_{\pmb\delta}^c - \mathbb{E}\mathcal{Y}_{\pmb\delta}^c|}{\mathbb{E}\mathcal{Y}_{\pmb\delta}^c}\right\}
$$

Since $\mathcal{X}_{\delta}^c \leq \mathcal{Y}_{\delta}^c$, we have

$$
\mathbb{E}\left\{\frac{\mathcal{X}^c_\delta}{\mathcal{Y}^c_\delta}\mathbb{I}(\mathcal{Y}^c_\delta>0)\frac{|\mathcal{Y}^c_\delta-\mathbb{E}\mathcal{Y}^c_\delta|}{\mathbb{E}\mathcal{Y}^c_\delta}\right\}\leq \mathbb{E}\left\{\frac{|\mathcal{Y}^c_\delta-\mathbb{E}\mathcal{Y}^c_\delta|}{\mathbb{E}\mathcal{Y}^c_\delta}\right\}\leq \frac{(\mathbb{E}|\mathcal{Y}^c_\delta-\mathbb{E}\mathcal{Y}^c_\delta|^2)^{1/2}}{\mathbb{E}\mathcal{Y}^c_\delta}=\frac{(\text{Var}\mathcal{Y}^c_\delta)^{1/2}}{\mathbb{E}\mathcal{Y}^c_\delta}
$$

By assumption (A3), we have $m\mathcal{Y}_{\delta_{OR}}^c \sim \text{Binom}(m, \eta)$ with $\eta > 0$. Therefore, $\mathbb{E} \mathcal{Y}_{\delta_{OR}}^c = \eta$ and $\textsf{Var}(\mathcal{Y}_{\pmb{\delta}_O R}^c)^{1/2} = \sqrt{\eta(1-\eta)/m}, \; |\text{FSR}_{\pmb{\delta}_{OR}}^c - \text{mFSR}_{\pmb{\delta}_{OR}}^c| = O(m^{-1/2}).$ In the setting of Theorem [4,](#page-20-0) the data driven procedure is mimicking δ_{OR} . It can be seen from the proof of Theorem [4](#page-20-0) that mFSR and FSR of the data driven procedure are also asymptotically equivalent. Similarly, for the setting of Theorem [3,](#page-19-0) consider the rule δ_Z defined in the proof of Theorem [3,](#page-19-0) by assumption (A3) we also have $|FSR_{\delta z}^c - mFSR_{\delta z}^c| = O(m^{-1/2})$. In the setting of Theorem [3,](#page-19-0) the data driven procedure is mimicking δ_Z . It can be seen from the proof of Theorem [3](#page-19-0) that mFSR and FSR of the data driven procedure are also asymptotically equivalent. \Box
