Orthogonal Approximate Message-Passing for Spatially Coupled Linear Models

Keigo Takeuchi, Member, IEEE

arXiv:2210.06019v2 [cs.IT] 19 May 2023

Abstract—Orthogonal approximate message-passing (OAMP) is proposed for signal recovery from right-orthogonally invariant linear measurements with spatial coupling. Conventional state evolution is generalized to a unified framework of state evolution for the spatial coupling and long-memory case. The unified framework is used to formulate the so-called Onsager correction in OAMP for spatially coupled systems. The state evolution recursion of Bayes-optimal OAMP is proved to converge for spatially coupled systems via Bayes-optimal long-memory OAMP and its state evolution. This paper proves the information-theoretic optimality of Bayes-optimal OAMP for noiseless spatially coupled systems with right-orthogonally invariant sensing matrices.

Index Terms—Compressed sensing, message passing, orthogonal invariance, spatial coupling, state evolution.

I. INTRODUCTION

A. Compressed Sensing with Zero-Mean i.i.d. Matrices

C OMPRESSED sensing [1], [2] is a technique to reconstruct unknown sparse signals from compressed measurements. When the signals are independent and identically distributed (i.i.d.), the Rényi information dimension [3] of each signal characterizes the information-theoretic compression limit [4] for noiseless measurements. For instance, the Bernoulli-Gaussian (BG) signal with signal density $\rho \in [0, 1]$ —the occurrence probability of non-zero signals—has the information dimension ρ . A goal in compressed sensing is to establish a reconstruction algorithm that achieves the information-theoretic compression limit.

Approximate message-passing (AMP) [5], [6] is a lowcomplexity and powerful algorithm for compressed sensing. AMP reconstructs unknown signals via message passing (MP) between the matched filter (MF) for interference suppression and a separable denoiser. AMP using the Bayes-optimal denoiser—called Bayes-optimal AMP—can be regarded as an asymptotically exact approximation of loopy belief propagation (BP) [7].

The performance of AMP was rigorously analyzed via state evolution [8], [9], which was motivated by Bolthausen's conditioning technique [10]. The asymptotic dynamics of AMP is characterized via one-dimensional (1D) discrete systems called state evolution recursions. When the compression rate is larger than a value called BP threshold [11] in this paper, Bayes-optimal AMP was proved to achieve the Bayes-optimal performance asymptotically for zero-mean i.i.d. sub-Gaussian sensing matrices [8], [9]. However, there is a gap between the BP threshold and the information-theoretic limit if the state evolution recursions have multiple fixed points.

Spatial coupling [12] was proposed to improve the BP performance of low-density parity-check (LDPC) codes toward the Bayes-optimal performance. This improvement was referred to as threshold saturation via spatial coupling in [12]. Spatial coupling is a universal technique to improve the performance of iterative algorithms in the other problems [13], [14]. In particular, AMP [11], [15], [16] was shown to achieve¹ the information-theoretic compression limit for spatially coupled zero-mean i.i.d. Gaussian sensing matrices. More precisely, state evolution [17] for spatially coupled dense systems was utilized in [16] to obtain rigorous state evolution recursions. On the other hand, spatially coupled sparse systems were used in [11] to bypass the technical difficulty in dense systems. The two systems result in the same state evolution recursions as each other, so that they can achieve the information-theoretic compression limit.

Spatial coupling was also applied to AMP decoding [18], [19] for sparse superposition codes [20] over the additive white Gaussian noise (AWGN) channel. Decoding in sparse superposition codes is equivalent to the reconstruction of signals having section-wise sparsity. Spatially coupled sparse superposition codes were proved to achieve the capacity of the AWGN channel via state evolution [19].

Threshold saturation via spatial coupling can be analyzed with a potential function [11], [21] that is defined from state evolution recursions without spatial coupling. This potentialfunction approach was originally motivated by [13], [14] and simplifies the proof of threshold saturation conducted by [16].

The potential function defined in [11] is equivalent to a replica-symmetric potential used in characterizing the Bayesoptimal performance for systems without spatial coupling [22], [23]. The potential was originally derived with the replica method under the replica-symmetry assumption—non-rigorous tool in statistical physics [24], [25]—and rigorously justified in [26], [27]. It is possible to simplify the proof of threshold saturation in [16] by using a relationship between the Rényi

¹Achievability in [16] is different from that in [4]. A compression rate was said to be achievable in [16] if the mean-square error averaged over all sections converges almost surely to zero. On the other hand, [4] defined achievability in terms of block error probability. This paper uses the achievability in [16].

information dimension and the mutual information [28, Theorem 6].

B. Beyond Zero-Mean i.i.d. Sensing Matrices

We have so far discussed zero-mean i.i.d. sensing matrices. Beyond zero-mean i.i.d. matrices, the replica-symmetric potential in [22], [23] was generalized to the case of right-orthogonally invariant sensing matrices via the replica method [29], [30]. Right-orthogonal invariance implies that the right-singular vectors of the sensing matrix are orthonormal and Haar-distributed [31], [32]. Zero-mean i.i.d. Gaussian matrices are included in the class of right-orthogonally invariant matrices. See [33], [34] for a theoretical progress to prove the replica-symmetric potential in [29], [30] rigorously.

There are general ensembles beyond zero-mean i.i.d. sensing matrices such that AMP fails to converge [35], [36]. To solve this convergence issue in AMP, several MP algorithms [37]–[43] were proposed. The most promising algorithm is orthogonal AMP (OAMP) [41] or equivalently vector AMP (VAMP) [42]. In this paper, they are called OAMP.

A prototype of OAMP was originally proposed in [44, Appendix D] as a single-loop algorithm to solve a fixed point of the expectation-consistent (EC) free energy. Bayes-optimal OAMP can be regarded as an asymptotically exact approximation [45], [46] of expectation propagation (EP) [47]. Bayes-optimal OAMP [41] can solve reconstruction problems beyond zero-mean i.i.d. sensing matrices while it needs the high-complexity linear minimum mean-square error (LMMSE) filter.

State evolution was generalized to the case of rightorthogonally invariant sensing matrices [42], [46] to prove a conjecture [41] for state evolution. The conjecture was resolved positively: State evolution recursions for Bayes-optimal OAMP was proved to have the same fixed points as the replicasymmetric potential derived in [29], [30], [33], [34]. See [48]– [50] for the convergence of the state evolution recursions to a fixed point.

The purpose of this paper is to prove that, via spatial coupling, Bayes-optimal OAMP achieves the information-theoretic compression limit for right-orthogonally invariant sensing matrices. There is a gap between the OAMP performance and information-theoretic limit when the state evolution recursions have multiple fixed points. Spatial coupling is utilized to fill this gap and prove the information-theoretic optimality of OAMP.

This paper proposes both OAMP and long-memory (LM) OAMP (LM-OAMP) [48], [49] for spatially coupled and rightorthogonally invariant systems. LM-OAMP should be regarded as a proof strategy to guarantee the convergence of Bayesoptimal OAMP to a fixed point. For systems without spatial coupling, Bayes-optimal LM-OAMP was proved in [48], [49] to converge and to be asymptotically equivalent to Bayesoptimal OAMP. This paper generalizes these results to the spatial coupling case.

LM-OAMP is an instance of LM-MP, which utilizes messages in all preceding iterations to update the current message while conventional MP uses messages only in the latest iteration. An instance of LM-MP was originally proposed in [51] via non-rigorous dynamical functional theory. On the basis of rigorous state evolution in this direction, LM-MP—called AMP for rotationally invariant matrices—was proposed in [52], [53].

Another LM-MP was proposed via state evolution in [54], which is a generalization of [46] to the LM case. Convolutional AMP (CAMP) [54]–[56] achieves the Bayes-optimal performance for right-orthogonally invariant sensing matrices with low-to-moderate condition numbers. Memory AMP (MAMP) [57] improves the convergence property of CAMP for high condition numbers. See [58], [59] for the other instance of LM-MP, inspired by [60]. Since the main purpose of these algorithms is a complexity reduction of OAMP, this type of LM-MP is out of the scope of this paper.

C. Contributions

The main contributions of this paper are fourfold: A first contribution is a connection between the information-theoretic compression limit [4] and the replica-symmetric potential for right-orthogonally invariant matrices [29], [30], [33], [34] in the noiseless limit (Corollary 2). This connection bridges a gap between the information-theoretic limit and the potential-function approach for analyzing spatial coupling [11], [21]. As a by-product, the proof in [16] can be simplified for the case of uniform spatial coupling: For spatially coupled zero-mean i.i.d. Gaussian sensing matrices, the information-theoretic optimality of AMP follows immediately from the state evolution in [17] and the replica-symmetric potential in [11] to characterize the AMP performance.

A second contribution is a generalization of conventional state evolution in [46], [54] to the case of spatial coupling, right-orthogonal invariance, and LM-MP (Theorem 8). As special cases, state evolution recursions for both OAMP and LM-OAMP are proved in Theorems 3 and 5, respectively. Bayes-optimal LM-OAMP is used to justify the convergence of state evolution recursions of Bayes-optimal OAMP for spatially coupled systems (Theorem 6), by proving the convergence of the state evolution recursions for LM-OAMP and the equivalence between Bayes-optimal LM-OAMP and Bayes-optimal OAMP, as proved in [48], [49]. As a by-product, the state evolution result can be utilized to evaluate the asymptotic performance of LM-MP that aims to reduce the computational complexity of OAMP for spatially coupled systems. However, research for complexity reduction is left as future work.

From a technical point of view, a third contribution is an asymptotically exact approximation of state evolution recursions for Bayes-optimal OAMP (Lemma 8). The state evolution recursions are approximated so that they are included in the class of spatially coupled systems considered in [11]. As a result, we can utilize the potential-function approach [11] to analyze the properties of the state evolution recursions for Bayes-optimal OAMP. By proving that a potential function defined in the approach [11] is equivalent to the replica-symmetric potential for right-orthogonally invariant matrices [29], [30], [33], [34], we arrive at the informationtheoretic optimality of Bayes-optimal OAMP for spatially coupled systems (Theorem 4). The last contribution is numerical results. Bayes-optimal OAMP for spatially coupled systems is shown to be superior to that for conventional systems without spatial coupling in the so-called waterfall region. For spatially coupled sensing matrices with orthogonal rows, Bayes-optimal OAMP is a low-complexity alternative of Bayes-optimal AMP for zero-mean i.i.d. Gaussian sensing matrices with spatial coupling.

The second and last contributions were presented in part in a conference paper [61].

D. Organization

The remainder of this paper is organized as follows: After summarizing the notation used in this paper, Section II reviews compressed sensing for conventional measurements without spatial coupling. Conditional mutual information is selected as performance measure in signal reconstruction and connected to the replica-symmetric potential for right-orthogonally invariant sensing matrices, which is defined with the R-transform [32] of the sensing matrix. After presenting basic properties of the Rtransform used throughout this paper, we prove a relationship between the information-theoretic compression limit and the replica-symmetric potential in Theorem 2.

Section III presents compressed sensing from spatially coupled measurements. In Section IV, we propose OAMP for signal recovery from the spatially coupled measurements.

The two main theorems—Theorems 3 and 4—are presented in Section V. State evolution recursions for OAMP are proved in Theorem 3. This paper also proves the convergence of the state evolution recursions of Bayes-optimal OAMP for the spatial coupling case in the same theorem. Theorem 4 claims the information-theoretic optimality of Bayes-optimal OAMP for spatially coupled systems in the noiseless case.

The proof of Theorem 3 is presented in Section VI. To prove the convergence of the state evolution recursions for Bayes-optimal OAMP, we follow [48], [49] to formulate LM-OAMP for the spatially coupled system. State evolution recursions for LM-OAMP are proved in Theorem 5—a special case of Theorem 8 presented in Appendix G, claiming state evolution results for the case of spatial coupling, rightorthogonal invariance, and LM-MP. Theorem 3 is obtained by proving the convergence of the state evolution recursions for Bayes-optimal LM-OAMP in Theorem 6, as well as the equivalence between Bayes-optimal OAMP and Bayes-optimal LM-OAMP.

The proof of Theorem 4 is presented in Section VII. After numerical results are presented in Section VIII, this paper is concluded in Section IX.

E. Notation

Throughout this paper, the transpose and trace of a matrix M are denoted by M^{T} and $\mathrm{Tr}(M)$, respectively. The vector e_n represents the *n*th column of the identity matrix I while 1 is a vector of which the elements are all one. The notation O represents an all-zero matrix. For $\{M_i\}_{i=1}^n$, the notation $\mathrm{diag}\{M_1,\ldots,M_n\}$ denotes the block diagonal matrix having the *i*th diagonal block M_i . The norm $\|\cdot\|$ represents

For a vector $v_{\mathcal{I}}$ with a set of indices \mathcal{I} , the *n*th element $[v_{\mathcal{I}}]_n$ of $v_{\mathcal{I}}$ is written as $v_{n,\mathcal{I}}$. Similarly, the *t*th column of a matrix $M_{\mathcal{I}}$ is represented as $m_{t,\mathcal{I}}$.

The notation $\boldsymbol{x} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ means that a random vector \boldsymbol{x} follows the Gaussian distribution with mean $\boldsymbol{\mu}$ and covariance $\boldsymbol{\Sigma}$. The almost sure convergence and equivalence are denoted by $\stackrel{\text{a.s.}}{\rightarrow}$ and $\stackrel{\text{a.s.}}{=}$, respectively. The notation $\stackrel{\text{a.s.}}{>}$ is defined in a similar manner.

For a scalar function $f : \mathbb{R} \to \mathbb{R}$ and a vector $x \in \mathbb{R}^n$, the notation f(x) means the element-wise application of f to x, i.e. $[f(x)]_i = f(x_i)$. The arithmetic mean of $x \in \mathbb{R}^n$ is written as $\langle x \rangle = n^{-1} \sum_{i=1}^n x_i$. For a multi-variate function $f : \mathbb{R}^t \to \mathbb{R}$, the notation ∂_i represents the partial derivative of f with respect to the *i*th variable.

The space of all possible $N \times N$ orthogonal matrices is denoted by \mathcal{O}_N . The notation $M^{\dagger} = (M^{\mathrm{T}}M)^{-1}M^{\mathrm{T}}$ represents the pseudo-inverse of a full-rank matrix $M \in \mathbb{R}^{m \times n}$ satisfying $m \geq n$. The singular-value decomposition (SVD) of M is written as $M = \Phi_M \Sigma_M \Psi_M^{\mathrm{T}}$ with $\Phi_M \in \mathcal{O}_m$ and $\Psi_M \in \mathcal{O}_n$. The matrix $P_M^{\perp} = I - M(M^{\mathrm{T}}M)^{-1}M^{\mathrm{T}}$ is the projection onto the orthogonal complement of the space spanned by the columns of M.

II. CONVENTIONAL COMPRESSED SENSING

A. System Model

This section reviews compressed sensing from linear measurements without spatial coupling. Let $M \in \mathbb{N}$ and $N \in \mathbb{N}$ denote the dimensions of measurement and signal vectors, respectively. The measurement vector $\boldsymbol{y} \in \mathbb{R}^M$ is given by

$$\boldsymbol{y} = \boldsymbol{A}\boldsymbol{x} + \boldsymbol{n}. \tag{1}$$

In (1), $A \in \mathbb{R}^{M \times N}$ represents a known sensing matrix. The vectors $x \in \mathbb{R}^N$ and $n \in \mathbb{R}^M$ denote sparse signal and noise vectors, respectively. The random variables in the triple $\{A, x, n\}$ are independent. The purpose of compressed sensing is to reconstruct the unknown sparse signal vector x from the knowledge on the sensing matrix A and the compressed measurement vector y with $M \leq N$.

The sensing matrix A is assumed to be sampled from the ensemble of right-orthogonally invariant matrices uniformly and randomly.

Definition 1: A matrix A is said to be right-orthogonally invariant if the SVD $A = U\Sigma V^{T}$ satisfies the following conditions:

- The orthogonal matrix V ∈ O_N is independent of UΣ and Haar-distributed on the space of all possible N × N orthogonal matrices.
- The empirical eigenvalue distribution of $A^T A$ converges almost surely to a compactly supported deterministic distribution with unit mean in the large system limit, where both M and N tend to infinity with the compression rate $\delta = M/N \in (0, 1]$ kept constant.

The unit-mean assumption implies the almost sure convergence $N^{-1}\text{Tr}(\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}) \xrightarrow{\text{a.s.}} 1$ in the large system limit.

The original definition of the right-orthogonal invariance only includes the former assumption. Nonetheless, this paper includes the latter assumption in the definitions of rightorthogonal invariant matrices. The latter assumption is needed to perform rigorous state evolution analysis.

We refer to the ensemble of right-orthogonally invariant matrices as (M, N)-ensemble. Note that (M, N)-ensemble is defined for fixed statistical properties of $U \in \mathcal{O}_M$ and diagonal $\Sigma \in \mathbb{R}^{M \times N}$. In other words, (M, N)-ensemble depends on the joint distribution of U and Σ while it is not written explicitly.

It is practically important to relax the right-orthogonal invariance to weaker assumptions, including discrete cosine transform (DCT) or Hadamard matrices with random permutation [62]. See [63]–[65] for theoretical progress in this direction.

B. Conditional Mutual Information

We measure the optimal reconstruction performance with the conditional mutual information I(x; y|A) in nats between the signal vector x and the measurement vector y given A. It might be standard to use the minimum mean-square error (MMSE) $\mathbb{E}[||x - \mathbb{E}[x|y, A]||^2]$ in compressed sensing. Nonetheless, the conditional mutual information is useful to define a potential that characterizes the MMSE performance.

This paper focuses on a rigorous result [33] on the conditional mutual information since another rigorous result requires a strong assumption [34, Assumption 1.4] on the condition number of the sensing matrix. To present the former rigorous result [33], we need the following assumptions:

Assumption 1:

- The signal vector x has i.i.d. bounded elements with zero mean and unit variance.
- The noise vector $\boldsymbol{n} \sim \mathcal{N}(\boldsymbol{0}, \sigma^2 \boldsymbol{I}_M)$ has independent Gaussian elements with zero mean and variance $\sigma^2 > 0$.
- The sensing matrix is represented as the product $\boldsymbol{A} = \boldsymbol{D}\boldsymbol{W}$ of two independent matrices $\boldsymbol{D} \in \mathbb{R}^{M \times M}$ and $\boldsymbol{W} \in \mathbb{R}^{M \times N}$. The matrix \boldsymbol{W} has independent zero-mean Gaussian elements with variance 1/M while \boldsymbol{D} is the product of a finite number of independent matrices having i.i.d. bounded or Gaussian elements. Furthermore, \boldsymbol{D} satisfies the almost sure convergence $M^{-1}\text{Tr}(\boldsymbol{D}^{T}\boldsymbol{D}) \stackrel{\text{a.s.}}{\rightarrow} 1$.

The boundedness of the signal vector excludes the BG prior. The ensemble of sensing matrices A = DW is a subclass of (M, N)-ensemble since the Gaussian matrix W is rightorthogonally invariant. The assumption $M^{-1}\text{Tr}(D^TD) \stackrel{\text{a.s.}}{\to} 1$ should be regarded as a normalization to include A = DW in (M, N)-ensemble. This structure A = DW was not required in the replica conjecture [29], [30], as well as the boundedness of the signal vector. Thus, it is still open to relax these assumptions.

Remark 1: Without loss of generality, we can transform D into a diagonal matrix. Consider the SVD $D = \Phi_D \Sigma_D \Psi_D^{\mathrm{T}}$. Left-multiplying (1) by Φ_D^{T} yields

$$\Phi_D^{\mathrm{T}} \boldsymbol{y} = \boldsymbol{\Sigma}_D \Psi_D^{\mathrm{T}} \boldsymbol{W} \boldsymbol{x} + \Phi_D^{\mathrm{T}} \boldsymbol{n} \sim \boldsymbol{\Sigma}_D \boldsymbol{W} \boldsymbol{x} + \boldsymbol{n}, \quad (2)$$

where the last statistical equivalence follows from the leftorthogonal invariance of W and the orthogonal invariance of $n \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I}_M)$. Thus, \mathbf{D} can be transformed into the diagonal matrix Σ_D . Since \mathbf{D} is the product of a finite number of independent matrices having i.i.d. bounded or Gaussian elements, Σ_D is in a subclass of general diagonal matrices.

The conditional mutual information can be described with a replica-symmetric potential, which was derived in [29], [30] via the replica method under the replica symmetry assumption. Let $f_{\rm RS} : [0,1] \times [0,\infty) \to \mathbb{R}$ denote the replica-symmetric potential, given by

$$f_{\rm RS}(E,s) = I(s) + \frac{1}{2} \int_0^{E/\sigma^2} R_{A^{\rm T}A}(-z) dz - \frac{sE}{2}.$$
 (3)

In (3), R_{A^TA} denotes the R-transform of the empirical eigenvalue distribution of A^TA in the large system limit [32], defined shortly. The first term $I(s) = I(x_1; \sqrt{sx_1+z_1})$ denotes the mutual information in nats between the first element x_1 of the signal vector and a virtual AWGN measurement $\sqrt{sx_1+z_1}$ with signal-to-noise ratio (SNR) $s \ge 0$ for $z_1 \sim \mathcal{N}(0, 1)$ independent of x_1 . The variable s is regarded as the asymptotic signal-to-interference-plus-noise ratio (SINR). In this sense, z_1 corresponds to the effective interference plus noise.

The variable E will be evaluated at E = MMSE(s), given by

$$\mathrm{MMSE}(s) = \mathbb{E}\left[(x_1 - \mathbb{E}[x_1|\sqrt{sx_1} + z_1])^2 \right]$$
(4)

We use the optimality of the posterior mean estimator to obtain the following trivial upper bound:

$$MMSE(s) \le \mathbb{E}[x_1^2],\tag{5}$$

considering the estimator $\hat{x}_1 = 0$ for x_1 given any observation $\sqrt{sx_1 + z_1}$. When $\mathbb{E}[x_1^2] = 1$ holds, thus, the finite interval [0, 1] is considered as the domain of $f_{\rm RS}$ for E while $[0, \infty)$ is considered for s.

Theorem 1 ([33]): Suppose that Assumption 1 holds. Then, the normalized conditional mutual information is given by

$$\frac{1}{N}I(\boldsymbol{x};\boldsymbol{y}|\boldsymbol{A}) \to \inf_{s \ge 0} \sup_{E \in [0,1]} f_{\mathrm{RS}}(E,s)$$
(6)

in the large system limit, where the replica-symmetric potential $f_{\rm RS}$ is defined as (3).

The optimizer (E_{opt}, s_{opt}) for the inf-sup problem (6) characterizes the asymptotic MMSE and SINR for the Bayesoptimal reconstruction of the signal vector based on the measurement model (1). More precisely, the MMSE $N^{-1}\mathbb{E}[||\boldsymbol{x} - \mathbb{E}[\boldsymbol{x}|\boldsymbol{A}, \boldsymbol{y}]||^2]$ converges to E_{opt} in the large system limit. See [33] for the details.

C. Optimizer

The goal of this section is to investigate properties of the optimizer in the inf-sup problem (6) as a technical step to characterize the information-theoretic compression limit. We first investigate properties of the optimizer in a general inf-sup problem including the inf-sup problem (6).

Lemma 1: Let $f : [E_{\min}, E_{\max}] \to [-\infty, \infty)$ denote a function satisfying $f(E) > -\infty$ for some $E \in [E_{\min}, E_{\max}]$. Suppose that $g : [0, \infty) \to [-\infty, \infty)$ is an upper semicontinuous and concave function such that $g(s) > -\infty$ holds for some $s \ge 0$, that the infimum of sE - g(s) over $s \ge 0$ is attained at s = 0, an interior point s > 0, and $s = \infty$ for all $E = E_{\max}$, $E \in (E_{\min}, E_{\max})$, and $E = E_{\min}$, respectively. The function $\psi(E, s) = f(E) + g(s) - sE$ satisfies the following properties:

Suppose that f is upper semicontinuous and concave, and that there are some s_{min} ≥ 0 and s_{max} > s_{min} such that the infimum of sE - f(E) over E ∈ [E_{min}, E_{max}] is attained at E = E_{min}, an interior point E ∈ (E_{min}, E_{max}), and E = E_{max} for all s = s_{max}, s ∈ (s_{min}, s_{max}), and s = s_{min}, respectively. Then, we have

$$\inf_{s\geq 0} \sup_{E\in[E_{\min},E_{\max}]} \psi(E,s) = \inf_{E\in[E_{\min},E_{\max}]} \sup_{s\geq 0} \psi(E,s).$$
(7)

• Suppose that g is differentiable and strictly concave, and that f is differentiable and non-decreasing. Then, we have

$$\inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E, s) = \inf_{(E, s)} \psi(E, s), \quad (8)$$

where the infimum on the right-hand side (RHS) is over

$$\{(E,s) \in [E_{\min}, E_{\max}] \times [0,\infty] : E = g'(s), s = f'(E)\}$$
(9)

Proof: The former and latter parts in Lemma 1 correspond to [66, Corollary 7] and [66, Lemma 23], respectively. We prove Lemma 1 under weaker conditions than in [66] by removing unnecessary conditions in [66]. See Appendix A for the details.

To use Lemma 1 for evaluation of the optimizer (E_{opt}, s_{opt}) in the inf-sup problem (6), we need to confirm that the first two terms in the replica-symmetric potential (3) satisfy the assumptions in Lemma 1. For that purpose, we start with the definition of the η -transform for the empirical eigenvalue distribution of $A^{T}A$ in the large system limit, which is used to define the R-transform.

Let η_{A^TA} denote the η -transform of the empirical eigenvalue distribution of A^TA in the large system limit [32, Definition 2.11], given by²

$$\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z) = \lim_{M=\delta N \to \infty} \frac{1}{N} \operatorname{Tr}\left\{ (\boldsymbol{I}_{N} + z\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A})^{-1} \right\}$$
(10)

for all $z \ge 0$. Let r denote the rank of $A^{T}A$. From the definition of the η -transform in (10) we have

$$\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(z) = \lim_{M=\delta N \to \infty} \left(\frac{1}{N} \sum_{n=1}^{r} \frac{1}{1+\lambda_n z} + 1 - \frac{r}{N} \right), \quad (11)$$

where $\{\lambda_n > 0\}$ are strictly positive eigenvalues of $A^T A$.

We define the *k*th moment of the asymptotic eigenvalue distribution of $A^{T}A$ as

$$\mu_k = \lim_{M = \delta N \to \infty} \frac{1}{N} \operatorname{Tr}\{(\boldsymbol{A}^{\mathrm{T}} \boldsymbol{A})^k\}.$$
 (12)

The η -transform has the following basic properties, which are trivial from the definition of the η -transform.

Lemma 2: The η -transform (10) satisfies the following properties:

• $z\eta_{A^TA}(z)$ is strictly increasing for all $z \ge 0$.

²The η -transform is also defined as $\tilde{\eta}_{A^TA}(z) = 1 - 1/\eta_{A^TA}(-z)$ in random matrix theory [67, Eq. (10.8)].

If all moments {μ_k} exist, the η-transform (10) is infinitely continuously-differentiable for all z ≥ 0.
 Proof: See Appendix B-A.

In the subsequent sections we consider sensing matrices with bounded μ_k for all k while the boundedness of μ_k is explicitly assumed in Section II. Thus, we need not investigate the differentiability of the η -transform in the subsequent sections. When all moments { μ_k } exist, the η -transform has the following series-expansion:

$$\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z) = \sum_{k=0}^{\infty} \mu_k (-z)^k \tag{13}$$

if (13) is bounded in a neighborhood of z = 0.

We next consider the R-transform R_{A^TA} , which is implicitly defined as

$$\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z) = \frac{1}{1 + zR_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(-z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z))},$$
(14)

with $R_{A^T A}(0) = \lim_{z \uparrow 0} R_{A^T A}(z)$. Solving the definition of the R-transform in (14) with respect to $R_{A^T A}$, we have

$$R_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(-z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z)) = \frac{1-\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z)}{z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(z)}.$$
 (15)

Lemma 2 implies that the domain of the R-transform is equal to the interval $(z_{\min}, 0]$ with $z_{\min} = -\lim_{z \to \infty} z \eta_{A^T} A(z)$.

The R-transform satisfies the following basic properties, which are trivial when the R-transform is defined with an equivalent definition: a formal power series with the coefficients equal to free cumulants [32, Eq. (2.84)].

Lemma 3: If all moments $\{\mu_k\}$ exist, the R-transform (14) is infinitely continuously-differentiable for all $z \in (z_{\min}, 0]$. In particular, we have

$$R_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(0) = \mu_1, \tag{16}$$

$$R'_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(0) = \mu_2 - \mu_1^2.$$
(17)

Proof: See Appendix B-B.

Lemma 3 allows us to use differentiability and continuity of the R-transform freely since bounded $\{\mu_k\}$ are considered in this paper. Nonetheless, we assume explicitly regularity conditions for the R-transform in Section II to clarify what conditions we use in their proofs.

In this paper, we consider the R-transform satisfying the following conditions:

Definition 2: The R-transform is said to be proper for all $z \leq 0$ if $z_{\min} = -\lim_{z \to \infty} z \eta_{A^T A}(z) = -\infty$ holds and if $\mu_2 > \mu_1^2$ holds.

The former condition $z_{\min} = -\infty$ in Definition 2 implies that the domain of the R-transform is the interval $(-\infty, 0]$. As a result, the replica-symmetric potential (3) is well defined in the limit $\sigma^2 \downarrow 0$. The latter condition $\mu_2 > \mu_1^2$ excludes the constant R-transform $R_{A^TA}(z) = \mu_1$ for all z, because of Lemma 3. The zero variance $\mu_2 - \mu_1^2 = 0$ holds when the empirical eigenvalue distribution of $A^T A$ converges almost surely to the Dirac distribution that takes μ_1 with probability 1. This convergence occurs when the sensing matrix is square and has identical singular values with the exception of o(N)singular values. Since the R-transform cannot distinguish this sensing matrix from the identity matrix, the constant R-transform is excluded as a trivial case.

The following two lemmas present sufficient conditions for technical assumptions required in proving the informationtheoretic optimality in compressed sensing.

Lemma 4: Suppose that all moments $\{\mu_k\}$ exist. Then,

- The R-transform (14) is non-negative for all z ∈ (z_{min}, 0]. In particular, it is positive for all z ∈ (z_{min}, 0] if μ₁ > 0 holds.
- The R-transform (14) is non-decreasing for all $z \in (z_{\min}, 0]$. In particular, it is strictly increasing for all $z \in (z_{\min}, 0]$ if $\mu_2 > \mu_1^2$ holds.

Proof: See Appendix B-C.

Lemma 5: Let r denote the rank of A and suppose that the ratio r/N tends to δ in the large system limit. If $\delta < 1$ or the following condition for $\delta = 1$ is satisfied:

$$\lim_{M=\delta N\to\infty} \frac{1}{N} \sum_{n=1}^{N} \frac{1}{\lambda_n} \to \infty,$$
(18)

then $\lim_{z\to\infty} z\eta_{A^TA}(z) = \infty$ and $\lim_{z\to\infty} zR_{A^TA}(-z) = \delta$ hold.

Proof: We first prove $\lim_{z\to\infty} \eta_{A^T A}(z) = 1 - \delta$ and $\lim_{z\to\infty} z\eta_{A^T A}(z) = \infty$. From the representation of the η -transform in (11), we have $\lim_{z\to\infty} \eta_{A^T A}(z) = 1 - \delta$. For $\delta < 1$, $\lim_{z\to\infty} z\eta_{A^T A}(z) = \infty$ is trivial from (11). On the other hand, for $\delta = 1$ we use the assumption (18) to prove

$$\lim_{z \to \infty} z \eta_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(z) = \lim_{z \to \infty} \lim_{M = \delta N \to \infty} \frac{1}{N} \sum_{n=1}^{N} \frac{z}{1 + \lambda_n z}$$
$$> \lim_{M = \delta N \to \infty} \frac{1}{N} \sum_{n=1}^{N} \frac{1}{\lambda_n} \to \infty.$$
(19)

We next prove $\lim_{z\to\infty} zR_{A^TA}(-z) = \delta$. Using the limit $z\eta_{A^TA}(z) \to \infty$ and the definition of the R-transform in (15), we obtain

$$\lim_{z \to \infty} z R_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(-z) = \lim_{z \to \infty} z \eta_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(z) R_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(-z \eta_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(z))$$
$$= 1 - \lim_{z \to \infty} \eta_{\mathbf{A}^{\mathrm{T}} \mathbf{A}}(z) = \delta, \qquad (20)$$

where the last follows from $\eta_{A^T A}(z) \rightarrow 1 - \delta$.

We are ready to investigate properties of the second term in the replica-symmetric potential (3). To investigate properties of the first term, we use a general formula between mutual information and MMSE [68] and the smoothness of MMSE [69, Propositions 7 and 9].

Proposition 1 ([68]):

$$\frac{d}{ds}I(s) = \frac{1}{2}\text{MMSE}(s).$$
(21)

Proposition 2 ([69]): The function MMSE(s) is infinitely continuously-differentiable for all $s \ge 0$. In particular, we have

$$\frac{d}{ds} \text{MMSE}(s) = -\mathbb{E}\left[\left\{\mathbb{E}[(x_1 - \mathbb{E}[x_1|u_1])^2|u_1]\right\}^2\right], \quad (22)$$

with $u_1 = \sqrt{sx_1 + z_1}$ and $z_1 \sim \mathcal{N}(0, 1)$ independent of x_1 .

The following lemma implies that it is sufficient to consider extremizers in solving the inf-sup problem (6): Lemma 6: Suppose $\mathbb{E}[x_1^2] = 1$ and assume that the R-transform $R_{A^T A}(z)$ is proper, continuous, non-decreasing, and non-negative for all $z \leq 0$. Then, the following identity holds:

$$\inf_{s \ge 0} \sup_{E \in [0,1]} f_{\rm RS}(E,s) = \inf_{(E,s) \in \mathcal{S}} f_{\rm RS}(E,s), \qquad (23)$$

where $\mathcal{S} \subset [0,1] \times [0,\infty]$ denotes the set of extremizers

$$S = \{ (E, s) \in [0, 1] \times [0, \infty] : E = \text{MMSE}(s), \\ s = R_{A^{\mathsf{T}}A} (-E/\sigma^2)/\sigma^2 \}.$$
(24)

Proof of Lemma 6: We utilize Lemma 1 to prove the identity (23). Let g(s) = 2I(s) and

$$f(E) = \int_0^{E/\sigma^2} R_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z)dz.$$
 (25)

Then, we have $\psi(E, s) = 2f_{RS}(E, s)$.

We confirm that g(s) = 2I(s) satisfies all conditions in Lemma 1. From the general formula (21) between mutual information and MMSE, we have g'(s) = MMSE(s), which implies g'(0) = 1 and $\lim_{s\to\infty} g'(s) = 0$. Since g' is continuous and strictly decreasing for $s \ge 0$ from Proposition 2, g(s) is continuously differentiable and strictly concave for all $s \ge 0$. Furthermore, the infimum of sE - g(s) over $s \ge 0$ is attained at s = 0, the unique solution $s = s^* > 0$ to $E = g'(s^*)$, and $s = \infty$ for $E = E_{\text{max}}$, $E \in (E_{\text{min}}, E_{\text{max}})$, and $E = E_{\text{min}}$, respectively, with $E_{\text{min}} = 0$ and $E_{\text{max}} = 1$. Thus, all conditions for g in Lemma 1 are satisfied.

We next investigate properties of f(E), which has the derivative $f'(E) = R_{A^TA}(-E/\sigma^2)/\sigma^2$. Since the R-transform $R_{A^TA}(z)$ has been assumed to be proper, continuous, non-decreasing, and non-negative for all $z \leq 0$, f(E) is a continuously differentiable, concave, and non-decreasing function of $E \in [E_{\min}, E_{\max}]$. Furthermore, we find that the infimum of sE - f(E) over $E \in [E_{\min}, E_{\max}]$ is attained at $E = E_{\min}$, an interior solution $E = E^* \in (E_{\min}, E_{\max})$ to $s = R_{A^TA}(-E^*/\sigma^2)/\sigma^2$, and $E = E_{\max}$ for $s = s_{\max}$, $s \in (s_{\min}, s_{\max})$, and $s = s_{\min}$, respectively, with $s_{\min} = R_{A^TA}(-E_{\max}/\sigma^2)/\sigma^2 \geq 0$ and $s_{\max} = R_{A^TA}(-E_{\min}/\sigma^2)/\sigma^2 = R_{A^TA}(0)/\sigma^2 > s_{\min}$, because of Lemma 3 and the assumption $\mu_2 > \mu_1^2$. Thus, f(E) satisfies all conditions in Lemma 1, so that we can use Lemma 1 to arrive at the identity (23).

Lemma 6 implies that the optimizer (E, s) for the inf-sup problem (23) satisfies E = MMSE(s). This allows us to regard the variable E as the MMSE.

D. Information-Theoretic Compression Limit

We consider the noiseless limit $\sigma^2 \downarrow 0$. The Rényi information dimension is useful to characterize the performance of the Bayes-optimal reconstruction in the system (1) without spatial coupling, as well as the performance of Bayes-optimal OAMP for spatially coupled systems.

Definition 3 ([3]): For a random variable $X \in \mathbb{R}$, let $X_n = \lfloor nX \rfloor / n$ denote a discrete random variable rounded down with the floor operation for $n \in \mathbb{N}$. The random variable X is said to have the Rényi information dimension d_{I} if the normalized entropy $-\mathbb{E}[\log \Pr(X_n)] / \log n$ converges to d_{I} as $n \to \infty$.

Theorem 2: Suppose that all moments $\{\mu_k\}$ are bounded and assume the following conditions:

- The signal x_1 has $\mathbb{E}[x_1^2] = 1$ and the Rényi information dimension d_{I} .
- The R-transform $R_{A^TA}(z)$ is proper, continuous, nondecreasing, and positive for all $z \leq 0$.
- $\lim_{z\to\infty} zR_{A^TA}(-z) = \delta$ holds.

If and only if the compression rate δ is larger than $d_{\rm I}$, the optimizer $(E_{\rm opt}, s_{\rm opt})$ for the inf-sup problem (6) is noise-limited: $E_{\rm opt} \downarrow 0$ and $s_{\rm opt} \to \infty$ hold as $\sigma^2 \downarrow 0$. In particular, the optimizer $(E_{\rm opt}, s_{\rm opt})$ is unique as $\sigma^2 \downarrow 0$ if δ is larger than $d_{\rm I}$.

Proof: See Appendix C.

Theorem 2 implies that error-free reconstruction $E_{\text{opt}} \downarrow 0$ is possible as long as the compression rate δ is larger than the information-theoretic compression limit d_{I} [4]. The last two assumptions in Theorem 2 provide sufficient conditions which the sensing matrix should satisfy.

Theorem 2 reproduces a known result on the optimality of zero-mean i.i.d. Gaussian sensing matrices [11], [16].

Corollary 1: Assume the following conditions:

- The signal x₁ has E[x₁²] = 1 and the Rényi information dimension d_I.
- The sensing matrix A has independent zero-mean Gaussian elements with variance 1/M.

If and only if $\delta > d_{\rm I}$ holds, the optimizer $(E_{\rm opt}, s_{\rm opt})$ satisfies $E_{\rm opt} \downarrow 0$ and $s_{\rm opt} \rightarrow \infty$ as $\sigma^2 \downarrow 0$. In particular, the optimizer $(E_{\rm opt}, s_{\rm opt})$ is unique as $\sigma^2 \downarrow 0$ if δ is larger than $d_{\rm I}$.

Proof: We know that the R-transform for zero-mean i.i.d. Gaussian sensing matrices is given by $R_{A^TA}(z) = \delta/(\delta - z)$ for all $z \leq 0$ [32, Section 2.4.2], which satisfies the last two assumptions in Theorem 2. Thus, Theorem 2 implies Corollary 1.

The replica symmetric potential (3) was used to characterize the asymptotic performance of AMP for spatially coupled zero-mean i.i.d. Gaussian sensing matrices in [11]. More precisely, state evolution recursions proved in [17] are equivalent to density evolution recursions considered in [11]. Thus, properties of the state evolution recursions are also characterized with the replica symmetric potential. To prove the informationtheoretic optimality of AMP, we can use Corollary 1 instead of a proof in [16].

It is an interesting issue to specify the class of sensing matrices that satisfy the last two assumptions for the Rtransform in Theorem 2. We have the following corollary:

Corollary 2: Suppose that all moments $\{\mu_k\}$ are bounded and that $\mu_1 > 0$ and $\mu_2 > \mu_1^2$ hold. Let r denote the rank of A and assume that the ratio r/N tends to δ in the large system limit. Furthermore, postulate the following conditions:

- The signal x_1 has $\mathbb{E}[x_1^2] = 1$ and the Rényi information dimension d_{I} .
- $\delta < 1$ or the condition (18) for $\delta = 1$ holds.

If and only if $\delta > d_{\rm I}$ holds, the optimizer $(E_{\rm opt}, s_{\rm opt})$ satisfies $E_{\rm opt} \downarrow 0$ and $s_{\rm opt} \rightarrow \infty$ as $\sigma^2 \downarrow 0$. In particular, the optimizer $(E_{\rm opt}, s_{\rm opt})$ is unique as $\sigma^2 \downarrow 0$ if δ is larger than $d_{\rm I}$.

Proof: Lemmas 3 and 4 imply the continuity, nondecreasing, and positivity properties of the R-transform $R_{A^TA}(z)$. Furthermore, we use Lemma 5 to find $\lim_{z\to\infty} zR_{A^TA}(-z) = \delta$ and $\lim_{z\to\infty} z\eta_{A^TA}(z) = \infty$. The latter property and the assumption $\mu_2 > \mu_1^2$ indicate that the R-transform (14) is proper for all $z \leq 0$. Thus, Theorem 2 implies Corollary 2.

Corollary 2 implies that the information-theoretic compression limit is achievable for the non-trivial case $\delta < 1$ when the sensing matrix A is picked up from (M, N)-ensemble with full rank.

III. SPATIAL COUPLING

We extend the conventional measurement model in (1) to a spatially coupled model with the number of sections L and coupling width W < L, defined via a deterministic base matrix $\mathbf{B}_{\Gamma} \in \mathbb{R}^{(L+W) \times L}$. The (ℓ, l) element $\gamma[\ell][l]$ of \mathbf{B}_{Γ} is non-zero for all $\ell \in \mathcal{L}_W = \{0, \ldots, L + W - 1\}$ and $l \in \mathcal{L}_0 = \{0, \ldots, L - 1\}$ satisfying $\ell - l \in \{0, \ldots, W\}$. Otherwise, $\gamma[\ell][l] = 0$ holds. Furthermore, we impose the power normalization

$$\frac{1}{L} \sum_{l=0}^{L-1} \sum_{w=0}^{W} \gamma^2 [l+w][l] = 1.$$
(26)

In particular, W = 0 implies no spatial coupling.

This paper does not postulate special structures of the base matrix B_{Γ} in state evolution analysis. In proving the information-theoretic optimality, as well as numerical evaluation, we focus on the following base matrix with uniform coupling weights:

$$\boldsymbol{B}_{\Gamma} = \frac{1}{\sqrt{W+1}} \begin{bmatrix} 1 & \boldsymbol{O} \\ \vdots & \ddots & \\ 1 & & 1 \\ & \ddots & \vdots \\ \boldsymbol{O} & & 1 \end{bmatrix} \in \mathbb{R}^{(L+W) \times L}.$$
(27)

For a given base matrix B_{Γ} , the $M[\ell]$ -dimensional measurement vector $\boldsymbol{y}[\ell] \in \mathbb{R}^{M[\ell]}$ for section $\ell \in \mathcal{L}_W$ in a spatially coupled system is defined as

$$\boldsymbol{y}[\ell] = \sum_{w=0}^{W} \gamma[\ell][\ell-w]\boldsymbol{A}[\ell][\ell-w]\boldsymbol{x}[\ell-w] + \boldsymbol{n}[\ell]. \quad (28)$$

In (28), $\boldsymbol{n}[\ell] \in \mathbb{R}^{M[\ell]}$ denotes an additive noise vector in section ℓ and satisfies $\lim_{M[\ell]\to\infty} M^{-1}[\ell]\mathbb{E}[\|\boldsymbol{n}[\ell]\|^2] = \sigma^2$ for variance $\sigma^2 > 0$. The N[l]-dimensional vector $\boldsymbol{x}[l] \in \mathbb{R}^{N[l]}$ represents unknown sparse signals in section $l \in \mathcal{L}_0$ and satisfies the power normalization $\lim_{N[l]\to\infty} N^{-1}[l]\mathbb{E}[\|\boldsymbol{x}[l]\|^2] =$ 1. The matrix $\boldsymbol{A}[\ell][l] \in \mathbb{R}^{M[\ell]\times N[l]}$ is a sensing matrix in section (ℓ, l) . The random variables in the triple $\{\{\boldsymbol{A}[\ell][l]\}, \{\boldsymbol{x}[l]\}, \{\boldsymbol{n}[\ell]\}\}$ are independent. For notational convenience, we introduce $\gamma[\ell][l] = 0$ for all $(\ell, l) \notin \mathcal{L}_W \times \mathcal{L}_0$, $\boldsymbol{x}[l] = \mathbf{0}$, and N[l] = 0 for $l \notin \mathcal{L}_0$. Since the system (28) is independent of $\boldsymbol{A}[\ell][l]$ in all positions (ℓ, l) satisfying $\gamma[\ell][l] = 0$, we assume $\boldsymbol{A}[\ell][l] = \boldsymbol{O}$ in the positions.

We rewrite the spatially coupled system (28) in a vector form. Focus on the summation in the spatially coupled system (28) for the bulk region $\ell \in \{W, \dots, L-1\}$. The

Fig. 1. Band structure of the overall sensing matrix.

summation may be regarded as the multiplication of the block matrix $(\gamma[\ell][\ell - W]A[\ell][\ell - W], \ldots, \gamma[\ell][\ell]A[\ell][\ell])$ by the block vector $(\boldsymbol{x}^{\mathrm{T}}[\ell-W], \ldots, \boldsymbol{x}^{\mathrm{T}}[\ell])^{\mathrm{T}}$. In the proposed OAMP, however, the summation should be regarded as the multiplication of $\boldsymbol{A}[\ell] = (W+1)^{-1/2} (\boldsymbol{A}[\ell][\ell-W], \ldots, \boldsymbol{A}[\ell][\ell])$ by $\vec{\boldsymbol{x}}[\ell] = (W+1)^{1/2} (\gamma[\ell][\ell-W]\boldsymbol{x}^{\mathrm{T}}[\ell-W], \ldots, \gamma[\ell][\ell]\boldsymbol{x}^{\mathrm{T}}[\ell])^{\mathrm{T}}$. In other words, the coupling coefficients $\{\gamma[\ell][l]\}$ are moved from the sensing-matrix side to the signal-vector side. The prefactor $(W+1)^{-1/2}$ in $\boldsymbol{A}[\ell]$ normalizes the eigenvalues of $\boldsymbol{A}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell]$ in the limit $W \to \infty$. The prefactor $(W+1)^{1/2}$ in $\vec{\boldsymbol{x}}[\ell]$ compensates for the normalization in $\boldsymbol{A}[\ell]$. Owing to this prefactor, each element in $\vec{\boldsymbol{x}}[\ell]$ is kept $\mathcal{O}(1)$ for the uniform coupling weights (27).

To present appropriate definitions in the boundary region, we first introduce several notations. As shown in Fig. 1, let $N_{\rm c}[\ell] = \sum_{l=\ell-W}^{\ell} N[l]$ denote the number of non-zero columns in the ℓ th row section of the sensing matrices. We write the numbers of zero columns on the left and right sides of the non-zero columns in row section ℓ as $N_{\rm l}[\ell] = \sum_{l=0}^{\ell-W-1} N[l]$ and $N_{\rm r}[\ell] = \sum_{l=\ell+1}^{L-1} N[l]$, respectively. The notation $N_{\rm all} = \sum_{l=0}^{L-1} N[l]$ represents the number of columns in section ℓ .

Define the normalized non-zero blocks $A[\ell] \in \mathbb{R}^{M[\ell] \times N_c[\ell]}$ in row section $\ell \in \mathcal{L}_W$ as

$$\boldsymbol{A}[\ell] = \left\{ |\mathcal{W}[\ell]|^{-1/2} \boldsymbol{A}[\ell][\ell - w] : w \in \mathcal{W}[\ell] \right\}, \qquad (29)$$

where the set of indices $\mathcal{W}[\ell]$ is given by

$$\mathcal{W}[\ell] = \{ w_{\min}[\ell], \dots, w_{\max}[\ell] \}, \tag{30}$$

with $w_{\min}[\ell] = \max\{\ell - (L-1), 0\}$ and $w_{\max}[\ell] = \min\{W, \ell\}$. The set $\mathcal{W}[\ell]$ reduces to $\mathcal{W}[\ell] = \{0, \ldots, \ell\}$, $\mathcal{W}[\ell] = \{0, \ldots, W\}$, and $\mathcal{W}[\ell] = \{\ell - (L-1), \ldots, W\}$ for $\ell < W$, $W \le \ell < L$, and $L \le \ell$, respectively. Using these notations, we find that the spatially coupled system (28) reduces to

$$\boldsymbol{y}[\ell] = \boldsymbol{A}[\ell]\boldsymbol{\vec{x}}[\ell] + \boldsymbol{n}[\ell], \qquad (31)$$

with

$$\vec{\boldsymbol{x}}[\ell] = \sqrt{|\mathcal{W}[\ell]|} \begin{bmatrix} \gamma[\ell][\ell - w_{\max}[\ell]]\boldsymbol{x}[\ell - w_{\max}[\ell]] \\ \vdots \\ \gamma[\ell][\ell - w_{\min}[\ell]]\boldsymbol{x}[\ell - w_{\min}[\ell]] \end{bmatrix}} .$$
(32)

Algorithm 1 Orthogonal AMP with T iterations 1: For all $\ell \in \mathcal{L}_W$, let $\vec{x}_{B\to A,0}[\ell] = \mathbf{0}$ and $v_{B\to A,0}[\ell] = |\mathcal{W}[\ell]|N_c^{-1}[\ell]\sum_{w\in \mathcal{W}[\ell]}N[\ell-w]\gamma^2[\ell][\ell-w].$ 2: for $t = 0, \ldots, T - 1$ do for $\ell = 0, ..., L + W - 1$ do 3: $ec{m{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] = ec{m{x}}_{\mathrm{B} ightarrow \mathrm{A},t}[\ell] + m{F}_t^{\mathrm{T}}[\ell](m{y}[\ell] - m{A}[\ell]ec{m{x}}_{\mathrm{B} ightarrow \mathrm{A},t}[\ell]).$ 4: $v_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left(\boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{F}_t[\ell]\right)$ 5: $+ \frac{v_{\mathrm{B} \to \mathrm{A},t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathrm{Tr} \left\{ (\boldsymbol{I} - \boldsymbol{F}_{t}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell]) (\boldsymbol{I} - \boldsymbol{F}_{t}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])^{\mathrm{T}} \right\}.$ $$\begin{split} &\eta_{\mathrm{A},t}[\ell] = N_{\mathrm{c}}^{-1}[\ell] \mathrm{Tr}(\boldsymbol{I} - \boldsymbol{F}_{t}^{T}[\ell]\boldsymbol{A}[\ell]), \\ & \boldsymbol{\vec{x}}_{\mathrm{A}\to\mathrm{B},t}[\ell] = \frac{\boldsymbol{\vec{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] - \eta_{\mathrm{A},t}[\ell] \boldsymbol{\vec{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{\sqrt{|\mathcal{W}[\ell]|(1 - \eta_{\mathrm{A},t}[\ell])}}, \\ & v_{\mathrm{A}\to\mathrm{B},t}[\ell] = \frac{v_{\mathrm{A},t}^{\mathrm{post}}[\ell] - \eta_{\mathrm{A},t}^{2}[\ell] v_{\mathrm{B}\to\mathrm{A},t}[\ell]}{|\mathcal{W}[\ell]|(1 - \eta_{\mathrm{A},t}[\ell])^{2}}. \end{split}$$ 6: 7: 8: end for 9:

To represent $\vec{x}[\ell] \in \mathbb{R}^{N_{c}[\ell]}$ with the overall signal vector $\boldsymbol{x} = (\boldsymbol{x}^{T}[0], \dots, \boldsymbol{x}^{T}[L-1])^{T} \in \mathbb{R}^{N_{all}}$, we define

$$\boldsymbol{\Gamma}[\ell] = \left(\boldsymbol{O}_{N_{c}[\ell] \times N_{l}[\ell]}, \tilde{\boldsymbol{\Gamma}}[\ell], \boldsymbol{O}_{N_{c}[\ell] \times N_{r}[\ell]}\right) \in \mathbb{R}^{N_{c}[\ell] \times N_{all}},$$
(33)

with $\tilde{\Gamma}[\ell] = \text{diag}\{\gamma[\ell][\ell - w]\boldsymbol{I}_{N[\ell-w]} : w \in \mathcal{W}[\ell]\}$. The product $\Gamma[\ell]\boldsymbol{x} \in \mathbb{R}^{N_c[\ell]}$ is a vector with $|\mathcal{W}[\ell]|$ sections. In particular, for $w \in \mathcal{W}[\ell]$ we have the *w*th section $\{\Gamma[\ell]\boldsymbol{x}\}_w = \gamma[\ell][\ell-w]\boldsymbol{x}[\ell-w] \in \mathbb{R}^{N[\ell-w]}$. Using these notations, we can rewrite the signal vector $\boldsymbol{x}[\ell]$ as

$$\vec{\boldsymbol{x}}[\ell] = \sqrt{|\mathcal{W}[\ell]|\boldsymbol{\Gamma}[\ell]\boldsymbol{x}}.$$
(34)

IV. ORTHOGONAL AMP

A. Overview

For the spatially coupled system (31), this paper proposes OAMP in Algorithm 1, which consists of the two modules called modules A and B. Module A uses a linear filter to compute posterior messages while module B utilizes a separable nonlinear denoiser to refine the messages in module A. To realize asymptotic Gaussianity for the estimation errors, each module computes extrinsic messages via the so-called Onsager correction of the posterior messages.

In module A for the spatial coupling case, the signal vectors $\{\vec{x}[\ell]\}\)$ in the extended space are estimated in parallel for all ℓ . Message computation for each ℓ is equivalent to that for conventional OAMP [41], [42], with the exception of normalization due to spatial coupling. In module A, the signal vectors $\{\vec{x}[\ell]\}\)$ for all row section $\ell \in \mathcal{L}_W$ are regarded as independent Gaussian random vectors with i.i.d. elements. Since each element in \boldsymbol{x} is broadcast over adjacent signal vectors $\{\vec{x}[\ell]\}\)$ via (34), the dependencies between $\{\vec{x}[\ell]\}\)$ through the original signal vector \boldsymbol{x} are not taken into account.

Module B for the spatial coupling case takes the dependencies into account, as well as the signal prior distributions. In other words, module B operates in the original space $\mathbb{R}^{N_{\text{all}}}$ while module A operates in $|\mathcal{L}_W|$ extended signal spaces $\{\mathbb{R}^{N_{\text{c}}[\ell]}\}_{\ell \in \mathcal{L}_W}$. The vector $\vec{x}[\ell]$ in (34) corresponds to the signal vector in the ℓ th extended space. Thus, the original signal vector x can be reconstructed from the extended spaces via the pseudo-inverse $|\mathcal{W}[\ell]|^{-1/2}\Gamma^{\dagger}\vec{x}$, with $\vec{x} = (\vec{x}^{\text{T}}[0], \ldots, \vec{x}^{\text{T}}[L + W - 1])^{\text{T}}$. This reconstruction of the original signal vector is performed in module B.

The main novelty in module B is in the Onsager correction to realize asymptotic Gaussianity for the estimation errors of messages fed back to module A. The asymptotic Gaussianity is realized in the extended signal space where module A operates, rather than in the original signal space where module B operates. To design this Onsager correction appropriately, this paper establishes a unified framework of state evolution for the spatial coupling case.

B. Module A (Linear Estimation)

Module A consists of two steps: A first step is computation of posterior messages based on linear filters. The second step is the Onsager correction of the posterior messages to realize asymptotic Gaussianity in module B.

Let $\vec{x}_{B\to A,t}[\ell] \in \mathbb{R}^{N_c[\ell]}$ and $v_{B\to A,t}[\ell] > 0$ denote the mean and variance messages of $\vec{x}[\ell]$ in (34) passed from module B to module A in iteration t, respectively. The variance message $v_{B\to A,t}[\ell]$ corresponds to a consistent estimator of the the mean-square error (MSE) $N_c^{-1}[\ell]\mathbb{E}[\|\vec{x}[\ell] - \vec{x}_{B\to A,t}[\ell]\|^2]$ in the large system limit.

Similarly, we write the mean and variance messages of $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] = \Gamma[\ell]x$ passed in the opposite direction as $\vec{x}_{A\to B,t}[\ell] \in \mathbb{R}^{N_c[\ell]}$ and $v_{A\to B,t}[\ell] > 0$. Owing to the prefactor in $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]$, the scaled MSE $N_c^{-1}[\ell]\mathbb{E}[||\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] - \vec{x}_{A\to B,t}[\ell]||^2]$ is kept $\mathcal{O}(1)$ in the limit $W \to \infty$.

In a first step of iteration t, module A computes the posterior mean and variance of $\vec{x}[\ell]$ based on a linear filter $F_t[\ell] \in \mathbb{R}^{M[\ell] \times N_c[\ell]}$ for each $\ell \in \mathcal{L}_W$. The posterior mean $\vec{x}_{A,t}^{\text{post}}[\ell] \in \mathbb{R}^{N_c[\ell]}$ in the ℓ th extended space is defined as

$$\vec{\boldsymbol{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell] + \boldsymbol{F}_{t}^{\mathrm{T}}[\ell](\boldsymbol{y}[\ell] - \boldsymbol{A}[\ell]\vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell]) \quad (35)$$

for section $\ell \in \mathcal{L}_W$. The corresponding posterior variance $v_{\mathrm{A},t}^{\mathrm{post}}[\ell]$ is given by

$$v_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left(\boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{F}_t[\ell]\right) + \frac{v_{\mathrm{B}\to\mathrm{A},t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left\{(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])^{\mathrm{T}}\right\}.$$
(36)

For t = 0, we use the initial conditions $\vec{x}_{B\to A,0}[\ell] = \mathbf{0}$ and $v_{B\to A,0}[\ell] = |\mathcal{W}[\ell]|N_c^{-1}[\ell]\sum_{w\in\mathcal{W}[\ell]} N[\ell-w]\gamma^2[\ell][\ell-w]$, of which the latter is equal to $|\mathcal{W}[\ell]|N_c^{-1}[\ell]\mathrm{Tr}(\mathbf{\Gamma}[\ell]\mathbf{\Gamma}^{\mathrm{T}}[\ell])$.

Consider the LMMSE filter $F_t[\ell] = v_{B \rightarrow A}$

$$\mathbf{F}_t[\ell] = v_{\mathrm{B}\to\mathrm{A},t}[\ell] \mathbf{\Xi}_t^{-1}[\ell] \mathbf{A}[\ell], \qquad (37)$$

with

$$\boldsymbol{\Xi}_{t}[\ell] = \sigma^{2} \boldsymbol{I}_{M[\ell]} + v_{\mathrm{B} \to \mathrm{A}, t}[\ell] \boldsymbol{A}[\ell] \boldsymbol{A}^{\mathrm{T}}[\ell].$$
(38)

Substituting (37) into the definition of $v_{A,t}^{\text{post}}[\ell]$ in (36), we find that $v_{A,t}^{\text{post}}[\ell]$ reduces to

$$v_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \eta_{\mathrm{A},t}[\ell] v_{\mathrm{B}\to\mathrm{A},t}[\ell], \qquad (39)$$

with

$$\eta_{\mathrm{A},t}[\ell] = \frac{1}{N_{\mathrm{c}}[\ell]} \mathrm{Tr} \left(\boldsymbol{I}_{N_{\mathrm{c}}[\ell]} - \boldsymbol{F}_{t}^{\mathrm{T}}[\ell] \boldsymbol{A}[\ell] \right).$$
(40)

The second step is the Onsager correction to realize asymptotic Gaussianity in module B. Module A computes the extrinsic mean $\vec{x}_{A\to B,t}[\ell]$ and variance $v_{A\to B,t}[\ell] > 0$ of $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]$ in the extended space as

$$\vec{x}_{A\to B,t}[\ell] = |\mathcal{W}[\ell]|^{-1/2} \frac{\vec{x}_{A,t}^{\text{post}}[\ell] - \eta_{A,t}[\ell] \vec{x}_{B\to A,t}[\ell]}{1 - \eta_{A,t}[\ell]}, \quad (41)$$

$$v_{A\to B,t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{v_{A,t}^{\text{post}}[\ell] - \eta_{A,t}^{2}[\ell] v_{B\to A,t}[\ell]}{(1 - \eta_{A,t}[\ell])^{2}}, \qquad (42)$$

with $\eta_{A,t}[\ell]$ defined in (40). In particular, for the LMMSE filter (37) we substitute the posterior variance (39) into the definition of $v_{A\to B,t}[\ell]$ in (42) to obtain

$$v_{A\to B,t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{\eta_{A,t}[\ell] v_{B\to A,t}[\ell]}{1 - \eta_{A,t}[\ell]}.$$
 (43)

The normalization in $v_{A\to B,t}[\ell]$ can be understood as follows: As $W \to \infty$, the vector $\boldsymbol{y}[\ell]$ in (31) is an extremely compressed measurement of $\boldsymbol{x}[\ell]$. Thus, signal reconstruction based on the LMMSE filter (37) results in poor performance. As proved in state evolution analysis, we have $1 - \eta_{A,t}[\ell] = \mathcal{O}(|\mathcal{W}[\ell]|^{-1})$ for $\ell \in \{W, \ldots, L-1\}$ as $W \to \infty$, which implies $\eta_{A,t}[\ell] \to 1$. As a result, the extrinsic variance $\bar{v}_{A\to B,t}[\ell]$ in (43) is kept $\mathcal{O}(1)$ as $W \to \infty$.

The discussion mentioned above is for individual variance messages $\{v_{B\to A,t}[\ell]\}$ and does not necessarily imply that module A cannot refine the messages passed from module B

at all as $W \to \infty$. Since $|\mathcal{W}[\ell]|$ extensive messages contribute to estimation of each signal element in x, module A can still provide an impact of $\mathcal{O}(1)$ on estimation performance of module B as $W \to \infty$.

C. Module B (Nonlinear Estimation)

Module B consists of four steps: A first step is the extraction of messages in the original space \mathbb{R}^N from the messages in the extended spaces $\{\mathbb{R}^{N_c[\ell]}\}_{\ell \in \mathcal{L}_W}$. A second step is computation of a sufficient statistic for estimation of the signal vector $x \in \mathbb{R}^N$ given the extracted messages. A third step is evaluation of posterior messages based on the sufficient statistic. These two steps are equivalent to direct computation of the posterior messages given the extracted messages in the original space. In the last step, the posterior messages in the original space are transformed into those in the extended spaces. Then, the transformed messages are Onsager-corrected to realize asymptotic Gaussianity in module A.

In the first step of iteration t, module B extracts information required for estimation of $\boldsymbol{x}[l]$ from $\{\vec{\boldsymbol{x}}_{A\to B,t}[\ell]\}$ in the extended space. Using the definitions of $\vec{\boldsymbol{x}}[\ell]$ and $\Gamma[\ell]$ in (34) and (33), respectively, we find that $\boldsymbol{x}[l]$ is contained only in $\{\vec{\boldsymbol{x}}[l+w][w]: w \in \{0,\ldots,W\}\}$, with $\vec{\boldsymbol{x}}[\ell][w] \in \mathbb{R}^{N[\ell-w]}$ denoting the *w*th section in $\vec{\boldsymbol{x}}[\ell] \in \mathbb{R}^{N_c[\ell]}$ for $w \in \mathcal{W}[\ell]$. More precisely, we have

$$|\mathcal{W}[l+w]|^{-1/2}\vec{x}[l+w][w] = \gamma[l+w][l]\boldsymbol{x}[l] \qquad (44)$$

for $w \in \mathcal{W}[\ell]$. Since $\vec{x}_{A\to B,t}[\ell]$ is the extrinsic mean for $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]$, the extracted message $x_{A\to B,t}[l][w] \in \mathbb{R}^{N[l]}$ in the original space is defined as

$$\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}[l][w] = \boldsymbol{\vec{x}}_{\mathrm{A}\to\mathrm{B},t}[l+w][w]$$
(45)

for $w \in \{0, \ldots, W\}$, where $\vec{x}_{A \to B, t}[\ell][w] \in \mathbb{R}^{N[\ell-w]}$ denotes the *w*th section in $\vec{x}_{A \to B, t}[\ell] \in \mathbb{R}^{N_c[\ell]}$ for $w \in \mathcal{W}[\ell]$.

The second step is computation of a sufficient statistic $\boldsymbol{x}_{A \to B,t}^{suf}[l] \in \mathbb{R}^{N[l]}$ for estimation of $\boldsymbol{x}[l]$ and the corresponding variance $v_{A \to B,t}^{suf}[l] > 0$. As derived in Appendix D-A, the mean message $\boldsymbol{x}_{A \to B,t}^{suf}[l]$ in section l and corresponding variance $v_{A \to B,t}^{suf}[l]$ are computed as

$$\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l] = v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l] \sum_{w=0}^{W} \gamma[l+w][l] \frac{\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}[l][w]}{v_{\mathrm{A}\to\mathrm{B},t}[l+w]}, \quad (46)$$

$$v_{A\to B,t}^{suf}[l] = \left(\sum_{w=0}^{W} \frac{\gamma^2[l+w][l]}{v_{A\to B,t}[l+w]}\right)^{-1}.$$
 (47)

The third step is computation of posterior messages $\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}} = [(\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[0])^{\mathrm{T}}, \ldots, (\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[L-1])^{\mathrm{T}}]^{\mathrm{T}}$ based on separable denoisers $\{f_t[l]\}$, given by

$$\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l] = f_t[l](\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]). \tag{48}$$

The corresponding variance $v_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ needs to be a consistent estimator of $N^{-1}[l]\mathbb{E}[\|\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l]\|^2]$ in the large system limit. See [49, Eq. (23)] for the details.

For the signal vector $\boldsymbol{x}[l]$ with i.i.d. elements, consider the Bayes-optimal denoiser $f_t[l](u) = f_{opt}(u; v_{A \to B, t}^{suf}[l])$, with

$$f_{\rm opt}(u; v_{\rm A \to B, t}^{\rm suf}[l]) = \mathbb{E}[x_1[l]|u = x_1[l] + z_t[l]],$$
(49)

otes a zero-mean Gauss

10

where $z_t[l] \sim \mathcal{N}(0, v_{A \to B,t}^{suf}[l])$ denotes a zero-mean Gaussian random variable with variance $v_{A \to B,t}^{suf}[l]$ and independent of $x_1[l]$. This definition is justified via state evolution. In this case, the following posterior variance should be used:

$$v_{\mathrm{B},t+1}^{\mathrm{post}}[l] = \frac{1}{N[l]} \mathbb{E} \Big[\big\| \boldsymbol{x}[l] - f_{\mathrm{opt}}(\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]; v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]) \big\|^2 \\ \Big\| \boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l], v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l] \Big].$$
(50)

The last step is the Onsager correction of the posterior mean $|\mathcal{W}[\ell]|^{1/2}\Gamma[\ell]\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}} \in \mathbb{R}^{N_{\mathrm{c}}[\ell]}$ in the extended space to realize asymptotic Gaussianity in module A. Let

$$\eta_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{N[\ell - w]}{N_{\mathrm{c}}[\ell]} \eta_{\mathrm{B},t}[\ell][w], \tag{51}$$

with

$$\eta_{\mathrm{B},t}[\ell][w] = \frac{|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[\ell-w]}{v_{\mathrm{A}\to\mathrm{B},t}[\ell]} \cdot \langle f_{t}'[\ell-w](\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[\ell-w])\rangle.$$
(52)

The normalized message $|\mathcal{W}[\ell]|^{-1/2}\eta_{\mathrm{B},t}[\ell][w]$ is the average of the partial derivative of the *n*th element in the *w*th section of $|\mathcal{W}[\ell]|^{1/2}\Gamma[\ell]\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}$ with respect to $\vec{x}_{\mathrm{A}\to\mathrm{B},n,t}[\ell][w]$ over all $n \in N[\ell - w]$. The extrinsic mean $\vec{x}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] \in \mathbb{R}^{N_{\mathrm{c}}[\ell]}$ and variance $v_{\mathrm{B}\to\mathrm{A},t+1}[\ell] > 0$ of $\vec{x}[\ell]$ in the extended spaces are computed as

$$(1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)\vec{x}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = |\mathcal{W}[\ell]|^{1/2}\Gamma[\ell]x_{\mathrm{B},t+1}^{\mathrm{post}} - |\mathcal{W}[\ell]|^{-1/2}\eta_{\mathrm{B},t}[\ell]\vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell], (53)$$

$$(1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)^{2}v_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{N[\ell - w]}{N_{\mathrm{c}}[\ell]}|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell - w]v_{\mathrm{B},t+1}^{\mathrm{post}}[\ell - w] - \frac{1}{|\mathcal{W}[\ell]|}\eta_{\mathrm{B},t}^{2}[\ell]v_{\mathrm{A}\to\mathrm{B},t}[\ell].$$
(54)

These non-trivial messages have been designed so as to realize asymptotic Gaussianity via state evolution. To confirm why the Onsager correction realizes asymptotic Gaussianity, one needs to understand a general error model proposed in Appendix G. The Onsager correction is a natural definition in terms of the general error model.

For the Bayes-optimal denoiser $f_{opt}(u; v_{A \to B,t}^{suf}[l])$ in (49), we use (51), (52), and the well-known identity $\langle \{f_{opt}(\boldsymbol{x}_{A \to B,t}^{suf}[l]; v_{A \to B,t}^{suf}[l])\}' \rangle = v_{B,t+1}^{post}[l]/v_{A \to B,t}^{suf}[l]$, with $v_{B,t+1}^{post}[l]$ given in (50), to find that the extrinsic variance (54) reduces to

 $v_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = \frac{\eta_{\mathrm{B},t}[\ell]v_{\mathrm{A}\to\mathrm{B},t}[\ell]}{1-\eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|},$

(55)

with

$$\eta_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} \frac{|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]v_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w]}{v_{\mathrm{A}\to\mathrm{B},t}[\ell]}.$$
(56)

When the uniform coupling weights (27) are considered, $\eta_{B,t}[\ell]$ is $\mathcal{O}(1)$ as $W \to \infty$. Thus, the extrinsic variance (55) tends to $v_{B\to A,t+1}[\ell] \to \eta_{B,t}[\ell]v_{A\to B,t}[\ell]$ as $W \to \infty$. This convergence and $\eta_{A,t}[\ell] \to 1$ are key properties to prove the information-theoretic optimality of Bayes-optimal OAMP.

V. MAIN RESULTS

State evolution analysis is presented for OAMP in the spatially coupled system (31). This paper extends a unified framework [54] of state evolution to that for the spatially coupled system. A general error model for the spatially coupled system is proposed and analyzed in the large system limit— $M[\ell]$ and N[l] tend to infinity for all ℓ and l while the ratio $\alpha[\ell][l] = N[l]/M[\ell]$ kept constant. By proving that the proposed general error model contains the error model for OAMP in the spatially coupled system, we derive state evolution recursions for OAMP.

In state evolution analysis, we postulate the following assumptions:

Assumption 2: For some $\epsilon > 0$, the signal vector $\boldsymbol{x} \in \mathbb{R}^{N_{\text{all}}}$ in (34) has i.i.d. elements with zero mean, unit variance, and a bounded $(2 + \epsilon)$ th moment.

Assumption 2 simplifies state evolution analysis. Nonseparable denoising [70]–[72] might be needed if dependent signal elements were considered.

Assumption 3: The rescaled row section $|\mathcal{W}[\ell]|^{1/2} \mathbf{A}[\ell]$ given via (29) is picked up from $(M[\ell], N_c[\ell])$ -ensemble in Definition 1 uniformly and randomly.

An important point in Assumption 3 is that the rightorthogonal invariance in Definition 1 is assumed not for each section $A[\ell][l]$ but each row section $A[\ell]$ in (29). This assumption allows us to analyze the dynamics of OAMP via rigorous state evolution.

Another important point is that the empirical eigenvalue distribution of $\mathbf{A}^{\mathrm{T}}[\ell]\mathbf{A}[\ell]$ converges almost surely to a compactly supported distribution in $(M[\ell], N_{\mathrm{c}}[\ell])$ -ensemble. As a result, all moments of the asymptotic eigenvalue distribution are bounded. Thus, we need not investigate the boundedness of the moments to use technical results in Section II.

Assumption 4: The noise vectors $\{\boldsymbol{n}[\ell] : \ell \in \mathcal{L}_W\}$ in (31) are independent vectors. Each vector $\boldsymbol{n}[\ell]$ satisfies orthogonal invariance, $\lim_{M[\ell]\to\infty} M^{-1}[\ell] \|\boldsymbol{n}[\ell]\|^2 \stackrel{\text{a.s.}}{=} \sigma^2 > 0$, and bounded $(2 + \epsilon)$ th moments for some $\epsilon > 0$.

The AWGN vector $\boldsymbol{n}[\ell] \sim \mathcal{N}(\boldsymbol{0}, \sigma^2 \boldsymbol{I}_{M[\ell]})$ with variance σ^2 satisfies Assumption 4. The orthogonal invariance in $\boldsymbol{n}[\ell]$ may be induced via the left-orthogonal invariance of the row section $\boldsymbol{A}[\ell]$.

Assumption 5: The linear filter $F_t[\ell]$ in module A has the same SVD structure $F_t[\ell] = U[\ell] \Sigma_{F_t[\ell]} V^{\mathrm{T}}[\ell]$ as the SVD $A[\ell] = U[\ell] \Sigma[\ell] V^{\mathrm{T}}[\ell]$, in which $\Sigma_{F_t[\ell]}^{\mathrm{T}} \Sigma_{F_t[\ell]} \Sigma_{F_t[\ell]}$ is in the space spanned by $\{(\Sigma^{\mathrm{T}}[\ell] \Sigma[\ell])^j\}_{j=0}^{\infty}$.

Assumption 5 contains practical linear filters, such as the LMMSE filter (81), the MF $F_t[\ell] = A[\ell]$, and the zero-forcing (ZF) filter $F_t[\ell] = A^{\dagger}[\ell]$.

Assumption 6: The scalar denoiser $f_t[l]$ in module B is Lipschitz-continuous and nonlinear.

The Lipschitz-continuity is the standard assumption in state evolution analysis. The nonlinearity is required to prevent module B from outputting $\vec{x}_{B\to A,t}[\ell] = 0$. This situation occurs in Bayes-optimal OAMP for Gaussian signaling since module B in the initial iteration can compute the Bayesoptimal estimator of the signal vector. Thus, the nonlinearity should be regarded as an assumption to exclude the trivial case in which no iterations are needed. We first define state evolution recursions for OAMP in the spatially coupled system (31), derived via state evolution. Let $\alpha_c[\ell] = N_c[\ell]/M[\ell] = \sum_{l=\ell-W}^{\ell} \alpha[\ell][l]$. State evolution recursions for module A with the initial condition $\bar{v}_{B\to A,0}[\ell] =$ $|\mathcal{W}[\ell]|\alpha_c^{-1}[\ell] \sum_{w \in \mathcal{W}[\ell]} \alpha[\ell][\ell-w]\gamma^2[\ell][\ell-w]$ are given by

$$\bar{v}_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \lim_{\{M[\ell],N[l]\}\to\infty} \frac{\sigma^2}{N_c[\ell]} \mathrm{Tr}\left(\boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{F}_t[\ell]\right) \\
+ \frac{\bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{N_c[\ell]} \mathrm{Tr}\left\{(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])^{\mathrm{T}}\right\},$$
(57)

$$\bar{v}_{A\to B,t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{\bar{v}_{A,t}^{\text{post}}[\ell] - \bar{\eta}_{A,t}^{2}[\ell]\bar{v}_{B\to A,t}[\ell]}{(1 - \bar{\eta}_{A,t}[\ell])^{2}}, \qquad (58)$$

where the limit in (57) represents the large system limit, with

$$\bar{\eta}_{\mathrm{A},t}[\ell] = \lim_{\{M[\ell], N[l]\} \to \infty} \frac{1}{N_{\mathrm{c}}[\ell]} \mathrm{Tr} \left(\boldsymbol{I}_{N_{\mathrm{c}}[\ell]} - \boldsymbol{F}_{t}^{\mathrm{T}}[\ell] \boldsymbol{A}[\ell] \right).$$
(59)

The variables $\bar{v}_{A,t}^{\text{post}}[\ell]$ and $\bar{\eta}_{A,t}[\ell]$ converge almost surely to deterministic quantities from Assumptions 3 and 5. They can be evaluated in closed form if the asymptotic eigenvalue distribution of $\boldsymbol{A}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell]$ has a closed-form expression.

State evolution recursions for module B are given by

$$\bar{v}_{A\to B,t}^{suf}[l] = \left(\sum_{w=0}^{W} \frac{\gamma^2[l+w][l]}{\bar{v}_{A\to B,t}[l+w]}\right)^{-1},$$
(60)

$$\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[l] = \mathbb{E}\left[\{ x_1[l] - f_t[l](x_1[l] + z_t[l]) \}^2 \right], \qquad (61)$$

$$(1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)^{2}\bar{v}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]}|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w] - \frac{1}{|\mathcal{W}[\ell]|}\bar{\eta}_{\mathrm{B},t}^{2}[\ell]\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell],$$
(62)

with

$$\bar{\eta}_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]} \bar{\eta}_{\mathrm{B},t}[\ell][w], \tag{63}$$

$$\bar{\eta}_{\mathrm{B},t}[\ell][w] = \frac{|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[\ell-w]}{\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell]} \cdot \mathbb{E}[f_{t}'[\ell-w](x_{1}[\ell-w]+z_{t}[\ell-w])]. \quad (64)$$

In these expressions, $z_t[l]$ denotes a zero-mean Gaussian random variable with variance $\bar{v}_{A\to B,t}^{suf}[l]$, independent of $x_1[l]$.

In particular, for Bayes-optimal OAMP with the LMMSE filter (37) and the Bayes-optimal denoiser $f_t[l](u) = f_{opt}(u; \bar{v}_{A \to B,t}^{suf}[l])$ in (49), (57) and (58) reduce to

$$\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{\bar{\eta}_{\mathrm{A},t}[\ell]\bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{1-\bar{\eta}_{\mathrm{A},t}[\ell]},\tag{65}$$

where $\bar{\eta}_{A,t}[\ell]$ is defined in (59), with

$$\boldsymbol{F}_{t}[\ell] = \bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]\boldsymbol{\Xi}_{t}^{-1}[\ell]\boldsymbol{A}[\ell], \qquad (66)$$

$$\boldsymbol{\Xi}_{t}[\ell] = \sigma^{2} \boldsymbol{I}_{M[\ell]} + \bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell] \boldsymbol{A}[\ell] \boldsymbol{A}^{\mathrm{T}}[\ell].$$
(67)

Furthermore, (63) and (62) reduce to

$$\bar{\eta}_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]} \frac{|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w]}{\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell]},$$
(68)

$$\bar{v}_{B\to A,t+1}[\ell] = \frac{\bar{\eta}_{B,t}[\ell]\bar{v}_{A\to B,t}[\ell]}{1 - \bar{\eta}_{B,t}[\ell]/|\mathcal{W}[\ell]|},$$
(69)

with $\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ defined in (61).

The state evolution recursions are the asymptotic counterpart to the variance messages in OAMP. Rather, the variance messages have been designed such that they become consistent estimators of the variables in the state evolution recursions.

Theorem 3: Suppose that Assumptions 2-6 hold.

- The MSE $N^{-1}[l] \| \boldsymbol{x}[l] \boldsymbol{x}_{\mathrm{B},t}[l] \|^2$ for OAMP converges almost surely to $\bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l]$ in the large system limit, in which $\bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l]$ is given via the state evolution recursions (57)–(62).
- Consider the LMMSE filter (37) and the Bayes-optimal denoiser (49). Then, the state evolution recursions (65)–(69) for Bayes-optimal OAMP converge to a fixed point as t → ∞.

Proof: See Section VI.

Theorem 3 implies asymptotic Gaussianity for the estimation error $\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t}[l]$: The MSE $N^{-1}[l] \|\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t}[l]\|^2$ converges almost surely to $\bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l]$ in (61)—given via the Gaussian random variable $z_t[l]$. The asymptotic Gaussianity implies that the Bayes-optimal denoiser $f_{\mathrm{opt}}(u; v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l])$ given in (49) minimizes the asymptotic MSE $\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$. In this sense, OAMP with the Bayes-optimal denoiser, as well as the LMMSE filter, is called Bayes-optimal OAMP.

We next prove the information-theoretic optimality of Bayes-optimal OAMP in terms of the Rényi information dimension. To use existing results [11], [21] on spatial coupling, we assume $M[\ell] = M$, N[l] = N, and the uniform coupling weights (27). In this case, $\bar{v}_{A\to B,t}^{suf}[l]$ and $\bar{\eta}_{B,t}[\ell]$ given in (60) and (68) for Bayes-optimal OAMP reduce to

$$\bar{v}_{A\to B,t}^{suf}[l] = \left(\frac{1}{W+1} \sum_{w=0}^{W} \frac{1}{\bar{v}_{A\to B,t}[l+w]}\right)^{-1}, \quad (70)$$

$$\bar{\eta}_{\mathrm{B},t}[\ell] = \frac{1}{W+1} \sum_{w \in \mathcal{W}[\ell]} \frac{\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w]}{\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell]},\tag{71}$$

respectively.

The overall compression rate $N_{\text{all}}^{-1} \sum_{\ell \in \mathcal{L}_W} M[\ell]$ tends to $(1 + \Delta)\delta$ in the continuum limit $L, W \to \infty$, with $\Delta = W/L$ kept constant, after taking the large system limit $M, N \to \infty$ with $\delta = M/N$ kept constant. Thus, the overall compression rate converges to δ as $\Delta \downarrow 0$.

The continuum limit was originally considered in [11], [16] to obtain an exact continuum approximation of state evolution recursions for AMP. This paper takes the same limit to utilize an existing result in [11].

To prove the information-theoretic optimality of Bayesoptimal OAMP, we need the following results:

Proposition 3: Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W =$

 ∞ and $\lim_{W\to\infty} a_W/W = 0$. Then, $|\mathcal{W}[\ell]| = W + 1$ and $|\mathcal{W}[\ell]| \ge 1 + W/a_W$ hold for all $\ell \in \{W, \dots, L-1\}$ and $\ell \in \{\lceil W/a_W \rceil, \dots, W-1\} \cup \{L, \dots, L+W-1-\lceil W/a_W \rceil\}$ in the continuum limit, respectively.

Proof: For $\ell \in \{W, \ldots, L-1\}$, we use the definition of $\mathcal{W}[\ell]$ in (30) to have $|\mathcal{W}[\ell]| = W + 1$. For $\ell \in \{\lceil W/a_W \rceil, \ldots, W-1\}$, similarly, we obtain $|\mathcal{W}[\ell]| = \ell + 1 \ge W/a_W + 1$. For $\ell \in \{L, \ldots, L+W-1-\lceil W/a_W \rceil\}$, we have $|\mathcal{W}[\ell]| = L + W - \ell \ge 1 + W/a_W$.

Proposition 3 implies $|\mathcal{W}[\ell]| \geq W/a_W \to \infty$ for all $\ell \in \{\lceil W/a_W \rceil, \ldots, L + W - 1 - \lceil W/a_W \rceil\}$. It is used to control approximation errors of the state evolution recursions in the boundaries.

Theorem 4: Consider $M[\ell] = M$, $N[\ell] = N$, and the uniform coupling weights (27). Suppose that Assumptions 2 and 3 hold. Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W = \infty$ and $\lim_{W\to\infty} a_W/W = 0$. Suppose that there is some function R(z) such that the R-transform of $G[\ell] = |W[\ell]| A^{\mathrm{T}}[\ell] A[\ell]$ satisfies

$$\lim_{W=\Delta L\to\infty} a_W \left| R_{\boldsymbol{G}[\ell]} \left(\frac{z}{|\mathcal{W}[\ell]|} \right) - R(z) \right| < \infty$$
 (72)

for all $\ell \in \{ \lceil W/a_W \rceil, \dots, L + W - 1 - \lceil W/a_W \rceil \}$. Furthermore, assume the following conditions:

- The signal x_1 has the Rényi information dimension d_{I} .
- R(z) is proper, twice continuously differentiable, strictly increasing, and positive for all z ≤ 0.
- $\lim_{z\to\infty} zR(-z) = \delta$ holds.

v

Let $E_{\text{opt}} > 0$ denotes the global minimizer of the replicasymmetric potential $f_{\text{RS}}(E, s)$ in (3) with $R_{A^{T}A}(z) = R(z)$ and $s = R(-E/\sigma^{2})/\sigma^{2}$. If E_{opt} is unique, then, the state evolution recursions for Bayes-optimal OAMP satisfies

$$\lim_{\Delta \downarrow 0} \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_0|} \sum_{l \in \mathcal{L}_0} \bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l] \le E_{\mathrm{opt}}.$$
 (73)

In particular, E_{opt} is unique and tends to zero as $\sigma^2 \downarrow 0$ if the ratio δ is larger than d_{I} .

Proof: See Section VII.

Theorem 4 implies that Bayes-optimal OAMP for the spatially coupled system (31) can achieve the Bayes-optimal MSE performance E_{opt} for the uncoupled system (1) with the Rtransform of the sensing matrix given by R(z). Furthermore, Bayes-optimal OAMP for the spatially coupled system can achieve the information-theoretic compression limit d_{I} .

Let us investigate the relationship between the original R-transform $R_{G[\ell]}$ and R for characterizing the performance of Bayes-optimal OAMP. The ensemble of zero-mean i.i.d. Gaussian matrices satisfies the conditions in Theorem 4.

Corollary 3: Consider $M[\ell] = M$, $N[\ell] = N$, and the uniform coupling weights (27). Suppose that Assumption 2 holds and that $|\mathcal{W}[\ell]|^{1/2}A[\ell]$ is picked up from the ensemble of zero-mean i.i.d. Gaussian matrices with variance 1/M. Furthermore, assume that the signal x_1 has the Rényi information dimension d_I . Then, the condition (72) in Theorem 4 holds for $R(z) = \delta/(\delta - z)$. Furthermore, the state evolution recursions for Bayes-optimal OAMP satisfies (73) if E_{opt} is unique. In particular, $E_{\rm opt}$ is unique and tends to zero as $\sigma^2 \downarrow 0$ if the ratio δ is larger than $d_{\rm I}$.

Proof: As shown in the proof of Corollary 1, we have

$$R_{\boldsymbol{G}[\ell]}(z) = \frac{|\mathcal{W}[\ell]|^{-1}\delta}{|\mathcal{W}[\ell]|^{-1}\delta - z},\tag{74}$$

which implies that the R-transform $R(z) = \delta/(\delta - z)$ satisfies the condition (72) in Theorem 4. It is straightforward to confirm that R(z) satisfies all conditions in Theorem 4. Thus, Corollary 3 holds.

Corollary 3 implies that R(z) is equal to the R-transform of zero-mean i.i.d. Gaussian sensing matrices without spatial coupling. Thus, Bayes-optimal OAMP for the spatially coupled system (31) achieves the Bayes-optimal performance for the underlying system (1) without spatial coupling when zeromean i.i.d. Gaussian sensing matrices are considered.

We next show that R(z) does not necessarily coincide with $R_{G[\ell]}(z)$ in general. To present examples in which they are different, the following result is useful when the η -transform of $G[\ell]$ can be evaluated explicitly:

Corollary 4: Consider $M[\ell] = M$, $N[\ell] = N$, and the uniform coupling weights (27). Suppose that Assumptions 2 and 3 hold. Let $r[\ell]$ denote the rank of $G[\ell]$ and suppose that the ratio $r[\ell]/N$ tends to δ in the large system limit. Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W = \infty$ and $\lim_{W\to\infty} a_W/W = 0$. Assume that there is some bounded function $\eta(z)$ such that the positive eigenvalues $\{\lambda_n[\ell] > 0\}$ of $G[\ell]$ satisfies

$$\lim_{W=\Delta L\to\infty} a_W \left| \lim_{M=\delta N\to\infty} \frac{1}{N} \sum_{n=1}^{r[\ell]} \frac{1}{1+\lambda_n[\ell]z/|\mathcal{W}[\ell]|} -\{\eta(z)-1+\delta\} \right| < \infty (75)$$

for all $\ell \in \{\lceil W/a_W \rceil, \dots, L + W - 1 - \lceil W/a_W \rceil\}$. Furthermore, let $R(z) = \{\eta(-z) - 1\}/z$ for z < 0, with R(0) = 1, and assume the following conditions:

- The signal x_1 has the Rényi information dimension d_I .
- R(z) is proper, twice continuously differentiable, strictly increasing, and positive for all z ≤ 0.

Then, R(z) satisfies the condition (72) in Theorem 4. Furthermore, the state evolution recursions for Bayes-optimal OAMP satisfies (73) if $E_{\rm opt}$ is unique. In particular, $E_{\rm opt}$ is unique and tends to zero as $\sigma^2 \downarrow 0$ if the ratio δ is larger than $d_{\rm I}$.

Proof: See Appendix E-A

From Corollary 4 we obtain two corollaries, of which the former is for sensing matrices with orthogonal rows while the latter considers sensing matrices with condition number larger than 1.

Corollary 5: Consider $M[\ell] = M$, $N[\ell] = N$, and the uniform coupling weights (27). Suppose that Assumption 2 holds and that $|\mathcal{W}[\ell]|^{1/2} \mathbf{A}[\ell] \in \mathbb{R}^{M \times |\mathcal{W}[\ell]|N}$ is right-orthogonally invariant and has the singular value $\sqrt{|\mathcal{W}[\ell]|/\delta}$ with multiplicity M, i.e. $\mathbf{A}[\ell]$ has orthogonal rows. Assume that the signal x_1 has the Rényi information dimension d_I . Then, the condition (72) in Theorem 4 holds for $R(z) = \delta/(\delta - z)$. Furthermore, the state evolution recursions for Bayes-optimal OAMP satisfies (73) if $E_{\rm opt}$ is unique. In particular, $E_{\rm opt}$ is unique and tends to zero as $\sigma^2 \downarrow 0$ if δ is larger than $d_{\rm I}$.

Proof: We prove the condition (75) in Corollary 4. Using $r[\ell]/N \to \delta$ and $\lambda_n = |W[\ell]|/\delta$ yields

$$\lim_{M=\delta N\to\infty} \frac{1}{N} \sum_{n=1}^{r[\ell]} \frac{1}{1+\lambda_n[\ell]z/|\mathcal{W}[\ell]|} = \frac{\delta}{1+\delta^{-1}z}.$$
 (76)

Since the condition (75) in Corollary 4 holds for $\eta(z) - 1 = -\delta z/(\delta + z)$, we arrive at

$$R(z) = \frac{\eta(-z) - 1}{z} = \frac{\delta}{\delta - z},\tag{77}$$

which satisfies the assumptions on R(z) in Corollary 4. Thus, Corollary 4 implies Corollary 5.

Corollary 5 implies that R(z) is not the R-transform of the underlying uncoupled sensing matrix with orthogonal rows but that of zero-mean i.i.d. Gaussian matrices. Thus, Bayesoptimal OAMP for spatially coupled sensing matrices with orthogonal rows achieves the same performance as that for spatially coupled zero-mean i.i.d. Gaussian sensing matrices as long as the continuum limit is considered.

Corollary 6: Consider $M[\ell] = M$, $N[\ell] = N$, and the uniform coupling weights (27). Suppose that Assumption 2 holds and that $|W[\ell]^{1/2}A[\ell] \in \mathbb{R}^{M \times |W[\ell]|N}$ is right-orthogonally invariant and has non-zero singular values $\sigma_0 \geq \cdots \geq$ $\sigma_{M-1} > 0$ satisfying condition number $\kappa = \sigma_0/\sigma_{M-1} >$ 1, $\sigma_m/\sigma_{m-1} = \kappa^{-1/(M-1)}$, and $\sigma_0^2 = |W[\ell]|N(1 - \kappa^{-2/(M-1)})/(1-\kappa^{-2M/(M-1)})$. Furthermore, assume that the signal x_1 has the Rényi information dimension d_I . Then, the condition (72) in Theorem 4 holds for

$$R(z) = \int_{1}^{\kappa^{2}} \frac{dy}{\kappa^{2} - 1 - Czy},$$
(78)

with $C = 2\delta^{-1} \ln \kappa$. The state evolution recursions for Bayesoptimal OAMP satisfies (73) if E_{opt} is unique. In particular, E_{opt} is unique and tends to zero as $\sigma^2 \downarrow 0$ if the ratio δ is larger than d_{I} .

Proof: See Appendix E-B.

Corollary 6 implies that R(z) in (78) is different from the R-transform of the underlying uncoupled sensing matrix with condition number $\kappa > 1$, which cannot be evaluated explicitly.

VI. PROOF OF THEOREM 3

A. Proof Strategy

This paper follow [48], [49] to prove the latter part in Theorem 3. LM-OAMP for the spatially coupled system (31) is proposed as a tool to prove the convergence of the state evolution recursions for Bayes-optimal OAMP. The convergence of the state evolution recursions for Bayes-optimal OAMP is guaranteed by proving their convergence for Bayes-optimal LM-OAMP and the reduction of Bayes-optimal LM-OAMP to Bayes-optimal OAMP.

The former part in Theorem 3 is proved by generalizing existing state evolution in [54] to the spatial coupling case. To derive state evolution recursions for both OAMP and LM-OAMP, this paper establishes a unified framework of state evolution for the spatial coupling case. A conventional general error model in [54] is extended to that for the spatial coupling case. The proposed general error model contains both OAMP and LM-OAMP as instances. The former part in Theorem 3 is obtained by proving the asymptotic Gaussianity for the general error model via state evolution.

B. Long-Memory Orthogonal AMP

1) Overview: We start with the definition of LM-OAMP. The main difference between OAMP and LM-OAMP is in the second and last steps of module B: In computing a sufficient statistic for estimation of x, LM-OAMP utilizes all messages in the preceding iterations while OAMP only uses the messages in the latest iteration. As a result, the Onsager correction in the last step depends on all preceding messages. The LM processing in the second step guarantees that the MSE for LM-OAMP is monotonically decreasing as the iteration proceeds.

LM-OAMP requires the covariance between estimation errors for different iterations in computing a sufficient statistic for estimation of x given all preceding messages. As a result, LM-OAMP computes mean and covariance messages in all steps while OAMP uses the mean and variance messages.

For notational convenience, we use the same notation for LM-OAMP as that for OAMP. This paper proves that Bayesoptimal LM-OAMP is equivalent to Bayes-optimal OAMP in the large system limit. Thus, we do not need to distinguish the two algorithms as long as the LMMSE filter and Bayesoptimal denoiser are considered.

Let $\vec{x}_{B\to A,t}[\ell] \in \mathbb{R}^{N_c[\ell]}$ and $V_{B\to A,t}[\ell] \in \mathbb{R}^{(t+1)\times(t+1)}$ denote the mean and covariance messages of $\vec{x}[\ell]$ passed from module B to module A in iteration t, respectively. We write the mean and covariance messages of $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]$ passed in the opposite direction as $\vec{x}_{A\to B,t}[\ell] \in \mathbb{R}^{N_c[\ell]}$ and $V_{A\to B,t}[\ell] \in \mathbb{R}^{(t+1)\times(t+1)}$.

The covariance matrix $V_{B\to A,t}[\ell]$ has the (τ', τ) element $v_{B\to A,\tau',\tau}[\ell]$, which corresponds to a consistent estimator of the error covariance $N_c^{-1}[\ell]\mathbb{E}[(\vec{x}[\ell] - \vec{x}_{B\to A,\tau'}[\ell])^T(\vec{x}[\ell] - \vec{x}_{B\to A,\tau}[\ell])]$. Similarly, the covariance matrix $V_{A\to B,t}[\ell]$ has the (τ', τ) element $v_{A\to B,\tau',\tau}[\ell]$.

2) Module A (Linear Estimation): Module A in LM-OAMP consists of two steps similar to those in OAMP. The main difference is in computing covariance messages, instead of the variance messages in OAMP.

In iteration t, module A first computes the posterior mean and covariance of $\vec{x}[\ell]$ based on a linear filter $F_t[\ell] \in \mathbb{R}^{M[\ell] \times N_c[\ell]}$ for each $\ell \in \mathcal{L}_W$. The posterior mean $\vec{x}_{\mathrm{A},t}^{\mathrm{post}}[\ell] \in \mathbb{R}^{N_c[\ell]}$ in the extended space is defined as

$$\vec{\boldsymbol{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] = \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell] + \boldsymbol{F}_{t}^{\mathrm{T}}[\ell](\boldsymbol{y}[\ell] - \boldsymbol{A}[\ell]\vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell]) \quad (79)$$

for $\ell \in \mathcal{L}_W$, which is exactly the same as (35) in OAMP. The corresponding posterior covariance $v_{A,t',t}^{\text{post}}[\ell]$ is given by

$$v_{\mathbf{A},t',t}^{\mathrm{post}}[\ell] = \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left(\boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{F}_{t'}[\ell]\right) + \frac{v_{\mathrm{B}\to\mathrm{A},t',t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left\{(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])(\boldsymbol{I} - \boldsymbol{F}_{t'}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])^{\mathrm{T}}\right\}$$

$$(80)$$

for section $\ell \in \mathcal{L}_W$, which is justified via state evolution. If $v_{\mathrm{B}\to\mathrm{A},t,t}[\ell]$ in LM-OAMP is equal to $v_{\mathrm{B}\to\mathrm{A},t}[\ell]$ in OAMP, we have the identity $v_{\mathrm{A},t,t}^{\mathrm{post}}[\ell] = v_{\mathrm{A},t}^{\mathrm{post}}[\ell]$ for (36) in OAMP. As is the case in OAMP, the LMMSE filter is defined as

$$\boldsymbol{F}_{t}[\ell] = \boldsymbol{v}_{\mathrm{B}\to\mathrm{A},t,t}[\ell]\boldsymbol{\Xi}_{t}^{-1}[\ell]\boldsymbol{A}[\ell], \qquad (81)$$

with

$$\boldsymbol{\Xi}_{t}[\ell] = \sigma^{2} \boldsymbol{I}_{M[\ell]} + \boldsymbol{v}_{\mathrm{B}\to\mathrm{A},t,t}[\ell] \boldsymbol{A}[\ell] \boldsymbol{A}^{\mathrm{T}}[\ell].$$
(82)

For t = 0, the initial conditions $\vec{x}_{B\to A,0}[\ell] = 0$ and $v_{B\to A,0,0}[\ell] = |\mathcal{W}[\ell]|N_c^{-1}[\ell]\sum_{w\in \mathcal{W}[\ell]} N[\ell-w]\gamma^2[\ell][\ell-w]$ are used.

The second step is the Onsager correction to realize asymptotic Gaussianity in module B. Module A computes the extrinsic mean $\vec{x}_{A\to B,t}[\ell]$ and covariance $v_{A\to B,t',t}[\ell]$ of $|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]$ in the extended space as

$$\vec{\boldsymbol{x}}_{\mathrm{A}\to\mathrm{B},t}[\ell] = |\mathcal{W}[\ell]^{-1/2} \frac{\vec{\boldsymbol{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] - \eta_{\mathrm{A},t}[\ell] \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{1 - \eta_{\mathrm{A},t}[\ell]}, \quad (83)$$

$$v_{A\to B,t',t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{v_{A,t',t}^{\text{post}}[\ell] - \eta_{A,t'}[\ell]\eta_{A,t}[\ell]v_{B\to A,t',t}[\ell]}{(1 - \eta_{A,t'}[\ell])(1 - \eta_{A,t}[\ell])},$$
(84)

with $\eta_{A,t}[\ell]$ defined in (40).

3) Module B (Nonlinear Estimation): Module B in LM-OAMP consists of four steps similar to those in OAMP. The first step is exactly the same as that in OAMP. A difference between OAMP and LM-OAMP is in the second step, i.e. computation of a sufficient statistic based on all preceding messages. In the last two steps, LM-OAMP computes posterior/extrinsic mean and *covariance* messages while OAMP computes posterior/extrinsic mean and variance messages. In particular, the Onsager correction in the last step uses all preceding messages.

In iteration t, module B first extracts information required for estimation of x[l] from $\{\vec{x}_{A\to B,t}[\ell]\}$ in the extended space. This computation is the same as (45) in OAMP.

The second step is computation of a sufficient statistic $\boldsymbol{x}_{A \to B,t}^{suf}[l] \in \mathbb{R}^{N[l]}$ for estimation of $\boldsymbol{x}[l]$ given all preceding messages and the corresponding covariance $\{\boldsymbol{v}_{A \to B,t',t}^{suf}[l]\}$. We write the mean messages for section l passed from module A to module B in all preceding iterations up to t as $\boldsymbol{X}_{A \to B,t+1}[l][w] = (\boldsymbol{x}_{A \to B,0}[l][w], \dots, \boldsymbol{x}_{A \to B,t}[l][w]) \in \mathbb{R}^{N[l] \times (t+1)}$, with $\boldsymbol{x}_{A \to B,t}[l][w]$ given in (45). For all $l \in \mathcal{L}_0$, the mean message $\boldsymbol{x}_{A \to B,t}^{suf}[l]$ in section l and corresponding covariance $\boldsymbol{v}_{A \to B,t',t}^{suf}[l]$ are given by

$$\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l] = \boldsymbol{v}_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[l] \sum_{w=0}^{W} \gamma[l+w][l] \\ \cdot \boldsymbol{X}_{\mathrm{A}\to\mathrm{B},t+1}[l][w] \boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[l+w] \boldsymbol{1}, \quad (85)$$

$$\frac{1}{v_{A\to B,t',t}^{\text{suf}}[l]} = \sum_{w=0}^{W} \gamma^2 [l+w][l] \mathbf{1}^{\mathrm{T}} \boldsymbol{V}_{A\to B,t}^{-1}[l+w] \mathbf{1} \quad (86)$$

for all $t' \in \{0, \ldots, t\}$. See Appendix D-B for the derivation of (85) and (86).

The third step is computation of posterior messages $\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}} = [(\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[0])^{\mathrm{T}}, \ldots, (\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[L-1])^{\mathrm{T}}]^{\mathrm{T}}$ based on separable denoisers $\{f_t[l]\}$, given by

$$\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l] = f_t[l](\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]), \qquad (87)$$

which is the same as (48) in OAMP. The corresponding covariance $v_{\mathrm{B},t',t+1}^{\mathrm{post}}[l]$ needs to be a consistent estimator of $N^{-1}[l]\mathbb{E}[(\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t'}^{\mathrm{post}}[l])^{\mathrm{T}}(\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l])]$. See [49, Eq. (23)] for the details.

For the signal vector $\boldsymbol{x}[l]$ with i.i.d. elements, consider the Bayes-optimal denoiser $f_t[l](u) = f_{\text{opt}}(u; v_{A \to B,t,t}^{\text{suf}}[l])$. In this case, the following posterior covariance should be used:

$$v_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[l]$$

$$= \frac{1}{N[l]} \mathbb{E} \left[\left\{ \boldsymbol{x}[l] - f_{\mathrm{opt}}(\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t'}^{\mathrm{suf}}[l]; v_{\mathrm{A}\to\mathrm{B},t',t'}^{\mathrm{suf}}[l]) \right\}^{\mathrm{T}} \cdot \left\{ \boldsymbol{x}[l] - f_{\mathrm{opt}}(\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]; v_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[l]) \right\} \left| \boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t'}^{\mathrm{suf}}[l], \boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l], v_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[l], v_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[l] \right\}, (88)$$

where conditioning with respect to $v_{A \to B, t', t}^{suf}[l]$ is omitted, because of $v_{A \to B, t', t}^{suf}[l] = v_{A \to B, t, t}^{suf}[l]$ for $t' \leq t$. The last step is the Onsager correction of the poste-

The last step is the Onsager correction of the posterior message $|\mathcal{W}[\ell]|^{1/2} \mathbf{\Gamma}[\ell] \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}$ in the extended space to realize asymptotic Gaussianity in module A. Let $|\mathcal{W}[\ell]|^{-1/2} \eta_{\mathrm{B},\tau,t}[\ell][w]$ denote the average of the partial derivative of the *n*th element in the *w*th section of $|\mathcal{W}[\ell]|^{1/2} \mathbf{\Gamma}[\ell] \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}$ with respect to $\vec{x}_{\mathrm{A}\to\mathrm{B},n,\tau}[\ell][w]$ over all $n \in N[\ell-w]$,

$$\eta_{\mathrm{B},\tau,t}[\ell][w] = \eta_{\mathrm{B},t}[\ell][w] \frac{\boldsymbol{e}_{\tau}^{\mathrm{T}} \boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell] \mathbf{1}}{\mathbf{1}^{\mathrm{T}} \boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell] \mathbf{1}}, \qquad (89)$$

with

$$\eta_{\mathrm{B},t}[\ell][w] = |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\mathbf{1}^{\mathrm{T}}\mathbf{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell]\mathbf{1}$$
$$\cdot v_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[\ell-w]\langle f_{t}'[\ell-w](\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[\ell-w])\rangle.(90)$$

Furthermore, we define

$$\eta_{\mathrm{B},\tau,t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} \eta_{\mathrm{B},\tau,t}[\ell][w].$$
(91)

The extrinsic mean $\vec{x}_{B\to A,t+1}[\ell] \in \mathbb{R}^{N_c[\ell]}$ and covariance $v_{B\to A,t'+1,t+1}[\ell]$ of $\vec{x}[\ell]$ are computed as

$$(1 - \eta_{\mathrm{B},t}[\ell] / |\mathcal{W}[\ell]|) \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = |\mathcal{W}[\ell]|^{1/2} \boldsymbol{\Gamma}[\ell] \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}$$
$$-|\mathcal{W}[\ell]|^{-1/2} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau,t}[\ell] \vec{\boldsymbol{x}}_{\mathrm{A}\to\mathrm{B},\tau}[\ell], \qquad (92)$$

$$(1 - \eta_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)(1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)v_{\mathrm{B}\to\mathrm{A},t'+1,t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]v_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[\ell-w] - \frac{1}{|\mathcal{W}[\ell]|} \frac{\eta_{\mathrm{B},t'}[\ell]\eta_{\mathrm{B},t}[\ell]}{\mathbf{1}^{\mathrm{T}}\mathbf{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell]\mathbf{1}},$$
(93)

with $\eta_{\mathrm{B},t}[\ell]$ given in (51).

Module A in LM-OAMP requires the covariance message $v_{B\to A,0,t+1}[\ell]$, which is obtained by letting $f_{-1}[l] = 0$ in (93),

$$(1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)v_{\mathrm{B}\to\mathrm{A},0,t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]v_{\mathrm{B},0,t+1}^{\mathrm{post}}[\ell-w],(94)$$

where the posterior covariance $v_{B,0,t+1}^{\text{post}}[l]$ needs to be a consistent estimator of $N^{-1}[l]\mathbb{E}[\boldsymbol{x}^{\mathrm{T}}[l](\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l])]$.

For the Bayes-optimal denoiser, we use

$$v_{\mathrm{B},0,t+1}^{\mathrm{post}}[l] = \frac{1}{N[l]} \mathbb{E} \Big[\big\| \boldsymbol{x}[l] - f_{\mathrm{opt}}(\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]; v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]) \big\|^{2} \\ \Big\| \boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l], v_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l] \Big],$$
(95)

which is justified via the fact that the posterior mean estimator f_{opt} is uncorrelated with its estimation error.

As expected from [48], [49], the following proposition implies the equivalence between Bayes-optimal OAMP and Bayes-optimal LM-OAMP.

Proposition 4: Consider the signal vector $\boldsymbol{x}[l]$ with i.i.d. elements, the LMMSE filter, and the Bayes-optimal denoiser. If the covariance matrix $V_{A\to B,t}[\ell]$ is positive definite, then LM-OAMP is equivalent to OAMP: The messages $\vec{x}_{A\to B,t}[\ell]$, $v_{A\to B,t',t}[\ell]$, $\vec{x}_{B\to A,t+1}[\ell]$, and $v_{B\to A,t'+1,t+1}[\ell]$ in (83), (84), (92), and (93) are respectively equal to (41), (43), (53), and (55) in OAMP for all t and $t' \in \{0, \ldots, t\}$. Furthermore, $v_{B\to A,0,t+1}[\ell]$ in (94) is equal to (55) in OAMP for all t.

Proof: See Appendix F.

The positive definiteness of $V_{A\to B,t}[\ell]$ is justified in the large system limit via state evolution. Proposition 4 allows us to analyze the asymptotic dynamics of Bayes-optimal OAMP and its convergence property via those for Bayes-optimal LM-OAMP. In particular, the convergence property of LM-OAMP can be analyzed more straightforwardly than that of OAMP. In this sense, LM-OAMP is regarded as a technical tool to prove the convergence of state evolution recursions for Bayesoptimal OAMP.

C. State Evolution

State evolution analysis is presented for LM-OAMP in the spatially coupled system (31). This paper extends a unified framework [54] of state evolution to that for the spatially coupled system. A general error model for the spatially coupled system is proposed and analyzed in the large system limit. By proving that the proposed general error model contains the error model for LM-OAMP in the spatially coupled system, we derive state evolution recursions for LM-OAMP.

We first define state evolution recursions for LM-OAMP. State evolution recursions for module A with the initial condition $\bar{v}_{B\to A,0,0}[\ell] = |\mathcal{W}[\ell]|\alpha_c^{-1}[\ell]\sum_{w\in \mathcal{W}[\ell]} \alpha[\ell][\ell-w]\gamma^2[\ell][\ell-w]$ are given by

$$\bar{v}_{\mathrm{A},t',t}^{\mathrm{post}}[\ell] = \lim_{\{M[\ell],N[\ell]\}\to\infty} \left\{ \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left(\boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{F}_{t'}[\ell]\right) + \frac{\bar{v}_{\mathrm{B}\to\mathrm{A},t',t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathrm{Tr}\left\{ (\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])(\boldsymbol{I} - \boldsymbol{F}_{t'}^{\mathrm{T}}[\ell]\boldsymbol{A}[\ell])^{\mathrm{T}} \right\} \right\},$$
(96)

$$\bar{v}_{A\to B,t',t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{\bar{v}_{A,t',t}^{\text{post}}[\ell] - \bar{\eta}_{A,t'}[\ell]\bar{\eta}_{A,t}[\ell]\bar{v}_{B\to A,t',t}[\ell]}{(1 - \bar{\eta}_{A,t'}[\ell])(1 - \bar{\eta}_{A,t}[\ell])},$$
(97)

where $\bar{\eta}_{A,t}[\ell]$ is the same as (59) for OAMP.

Let $\bar{\mathbf{V}}_{A\to B,t}[\ell] \in \mathbb{R}^{(t+1)\times(t+1)}$ denote the covariance matrix with the (τ', τ) element $[\bar{\mathbf{V}}_{A\to B,t}[\ell]]_{\tau',\tau} = \bar{v}_{A\to B,\tau',\tau}[\ell]$. State evolution recursions for module B are given by

$$\frac{1}{\bar{v}_{A\to B,t',t}^{suf}[l]} = \sum_{w=0}^{W} \gamma^2 [l+w][l] \mathbf{1}^T \bar{\boldsymbol{V}}_{A\to B,t}^{-1}[l+w] \mathbf{1}, \quad (98)$$

$$\bar{v}_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[l] = \mathbb{E}[\{x_1[l] - f_{t'}[l](x_1[l] + z_{t'}[l])\} \\ \cdot \{x_1[l] - f_t[l](x_1[l] + z_t[l])\}], \quad (99)$$

$$(1 - \bar{\eta}_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)(1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)\bar{v}_{\mathrm{B}\to\mathrm{A},t'+1,t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]} |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[\ell-w] - \frac{1}{|\mathcal{W}[\ell]|} \frac{\bar{\eta}_{\mathrm{B},t'}[\ell]\bar{\eta}_{\mathrm{B},t}[\ell]}{\mathbf{1}^{\mathrm{T}}\bar{\boldsymbol{V}}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell]\mathbf{1}},$$
(100)

with

$$\bar{\eta}_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]} \bar{\eta}_{\mathrm{B},t}[\ell][w], \qquad (101)$$

$$\bar{\eta}_{\mathrm{B},t}[\ell][w] = |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\mathbf{1}^{\mathrm{T}}\bar{\boldsymbol{V}}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell]\mathbf{1}$$
$$\cdot\bar{v}_{\mathrm{A}\to\mathrm{B},t,t}^{\mathrm{suf}}[\ell-w]\mathbb{E}\left[f_{t}'[\ell-w](x_{1}[\ell-w]+z_{t}[\ell-w])\right]$$
(102)

In these expressions, $\{z_t[l]\}$ denote zero-mean Gaussian random variables with covariance $\mathbb{E}[z_{t'}[l]z_t[l]] = \bar{v}_{A \to B,t',t}^{suf}[l]$, independent of $x_1[l]$.

For t' = -1, we use

$$(1 - \bar{\eta}_{\mathrm{B},t}[\ell] / |\mathcal{W}[\ell]|) \bar{v}_{\mathrm{B}\to\mathrm{A},0,t+1}[\ell] = \sum_{w\in\mathcal{W}[\ell]} \frac{\alpha[\ell][\ell-w]}{\alpha_{\mathrm{c}}[\ell]} |\mathcal{W}[\ell]| \gamma^{2}[\ell][\ell-w] \bar{v}_{\mathrm{B},0,t+1}^{\mathrm{post}}[\ell-w] \mathbf{03})$$

instead of (100), with

$$\bar{v}_{\mathrm{B},0,t+1}^{\mathrm{post}}[l] = \mathbb{E}[x_1[l]\{x_1[l] - f_t[l](x_1[l] + z_t[l])\}].$$
(104)

The following theorem implies that the former part in Theorem 3 is correct.

Theorem 5: Suppose that Assumptions 2–6 hold. Then, the MSE $N^{-1}[l] \| \boldsymbol{x}[l] - \boldsymbol{x}_{B,t}[l] \|^2$ for OAMP and the error covariance $N^{-1}[l] (\boldsymbol{x}[l] - \boldsymbol{x}_{B,t'}[l])^T (\boldsymbol{x}[l] - \boldsymbol{x}_{B,t}[l])$ for LM-OAMP converge almost surely to $\bar{v}_{B,t}^{\text{post}}[l]$ and $\bar{v}_{B,t',t}^{\text{post}}[l]$ in the large system limit, respectively. The asymptotic MSE $\bar{v}_{B,t}^{\text{post}}[l]$ is given via the state evolution recursions (57)–(62) for OAMP while $\bar{v}_{B,t',t}^{\text{post}}[l]$ is given via the state evolution recursions (96)– (100) for LM-OAMP. Furthermore, the covariance matrix $\bar{V}_{A\to B,t}[\ell]$ is positive definite.

Proof: See Appendix G.

Theorem 5 implies asymptotic Gaussianity for the estimation error $\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t}[l]$: The error covariance $N^{-1}[l](\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t'}[l])^{\mathrm{T}}(\boldsymbol{x}[l] - \boldsymbol{x}_{\mathrm{B},t}[l])$ converges almost surely to $\bar{v}_{\mathrm{B},t',t}^{\mathrm{post}}[l]$ in (99)—given via the Gaussian random variables $\{z_{t'}[l], z_t[l]\}$. As a conclusion of Theorem 5 and Proposition 4, we arrive at the equivalence between Bayes-optimal OAMP and Bayesoptimal LM-OAMP in the large system limit. The latter part in Theorem 3 is obtained by proving the convergence of state evolution recursions for Bayes-optimal OAMP.

Theorem 6: Consider the LMMSE filter (37) and the Bayesoptimal denoiser (49). Suppose that Assumptions 2–6 hold.

- LM-OAMP is asymptotically equivalent to OAMP: The messages $\vec{x}_{A\to B,t}[\ell]$, $v_{A\to B,t',t}[\ell]$, $\vec{x}_{B\to A,t+1}[\ell]$, and $v_{B\to A,t'+1,t+1}[\ell]$ in (83), (84), (92), and (93) are respectively equal to (41), (43), (53), and (55) in OAMP for all t and $t' \in \{0, \ldots, t\}$ in the large system limit. Furthermore, $v_{B\to A,0,t+1}[\ell]$ in (94) is equal to (55) in OAMP for all t.
- The error covariance $N^{-1}[l](\boldsymbol{x}[l] \boldsymbol{x}_{\mathrm{B},t'}[l])^{\mathrm{T}}(\boldsymbol{x}[l] \boldsymbol{x}_{\mathrm{B},t'}[l])$ for Bayes-optimal LM-OAMP converges almost surely to $\bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l]$ for all $t' \in \{0, \ldots, t\}$ in the large system limit, in which $\bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l]$ is given via the state evolution recursions (65)–(69) for Bayes-optimal OAMP.
- The state evolution recursions (65)–(69) for Bayesoptimal OAMP converge to a fixed point as t → ∞.

Proof: The first statement follows from Proposition 4 and the positive definiteness of $\bar{V}_{A\to B,t}[\ell]$ in Theorem 5. The second statement can be proved by repeating the proof of Proposition 4 for the state evolution recursions (96)–(100), which describe the asymptotic dynamics of the error covariance $N^{-1}[l](\boldsymbol{x}[l] - \boldsymbol{x}_{B,t'}[l])^{T}(\boldsymbol{x}[l] - \boldsymbol{x}_{B,t}[l])$ from Theorem 5.

We prove the last statement. The first two statements in Theorem 6 imply that it is sufficient to prove the convergence of the state evolution recursions for Bayes-optimal LM-OAMP, because of the equivalence between Bayes-optimal OAMP and Bayes-optimal LM-OAMP.

Let us prove the convergence. We use [49, Lemma 2] to find that the asymptotic MSE $\bar{v}_{B,t+1,t+1}^{\text{post}}[l]$ in (99) for Bayes-optimal LM-OAMP is monotonically non-increasing as t increases. As a result, there exists $\lim_{t\to\infty} \bar{v}_{B,t+1,t+1}^{\text{post}}[l]$. Since the second statement in Theorem 6 implies $\bar{v}_{B,t',t+1}^{\text{post}}[l] = \bar{v}_{B,t',t+1}^{\text{post}}[l]$ for all $t' \in \{0, \ldots, t+1\}$, the covariance $\bar{v}_{B,t',t+1}^{\text{post}}[l]$ converges for all $t' \in \{0, \ldots, t+1\}$ as $t \to \infty$. Thus, the state evolution recursions for Bayes-optimal LM-OAMP converge to a fixed point.

Theorem 6 implies that LM-OAMP is equivalent to OAMP in the large system limit, as long as the LMMSE filter and the Bayes-optimal denoiser are considered. Theorem 3 follows from Theorem 5 and the last statement in Theorem 6.

VII. PROOF OF THEOREM 4

A. Overview

The proof of Theorem 4 consists of three steps: In a first step, via the change of variables, the state evolution recursions for Bayes-optimal OAMP are connected to the replica-symmetric potential (3). Unfortunately, the state evolution recursions obtained via the change of variables are not included in the class of spatially coupled systems analyzed in [11], [21].

In a second step, we approximate the state evolution recursions so that the obtained recursions are included in the class of spatially coupled systems in [11], [21]. We prove that the approximate state evolution recursions are an exact approximation of the original state evolution recursions in the continuum limit.

The last step is evaluation of the fixed point of the approximate state evolution recursions via existing results [11], [21]. By proving that a potential for characterizing the fixed point is connected to the replica-symmetric potential (3), we arrive at Theorem 4.

B. Change of Variables

To connect the state evolution recursions for Bayes-optimal OAMP with the replica symmetric potential (3), we consider the change of variables $s_t[l] = 1/\bar{v}_{A\to B,t}^{suf}[l]$ and

$$E_{t+1}[\ell] = \frac{1}{W+1} \sum_{w \in \mathcal{W}[\ell]} \bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w]$$
$$= \frac{1}{W+1} \sum_{w \in \mathcal{W}[\ell]} \mathrm{MMSE}(s_t[\ell-w]), \quad (105)$$

where we have represented the MMSE $\bar{v}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ in (61) with MMSE(·) given in (4). For t = 0, we use the initial condition $s_0[l] = 1/\bar{v}_{\mathrm{A}\to\mathrm{B},0}^{\mathrm{suf}}[l]$, computed via the state evolution recursions for Bayes-optimal OAMP.

The goal in the first step is to derive the following state evolution recursion:

$$s_t[l] = \frac{1}{W+1} \sum_{\ell=l}^{l+W} g[\ell] \left(\frac{\bar{\eta}_{\mathrm{A},t}[\ell] E_t[\ell]}{1 - \bar{\eta}_{\mathrm{B},t-1}[\ell]/|\mathcal{W}[\ell]|} \right), \quad (106)$$

with

$$g[\ell](z) = \frac{1}{\sigma^2} R_{\boldsymbol{G}[\ell]} \left(-\frac{z}{|\mathcal{W}[\ell]|\sigma^2} \right).$$
(107)

The functions $g[\ell](z)$ in (107) and MMSE(s) are connected to the second term in the replica-symmetric potential (3) and the derivative of the first term, respectively, via the relationship (21) between mutual information and MMSE.

We first represent the state evolution recursion (65) for module A with the R-transform. Repeating the derivation of (11) for $\bar{\eta}_{A,t}[\ell]$ in (59) with the LMMSE filter (66), we obtain

$$\bar{\eta}_{\mathrm{A},t}[\ell] = \eta_{\boldsymbol{A}^{\mathrm{T}}[\ell]} \boldsymbol{A}[\ell] \left(\frac{\bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{\sigma^2}\right), \tag{108}$$

where $\eta_{A^{\mathrm{T}}[\ell]A[\ell]}$ denotes the η -transform (10) of $A^{\mathrm{T}}[\ell]A[\ell]$ in the large system limit. Using the identity $\eta_{A^{\mathrm{T}}[\ell]A[\ell]}(z) = \eta_{G[\ell]}(z/|\mathcal{W}[\ell]|)$ obtained from the definition of the η transform in (10) yields

$$\bar{\eta}_{\mathrm{A},t}[\ell] = \eta_{\boldsymbol{G}[\ell]} \left(\frac{\bar{v}_{\mathrm{B} \to \mathrm{A},t}[\ell]}{|\mathcal{W}[\ell]|\sigma^2} \right).$$
(109)

Thus, from the representation of the R-transform in (15) at $z = \bar{v}_{B \to A,t}[\ell]/(\sigma^2 |W[\ell]|)$ we have

$$\frac{1}{\sigma^2} R_{\boldsymbol{G}[\ell]} \left(-\frac{\bar{\eta}_{\mathrm{A},t}[\ell] \bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{\sigma^2 |\mathcal{W}[\ell]|} \right) = \frac{|\mathcal{W}[\ell]|(1-\bar{\eta}_{\mathrm{A},t}[\ell])}{\bar{\eta}_{\mathrm{A},t}[\ell] \bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}.$$
(110)

Applying this expression to the definition of $\bar{v}_{A\to B,t}[\ell]$ in (65), we arrive at

$$\frac{1}{\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell]} = \frac{1}{\sigma^2} R_{\boldsymbol{G}[\ell]} \left(-\frac{\bar{\eta}_{\mathrm{A},t}[\ell] \bar{v}_{\mathrm{B}\to\mathrm{A},t}[\ell]}{|\mathcal{W}[\ell]|\sigma^2} \right).$$
(111)

We next derive the state evolution recursion (106). Substituting the expression of $\bar{v}_{A\to B,t}[\ell]$ in (111) into the definition of $\bar{v}_{A\to B,t}^{suf}[l]$ in (70) for Bayes-optimal OAMP, we have

$$s_t[l] = \frac{1}{\bar{v}_{A\to B,t}^{suf}[l]} = \frac{1}{W+1} \sum_{\ell=l}^{l+W} g[\ell](\bar{\eta}_{A,t}[\ell]\bar{v}_{B\to A,t}[\ell]),$$
(112)

with $g[\ell](z)$ defined in (107). Using the identity $E_{t+1}[\ell] = \bar{\eta}_{\mathrm{B},t}[\ell]\bar{v}_{\mathrm{A}\to\mathrm{B},t}[\ell]$ obtained from $E_{t+1}[\ell]$ in (105) and $\bar{\eta}_{\mathrm{B},t}[\ell]$ in (71), we find that (69) reduces to

$$\bar{v}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] = \frac{E_{t+1}[\ell]}{1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|}.$$
(113)

Substituting this expression into (112), we arrive at the state evolution recursion (106).

C. Approximate State Evolution Recursions

The state evolution recursions (105) and (106) with respect to $s_t[l]$ and $E_t[\ell]$ are not included in the class of spatially coupled dynamical systems in [11], [21]. Thus, we consider approximate state evolution recursions with the initial condition $\tilde{s}_0[l] = s_0[l]$, given by

$$\tilde{E}_{t+1}[\ell] = \frac{1}{W+1} \sum_{w \in \mathcal{W}[\ell]} \text{MMSE}(\tilde{s}_t[\ell-w]), \qquad (114)$$

$$\tilde{s}_t[l] = \frac{1}{W+1} \sum_{\ell=l}^{l+W} g(\tilde{E}_t[\ell]),$$
(115)

with

$$g(z) = \frac{1}{\sigma^2} R\left(-\frac{z}{\sigma^2},\right),\tag{116}$$

where R(z) is defined in the assumption (72) in Theorem 4. The approximate state evolution recursions are included in the class of spatially coupled systems in [11], [21].

The former state evolution recursion (114) is equivalent to the original recursion (105). On the other hand, the latter (115) is obtained by letting $\bar{\eta}_{A,t}[\ell] = 1$, $\bar{\eta}_{B,t-1}[\ell]/|\mathcal{W}[\ell]| = 0$, and $R_{G[\ell]}(z/|\mathcal{W}[\ell]|) = R(z)$ in the original recursion (106), of which the last is motivated by the assumption (72) in Theorem 4. The first two replacements are due to the following lemma:

Lemma 7: Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W = \infty$ and $\lim_{W\to\infty} a_W/W = 0$. Suppose $\mathbb{E}[x_1^2[l]] = 1$ holds and that there is some function R(z) such that the Rtransform of $G[\ell]$ satisfies the assumption (72) in Theorem 4 for all $\ell \in \{\lceil W/a_W \rceil, \ldots, L + W - 1 - \lceil W/a_W \rceil\}$ and $\lim_{z\to\infty} zR(-z) = \delta$ holds. Then, we have

$$\lim_{W=\Delta L\to\infty}\frac{W}{a_W}|\bar{\eta}_{\mathrm{A},t}[\ell]-1|<\infty,\tag{117}$$

$$\lim_{W=\Delta L\to\infty}\frac{W}{a_W}\frac{\bar{\eta}_{\mathrm{B},t}[\ell]}{|\mathcal{W}[\ell]|} < \infty \tag{118}$$

in the continuum limit, for all $\ell \in \{ \lceil W/a_W \rceil, \dots, L + W - 1 - \lceil W/a_W \rceil \}$.

Proof: We first prove the former bound (117). Let $y = v\eta_{\mathbf{G}[\ell]}(v/|\mathcal{W}[\ell]|)$ with $v = \bar{v}_{B\to A,t}[\ell]/\sigma^2$. Evaluating the representation of the R-transform $R_{\mathbf{G}[\ell]}$ in (15) at $z = v/|\mathcal{W}[\ell]|$ yields

$$R_{\boldsymbol{G}[\ell]}\left(-\frac{y}{|\mathcal{W}[\ell]|}\right) = |\mathcal{W}[\ell]|\frac{1 - \eta_{\boldsymbol{G}[\ell]}(v/|\mathcal{W}[\ell]))}{y}.$$
 (119)

We use the definition of $\bar{\eta}_{A,t}[\ell]$ in (109) and the assumption (72) in Theorem 4 to obtain

$$|\mathcal{W}[\ell]||\bar{\eta}_{\mathrm{A},t}[\ell] - 1| = |yR(-y)| + \mathcal{O}(a_W^{-1}).$$
(120)

The assumption $\lim_{y\to\infty} yR(-y) = \delta$ in Lemma 7 implies the boundedness of the RHS. Since Proposition 3 implies $|\mathcal{W}[\ell]| \ge W/a_W$, we arrive at the former bound (117).

We next prove the latter bound (118). It is sufficient to prove the boundedness of $\bar{\eta}_{B,t}[\ell]$ in (71). As shown in (5), the MMSE $\bar{v}_{B,t+1}^{post}[l]$ in the numerator is bounded from above by the prior variance $\mathbb{E}[x_1^2[l]] = 1$. The variance $\bar{v}_{A \to B,t}[\ell]$ in the denominator has to be positive since $\bar{V}_{A \to B,t}[\ell]$ has been proved to be positive definite in Theorem 5. Thus, $\bar{\eta}_{B,t}[\ell]$ in (71) is bounded.

The goal in the second step is to prove that the approximate state evolution recursions (114) and (115) are an exact approximation of the original state evolution recursions in the continuum limit.

Lemma 8: Suppose that $\mathbb{E}[x_1^2[l]] = 1$ holds and that all moments for the asymptotic eigenvalue distribution of $G[\ell]$ are bounded. Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W = \infty$ and $\lim_{W\to\infty} a_W/W = 0$. Assume the following conditions:

- There is some function R(z) such that the R-transform of G[ℓ] satisfies the assumption (72) in Theorem 4 for all ℓ ∈ {[W/a_W],..., L + W − 1 − [W/a_W]}.
- R(z) is proper, continuously differentiable, and nondecreasing for all $z \leq 0$.
- $\lim_{z\to\infty} zR(-z) = \delta$ holds.

Then, for all $\ell \in \mathcal{L}_W$, $l \in \mathcal{L}_0$, and iteration τ ,

$$\lim_{W=\Delta L\to\infty} a_W |\tilde{E}_{\tau+1}[\ell] - E_{\tau+1}[\ell]| < \infty,$$
(121)

$$\lim_{W=\Delta L\to\infty} a_W |\tilde{s}_\tau[l] - s_\tau[l]| < \infty.$$
(122)

Proof: See Appendix H.

Lemma 8 allows us to evaluate the dynamics of the original state evolution recursions for Bayes-optimal OAMP via the approximate state evolution (114) and (115) as long as the continuum limit is considered.

D. Analysis via Potential

The fixed point of the approximate state evolution recursions (114) and (115) was analyzed in [11], [21]. The existing results are different in terms of the order of limits: [11] considered $\lim_{\Delta \downarrow 0} \lim_{t\to\infty} \lim_{W=\Delta L\to\infty} while$ [21] took $\lim_{W\to\infty} \lim_{L\to\infty} \lim_{t\to\infty} .$ In the proof of Theorem 4, we focus on the former limit to use Lemma 8. Define a potential function $F: [0,1] \to \mathbb{R}$ as

$$F(\tilde{E}) = \int_0^{g(\tilde{E})} \text{MMSE}(s) ds + \int_0^{\tilde{E}} g(z) dz - \tilde{E}g(\tilde{E}),$$
(123)

where g(z) is given in (116). Note that $F(\tilde{E})$ depends on δ through R(z) in g(z).

Theorem 7 ([11]): Suppose that R(z) in (116) is strictly increasing and twice continuously differentiable for all $z \leq 0$. Let \tilde{E}_{opt} denote the global minimizer of the potential function (123). If \tilde{E}_{opt} is unique, then

$$\lim_{\Delta \downarrow 0} \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} \tilde{E}_t[\ell] \le \tilde{E}_{\text{opt}}.$$
 (124)

Proof: Consider $v_{\ell}(t) = -\tilde{E}_t[\ell]$ and $u_l(t) = s_t[l]$ with $\phi(s) = -\text{MMSE}(s), \ \psi(v) = g(-v)$, and $\beta = 1$ in [11, Eqs. (41) and (42)]. From Proposition 2 and the assumption on R(z) in Theorem 7, the two functions ϕ and ψ are strictly increasing and twice continuously differentiable. A potential function $V(\psi(-\tilde{E}))$ in [11, Eq. (58)] reduces to (123). Thus, from [11, Theorem 5 and Corollary 1] there is some function $\tilde{E} : [0, 1] \rightarrow [0, 1]$ such that the upper bound $\tilde{E}(x) \leq \tilde{E}_{\text{opt}}$ holds for all x and

$$\lim_{\Delta \downarrow 0} \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \left| \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} \left\{ \tilde{E}_t[\ell] - \tilde{E}\left(\frac{\ell}{|\mathcal{L}_W|}\right) \right\} \right| = 0$$
(125)

Applying the upper bound $E(x) \leq E_{opt}$ to this expression, we arrive at Theorem 7.

Remark 2: The other existing result [21, Theorem 1] implies

$$\lim_{W \to \infty} \lim_{L \to \infty} \lim_{t \to \infty} \max_{\ell \in \mathcal{L}_W} \tilde{E}_t[\ell] \le \tilde{E}_{\text{opt}}$$
(126)

under slightly weaker assumptions than those in Theorem 7, where R(z) is assumed to be non-decreasing and continuously differentiable for all $z \leq 0$. However, this upper bound is not matched with Lemma 8 since the limit $t \to \infty$ is taken before the continuum limit.

Remark 3: The so-called BP threshold [11] was defined as the infimum δ_{BP} of δ such that the potential function (123) has a unique minimizer for all $\delta \in (\delta_{BP}, 1]$. Furthermore, define the potential threshold δ_{opt} as the infimum of δ such that the global minimizer \tilde{E}_{opt} of the potential function (123) is unique and equal to the smallest local minimizer of (123). When $\delta_{opt} < \delta_{BP}$ holds, the potential function (123) has multiple minimizers for all $\delta \in [\delta_{opt}, \delta_{BP})$. In this case, the state evolution recursions for Bayes-optimal OAMP have multiple fixed points for all $\delta \in [\delta_{opt}, \delta_{BP})$. Spatial coupling is a general technique to guarantee that the state evolution recursions converge to the best fixed point as long as δ is larger than the potential threshold δ_{opt} .

We are ready to prove Theorem 4.

Proof of Theorem 4: We first prove the upper bound,

$$\lim_{\Delta \downarrow 0} \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} E_t[\ell] \le \tilde{E}_{\text{opt}}$$
(127)

if $\tilde{E}_{\rm opt}$ is unique. Using the triangle inequality and Lemma 8 yields

$$\frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} E_t[\ell]$$

$$\leq \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} |E_t[\ell] - \tilde{E}_t[\ell]| + \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} \tilde{E}_t[\ell]$$

$$\rightarrow \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} \tilde{E}_t[\ell]$$
(128)

in the continuum limit. Applying Theorem 7, we arrive at the upper bound (127) if \tilde{E}_{opt} is unique.

We next prove the identity $\dot{E}_{opt} = E_{opt}$. Applying g(z) given in (116) and the general formula (21) between mutual information and MMSE to the potential function (123), we have

$$F(\tilde{E}) = 2I(s) + \int_0^{\tilde{E}} \frac{1}{\sigma^2} R\left(-\frac{z}{\sigma^2}\right) dz - s\tilde{E}, \qquad (129)$$

with $s = R(-\tilde{E}/\sigma^2)/\sigma^2$. Using the change of variables $\tilde{z} = z/\sigma^2$ for the second term, we find that $F(\tilde{E})/2$ is equal to the replica-symmetric potential $f_{\rm RS}(\tilde{E},s)$ in (3) with $R_{A^TA}(z) = R(z)$ and $s = R(-\tilde{E}/\sigma^2)/\sigma^2$. Lemma 6 for $R_{A^TA}(z) = R(z)$ implies that the global minimizer $\tilde{E}_{\rm opt}$ of the potential function (123) is equal to $E_{\rm opt}$ in the global optimizer ($E_{\rm opt}, s_{\rm opt}$) of the optimization problem (23).

We prove the main statement (73) in Theorem 4. Using the following identity obtained from the definition of $E_t[\ell]$ in (105):

$$\sum_{\ell \in \mathcal{L}_W} E_t[\ell] = \sum_{l \in \mathcal{L}_0} \bar{v}_{\mathrm{B},t}^{\mathrm{post}}[l], \qquad (130)$$

we have

$$\lim_{\Delta \downarrow 0} \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_0|} \sum_{l \in \mathcal{L}_0} \bar{v}_{B,t}^{\text{post}}[l]$$
$$= \lim_{\Delta \downarrow 0} (1 + \Delta) \lim_{t \to \infty} \lim_{W = \Delta L \to \infty} \frac{1}{|\mathcal{L}_W|} \sum_{\ell \in \mathcal{L}_W} E_t[\ell] \le E_{\text{opt}},$$
(131)

where the inequality follows from $E_{opt} = E_{opt}$, the uniqueness assumption of E_{opt} , and the upper bound (127). Thus, we arrive at the main statement (73).

Finally, we evaluate E_{opt} . Since E_{opt} is the global optimizer of the optimization problem (23), Theorem 2 for $R_{A^TA}(z) = R(z)$ implies that E_{opt} is unique and tends to zero as $\sigma^2 \downarrow 0$ for all $\delta > d_{\text{I}}$. Thus, Theorem 4 holds.

VIII. NUMERICAL RESULTS

A. Numerical Conditions

In all numerical results, the BG prior with signal density $\rho \in [0, 1]$ was assumed: The signal vector \boldsymbol{x} has independent elements that take 0 with probability $1 - \rho$ and are sampled from the Gaussian distribution $\mathcal{N}(0, 1/\rho)$ with probability ρ . This signal vector satisfies Assumption 2.

For spatially coupled systems, we assumed $M[\ell] = M$, N[l] = N, and the uniform coupling weights (27). Two kinds of sensing matrices were considered: One is i.i.d. Gaussian

sensing matrices $|\mathcal{W}[\ell]|^{1/2} \mathbf{A}[\ell]$ given via (29) that have independent zero-mean Gaussian elements with variance 1/M. The other is artificial ill-conditioned sensing matrices [54]. The SVD structure $|\mathcal{W}[\ell]|^{1/2} \mathbf{A}[\ell] = \mathbf{\Sigma}[\ell] \mathbf{H}[\ell]$ is considered. The singular values in $\mathbf{\Sigma}[\ell] \in \mathbb{R}^{M \times |\mathcal{W}[\ell]|N}$ are defined in Corollary 6 with condition number $\kappa > 1$. The unit condition number $\kappa = 1$ indicates that the sensing matrix has orthogonal rows, as considered in Corollary 5. The orthogonal matrix $\mathbf{H}[\ell] \in \mathcal{O}_{|\mathcal{W}[\ell]|N}$ denotes the Hadamard matrix with random row permutation, which can be regarded as a practical alternative of Haar-distributed orthogonal matrices [65].

We considered damped OAMP with the LMMSE filter and the Bayes-optimal denoiser—called Bayes-optimal OAMP. Damping [42] was employed in module B: The original messages passed from module B to module A for t > 0 were replaced by

$$\vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] := \zeta \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] + (1-\zeta)\vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell], \quad (132)$$

$$v_{B\to A,t+1}[\ell] := \zeta v_{B\to A,t+1}[\ell] + (1-\zeta)v_{B\to A,t}[\ell], \quad (133)$$

with damping factor $\zeta \in [0,1]$, where $\vec{x}_{B\to A,t+1}[\ell]$ and $v_{B\to A,t+1}[\ell]$ on the RHSs are given in (53) and (54), respectively. The damping technique is empirically known to improve the convergence property of OAMP for finite-sized systems.

For comparison, damped AMP with the Bayes-optimal denoiser [5], [16]—called Bayes-optimal AMP—was considered. Damping [36] was applied to mean and variance messages just before denoising since damping after denoising was not effective.

For spatially coupled systems, different MSEs are achieved in different sections. We focus on the largest MSE among all sections. 10^4 independent numerical trials were simulated for spatially coupled systems while 10^5 independent trials were simulated for conventional systems without spatial coupling.

B. State Evolution

The asymptotic dynamics of OAMP is investigated via state evolution. As shown in Fig. 2, the MSEs at both ends decrease to a small value in the early stage. Then, the small MSEs propagate toward the center sections. Eventually, the MSEs in all sections converge to the MSE shown as the bottom horizontal line, which is equal to the Bayes-optimal MSE for M/N = 0.18 [29], [30], [33], while the MSE of OAMP without spatial coupling converges to the top horizontal line.

In terms of the comparison between OAMP and AMP, OAMP converges to the Bayes-optimal MSE faster than AMP. When the SVDs of $A[\ell]$ in (29) are pre-computed, the periteration complexity of OAMP is the same as that of AMP. Since the SVD pre-computation is of course dominant in the complexity, a reduction in the complexity of OAMP is an important future direction.

We next focus on thresholds [11]. For systems without spatial coupling, a threshold δ^* is defined as the infimum of $\delta = M/N$ such that the state evolution recursions converge to a unique fixed point, which corresponds to the Bayes-optimal performance. Thus, OAMP is Bayes-optimal for $\delta > \delta^*$ while it is not for $\delta < \delta^*$.

Fig. 2. Asymptotic MSE versus section l for zero-mean i.i.d. Gaussian sensing matrices, L = 50, W = 1, M/N = 0.18, $\rho = 0.1$, and $1/\sigma^2 = 30$ dB. The top and bottom horizontal lines are the asymptotic MSEs to which the state evolution recursions without spatial coupling converge when the original initialization and the artificial initialization $\bar{v}_{B\to A,0}[\ell] = 10^{-6}$ are used, respectively.

For spatially coupled systems, a threshold δ_{SC}^* is defined as the infimum of δ such that the state evolution recursions converge to the Bayes-optimal MSE. In general, the threshold δ_{SC}^* is smaller than δ^* when the state evolution recursions have multiple fixed points for systems without spatial coupling.

Figure 3 shows the thresholds for systems without spatial coupling (W = 0) and spatially coupled systems $(W \ge 1)$. A a fair comparison, $(1+W/L)\delta_{\rm SC}^*$ is plotted for spatially coupled systems while δ^* is shown for W = 0. The thresholds were numerically estimated via 1000 iterations of the state evolution recursions.

We first focus on the spatially coupled systems with $W \ge 1$. As shown in Fig. 3, $(1 + W/L)\delta_{SC}^*$ degrades as W increases while numerical evaluation showed that the threshold δ_{SC}^* itself improves as W grows. This observation implies that a loss in the compression rate is more dominant than an improvement in the threshold for L = 50 and $W \ge 1$. We need to consider larger L to reduce the loss factor (1+W/L) in the compression rate.

We next compare W = 0 and W = 1. For W = 1, as implied in Corollary 5, the threshold δ_{SC}^* of OAMP for $\kappa = 1$ is equal to that of AMP for zero-mean i.i.d. Gaussian sensing matrices with spatial coupling. As the condition number κ increases, the gap between δ^* and δ_{SC}^* shrinks. As a result, W = 1 is better than W = 0 only for low-to-moderate condition number when a loss in the compression rate is taken into account. Thus, spatial coupling is effective for small-tomoderate κ . Note that this conclusion depends heavily on the signal prior: It depends heavily on the signal prior whether the state evolution recursions have a unique fixed point for high condition number.

C. Numerical Simulations

OAMP for spatially coupled systems is compared to that for systems without spatial coupling. Figure 4 shows the largest

Fig. 3. Threshold of OAMP for ill-conditioned sensing matrices, L = 50, $\rho = 0.1$, $1/\sigma^2 = 30$ dB, and 1000 iterations.

MSE among all sections for sensing matrices with condition number $\kappa = 10$. The used damping factors are presented in Table I. Since the threshold improves via spatial coupling, OAMP for spatially coupled systems with W = 1 achieves small MSEs for smaller compression rates than that for W = 0.

A disadvantage of spatial coupling is in the region of large compression rates. The MSEs for W = 1 are slightly larger than those for W = 0 in that region, because the W-dependency of the R-transform for the sensing matrices (29) and the rate loss via spatial coupling. While the rate loss decreases as L grows, the change of the R-transform degrades the performance as W increases. Thus, small W should be used in spatially coupled systems.

OAMP is compared to AMP for zero-mean i.i.d. Gaussian sensing matrices. As shown in Fig. 5, the two algorithms are comparable to each other for both W = 0 and W = 1. Furthermore, OAMP for the unit condition number $\kappa = 1$ is also comparable to that for zero-mean i.i.d. Gaussian sensing matrices for W = 1. The latter result is consistent with Corollary 5, claiming that the R-transform for the unit condition number $\kappa = 1$ reduces to that for zero-mean i.i.d. Gaussian matrices in the limit $W \to \infty$. These results imply that sensing matrices with the unit condition number are a low-complexity alternative of zero-mean i.i.d. Gaussian sensing matrices for OAMP to achieve the information-theoretic compression limit via spatial coupling.

IX. CONCLUSIONS

This paper has established the unified framework of state evolution for LM-MP to reconstruct the signal vectors from right-orthogonally invariant linear measurements with spatial coupling. The unified framework has been utilized to propose OAMP and LM-OAMP for spatially coupled systems, of which the latter is regarded as a tool for proving the convergence of the state evolution recursions for Bayes-optimal OAMP. For the noiseless case, Bayes-optimal OAMP has been

proved to achieve the information-theoretic compression limit for right-orthogonally invariant matrices with spatial coupling.

Possible directions for future research are twofold: One direction is a construction of low-complexity LM-MP that achieves the information-theoretic compression limit. We need to generalize existing LM-MP, such as MAMP [57] or VAMP with warm-started conjugate gradient (WS-CG) [58], [59], to the spatial coupling case.

The other direction is challenging. This paper has assumed the joint right-orthogonal invariance of all non-zero sensing matrices in each row section. As a result, the R-transform of the sensing matrices depends on the coupling width W. Numerical results have shown that the W-dependency of the R-transform degrades the performance of OAMP in the largecompression-rate regime compared to W = 0. To circumvent this disadvantage, we need to assume the right-orthogonal invariance of *each* non-zero sensing matrix in each row section. For spatially coupled systems under such an assumption, however, it is challenging to establish a unified framework of state evolution.

APPENDIX A Proof of Lemma 1

We follow an existing proof strategy [66, Appendix D] to prove Lemma 1. If the two functions f and g were defined on \mathbb{R} , the former part in Lemma 1 could be proved straightforwardly by using the Legendre-Fenchel transform and its inverse transform. However, we need a technical result (i.e.

Lemma 10) to restrict the domains of f and g to $[E_{\min}, E_{\max}]$ and $[0, \infty)$, respectively.

We start with the definition of the Legendre-Fenchel transform for concave functions.

Definition 4: Let $\phi : [x_{\min}, x_{\max}] \to [-\infty, \infty)$ denote a concave function such that $\phi(x) > -\infty$ holds for some $x \in [x_{\min}, x_{\max}]$. The Legendre-Fenchel transform ϕ^* of ϕ is defined as

$$\phi^*(y) = \inf_{x \in [x_{\min}, x_{\max}]} \{xy - \phi(x)\}$$
(134)

for all $y \in \mathbb{R}$.

Extend the domain of ϕ from $[x_{\min}, x_{\max}]$ to \mathbb{R} , by letting $\phi(x) = -\infty$ for all $x \notin [x_{\min}, x_{\max}]$. If ϕ is upper semicontinuous and concave on the closed interval $[x_{\min}, x_{\max}]$, the extended function ϕ is also upper semicontinuous and concave on \mathbb{R} . Since the infimum in (134) is not attained at $x \notin [x_{\min}, x_{\max}]$, we have the following proposition:

Proposition 5: Suppose that $\phi : \mathbb{R} \to [-\infty, \infty)$ is a concave function such that $\phi(x) > -\infty$ and $\phi(x') = -\infty$ hold for some $x \in [x_{\min}, x_{\max}]$ and all $x' \notin [x_{\min}, x_{\max}]$. Then,

$$\inf_{x \in \mathbb{R}} \{ xy - \phi(x) \} = \inf_{x \in [x_{\min}, x_{\max}]} \{ xy - \phi(x) \}$$
(135)

for all $y \in \mathbb{R}$.

From Proposition 5, without loss of generality, we can extend the domain of ϕ to \mathbb{R} . Similarly, we can extend the domain of another function on $[0, \infty)$ to \mathbb{R} . In proving Lemma 1,

we use the Fenchel-Moreau theorem [73, Theorem VI.5.3(e)], i.e. the invertibility of the Legendre-Fenchel transform.

Lemma 9 (Fenchel-Moreau Theorem): Suppose that ϕ : $\mathbb{R} \to [-\infty, \infty)$ is an upper semicontinuous and concave function such that $\phi(x) > -\infty$ holds for some $x \in \mathbb{R}$. Then, $(\phi^*)^*(x) = \phi(x)$ holds for all $x \in \mathbb{R}$.

Note that the lower semicontinuity is required in the Fenchel-Moreau theorem for convex functions.

The following result is useful in considering the inverse transform for the Legendre-Fenchel transform of ϕ with the domain $[x_{\min}, x_{\max}]$ extended to \mathbb{R} .

Lemma 10: Suppose that $\phi : \mathbb{R} \to [-\infty, \infty)$ is a concave function such that $\phi(x) > -\infty$ and $\phi(x') = -\infty$ hold for some $x \in [x_{\min}, x_{\max}]$ and all $x' \notin [x_{\min}, x_{\max}]$. Define $\mathcal{Y} \subset \mathbb{R}$ denote the set of $y \in \mathbb{R}$ such that the infimum in the Legendre-Fenchel transform (134) is attained in the interior of $[x_{\min}, x_{\max}]$, i.e.

$$\mathcal{Y} = \left\{ y \in \mathbb{R} : \operatorname{arginf}_{x \in [x_{\min}, x_{\max}]} \{ xy - \phi(x) \} \in (x_{\min}, x_{\max}) \right\}.$$
(136)

Let $y_0 \in \mathbb{R}$ denote the unique intersection of two affine functions: $x_{\min}y - \phi(x_{\min}) = x_{\max}y - \phi(x_{\max})$ at $y = y_0$. If the infimum in (134) is attained at $x = x_{\min}$ and $x = x_{\max}$ for $y = \sup \mathcal{Y}$ and $y = \inf \mathcal{Y}$, respectively, and if $y_0 \notin \mathcal{Y}_1 = \{y \in$ $(\inf \mathcal{Y}, \sup \mathcal{Y}) : y \notin \mathcal{Y}\}$ holds, then the Legendre-Fenchel transform ϕ^* satisfies

$$\inf_{y \in \mathbb{R}} \{ xy - \phi^*(y) \} = \inf_{y \in \bar{\mathcal{Y}}} \{ xy - \phi^*(y) \}$$
(137)

for all $x \in [x_{\min}, x_{\max}]$, with $\overline{\mathcal{Y}} = \mathcal{Y} \cup \{\inf \mathcal{Y}, \sup \mathcal{Y}\}.$

Proof: Since $\inf_{y \in \mathbb{R}} \{xy - \phi^*(y)\} \leq \inf_{y \in \overline{\mathcal{Y}}} \{xy - \phi^*(y)\}$ is trivial, we prove $\inf_{y \in \mathbb{R}} \{xy - \phi^*(y)\} \geq \inf_{y \in \overline{\mathcal{Y}}} \{xy - \phi^*(y)\}$ for all $x \in [x_{\min}, x_{\max}]$.

We first focus on $y \ge \sup \mathcal{Y}$. The definition of \mathcal{Y} implies that the infimum in (134) is attained at $x = x_{\min}$ or $x = x_{\max}$. For all $y \ge \sup \mathcal{Y}$ we use $x_{\max} \ge x_{\min}$ to have

$$\begin{aligned} x_{\max}y - \phi(x_{\max}) - \{x_{\min}y - \phi(x_{\min})\} \\ \ge x_{\max}\sup\mathcal{Y} - \phi(x_{\max}) - \{x_{\min}\sup\mathcal{Y} - \phi(x_{\min})\} \ge 0, \end{aligned}$$
(138)

where the last inequality follows from the optimality assumption of $x = x_{\min}$ at $y = \sup \mathcal{Y}$. Thus, we obtain

$$\phi^*(y) = x_{\min}y - \phi(x_{\min}) \tag{139}$$

for all $y \ge \sup \mathcal{Y}$. Using this expression, for all $x \ge x_{\min}$ we arrive at

$$\inf_{y \ge \sup \mathcal{Y}} \{xy - \phi^*(y)\} = \inf_{y \ge \sup \mathcal{Y}} \{(x - x_{\min})y + \phi(x_{\min})\}$$
$$= x \sup \mathcal{Y} - \phi^*(\sup \mathcal{Y}) \ge \inf_{y \in \overline{\mathcal{Y}}} \{xy - \phi^*(y)\}.$$
(140)

We next consider $y \leq \inf \mathcal{Y}$. Repeating the same argument with the optimality assumption of $x = x_{\max}$ at $y = \inf \mathcal{Y}$, for all $x \leq x_{\max}$ we have

$$\inf_{y \le \inf \mathcal{Y}} \{ xy - \phi^*(y) \} \ge \inf_{y \in \bar{\mathcal{Y}}} \{ xy - \phi^*(y) \}.$$
(141)

Finally, we focus on the remaining set $\mathcal{Y}_1 = \{y \in (\inf \mathcal{Y}, \sup \mathcal{Y}) : y \notin \mathcal{Y}\}$ if $\mathcal{Y}_1 \neq \emptyset$. Since the intersection $y_0 \notin \mathcal{Y}_1$ has been assumed, $\phi^*(y) = \min\{x_{\min}y - \phi(x_{\min}), x_{\max}y - \phi(x_{\max})\}$ reduces to $\phi^*(y) = x_{\max}y - \phi(x_{\max})$ and $\phi^*(y) = x_{\min}y - \phi(x_{\min})$ for all $y \in \{y \in \mathcal{Y}_1 : y < y_0\}$ and $y \in \{y \in \mathcal{Y}_1 : y > y_0\}$, respectively. Thus, the infimum of $xy - \phi^*(y)$ over $y \in \mathcal{Y}_1$ is attained at an endpoint for \mathcal{Y}_1 , which is also an endpoint for $\overline{\mathcal{Y}}$. These observations imply

$$\inf_{y \in \mathcal{Y}_1} \{ xy - \phi^*(y) \} \ge \inf_{y \in \bar{\mathcal{Y}}} \{ xy - \phi^*(y) \}.$$
(142)

Since $(-\infty, \inf \mathcal{Y}] \cup \mathcal{Y}_1 \cup \mathcal{Y} \cup [\sup \mathcal{Y}, \infty) = \mathbb{R}$ holds, we combine these inequalities to arrive at $\inf_{y \in \mathbb{R}} \{xy - \phi^*(y)\} \ge \inf_{y \in \mathcal{Y}} \{xy - \phi^*(y)\}$ for all $x \in [x_{\min}, x_{\max}]$.

Lemma 10 is useful for restricting the domain of the Legendre-Fenchel transform. When the intersection y_0 is included in \mathcal{Y}_1 , the infimum of $xy - \phi^*(y)$ over $y \in \mathcal{Y}_1$ is attained at $y = y_0 \notin \mathcal{Y}$. Thus, the condition $y_0 \notin \mathcal{Y}_1$ is necessary for Lemma 10.

We are ready for proving the former part in Lemma 1.

Proof of (7): Using $\psi(E,s) = f(E) + g(s) - sE$ and the definition of the Legendre-Fenchel transform, we have

$$\inf_{s \ge 0} \sup_{E \in [E_{\min}, E_{\max}]} \psi(E, s) = \inf_{s \ge 0} \{g(s) - f^*(s)\}, \quad (143)$$

where f^* is the Legendre-Fenchel transform of f on \mathbb{R} , which satisfies $f(E) = -\infty$ for all $E \notin [E_{\min}, E_{\max}]$. See Proposition 5.

Extend the domain of g from $[0,\infty)$ to \mathbb{R} by letting $g(s) = -\infty$ for all s < 0. Proposition 5 implies that the Legendre-Fenchel transform g^* of g on \mathbb{R} is equal to $g^*(E) = \inf_{s \ge 0} \{sE - g(s)\}$. Since g is upper semicontinuous and concave on \mathbb{R} , Lemma 9 implies $g(s) = \inf_{E \in \mathbb{R}} \{sE - g^*(E)\}$. From the assumption for the Legendre-Fenchel transform of g in Lemma 1, we use Lemma 10 with $\mathcal{Y} = (E_{\min}, E_{\max})$ and $\mathcal{Y}_1 = \emptyset$ to obtain $g(s) = \inf_{E \in [E_{\min}, E_{\max}]} \{sE - g^*(E)\}$ for all $s \ge 0$. Substituting this expression into the RHS of (143) yields

$$\inf_{s \ge 0} \sup_{E \in [E_{\min}, E_{\max}]} \psi(E, s)
= \inf_{s \ge 0} \left\{ \inf_{E \in [E_{\min}, E_{\max}]} \{sE - g^{*}(E)\} - f^{*}(s) \right\}
= \inf_{E \in [E_{\min}, E_{\max}]} \left\{ \inf_{s \ge 0} \{sE - f^{*}(s)\} - g^{*}(E) \right\}. \quad (144)$$

To evaluate $\inf_{s\geq 0}\{sE - f^*(s)\}$, we use the assumption for the Legendre-Fenchel transform of f in Lemma 1. Lemma 10 with $\mathcal{Y} = (s_{\min}, s_{\max})$ and $\mathcal{Y}_1 = \emptyset$ implies $\inf_{s\in [s_{\min}, s_{\max}]}\{sE - f^*(s)\} = \inf_{s\in \mathbb{R}}\{sE - f^*(s)\}$. Since we have $\inf_{s\geq 0}\{sE - f^*(s)\} \leq \inf_{s\in [s_{\min}, s_{\max}]}\{sE - f^*(s)\}$ from the inclusion $[s_{\min}, s_{\max}] \subset [0, \infty)$, we obtain the inequality $\inf_{s\geq 0}\{sE - f^*(s)\} \leq \inf_{s\in \mathbb{R}}\{sE - f^*(s)\}$. Using the trivial inequality $\inf_{s\geq 0}\{sE - f^*(s)\} \geq \inf_{s\in \mathbb{R}}\{sE - f^*(s)\}$, we have $\inf_{s\geq 0}\{sE - f^*(s)\} = \inf_{s\in \mathbb{R}}\{sE - f^*(s)\} = f(E)$, in which the last follows from Lemma 9. Substituting this expression into (144) yields

$$\inf_{s \ge 0} \sup_{E \in [E_{\min}, E_{\max}]} \psi(E, s) = \inf_{E \in [E_{\min}, E_{\max}]} \{f(E) - g^{*}(E)\}$$

$$= \inf_{E \in [E_{\min}, E_{\max}]} \left\{ f(E) - \inf_{s \ge 0} \{sE - g(s)\} \right\}$$

$$= \inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E, s). \quad (145)$$

Thus, (7) is correct.

To prove the latter part in Lemma 1, we present known properties of a differentiable and strictly concave function ϕ on $[x_{\min}, x_{\max}]$.

Lemma 11: Suppose that $\phi : [x_{\min}, x_{\max}] \to [-\infty, \infty)$ is differentiable and strictly concave. Let $\mathcal{Y}^* \subset \mathbb{R}$ denote the set of $y \in \mathbb{R}$ such that $y = \phi'(x)$ has a unique solution $x = x^* \in [x_{\min}, x_{\max}]$. Then, the Legendre-Fenchel transform ϕ^* in (134) reduces to

$$\phi^*(y) = x^* y - \phi(x^*) \tag{146}$$

for all $y \in \mathcal{Y}^*$. Furthermore, ϕ^* is differentiable. In particular, we have

$$(\phi^*)'(y) = x^* \tag{147}$$

for all $y \in \mathcal{Y}^*$.

Proof: The expression (146) is trivial. The differentiability of ϕ^* follows from the strict concavity of ϕ [73, Theorem VI.5.6]. The expression (147) is due to [73, Theorem VI.5.3(d)].

We are ready for proving the latter part in Lemma 1.

Proof of (8): Let $g^*(E) = \inf_{s \ge 0} \{sE - g(s)\}$ denote the Legendre-Fenchel transform of g. We use $\psi(E, s) = f(E) + g(s) - sE$ to have $\inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E, s) = \inf_{E \in [E_{\min}, E_{\max}]} \{f(E) - g^*(E)\}$. The derivative g' is strictly decreasing since g is differentiable and strictly concave. From Lemma 11 and the assumption for the Legendre-Fenchel transform of g in Lemma 1, we obtain $g^*(E) = s^*E - g(s^*)$ for all $E \in [E_{\min}, E_{\max}]$, with $E_{\min} = \lim_{s \to \infty} g'(s)$ and $E_{\max} = g'(0)$, in which $s^* \ge 0$ is the unique solution to $E = g'(s^*)$.

Let $E^* \in [E_{\min}, E_{\max}]$ denote a solution to the minimization problem $\inf_{E \in [E_{\min}, E_{\max}]} \{f(E) - g^*(E)\}$. Since Lemma 11 implies the differentiability of g^* , we find that the first-order optimality condition for the minimization problem is equal to

$$f'(E^*) - (g^*)'(E^*) - \mu_{\min} + \mu_{\max} = 0,$$

$$\mu_{\min}(E_{\min} - E^*) = 0, \quad \mu_{\max}(E^* - E_{\max}) = 0, \quad (148)$$

with some Lagrange multipliers $\mu_{\min}, \mu_{\max} \ge 0$.

It is sufficient to confirm $f'(E^*) = s^*$ since $E^* = g'(s^*)$ holds for $E^* \in [E_{\min}, E_{\max}]$. In the case $E^* \in (E_{\min}, E_{\max})$, i.e. $\mu_{\min} = \mu_{\max} = 0$, we use (147) for $\phi = g$ and $\mathcal{Y}^* = [E_{\min}, E_{\max}]$ to find that the first-order optimality condition (148) reduces to $f'(E^*) = (g^*)'(E^*) = s^*$. Thus, the solution (E^*, s^*) is included in the set (9).

Consider the case $E^* = E_{\min}$, i.e. $\mu_{\max} = 0$. The definition $E_{\min} = \lim_{s\to\infty} g'(s)$ implies the optimizer $(E^*, s^*) = (E_{\min}, \infty)$. We use (147) for $\phi = g$ and $\mathcal{Y}^* = [E_{\min}, E_{\max}]$

to have $(g^*)'(E^*) = s^* = \infty$. Thus, the first-order optimality condition (148) implies $f'(E^*) = \infty = s^*$. Thus, (E^*, s^*) is included in the set (9).

Finally, consider $E^* = E_{\max}$, i.e. $\mu_{\min} = 0$. The definition $E_{\max} = g'(0)$ implies the optimizer $(E^*, s^*) = (E_{\max}, 0)$. From the first-order optimality condition (148) we have $f'(E^*) - (g^*)'(E^*) + \mu_{\max} = 0$. Since $(g^*)'(E^*) = s^* = 0$ holds from (147) for $\phi = g$ and $\mathcal{Y}^* = [E_{\min}, E_{\max}]$, we have $f'(E^*) = -\mu_{\max} \leq 0$. Using the non-decreasing assumption $f'(E^*) \geq 0$, we arrive at $f'(E^*) = 0 = s^*$. Thus, (E^*, s^*) is included in the set (9).

We have proved the lower bound

$$\inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E, s) \ge \inf_{(E, s)} \psi(E, s), \tag{149}$$

where the infimum on the RHS is over the set (9). To prove the converse inequality, we assume that (E^*, s^*) is included in the set (9). We use the definition of g^* to obtain the lower bound $\psi(E^*, s^*) = f(E^*) - \inf_{s \ge 0} \{sE^* - g(s)\} =$ $\sup_{s \ge 0} \psi(E^*, s) \ge \inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E, s)$, which implies

$$\inf_{(E,s)} \psi(E,s) \ge \inf_{E \in [E_{\min}, E_{\max}]} \sup_{s \ge 0} \psi(E,s).$$
(150)

Combining the two bounds, we arrive at (8).

Appendix B Properties of η -Transform and R-Transform

A. Proof of Lemma 2

We first prove the former property. Repeating the derivation of (11) yields

$$z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(z) = \lim_{M=\delta N\to\infty} \left\{ \frac{1}{N} \sum_{n=1}^{r} \frac{z}{1+\lambda_{n}z} + \left(1-\frac{r}{N}\right)z \right\},$$
(151)

which is strictly increasing for all $z \ge 0$ since (151) is the sum of strictly increasing functions of $z \ge 0$.

We next prove the latter property. Let $f(z; \lambda_n) = (1 + \lambda_n z)^{-1}$ denote the *n*th term in the summation on the RHS of (11). Evaluating the *k*th derivative $f^{(k)}$ of f with respect to z for any $k \in \mathbb{N}$ yields

$$f^{(k)}(z;\lambda_n) = \frac{(-1)^k k! \lambda_n^k}{(1+\lambda_n z)^{k+1}},$$
(152)

which has the z-independent upper bound $|f^{(k)}(z;\lambda_n)| \leq k!\lambda_n^k$ for all $z \geq 0$. Furthermore, the assumption $\mu_k < \infty$ is equivalent to the boundedness of $N^{-1}\sum_{n=1}^r \lambda_n^k$ in the large system limit. Thus, we can interchange the kth derivative and the large system limit in (11) to obtain

$$\eta_{A^{T}A}^{(k)}(z) = \lim_{M=\delta N \to \infty} \frac{1}{N} \sum_{n=1}^{r} f^{(k)}(z;\lambda_{n}),$$
(153)

which is bounded. Thus, the latter property in Lemma 2 holds.

B. Proof of Lemma 3

We first prove that the R-transform (14) is infinitely continuously-differentiable for all $z \in (z_{\min}, 0)$. From Lemma 2 and the implicit function theorem, it is sufficient to confirm that the image of $z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(z)$ for z > 0 is $(0, -z_{\min})$, which follows from Lemma 2.

We next prove the differentiability of the R-transform at z = 0. Since all moments $\{\mu_k\}$ are assumed to be bounded, we have the series-expansion [32, Eq. (2.84)] in a neighborhood of z = 0,

$$R_{A^{\mathrm{T}}A}(z) = \sum_{k=1}^{\infty} c_k z^{k-1},$$
 (154)

where c_k denotes the so-called kth free cumulant of the asymptotic eigenvalue distribution of $A^T A$. Thus, the R-transform is infinitely continuously-differentiable at z = 0.

Finally, we confirm the well-known results $c_1 = \mu_1$ and $c_2 = \mu_2 - \mu_1^2$ [32, p. 48] to prove (16) and (17). We use Taylor's theorem to expand the η -transform in (10) around z = 0 up to the second order,

$$\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z) = 1 + \mu_{1}z + \mu_{2}z^{2} + o(1)$$
(155)

as $z \rightarrow 0$. Evaluating the series-expansion of the RHS in the R-transform (15) yields

$$\frac{1 - \eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z)}{-z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z)} = \mu_{1} + (\mu_{2} - \mu_{1}^{2})z + o(1)$$
(156)

as $z \to 0$. Since $\eta_{A^T A}(0) = 1$ holds, we take the limit $z \to 0$ in (15) to obtain $R_{A^T A}(0) = \lim_{z \uparrow 0} R_{A^T A}(z \eta_{A^T A}(-z)) = \mu_1$. Similarly, we have

$$R'_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(0) = \lim_{z \uparrow 0} \frac{R_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z)) - \mu_{1}}{z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(-z)} = \mu_{2} - \mu_{1}^{2}.$$
(157)

Thus, Lemma 3 holds.

C. Proof of Lemma 4

We first confirm $\eta_{A^TA}(z) \in (0,1)$ for all z > 0. Since the positivity follows from the definition of the η -transform in (10), we need to prove $\eta_{A^TA}(z) < 1$. Applying the strict upper bound $1/(1 + \lambda_n z) < 1$ due to $\lambda_n z > 0$ to (11), we have

$$\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}(z) < \lim_{M=\delta N \to \infty} \left(\frac{r}{N} + 1 - \frac{r}{N}\right) = 1$$
(158)

for all z > 0.

We next prove the former properties. The properties for z = 0 follow from Lemma 3 and the assumption $\mu_1 > 0$. For all $z \in (z_{\min}, 0)$, on the other hand, we use $\eta_{A^T A}(z) \in (0, 1)$ for all z > 0 to find that the R-transform $R_{A^T A}(z)$ in (15) is positive for all $z \in (z_{\min}, 0)$. Thus, we arrive at the former properties.

Finally, we prove the latter properties. The properties for z = 0 follow from Lemma 3 and the assumption $\mu_2 > \mu_1^2$. Thus, we focus on the open interval $(z_{\min}, 0)$. Differentiating both sides in (15) with respect to z yields

$$R'_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(-z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}) = \frac{z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}\eta'_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}} + (1-\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}})(z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}})'}{(z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}})^2(z\eta_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}})'}.$$
(159)

Lemma 2 implies that $-z\eta_{A^TA}(z)$ is one-to-one mapping from $(0, \infty)$ onto $(z_{\min}, 0)$. Thus, it is sufficient to prove that the numerator in (159) is positive for all z > 0.

To prove the positivity of the numerator, we use definition of the η -transform in (11) to evaluate $(z\eta_{A^T}A)'$ as

$$(z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}})' = \lim_{M=\delta N \to \infty} \left\{ \frac{1}{N} \sum_{n=1}^{r} \frac{1}{(1+\lambda_{n}z)^{2}} + 1 - \frac{r}{N} \right\}$$
$$= \lim_{M=\delta N \to \infty} \frac{1}{N} \operatorname{Tr} \left\{ (\mathbf{I}_{N} + z\mathbf{A}^{\mathrm{T}}\mathbf{A})^{-2} \right\}. \quad (160)$$

Using this identity and the definition of the η -transform in (10), we find that the numerator in (159) reduces to

$$z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}\eta'_{\mathbf{A}^{\mathrm{T}}\mathbf{A}} + (1 - \eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}})(z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}})' = (z\eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}})' - \eta_{\mathbf{A}^{\mathrm{T}}\mathbf{A}}^{2}$$
$$= \lim_{M = \delta N \to \infty} \left\{ \frac{1}{N} \operatorname{Tr}\left(\mathbf{S}_{z}^{2}\right) - \left[\frac{1}{N} \operatorname{Tr}\left(\mathbf{S}_{z}\right)\right]^{2} \right\} \ge 0 \qquad (161)$$

for all z > 0, with $S_z = (I_N + zA^TA)^{-1}$, where the last inequality follows from Jensen's inequality. In particular, the equality holds only when all eigenvalues of S_z are identical, so that we have the strict inequality under the assumption $\mu_2 > \mu_1^2$. Thus, the latter properties hold.

APPENDIX C Proof of Theorem 2

A. Overview

The converse theorem is due to [4]. Thus, we only prove the achievability: The optimizer (E_{opt}, s_{opt}) is unique and noise-limited if $\delta > d_I$ holds. We use Lemma 6 to focus on the extremizers $(E, s) \in S$ in (24) in solving the inf-sup problem (23).

We classify the extremizers (24) into two classes: A first class contains noise-limited extremizers satisfying $\sigma^2 s > 0$ in the limit $\sigma^2 \downarrow 0$ while the other class includes interference-limited extremizers $\sigma^2 s \downarrow 0$ as $\sigma^2 \downarrow 0$. The noise-limited extremizers require diverging SINR $s \to \infty$ in the noiseless limit $\sigma^2 \downarrow 0$ while the interference-limited extremizers include extremizers with bounded SINR $s < \infty$ in the noiseless limit.

We prove the achievability by showing

$$\lim_{\sigma^{2} \downarrow 0} \frac{1}{\ln \sigma^{-2}} \left\{ f_{\rm RS}(E,s) + \frac{d_{\rm I}}{2} \ln \sigma^{2} \right\} = 0$$
 (162)

for the former class of extremizers $(s, E) \in S$ that satisfy $\sigma^2 s > 0$ in the limit $\sigma^2 \downarrow 0$. Otherwise, for any $\epsilon > 0$ and $\delta \neq d_{\rm I}$

$$\liminf_{\sigma^2 \downarrow 0} \frac{1}{\ln \sigma^{-2}} \left\{ f_{\rm RS}(s, E) + \frac{d_{\rm I}}{2} \ln \sigma^2 \right\} \ge \frac{\delta - d_{\rm I} - \epsilon}{2}$$
(163)

for the latter class of extremizers $(s, E) \in S$ satisfying $\sigma^2 s \downarrow 0$ as $\sigma^2 \downarrow 0$. The proofs of (162) and (163) are given in Appendices C-B and C-C, respectively.

We confirm that extremizers in the former class are the solution to the minimization problem (23) for $\delta > d_I$. Let $\epsilon = (\delta - d_I)/2 > 0$ in (163). Since the lower bound $(\delta - d_I - \epsilon)/2$ in (163) is positive, the left-hand side (LHS) of (163) is larger than that of (162). This observation implies that the former extremizers satisfying $\sigma^2 s > 0$ are the solution

to the minimization problem (23) of the replica-symmetric potential (3) for $\delta > d_{\rm I}$.

Extremizers in the former class satisfy $s \to \infty$ as $\sigma^2 \downarrow 0$, so that E = MMSE(s) must converge to zero. These observations imply that $(E_{\text{opt}}, s_{\text{opt}}) = (0, \infty)$ is the unique and global optimizer of (23) as $\sigma^2 \downarrow 0$. Thus, Theorem 2 holds.

B. Proof of (162)

We first prove the following result on the R-transform:

Lemma 12: Suppose that all moments $\{\mu_k\}$ are bounded and that $R_{\mathbf{A}^T\mathbf{A}}(z)$ is non-decreasing and non-negative for all $z \leq 0$. Then, the R-transform $R_{\mathbf{A}^T\mathbf{A}}(z)$ is bounded for all $z \leq 0$.

Proof: The boundedness of $R_{A^T A}(z)$ for $z \leq 0$ follows from $R_{A^T A}(0) = \mu_1 < \infty$, obtained from Lemma 3, and the assumptions for $R_{A^T A}(z)$.

We next prove the boundedness $\sigma^2 s < \infty$ and $E/\sigma^2 < \infty$ as $\sigma^2 \downarrow 0$ for the noise-limited extremizer $(E,s) \in S$ satisfying $\sigma^2 s > 0$ in the limit $\sigma^2 \downarrow 0$. From the definition of S in (24), we use Lemma 12 to have the boundedness $\sigma^2 s = R_{A^T A}(-E/\sigma^2) < \infty$ as $\sigma^2 \downarrow 0$. Furthermore, we utilize the upper bound $\text{MMSE}(s) \leq s^{-1}$ [28, Eq. (6)] to obtain $E/\sigma^2 = \text{MMSE}(s)/\sigma^2 \leq (\sigma^2 s)^{-1} < \infty$, because of the assumption $\sigma^2 s > 0$.

Finally, we prove the limit (162). Using a general formula [28, Theorem 6] between the mutual information and Rényi information dimension yields

$$I(s) = \frac{d_{\mathrm{I}}}{2} \ln s + o(\ln s) \tag{164}$$

as $s \to \infty$. Furthermore, we use [28, Theorem 8] to obtain $MMSE(s) = d_I/s + o(s^{-1})$ as $s \to \infty$, which implies

$$sE = s\text{MMSE}(s) = d_{\text{I}} + o(1). \tag{165}$$

Substituting the former formula (164) into the replicasymmetric potential (3), we have

$$f_{\rm RS}(s,E) + \frac{d_{\rm I}}{2} \ln \sigma^2 = o(\ln(\sigma^2 s) + \ln \sigma^{-2}) + \frac{d_{\rm I}}{2} \ln(\sigma^2 s) + \frac{1}{2} \int_0^{E/\sigma^2} R_{\mathbf{A}^{\rm T} \mathbf{A}}(-z) dz - \frac{sE}{2}, \quad (166)$$

where the last three terms are bounded, because of $0 < \sigma^2 s < \infty$, $E/\sigma^2 < \infty$, Lemma 12, and (165). Thus, we arrive at the limit (162).

C. Proof of (163)

We first prove the three properties $E/\sigma^2 \to \infty$, $s < \infty$, and E > 0 for the interference-limited extremizer $(s, E) \in S$ satisfying $\sigma^2 s \downarrow 0$ as $\sigma^2 \downarrow 0$. From the definition of S in (24), we have $R_{A^TA}(-E/\sigma^2) = \sigma^2 s \downarrow 0$ as $\sigma^2 \downarrow 0$. Since $R_{A^TA}(z)$ has been assumed to be positive for $z \le 0$, we have the first property $E/\sigma^2 \to \infty$.

Since the last property E = MMSE(s) > 0 follows from the second property $s < \infty$, we prove the second property $s < \infty$ by contradiction. Assume $s \to \infty$. The last assumption in Theorem 2 implies $(E/\sigma^2)R_{\mathbf{A}^T\mathbf{A}}(-E/\sigma^2) = \delta + o(1)$, because of $E/\sigma^2 \to \infty$. Using $R_{\mathbf{A}^T\mathbf{A}}(-E/\sigma^2) = \sigma^2 s$ in (24) yields $sE = \delta + o(1)$, which is a contradiction because of (165) in the limit $s \to \infty$ and $\delta \neq d_{\rm I}$. Thus, there are no extremizers $(s, E) \in S$ satisfying $s \to \infty$ and $\sigma^2 s \downarrow 0$ as $\sigma^2 \downarrow 0$.

We next prove the lower bound (163). Using the nonnegativity of mutual information, we lower-bound the replicasymmetric potential (3) as

$$f_{\rm RS}(s,E) \ge \frac{1}{2} \int_0^{E/\sigma^2} R_{A^{\rm T}A}(-z) dz - \frac{sE}{2}.$$
 (167)

Since s is bounded, $sE = sMMSE(s) < \infty$ is trivial. Thus, we can focus on the first term in the lower bound (167) to evaluate (163).

The last assumption in Theorem 2 implies that, for any $\epsilon > 0$, there is some $z_0 > 0$ such that $|zR_{A^TA}(-z) - \delta| < \epsilon$ holds for all $z > z_0$. Thus, we use $E/\sigma^2 \to \infty$ and the positivity assumption for $R_{A^TA}(z)$ to have

$$\lim_{\sigma^{2}\downarrow0} \inf \frac{1}{2\ln\sigma^{-2}} \int_{0}^{E/\sigma^{2}} R_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(-z)dz$$

>
$$\lim_{\sigma^{2}\downarrow0} \inf \frac{1}{2\ln\sigma^{-2}} \int_{z_{0}}^{E/\sigma^{2}} R_{\boldsymbol{A}^{\mathrm{T}}\boldsymbol{A}}(-z)dz$$

>
$$\lim_{\sigma^{2}\downarrow0} \inf \frac{1}{2\ln\sigma^{-2}} \int_{z_{0}}^{E/\sigma^{2}} \frac{\delta-\epsilon}{z}dz$$

$$= \frac{\delta-\epsilon}{2} \lim_{\sigma^{2}\downarrow0} \frac{\ln E + \ln\sigma^{-2} - \ln z_{0}}{\ln\sigma^{-2}} = \frac{\delta-\epsilon}{2}, \quad (168)$$

where the last follows from the fact that z_0 is independent of σ^2 , as well as E > 0. Combining these observations, we arrive at the lower bound (163).

APPENDIX D SUFFICIENT STATISTIC

A. Memoryless Processing

Consider a virtual AWGN measurement $Y_t[w] \in \mathbb{R}$ for $w \in \{0, \ldots, W\}$, given by

$$Y_t[w] = \gamma[l+w][l]X + Z_t[w], \quad Z_t[w] \sim \mathcal{N}(0, v_t[w]),$$
(169)

where X and $\{Z_t[w] : w \in \{0, ..., W\}\}$ are independent. The goal of this appendix is to derive a sufficient statistic for estimation of a scalar signal X given $\{Y_t[w]\}_{w=0}^W$.

To understand the significance of this problem, we use (44) to find that $X = x_n[l]$ is included only in $\{\vec{x}_n[l + w][w] : w \in \{0, \ldots, W\}\}$. Since $\vec{x}_{A \to B,t}[l + w]$ is an estimator of $|\mathcal{W}[l+w]|^{-1/2}\vec{x}[l+w]$, we associate $Y_t[w]$ with the message $\vec{x}_{A \to B,n,t}[l + w][w]$ to obtain the relationship $v_t[w] = v_{A \to B,t}[l+w]$.

We derive a sufficient statistic for estimation of X given $\{Y_t[w]\}_{w=0}^W$. Since $\{Z_t[w]\}$ are independent, we have the log likelihood

$$\ln p(\{Y_t[w]\}|X) = -\sum_{w=0}^{W} \frac{(Y_t[w] - \gamma[l+w][l]X)^2}{2v_t[w]} + \text{Const.}$$
(170)

Expanding the square implies that the sum $\sum_{w=0}^{W} \gamma[l + w][l]Y_t[w]/v_t[w]$ is a sufficient statistic for estimation of X given $\{Y_t[w]: w \in \{0, \ldots, W\}\}$.

Consider the following normalized sufficient statistic

$$S_t = \frac{\sum_{w=0}^{W} \gamma[l+w][l]Y_t[w]v_t^{-1}[w]}{\sum_{w=0}^{W} \gamma^2[l+w][l]v_t^{-1}[w]}.$$
(171)

Substituting the virtual measurement (169) into this expression, we have

$$S_t = X + Z_t, \quad Z_t = \frac{\sum_{w=0}^W \gamma[l+w][l] Z_t[w] v_t^{-1}[w]}{\sum_{w=0}^W \gamma^2[l+w][l] v_t^{-1}[w]}, \quad (172)$$

which is a zero-mean Gaussian random variable with variance

$$\mathbb{E}[Z_t^2] = \frac{1}{\sum_{w=0}^W \gamma^2 [l+w][l] v_t^{-1}[w]}.$$
 (173)

We derive the mean message $\boldsymbol{x}_{A\to B,t}^{suf}[l]$ and variance message $v_{A\to B,t}^{suf}[l]$. Applying $v_t[w] = v_{A\to B,t}[l+w]$ to (173) yields the variance message (47). Similarly, substituting $Y_t[w] = \vec{x}_{A\to B,n,t}[l+w][w] = x_{A\to B,n,t}[l][w]$ —obtained from (45)—and $v_t[w] = v_{A\to B,t}[l+w]$ into (172), we arrive at the mean message (46).

B. Long Memory Processing

Instead of the scalar AWGN measurement (169), consider the virtual AWGN measurement vector $\boldsymbol{Y}_t[w] \in \mathbb{R}^{1 \times (t+1)}$ for $w \in \{0, \dots, W\}$, given by

$$\boldsymbol{Y}_{t}[w] = \gamma[l+w][l]\boldsymbol{X}\boldsymbol{1}^{\mathrm{T}} + \boldsymbol{Z}_{t}[w], \quad \boldsymbol{Z}_{t}[w] \sim \mathcal{N}(\boldsymbol{0}, \boldsymbol{V}_{t}[w]),$$
(174)

where X and $\{\mathbf{Z}_t[w] : w \in \{0, ..., W\}\}$ are independent. The goal is to derive a sufficient statistic for estimation of a scalar signal X given $\{\mathbf{Y}_t[w]\}_{w=0}^W$. The significance of this problem is in the relationship $\mathbf{V}_t[w] = \mathbf{V}_{A \to B, t}[l+w]$ when $[\mathbf{Y}_t[w]]_{\tau}$ is associated with the corresponding element in the message $\vec{\mathbf{x}}_{A \to B, \tau}[l+w]$.

We derive a sufficient statistic for estimation of X given $\{Y_t[w]\}$. Since $\{Z_t[w]\}$ are independent, we have the log likelihood

$$\ln p(\{\boldsymbol{Y}_t[w]\}|X) = -\frac{1}{2} \sum_{w=0}^{W} (\boldsymbol{Y}_t[w] - \gamma[l+w][l]X\boldsymbol{1}^{\mathrm{T}})$$
$$\cdot \boldsymbol{V}_t^{-1}[w](\boldsymbol{Y}_t[w] - \gamma[l+w][l]X\boldsymbol{1}^{\mathrm{T}})^{\mathrm{T}} + \text{Const.} \quad (175)$$

Expanding the square, we find that the sum $\sum_{w=0}^{W} \gamma[l + w][l] \mathbf{Y}_t[w] \mathbf{V}_t^{-1}[w] \mathbf{1}$ is a sufficient statistic for estimation of X given $\{\mathbf{Y}_t[w]: w \in \{0, \dots, W\}\}$.

Consider the following normalized sufficient statistic

$$S_{t} = \frac{\sum_{w=0}^{W} \gamma[l+w][l] \boldsymbol{Y}_{t}[w] \boldsymbol{V}_{t}^{-1}[w] \boldsymbol{1}}{\sum_{w=0}^{W} \gamma^{2}[l+w][l] \boldsymbol{1}^{\mathrm{T}} \boldsymbol{V}_{t}^{-1}[w] \boldsymbol{1}}.$$
 (176)

Substituting the virtual measurement vector (174) into this expression, we have

$$S_{t} = X + Z_{t}, \quad Z_{t} = \frac{\sum_{w=0}^{W} \gamma[l+w][l] \mathbf{Z}_{t}[w] \mathbf{V}_{t}^{-1}[w] \mathbf{1}}{\sum_{w=0}^{W} \gamma^{2}[l+w][l] \mathbf{1}^{\mathrm{T}} \mathbf{V}_{t}^{-1}[w] \mathbf{1}},$$
(177)

where $\{Z_t\}$ are zero-mean Gaussian random variables with covariance

$$\mathbb{E}[Z_{t'}Z_t] = \frac{1}{\sum_{w=0}^{W} \gamma^2 [l+w][l] \mathbf{1}^{\mathrm{T}} \boldsymbol{V}_t^{-1}[w] \mathbf{1}}$$
(178)

for all $t' \leq t$.

We derive the mean message $\boldsymbol{x}_{A\to B,t}^{\text{suf}}[l]$ and covariance message $\boldsymbol{v}_{A\to B,t',t}^{\text{suf}}[l]$. Substituting $\boldsymbol{V}_t[w] = \boldsymbol{V}_{A\to B,t}[l+w]$ into (178) yields the covariance message (86). Similarly, associating $\boldsymbol{Y}_t[w]$ with each row of $\boldsymbol{X}_{A\to B,t+1}[l][w]$, as well as using $\boldsymbol{V}_t[w] = \boldsymbol{V}_{A\to B,t}[l+w]$, from (176) we arrive at the mean message (85).

APPENDIX E PROOFS OF COROLLARIES

A. Proof of Corollary 4

It is straightforward to confirm $R_{G[\ell]}(0) = R(0)$ since Lemma 3 and Assumption 3 imply $R_{G[\ell]}(0) = 1$.

We next prove that the condition (72) in Theorem 4 holds for z < 0. From the representation of the R-transform in (15) we obtain

$$R_{\boldsymbol{G}[\ell]}\left(-\frac{z\eta_{\boldsymbol{G}[\ell]}(z/|\mathcal{W}[\ell]|)}{|\mathcal{W}[\ell]|}\right) = \frac{|\mathcal{W}[\ell]|\{1-\eta_{\boldsymbol{G}[\ell]}(z/|\mathcal{W}[\ell]|)\}}{z\eta_{\boldsymbol{G}[\ell]}(z/|\mathcal{W}[\ell]|)}$$
(179)

Since the normalized rank $r[\ell]/N$ has been assumed to converge toward δ in the large system limit, repeating the derivation of the η -transform (11) for $G[\ell]$ yields

$$\eta_{\boldsymbol{G}[\ell]}\left(\frac{z}{|\mathcal{W}[\ell]|}\right) = 1 - \frac{\delta}{|\mathcal{W}[\ell]|} + \lim_{M=\delta N \to \infty} \frac{1}{|\mathcal{W}[\ell]|N} \sum_{n=1}^{r[\ell]} \frac{1}{1 + \lambda_n[\ell]z/|\mathcal{W}[\ell]|}.$$
 (180)

Applying the assumption (75) in Corollary 4 to the η -transform $\eta_{\boldsymbol{G}[\ell]}(z/|\mathcal{W}[\ell]|)$ in (180) yields

$$\eta_{\boldsymbol{G}[\ell]}(z/|\mathcal{W}[\ell]|) = 1 + \mathcal{O}(|\mathcal{W}[\ell]|^{-1})$$
(181)

in the continuum limit. Similarly, we have

$$|\mathcal{W}[\ell]|\left\{1 - \eta_{\boldsymbol{G}[\ell]}\left(\frac{z}{|\mathcal{W}[\ell]|}\right)\right\} = 1 - \eta(z) + \mathcal{O}(a_W^{-1}) \quad (182)$$

in the continuum limit. Using (181) and (182), we find that the R-transform (179) reduces to

$$R_{\boldsymbol{G}[\ell]}\left(-\frac{z}{|\mathcal{W}[\ell]|}\right) = \frac{1-\eta(z)}{z} + \mathcal{O}(a_W^{-1}) \tag{183}$$

for z > 0, where we have used Proposition 3. Thus, the condition (72) holds for $R(-z) = \{1 - \eta(z)\}/z$ for z > 0.

Finally, we prove that R(z) satisfies $\lim_{z\to\infty} zR(-z) = \delta$ or equivalently $\lim_{z\to\infty} \eta(z) = 1 - \delta$. From the assumption (75) in Corollary 4, it is sufficient to prove

$$\lim_{z \to \infty} \lim_{W = \Delta L \to \infty} \lim_{M = \delta N \to \infty} \frac{1}{N} \sum_{n=1}^{r[\ell]} \frac{1}{1 + \lambda_n[\ell] z / |\mathcal{W}[\ell]|} = 0.$$
(184)

Since the summation is bounded from above by δ , we can interchange the limit $z \to \infty$ and the other two limits to arrive at (184).

B. Proof of Corollary 6

The representation (78) implies that R(z) is proper, twice continuously differentiable, strictly increasing, and positive for all $z \leq 0$. Thus, it is sufficient to prove the condition (75) in Corollary 4.

We know that the *k*th moment $\mu_k[\ell]$ of the asymptotic eigenvalue distribution of $G[\ell]$ is given by $\mu_k[\ell] = |\mathcal{W}[\ell]|^{k-1}\mu_k$ for k > 0 [54, Eq. (64)], with

$$\mu_k = \left(\frac{C}{1-\kappa^{-2}}\right)^k \frac{1-\kappa^{-2k}}{Ck},\tag{185}$$

which is equal to the *k*th moment of the asymptotic eigenvalue distribution of $G[\ell]$ for $|\mathcal{W}[\ell]| = 1$. Thus, we use the series-expansion $(1+z)^{-1} = \sum_{k=0}^{\infty} (-z)^k$ for all |z| < 1 to have

$$\lim_{M=\delta N\to\infty} \frac{1}{N} \sum_{n=1}^{r[\ell]} \frac{1}{1+\lambda_n[\ell]z/|\mathcal{W}[\ell]|} = \delta + \lim_{M=\delta N\to\infty} \frac{1}{|\mathcal{W}[\ell]|N} \sum_{n=1}^{r[\ell]} \sum_{k=1}^{\infty} \frac{\lambda_n^k[\ell](-z)^k}{|\mathcal{W}[\ell]|^{k-1}} = \delta + \sum_{k=1}^{\infty} \mu_k(-z)^k = \delta - \frac{1}{C} \ln\left(\frac{\kappa^2 - 1 + \kappa^2 Cz}{\kappa^2 - 1 + Cz}\right) (186)$$

where the last follows from [54, Eq. (65)]. This implies that the condition (75) in Corollary 4 holds for $\eta(z)$, given by

$$\eta(z) = 1 - \frac{1}{C} \ln\left(\frac{\kappa^2 - 1 + \kappa^2 C z}{\kappa^2 - 1 + C z}\right).$$
 (187)

We next evaluate $R(z) = \{\eta(-z)-1\}/z$, which satisfies the condition (72) in Theorem 4 from Corollary 4. By definition,

$$R(z) = -\frac{1}{Cz} \ln\left(\frac{\kappa^2 - 1 - \kappa^2 Cz}{\kappa^2 - 1 - Cz}\right)$$
(188)

for z < 0, with R(0) = 1. It is straightforward to confirm that R(z) can be represented as (78) for $z \le 0$.

APPENDIX F PROOF OF PROPOSITION 4

A. Overview

The proof is by induction. The proof for t = 0 is omitted since it is the same as that for general t. The remaining proof consists of two steps. In a first step, for some t, we assume that $\vec{x}_{B\to A,\tau}[\ell]$ in (92) and $v_{B\to A,\tau',\tau}[\ell]$ in (93) or (94) are respectively equal to $\vec{x}_{B\to A,\tau}[\ell]$ in (53) and $v_{B\to A,\tau}[\ell]$ in (55) for all $\tau \in \{0, \ldots, t\}$ and $\tau' \in \{0, \ldots, \tau\}$. We need to prove that $\vec{x}_{A\to B,t}[\ell]$ in (83) and $v_{A\to B,t',t}[\ell]$ in (84) are equal to (41) and (43) in OAMP for all $t' \in \{0, \ldots, t\}$.

In the second step, we postulate that $\vec{x}_{A\to B,\tau}[\ell]$ in (83) and $v_{A\to B,\tau',\tau}[\ell]$ in (84) are respectively equal to $\vec{x}_{A\to B,\tau}[\ell]$ in (53) and $v_{A\to B,\tau}[\ell]$ in (55) for all $\tau \in \{0,\ldots,t\}$ and $\tau' \in \{0,\ldots,\tau\}$. We need to prove that $\vec{x}_{B\to A,t+1}[\ell]$ in (92) and $v_{B\to A,t',t+1}[\ell]$ in (93) or (94) are equal to (53) and (55) in OAMP for all $t' \in \{0,\ldots,t+1\}$. These proofs by induction imply that Proposition 4 holds.

B. Proof for module A

For some t, assume that $\vec{x}_{B\to A,\tau}[\ell]$ in (92) and $v_{B\to A,\tau',\tau}[\ell]$ in (93) or (94) are respectively equal to $\vec{x}_{B\to A,\tau}[\ell]$ in (53) and $v_{B\to A,\tau}[\ell]$ in (55) for all $\tau \in \{0,\ldots,t\}$ and $\tau' \in \{0,\ldots,\tau\}$. We first prove that the posterior messages $\vec{x}_{A,t}^{\text{post}}[\ell]$ and $v_{A,t',t}^{\text{post}}[\ell]$ in LM-OAMP are equivalent to those in OAMP when the LMMSE filter (81) is used.

Under the induction hypothesis on the equivalence between (53) and (92) for $\vec{x}_{B\to A,t}[\ell]$, as well as $v_{B\to A,t,t}[\ell] = v_{B\to A,t}[\ell]$, we find that $\vec{x}_{A,t}^{\text{post}}[\ell]$ in (79) is equal to (35) for OAMP. By substituting the LMMSE filter (81) into the definition of $v_{A,t',t}^{\text{post}}[\ell]$ in (80), it is straightforward to confirm that, under the induction hypothesis $v_{B\to A,t',t}[\ell] = v_{B\to A,t}[\ell]$, the posterior covariance $v_{A,t',t}^{\text{post}}[\ell]$ reduces to

$$v_{\mathrm{A},t',t}^{\mathrm{post}}[\ell] = \eta_{\mathrm{A},t}[\ell] v_{\mathrm{B}\to\mathrm{A},t}[\ell]$$
(189)

for all $t' \in \{0, \ldots, t\}$, with $\eta_{A,t}[\ell]$ defined in (40). This expression implies $v_{A,t',t}^{\text{post}}[\ell] = v_{A,t}^{\text{post}}[\ell]$ given in (39) for all $t' \in \{0, \ldots, t\}$.

We next prove the equivalence between OAMP and LM-OAMP for the extrinsic messages in module A. Since we have already proved the equivalence between (35) and (79) for $\vec{x}_{A,t}^{\text{post}}[\ell]$, we find that $\vec{x}_{A\to B,t}[\ell]$ in (83) is the same as (41) in OAMP under the induction hypothesis. For the extrinsic covariance (84), we use the identity (189) for the LMMSE filter and the induction hypothesis $v_{B\to A,t',t}[\ell] = v_{B\to A,t}[\ell]$ to obtain

$$v_{A\to B,t',t}[\ell] = \frac{1}{|\mathcal{W}[\ell]|} \frac{\eta_{A,t}[\ell] v_{B\to A,t}[\ell]}{1 - \eta_{A,t}[\ell]}, \qquad (190)$$

which is equal to (43) in OAMP.

C. Proof for module B

Assume that $\vec{x}_{A\to B,\tau}[\ell]$ in (83) and $v_{A\to B,\tau',\tau}[\ell]$ in (84) are respectively equal to $\vec{x}_{A\to B,\tau}[\ell]$ in (41) and $v_{A\to B,\tau}[\ell]$ in (43) for all $\tau \in \{0, \ldots, t\}$ and $\tau' \in \{0, \ldots, \tau\}$. We first prove that $x_{A\to B,t}^{suf}[l]$ in (85) and $v_{A\to B,t',t}^{suf}[l]$ in (86) are respectively equal to (46) and (47) for OAMP.

As proved in [49, Lemma 3], we use the positivedefiniteness assumption of $V_{A\to B,t}$ and the induction hypothesis $v_{A\to B,\tau',\tau}[\ell] = v_{A\to B,\tau}[\ell]$ for all $\tau \in \{0,\ldots,t\}$ and $\tau' \in \{0,\ldots,\tau\}$ to obtain

$$\boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}\boldsymbol{1} = \boldsymbol{v}_{\mathrm{A}\to\mathrm{B},t}^{-1}\boldsymbol{e}_t.$$
 (191)

Using the identity (191), we find that $v_{A\to B,t',t}^{\text{suf}}[l]$ in (86) reduces to $v_{A\to B,t}^{\text{suf}}[l]$ in (47) for all $t' \in \{0, \ldots, t\}$. Similarly, $x_{A\to B,t}^{\text{suf}}[l]$ in (85) is equal to (46) for OAMP.

We have proved that the second step in LM-OAMP is equivalent to that in OAMP. In this sense, Bayes-optimal LM-OAMP is regarded as a tool to prove that $x_{A\to B,t}^{suf}[l]$ in Bayes-optimal OAMP is a sufficient statistic for estimation of x[l] given not only $\{\vec{x}_{A\to B,t}[\ell]\}$ but also given the preceding messages $\{\vec{x}_{A\to B,\tau}[\ell]\}$ for all $\tau < t$.

We next prove that $\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ in (87) and $\boldsymbol{v}_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[l]$ in (88) are respectively equal to $\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ in (48) and $\boldsymbol{v}_{\mathrm{B},t+1}^{\mathrm{post}}[l]$ in (50) for all $t' \in \{0, \ldots, t\}$. Since we have proved the equivalence between the second steps in module B for OAMP

and LM-OAMP, it is trivial that (87) is equivalent to (48). From the identity $v_{A \to B, t', t}^{suf}[l] = v_{A \to B, t}^{suf}[l]$ for all $t' \in \{0, \ldots, t\}$, on the other hand, we use [49, Lemma 2] for the Bayes-optimal denoiser to obtain $v_{B,t'+1,t+1}^{post}[l] = v_{B,t+1}^{post}[l]$ in (50) for all $t' \in \{0, \ldots, t\}$.

Finally, we prove that $\vec{x}_{B\to A,t+1}[\ell]$ in (92) and $v_{B\to A,t',t+1}[\ell]$ in (93) or (94) are respectively equal to (53) and (55) in OAMP for all $t' \in \{0, \ldots, t+1\}$. We use the identity (191) and $v_{A\to B,t,t}^{suf}[l] = v_{A\to B,t}^{suf}[l]$ to find that $\eta_{B,t}[\ell][w]$ in (90) is equivalent to (52) for OAMP. For (89) we use the identity (191) to have $\eta_{B,t,t}[\ell][w] = \eta_{B,t}[\ell][w]$ and $\eta_{B,\tau,t}[\ell][w] = 0$ for all $\tau \neq t$. These observations imply that $\vec{x}_{B\to A,t+1}[\ell]$ in (92) is equal to (53) for OAMP.

Consider $v_{B\to A,t'+1,t+1}[\ell]$ for $t' \in \{0, \ldots, t\}$. Applying the identity $\langle f'_{opt}(\boldsymbol{x}_{A\to B,t}^{suf}[l]; v_{A\to B,t}^{suf}[l]) \rangle = v_{B,t+1}^{post}[l]/v_{A\to B,t}^{suf}[l]$ for the Bayes-optimal denoiser to the definition of $\eta_{B,t}[\ell][w]$ in (52) yields

$$\eta_{\mathrm{B},t}[\ell][w]v_{\mathrm{A}\to\mathrm{B},t}[\ell] = |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]v_{\mathrm{B},t+1}^{\mathrm{post}}[\ell-w].$$
(192)

Substituting (192) into the definition of $v_{B\to A,t'+1,t+1}[\ell]$ in (93) with $v_{B,t'+1,t+1}^{\text{post}}[\ell-w] = v_{B,t+1}^{\text{post}}[\ell-w]$ for all $t' \in \{0,\ldots,t\}$ and using the definition of $\eta_{B,t}[\ell]$ in (51) and the identity (191), we arrive at

$$v_{\rm B\to A, t'+1, t+1}[\ell] = \frac{\eta_{\rm B, t}[\ell] v_{\rm A\to B, t}[\ell]}{1 - \eta_{\rm B, t}[\ell] / |\mathcal{W}[\ell]|},$$
(193)

which is equivalent to (55) for OAMP.

Consider $v_{B\to A,0,t+1}[\ell]$ given in (94). From the definition of $v_{B\to A,0,t+1}^{\text{post}}[\ell]$ in (95), we have $v_{B\to A,0,t+1}^{\text{post}}[\ell] = v_{B\to A,t+1}^{\text{post}}[\ell]$ given in (50). Substituting this identity into (94) and using the identity (192) and the definition of $\eta_{B,t}[\ell]$ in (51), we arrive at

$$v_{\mathrm{B}\to\mathrm{A},0,t+1}[\ell] = \frac{\eta_{\mathrm{B},t}[\ell]v_{\mathrm{A}\to\mathrm{B},t}[\ell]}{1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|},$$
(194)

which is equivalent to (55) for OAMP.

APPENDIX G PROOF OF THEOREM 5

A. Overview

Theorem 5 is a generalization of conventional state evolution [42], [46] to the long-memory and spatial coupling cases. We follow [54] to treat the long-memory case. The spatial coupling case was addressed only for zero-mean i.i.d. Gaussian matrices in existing state evolution [17], [19]. This paper generalizes the existing state evolution to the spatial coupling case for right-orthogonally invariant matrices.

The proof of Theorem 5 consists of three steps: A first step is to propose a general error model for the spatial coupling case and prove the inclusion of the error models for both OAMP and LM-OAMP in the proposed general error model. The general error model should be defined so as to realize the asymptotic Gaussianity of errors. Unless the general error model is defined appropriately, the errors are not Gaussiandistributed. The design guideline is to define the general error model such that it can be analyzed via a natural generalization of conventional state evolution [54]. The last step is to prove the state evolution recursions for both OAMP and LM-OAMP via the state evolution analysis in the second step. The last step itself is elementary since all evaluation tools needed in the last step are prepared in the second step.

B. Pseudo-Lipschitz Function

Before presenting the proposed general error model, we follow [54, Section II-A] to define pseudo-Lipschitz functions. They are used to regularize separable functions in the proposed general error model for the spatial coupling case.

Definition 5: A function $f : \mathbb{R}^t \to \mathbb{R}$ is said to be pseudo-Lipschitz of order k [8] if there are some Lipschitz constant L > 0 and some order $k \in \mathbb{N}$ such that for all $x \in \mathbb{R}^t$ and $y \in \mathbb{R}^t$ the following holds:

$$|f(\boldsymbol{x}) - f(\boldsymbol{y})| \le L(1 + \|\boldsymbol{x}\|^{k-1} + \|\boldsymbol{y}\|^{k-1})\|\boldsymbol{x} - \boldsymbol{y}\|.$$
 (195)

The first-order pseudo-Lipschitz property is equivalent to the Lipschitz-continuity. The Lipschitz constant L can depend on the dimension t, which is finite throughout state evolution analysis.

To use [54, Lemma 3] sequentially, we use the following proposition, which is explicitly presented in this paper while it was implicitly used in existing state evolution [46], [54].

Proposition 6: Suppose that $f : \mathbb{R}^t \to \mathbb{R}$ is pseudo-Lipschitz of order k and consider the vector of variables $\boldsymbol{x} = (\boldsymbol{x}_1, \boldsymbol{x}_2) \in$ $\mathbb{R}^{1 \times t}$ with two sections \boldsymbol{x}_1 and \boldsymbol{x}_2 . Then, the marginalized function $g(\boldsymbol{x}_2) = \mathbb{E}_{\boldsymbol{x}_1}[f(\boldsymbol{x}_1, \boldsymbol{x}_2)]$ over the first section \boldsymbol{x}_1 is pseudo-Lipschitz of order k if $\mathbb{E}[\|\boldsymbol{x}_1\|^{k-1}]$ is bounded.

Proof: We first prove

$$(a+b)^p \le \max\{1, 2^{p-1}\}(a^p + b^p) \tag{196}$$

for all $a, b \ge 0$ and p > 0. For $p \in (0, 1]$, we let $q = 1/p \ge 1$ to have $(a + b)^p = \{(a^{1/q})^q + (b^{1/q})^q\}^{1/q} \le a^{1/q} + b^{1/q}$, because of $\|\cdot\|_q \le \|\cdot\|_1$ for the *q*-norm $\|\cdot\|_q$. For p > 1, on the other hand, we use Hölder's inequality to obtain $a + b \le 2^{1-1/p}(a^p + b^p)^{1/p}$. Thus, we arrive at (196).

We next prove that g is pseudo-Lipschitz. Since f is pseudo-Lipschitz of order k, we have

$$|g(\boldsymbol{x}_{2}) - g(\boldsymbol{y}_{2})| = |\mathbb{E}_{\boldsymbol{x}_{1}} \left[f(\boldsymbol{x}_{1}, \boldsymbol{x}_{2}) - f(\boldsymbol{x}_{1}, \boldsymbol{y}_{2}) \right]|$$

$$\leq L \left\{ 1 + \mathbb{E}_{\boldsymbol{x}_{1}} \left[(\|\boldsymbol{x}_{1}\|^{2} + \|\boldsymbol{x}_{2}\|^{2})^{(k-1)/2} \right] + \mathbb{E}_{\boldsymbol{x}_{1}} \left[(\|\boldsymbol{x}_{1}\|^{2} + \|\boldsymbol{y}_{2}\|^{2})^{(k-1)/2} \right] \right\} \|\boldsymbol{x}_{2} - \boldsymbol{y}_{2}\| \quad (197)$$

for some Lipschitz constant L > 0. For k = 1, the function g is obviously Lipschitz-continuous.

For k > 1, we use the inequality (196) to obtain

$$\mathbb{E}_{\boldsymbol{x}_{1}}\left[(\|\boldsymbol{x}_{1}\|^{2}+\|\boldsymbol{u}\|^{2})^{(k-1)/2}\right] \leq \max\{1, 2^{(k-3)/2}\} \left(\mathbb{E}\left[\|\boldsymbol{x}_{1}\|^{k-1}\right]+\|\boldsymbol{u}\|^{k-1}\right) \quad (198)$$

for $u = x_2$ and $u = y_2$. Thus, the function g is pseudo-Lipschitz of order k.

Separable vector-valued functions are used in state evolution analysis. A vector-valued function $\boldsymbol{f} = (f_1, \ldots, f_N)^T$ is said to be pseudo-Lipschitz if all element functions $\{f_n\}$ are pseudo-Lipschitz.

Definition 6: A vector-valued function $\boldsymbol{f} : \mathbb{R}^{N \times t} \to \mathbb{R}^N$ is said to be separable if $[\boldsymbol{f}(\boldsymbol{x}_1, \ldots, \boldsymbol{x}_t)]_n = f_n(x_{n,1}, \ldots, x_{n,t})$ holds for all n.

Definition 7: A separable pseudo-Lipschitz function f: $\mathbb{R}^{N \times t} \to \mathbb{R}^N$ is said to be proper if the Lipschitz constant $L_n > 0$ for the *n*th function f_n satisfies

$$\limsup_{N \to \infty} \frac{1}{N} \sum_{n=1}^{N} L_n^j < \infty$$
(199)

for any $j \in \mathbb{N}$.

This paper considers separable, Lipschitz-continuous, and proper denoisers while separable, pseudo-Lipschitz, and proper functions are used to treat general performance measure. In particular, pseudo-Lipschitz functions of order k = 2 are used for the error covariance.

C. General Error Model with Spatial Coupling

We define a general error model for the spatial coupling case. The proposed general error model is a discrete-time dynamical system with respect to six vectors $\vec{b}_t[\ell]$, $\vec{m}_t^{\text{post}}[\ell]$, $\vec{m}_t^{\text{ext}}[\ell]$, $\vec{d}_t^{\text{post}}[\ell]$, and $\vec{q}_t^{\text{ext}}[\ell]$ in the extended signal space $\mathbb{R}^{N_c[\ell]}$ for iteration $t = 0, 1, \ldots$ and row section index $\ell \in \mathcal{L}_W$.

To present the proposed general error model, we write the SVD of $\boldsymbol{A}[\ell] \in \mathbb{R}^{M[\ell] \times N_c[\ell]}$ defined in (29) as $\boldsymbol{A}[\ell] = \boldsymbol{U}[\ell]\boldsymbol{\Sigma}[\ell]\boldsymbol{V}^{\mathrm{T}}[\ell]$. We define $\boldsymbol{B}_t[\ell] = (\boldsymbol{b}_0[\ell], \dots, \boldsymbol{b}_{t-1}[\ell]) \in \mathbb{R}^{N_c[\ell] \times t}$. The matrices $\boldsymbol{\tilde{M}}_t^{\mathrm{ext}}[\ell]$, $\boldsymbol{H}_t[\ell]$, and $\boldsymbol{\tilde{Q}}_t^{\mathrm{ext}}[\ell]$ are defined in the same manner as for $\boldsymbol{B}_t[\ell]$.

For $N_c = \max_{\ell \in \mathcal{L}_W} N_c[\ell]$, we let $\mathcal{B}_t = \{[\vec{B}_t^T[\ell], O]^T \in \mathbb{R}^{N_c \times t} : \ell \in \mathcal{L}_W\}, \Omega = \{[(U^T[\ell]n[\ell])^T, \mathbf{0}^T]^T \in \mathbb{R}^{N_c} : \ell \in \mathcal{L}_W\}$, and $\Lambda = \{[\vec{\lambda}^T[\ell], \mathbf{0}]^T \in \mathbb{R}^{N_c} : \ell \in \mathcal{L}_W\}$, in which $\vec{\lambda}[\ell] \in \mathbb{R}^{N_c[\ell]}$ is a vector that consists of all eigenvalues of $A^T[\ell]A[\ell]$. Similarly, we define $\mathcal{H}_t = \{[\vec{H}_t^T[\ell], O]^T \in \mathbb{R}^{N_c \times t} : \ell \in \mathcal{L}_W\}$ and $\mathcal{X} = \{(\operatorname{diag}\{\mathbf{1}_{N_c[\ell]}, \mathbf{0}\}, O)P_x[\ell]\mathbf{x} \in \mathbb{R}^{N_c} : \ell \in \mathcal{L}_W\}$ for deterministic $N_{\operatorname{all}} \times N_{\operatorname{all}}$ permutation matrices $\{P_x[\ell]\}$. The permutation matrix $P_x[\ell]$ are used to extract $N_c[\ell]$ desired elements from the signal vector \mathbf{x} .

For vector-valued functions $\phi_t[\ell] : \mathbb{R}^{N_c \times (t+3)|\mathcal{L}_W|} \to \mathbb{R}^{N_c}$ and $\psi_t[\ell] : \mathbb{R}^{N_c \times (t+2)|\mathcal{L}_W|} \to \mathbb{R}^{N_c}$, the general error model for the spatial coupling case is given by

$$\vec{\boldsymbol{b}}_t[\ell] = \boldsymbol{V}^{\mathrm{T}}[\ell] \vec{\boldsymbol{q}}_t^{\mathrm{ext}}[\ell], \qquad (200)$$

$$\vec{\boldsymbol{m}}_{t}^{\text{post}}[\ell] = (\boldsymbol{I}_{N_{\text{c}}[\ell]}, \boldsymbol{O}) \boldsymbol{\phi}_{t}[\ell](\mathcal{B}_{t+1}, \Omega, \Lambda),$$
(201)

$$\vec{\boldsymbol{m}}_{t}^{\text{ext}}[\ell] = \vec{\boldsymbol{m}}_{t}^{\text{post}}[\ell] - \sum_{\tau=0}^{\iota} \xi_{\text{A},\tau,t}[\ell] \vec{\boldsymbol{b}}_{\tau}[\ell], \qquad (202)$$

$$\vec{h}_t[\ell] = \boldsymbol{V}[\ell] \vec{\boldsymbol{m}}_t^{\text{ext}}[\ell], \qquad (203)$$

$$\vec{\boldsymbol{q}}_{t+1}^{\text{post}}[\ell] = (\boldsymbol{I}_{N_{c}[\ell]}, \boldsymbol{O})\boldsymbol{\psi}_{t}[\ell](\mathcal{H}_{t+1}, \mathcal{X}), \quad (204)$$

$$\vec{q}_{t+1}^{\text{ext}}[\ell] = \vec{q}_{t+1}^{\text{post}}[\ell] - \sum_{\tau=0}^{t} \xi_{\mathrm{B},\tau,t}[\ell] \vec{h}_{\tau}[\ell], \qquad (205)$$

with the initial condition $\vec{q}_0^{\text{ext}}[\ell] = (I_{N_c[\ell]}, O)\psi_{-1}[\ell](\mathcal{X})$. In (202) and (205), $\xi_{A,\tau,t}[\ell] \in \mathbb{R}$ and $\xi_{B,\tau,t}[\ell] \in \mathbb{R}$ are given by

$$\xi_{\mathrm{A},\tau,t}[\ell] = \frac{1}{N_{\mathrm{c}}[\ell]} \sum_{n=1}^{N_{\mathrm{c}}[\ell]} \partial_{(t+1)\ell+\tau} [\vec{m}_{t}^{\mathrm{post}}[\ell]]_{n}, \qquad (206)$$

$$\xi_{\mathrm{B},\tau,t}[\ell] = \frac{1}{N_{\mathrm{c}}[\ell]} \sum_{n=1}^{N_{\mathrm{c}}[\ell]} \partial_{(t+1)\ell+\tau} \left[\vec{\boldsymbol{q}}_{t+1}^{\mathrm{post}}[\ell] \right]_{n}.$$
 (207)

The Onsager correction of $\vec{m}_t^{\text{post}}[\ell]$ and $\vec{q}_{t+1}^{\text{post}}[\ell]$ in (202) and (205) has been defined so as to realize the asymptotic Gaussianity for the vectors $\vec{b}_t[\ell]$ and $\vec{h}_t[\ell]$ in the large system limit. The significance of the Onsager correction should be understood via state evolution in the second step.

Assumption 7: The function $\phi_t[\ell]$ is separable with respect to all variables and proper Lipschitz-continuous with respect to \mathcal{B}_{t+1} and Ω while $\psi_t[\ell]$ is separable and proper Lipschitz-continuous with respect to all variables. Furthermore, $\|\vec{m}_t^{\text{ext}}[\ell]\| \neq 0$ and $\|\vec{q}_{t+1}^{\text{ext}}[\ell]\| \neq 0$ hold for all t.

The properties $\|\vec{m}_t^{\text{ext}}[\ell]\| \neq 0$ and $\|\vec{q}_{t+1}^{\text{ext}}[\ell]\| \neq 0$ are required to guarantee the positive definiteness of the covariance matrix $V_{A\to B,t}[\ell]$ in the large system limit. Intuitively, $\|\vec{m}_t^{\text{ext}}[\ell]\| = 0$ or $\|\vec{q}_{t+1}^{\text{ext}}[\ell]\| = 0$ implies that asymptotically zero MSE is achieved in iteration t. Thus, additional iteration cannot improve the MSE anymore.

A general error model proposed in [54] was used to conduct state evolution of LM-MP in the conventional system (1) without spatial coupling, such as CAMP [54], MAMP [57], WS-CG VAMP [58], [59], and LM-OAMP [49]. Furthermore, it was utilized in [74] to reproduce state evolution for AMP [8]. The proposed general error model (200)–(205) can be applied to state evolution of such LM-MP algorithms in the spatially coupled system (31). Furthermore, it may be utilized to reproduce state evolution of AMP for the spatial coupling case [17]. Since such applications are outside the scope of this paper, however, we focus on state evolution analysis for LM-OAMP in the spatially coupled system.

The following lemma implies that the general error model contains error models for both OAMP and LM-OAMP in the spatially coupled system (31):

Lemma 13: Suppose that Assumption 3–6 hold. Let $\vec{q}_0^{\text{ext}}[\ell] = -\vec{x}[\ell]$,

$$\vec{m}_{t}^{\text{post}}[\ell] = |\mathcal{W}[\ell]|^{-1/2} \frac{V^{\text{T}}[\ell](\vec{x}_{\text{A},t}^{\text{post}}[\ell] - \vec{x}[\ell])}{1 - \bar{\eta}_{\text{A},t}[\ell]}, \qquad (208)$$

and

$$\vec{\boldsymbol{q}}_{t+1}^{\text{post}}[\ell] = \frac{\sqrt{|W[\ell]|} \boldsymbol{\Gamma}[\ell] \boldsymbol{x}_{\text{B},t+1}^{\text{post}} - \vec{\boldsymbol{x}}[\ell]}{1 - \bar{\eta}_{\text{B},t}[\ell] / |\mathcal{W}[\ell]|}.$$
 (209)

The messages $\vec{x}_{A,t}^{\text{post}}[\ell]$, $\bar{\eta}_{A,t}[\ell]$, $x_{B,t+1}^{\text{post}}$, and $\bar{\eta}_{B,t}[\ell]$ are given in (79), (59), (87), and (101) for LM-OAMP, respectively, while they are given in (35), (59), (48), and (63) for OAMP.

• If $\vec{q}_t^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B \to A,t}[\ell] - \vec{x}[\ell] + o(1)$ holds in the large system limit and if $\eta_{A,t}[\ell]$ in (40) converges almost surely

to $\bar{\eta}_{\mathrm{A},t}[\ell]$, then $\vec{h}_t[\ell] \stackrel{\mathrm{a.s.}}{=} \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ and the properties for $\phi_t[\ell]$ in Assumption 7 hold.

• If $\vec{h}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A\to B,\tau}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ holds in the large system limit for all $\tau \in \{0, \ldots, t\}$, if $V_{A\to B,t}[\ell]$ given via (84) converges almost surely to positive definite $\bar{V}_{A\to B,t}[\ell]$ for LM-OAMP, and if $\eta_{B,t}[\ell]$ in (51) converges almost surely to $\bar{\eta}_{B,t}[\ell]$, then $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell] + o(1)$ and the properties for $\psi_t[\ell]$ in Assumption 7 hold.

Proof: We only prove Lemma 13 for LM-OAMP since the lemma for OAMP can be proved in the same manner as for LM-OAMP. Prove the former statement. By proving the following identity:

$$\vec{\boldsymbol{m}}_{t}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \boldsymbol{V}^{\mathrm{T}}[\ell](\vec{\boldsymbol{x}}_{\mathrm{A}\to\mathrm{B},t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{\boldsymbol{x}}[\ell]) + o(1),$$
(210)

we use the definition of $\vec{h}_t[\ell]$ in (203) to arrive at $\vec{h}_t[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A\to B,t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1).$

We first evaluate the LHS in (210). Substituting the definition of $\vec{x}_{A,t}^{\text{post}}[\ell]$ in (79) into (208) and using the spatially coupled system (31), the SVD $\boldsymbol{A}[\ell] = \boldsymbol{U}[\ell]\boldsymbol{\Sigma}[\ell]\boldsymbol{V}^{\mathrm{T}}[\ell]$, and $\boldsymbol{F}_t[\ell] = \boldsymbol{U}[\ell]\boldsymbol{\Sigma}_{\boldsymbol{F}_t[\ell]}\boldsymbol{V}^{\mathrm{T}}[\ell]$ in Assumption 5, we have

$$\sqrt{|\mathcal{W}[\ell]|} (1 - \bar{\eta}_{\mathrm{A},t}[\ell]) \vec{\boldsymbol{m}}_{t}^{\mathrm{post}}[\ell] = \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{U}^{\mathrm{T}}[\ell] \boldsymbol{n}[\ell] + (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell]) \boldsymbol{V}^{\mathrm{T}}[\ell] (\vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},t}[\ell] - \vec{\boldsymbol{x}}[\ell]). (211)$$

Under the assumption $\vec{q}_t^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t}[\ell] - \vec{x}[\ell] + o(1)$, we use the definition of $\vec{b}_t[\ell]$ in (200) to find

$$\sqrt{|\mathcal{W}[\ell]|} (1 - \bar{\eta}_{\mathrm{A},t}[\ell]) \vec{\boldsymbol{m}}_{t}^{\mathrm{post}}[\ell] \stackrel{\mathrm{a.s.}}{=} \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{U}^{\mathrm{T}}[\ell] \boldsymbol{n}[\ell]$$
$$+ (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell]) \vec{\boldsymbol{b}}_{t}[\ell] + o(1).(212)$$

Since $\vec{m}_t^{\text{post}}[\ell]$ is a function of $\vec{b}_t[\ell]$, applying this expression to the definition of $\vec{m}_t^{\text{ext}}[\ell]$ in (202) yields

$$\vec{\boldsymbol{m}}_{t}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{\boldsymbol{m}}_{t}^{\text{post}}[\ell] - |\mathcal{W}[\ell]|^{-1/2} \frac{\eta_{\text{A},t}[\ell]}{1 - \bar{\eta}_{\text{A},t}[\ell]} \vec{\boldsymbol{b}}_{t}[\ell] + o(1),$$
(213)

with $\eta_{A,t}[\ell]$ defined in (40), in which we have used the identity $\operatorname{Tr}(\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_t[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell]) = \operatorname{Tr}(\boldsymbol{I} - \boldsymbol{F}_t^{\mathrm{T}}[\ell] \boldsymbol{A}[\ell]).$

We next evaluate the RHS in (210). Using the definitions of $\vec{x}_{A\to B,t}[\ell]$ and $\vec{m}_t^{\text{post}}[\ell]$ in (83) and (208) yields

$$\boldsymbol{V}^{\mathrm{T}}[\ell](\boldsymbol{\vec{x}}_{\mathrm{A}\to\mathrm{B},t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\boldsymbol{\vec{x}}[\ell])$$

= $\boldsymbol{\vec{m}}_{t}^{\mathrm{post}}[\ell] - |\mathcal{W}[\ell]|^{-1/2} \frac{\eta_{\mathrm{A},t}[\ell]}{1 - \eta_{\mathrm{A},t}[\ell]} \boldsymbol{\vec{b}}_{t}[\ell] + o(1)$ (214)

under the assumptions $\vec{q}_t^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t}[\ell] - \vec{x}[\ell] + o(1)$ and $\eta_{A,t}[\ell] \stackrel{\text{a.s.}}{\to} \bar{\eta}_{A,t}[\ell]$. Comparing the obtained two results under the assumption $\eta_{A,t}[\ell] \stackrel{\text{a.s.}}{\to} \bar{\eta}_{A,t}[\ell]$, we arrive at the identity (210).

Let us prove the properties for $\vec{m}_t^{\text{post}}[\ell] = \phi_t[\ell]$ in Assumption 7. The separability and proper Lipschitz-continuity of $\vec{m}_t^{\text{post}}[\ell]$ follow from (212) and Assumption 3. The property $\|\vec{m}_t^{\text{ext}}[\ell]\| \neq 0$ is satisfied, because of (212), (213), and Assumption 4. Thus, the former statement in Lemma 13 holds.

We prove $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell] + o(1)$ in the latter statement. We first evaluate the LHS $\vec{q}_{t+1}^{\text{ext}}[\ell]$. Define

$$\vec{q}_{t+1}^{\text{post}}[\ell] = \begin{pmatrix} \vec{q}_{t+1}^{\text{post}}[\ell][\min\{W, \ell\}] \\ \vdots \\ \vec{q}_{t+1}^{\text{post}}[\ell][\max\{\ell - (L-1), 0\}] \end{pmatrix}.$$
 (215)

Applying the definition of $\vec{q}_{t+1}^{\text{post}}[\ell]$ in (209) and $\vec{x}[\ell] = |\mathcal{W}[\ell]|^{1/2} \Gamma[\ell] x$ yields

$$\vec{\boldsymbol{q}}_{t+1}^{\text{post}}[\ell][w] = \frac{\sqrt{|\mathcal{W}[\ell]|}\gamma[\ell][\ell-w]}{1-\bar{\eta}_{\text{B},t}[\ell]/|\mathcal{W}[\ell]|} (\boldsymbol{x}_{\text{B},t+1}^{\text{post}}[\ell-w] - \boldsymbol{x}[\ell-w])$$
(216)

for $w \in \mathcal{W}[\ell]$, where we have utilized the relationship (44) between the signal vectors in the original and extended spaces. The difference $\boldsymbol{x}_{\mathrm{B},t+1}^{\mathrm{post}}[\ell - w] - \boldsymbol{x}[\ell - w]$ defined in (87) depends on $\{\vec{h}_{\tau}[\ell]\}_{\tau=0}^{t}$ through $\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[\ell - w]$ in (85): We use the definition of $\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},\tau}[l][w]$ in (45) and the assumption $\vec{h}_{\tau}[\ell] \stackrel{\mathrm{a.s.}}{=} \vec{x}_{\mathrm{A}\to\mathrm{B},\tau}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ to find that $\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},\tau}[l][w]$ contained in $\boldsymbol{x}_{\mathrm{A}\to\mathrm{B},t}^{\mathrm{suf}}[l]$ is given by

$$\begin{aligned} \boldsymbol{x}_{\mathrm{A}\to\mathrm{B},\tau}[l][w] &\stackrel{\mathrm{a.s.}}{=} |\mathcal{W}[l+w]|^{-1/2} \boldsymbol{\vec{x}}[l+w][w] + \boldsymbol{\vec{h}}_{\tau}[l+w][w] \\ + o(1) \end{aligned}$$
(217)

for $\tau \in \{0, ..., t\}$, with $\vec{h}_{\tau}[\ell][w]$ defined in the same manner as for $\vec{q}_{t+1}^{\text{post}}[\ell][w]$.

We evaluate $\xi_{B,\tau,t}[\ell]$ given in (207). Using the definition of $x_{B,t+1}^{\text{post}}[\ell-w]$ in (87) and the representation (216) yields

$$\frac{\partial \bar{q}_{n,t+1}^{\text{post}}[\ell][w]}{\partial \vec{h}_{n,\tau}[\ell][w]} = \frac{\sqrt{|\mathcal{W}[\ell]|}\gamma[\ell][\ell-w]}{1-\bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|}$$
$$\cdot f_t'[l](x_{\mathrm{A}\to\mathrm{B},n,t}^{\mathrm{suf}}[\ell-w])\frac{\partial x_{\mathrm{A}\to\mathrm{B},n,t}^{\mathrm{suf}}[l]}{\partial \vec{h}_{n,\tau}[l+w][w]}, \qquad (218)$$

with $l = \ell - w$. Under the assumption $V_{A \to B,t}[\ell] \xrightarrow{a.s.} \bar{V}_{A \to B,t}[\ell]$, the covariance $v_{A \to B,t',t}^{suf}[l]$ in (86) converges almost surely to $\bar{v}_{A \to B,t',t}^{suf}[l]$. Thus, the last factor reduces to

$$\frac{\partial x_{\mathbf{A}\to\mathbf{B},n,t}^{\mathrm{suf}}[l]}{\partial \vec{h}_{n,\tau}[l+w][w]} \stackrel{\mathrm{a.s.}}{=} \vec{v}_{\mathbf{A}\to\mathbf{B},t,t}^{\mathrm{suf}}[l] \sum_{w'=0}^{W} \gamma[l+w'][l] \\ \cdot \boldsymbol{e}_{\tau}^{\mathrm{T}} \bar{\boldsymbol{V}}_{\mathbf{A}\to\mathbf{B},t}^{-1}[l+w'] \mathbf{1} \frac{\partial x_{\mathbf{A}\to\mathbf{B},n,\tau}[l][w']}{\partial \vec{h}_{n,\tau}[l+w][w]} + o(1) \quad (219)$$

because of the definition of $x_{\mathrm{A} \to \mathrm{B},t}^{\mathrm{suf}}[l]$ in (85), with

$$\frac{\partial x_{\mathrm{A}\to\mathrm{B},n,\tau}[l][w']}{\partial \vec{h}_{n,\tau}[l+w][w]} \stackrel{\mathrm{a.s.}}{=} \delta_{w,w'} + o(1), \qquad (220)$$

obtained from the representation (217). Applying these results to the definition of $\xi_{\mathrm{B},\tau,t}[\ell]$ in (207), we arrive at

$$\xi_{\mathrm{B},\tau,t}[\ell] = \frac{1}{N_{\mathrm{c}}[\ell]} \sum_{w \in \mathcal{W}[\ell]} \sum_{n=1}^{N[\ell-w]} \frac{\partial \vec{q}_{n,t+1}^{\mathrm{post}}[\ell][w]}{\partial \vec{h}_{n,\tau}[\ell][w]}$$

$$\stackrel{\mathrm{a.s.}}{=} \frac{|\mathcal{W}[\ell]|^{-1/2}}{1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|} \eta_{\mathrm{B},\tau,t}[\ell] + o(1), \quad (221)$$

with $\eta_{\mathrm{B},\tau,t}[\ell]$ given by (91), where we have used $V_{\mathrm{A}\to\mathrm{B},t}[\ell] \xrightarrow{\mathrm{a.s.}} \bar{V}_{\mathrm{A}\to\mathrm{B},t}[\ell]$ and $v_{\mathrm{A}\to\mathrm{B},t',t}^{\mathrm{suf}}[l] \xrightarrow{\mathrm{a.s.}} \bar{v}_{\mathrm{A}\to\mathrm{B},t',t}^{\mathrm{suf}}[l]$ again.

We next evaluate the RHS $\vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell]$. Using the definitions of $\vec{x}_{B\to A,t+1}[\ell]$ and $\vec{q}_{t+1}^{\text{post}}[\ell]$ in (92) and (209), as well as the assumptions $\vec{h}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A \to B,\tau}[\ell] |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ for all $\tau \in \{0, \ldots, t\}$ and $\eta_{\mathrm{B},t}[\ell] \xrightarrow{\mathrm{a.s.}}$ $\bar{\eta}_{\mathrm{B},t}[\ell]$, yields

$$\vec{x}_{\mathrm{B}\to\mathrm{A},t+1}[\ell] - \vec{x}[\ell] \stackrel{\mathrm{a.s.}}{=} \vec{q}_{t+1}^{\mathrm{post}}[\ell] - \frac{|\mathcal{W}[\ell]|^{-1/2}}{1 - \eta_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau,t}[\ell] \vec{h}_{\tau}[\ell] + o(1), \quad (222)$$

where we have used the definitions of $\eta_{B,t}[\ell]$ and $\eta_{\mathrm{B},\tau,t}[\ell]$ in (51) and (91), respectively, and the identity $\sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau,t}[\ell][w] = \eta_{\mathrm{B},t}[\ell][w]$ obtained from (89). Comparing this expression to the definition of $\vec{q}_{t+1}^{\text{ext}}[\ell]$ in (205) with $\xi_{\text{B},\tau,t}[\ell]$ given in (221), we arrive at $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{\text{B}\to\text{A},t+1}[\ell] \vec{x}[\ell] + o(1).$

The separability and proper Lipschitz-continuity of $\vec{q}_{t+1}^{\text{post}}[\ell]$ follow from (87), (216), and Assumption 6. Furthermore, the nonlinearity of the denoiser in Assumption 6 implies $\|\vec{q}_{t+1}^{\text{ext}}[\ell]\| \neq 0$, so that we have the properties for $\vec{q}_{t+1}^{\text{post}}[\ell] =$ $\psi_t[\ell]$ in Assumption 7. Thus, the latter statement holds.

Lemma 13 implies that the asymptotic dynamics of both OAMP and LM-OAMP can be analyzed via state evolution of the general error model in the spatial coupling case.

D. State Evolution

As the second step in the proof of Theorem 5, we present state evolution analysis for the general error model in the spatial coupling case. The proof is based on Bolthausen's conditioning technique [10]. The set $\mathfrak{F} = \{\Omega, \Lambda, \mathcal{X}\}$ is always conditioned. Define the set $\mathfrak{E}_{t,t'} = \{\mathcal{B}_{t'}, \mathcal{M}_{t'}^{\mathrm{ext}}, \mathcal{H}_t, \mathcal{Q}_{t+1}^{\mathrm{ext}}\}$ with $\mathcal{M}_t^{\text{ext}} = \{ \vec{M}_t^{\text{ext}}[\ell] : \ell \in \mathcal{L}_W \}$ and $\mathcal{Q}_t^{\text{ext}} = \{ \vec{Q}_t^{\text{ext}}[\ell] : \ell \in \mathcal{L}_W \}$. The set $\mathfrak{E}_{t,t}$ contains the messages that have been already computed just before updating $b_t[\ell]$ in (200) while $\mathfrak{E}_{t,t+1}$ includes the messages just before updating $h_t[\ell]$ in (203). The asymptotic dynamics of the general error model is analyzed via the conditional distributions of $\{V[\ell]\}$ given (A4) The inner product $N_c^{-1}[\ell](\vec{m}_{\tau'}^{ext}[\ell])^T\vec{m}_{\tau}^{ext}[\ell]$ converges \mathfrak{F} and $\mathfrak{E}_{t,t'}$.

The following theorem presents five asymptotic properties in each module. A first property in each module is obtained via Bolthausen's conditioning technique. Second and third properties are the asymptotic Gaussianity for the general error model. The last two properties are technical results for establishing a proof by induction.

Theorem 8: Suppose that Assumptions 2, 3, 4, and 7 hold. Then, the following properties in module A hold for all $\tau =$ $0, 1, \ldots$ in the large system limit.

(A1) Suppose that $\{V[\ell] \in \mathcal{O}_{N_{\mathrm{c}}[\ell]-2\tau}\}$ are independent Haar-distributed orthogonal matrices. Let $\vec{q}_{\tau}^{\text{ext},\perp}[\ell]$ $P_{\vec{Q}_{\tau}^{\text{ext}}[\ell]}^{\perp}\vec{q}_{\tau}^{\text{ext}}[\ell], \vec{\beta}_{\tau}[\ell] = (\vec{Q}_{\tau}^{\text{ext}}[\ell])^{\dagger}\vec{q}_{\tau}^{\text{ext}}[\ell]$, and

$$\vec{\boldsymbol{\omega}}_{\mathrm{A},\tau}[\ell] = \tilde{\boldsymbol{V}}[\ell] (\boldsymbol{\Phi}_{(\vec{\boldsymbol{Q}}_{\tau}^{\mathrm{ext}}[\ell],\vec{\boldsymbol{H}}_{\tau}[\ell])}^{\perp})^{\mathrm{T}} \vec{\boldsymbol{q}}_{\tau}^{\mathrm{ext}}[\ell].$$
(223)

Then, for $\tau > 0$ we have

$$\vec{\boldsymbol{b}}_{\tau}[\ell] \sim \vec{\boldsymbol{B}}_{\tau}[\ell] \vec{\boldsymbol{\beta}}_{\tau}[\ell] + \boldsymbol{\Phi}_{(\vec{\boldsymbol{B}}_{\tau}[\ell],\vec{\boldsymbol{M}}_{\tau}^{\text{ext}}[\ell])}^{\perp} \vec{\boldsymbol{\omega}}_{\mathrm{A},\tau}[\ell] + \vec{\boldsymbol{M}}_{\tau}^{\text{ext}}[\ell]\boldsymbol{o}(1) + \vec{\boldsymbol{B}}_{\tau}[\ell]\boldsymbol{o}(1)$$
(224)

conditioned on \mathfrak{F} and $\mathfrak{E}_{\tau,\tau}$ in the large system limit, with

$$\frac{1}{N_{\rm c}[\ell]} \left\{ \|\vec{\boldsymbol{\omega}}_{{\rm A},\tau}[\ell]\|^2 - \|\vec{\boldsymbol{q}}_{\tau}^{\rm ext,\perp}[\ell]\|^2 \right\} \stackrel{\rm a.s.}{\to} 0.$$
(225)

(A2) Suppose that $\tilde{\phi}_{\tau}(\mathcal{B}_{\tau+1},\Omega,\Lambda): \mathbb{R}^{N_{\mathrm{c}} \times (\tau+3)|\mathcal{L}_W|} \to \mathbb{R}^{N_{\mathrm{c}}}$ is separable, pseudo-Lipschitz of order 2 with respect to $\mathcal{B}_{\tau+1}$ and Ω , and proper. If $N_{\rm c}^{-1}[\ell](\vec{q}_{t'}^{\rm ext}[\ell])^{\rm T}\vec{q}_{t}^{\rm ext}[\ell]$ converges almost surely to some constant $\kappa_{t',t}[\ell] \in \mathbb{R}$ in the large system limit for all $t', t = 0, \ldots, \tau$, then

$$\langle \tilde{\boldsymbol{\phi}}_{\tau}(\mathcal{B}_{\tau+1},\Omega,\Lambda) \rangle - \mathbb{E} \left[\langle \tilde{\boldsymbol{\phi}}_{\tau}(\mathcal{Z}_{\mathrm{A},\tau+1},\tilde{\Omega},\Lambda) \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0,$$
(226)

with the sets of independent random matrices $\mathcal{Z}_{A,\tau+1} =$ $\{[\vec{\boldsymbol{Z}}_{A,\tau+1}^{\mathrm{T}}[\ell], \boldsymbol{O}]^{\mathrm{T}} \in \mathbb{R}^{N_{\mathrm{c}} \times (\tau+1)} : \ell \in \mathcal{L}_{W}\}$ and vectors $\tilde{\Omega} = \{[\tilde{\boldsymbol{n}}^{\mathrm{T}}[\ell], \boldsymbol{0}]^{\mathrm{T}} \in \mathbb{R}^{N_{\mathrm{c}}} : \ell \in \mathcal{L}_{W}\}$. Here, each $\vec{Z}_{\mathrm{A},\tau+1}[\ell] = (\vec{z}_{\mathrm{A},0}[\ell], \dots, \vec{z}_{\mathrm{A},\tau}[\ell])$ has zero-mean Gaussian random vectors with covariance $\mathbb{E}[\vec{z}_{A,t}[\ell]\vec{z}_{A,t'}^{T}[\ell]] =$ $\kappa_{t',t}[\ell] \mathbf{I}_{N_c[\ell]}$ for all $t', t \in \{0, \ldots, \tau\}$. Furthermore, each $\tilde{n}[\ell] \in \mathbb{R}^{M[\ell]}$ has independent zero-mean Gaussian random elements with variance σ^2 .

Suppose that $\tilde{\phi}_{\tau}(\mathcal{B}_{\tau+1},\Omega,\Lambda): \mathbb{R}^{N_{c}\times(\tau+3)|\mathcal{L}_{W}|} \to \mathbb{R}^{N_{c}}$ (A3) is separable, Lipschitz-continuous with respect to $\mathcal{B}_{\tau+1}$ and Ω , and proper. Then,

$$\left\langle \partial_{\tau'} \tilde{\boldsymbol{\phi}}_{\tau} (\mathcal{B}_{\tau+1}, \Omega, \Lambda) \right\rangle - \mathbb{E} \left[\left\langle \partial_{\tau'} \tilde{\boldsymbol{\phi}}_{\tau} (\mathcal{Z}_{\mathrm{A}, \tau+1}, \tilde{\Omega}, \Lambda) \right\rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0$$
(227)

for all $\tau' \in \{0, \dots, (\tau+1)|\mathcal{L}_W| - 1\}$ and

$$\frac{1}{N_{c}[\ell]}\vec{\boldsymbol{b}}_{\tau'}^{T}[\ell]\left((\boldsymbol{I}_{N_{c}[\ell]},\boldsymbol{O})\tilde{\boldsymbol{\phi}}_{\tau}-\sum_{t'=0}^{\tau}\tilde{\xi}_{A,t',\tau}[\ell]\vec{\boldsymbol{b}}_{t'}[\ell]\right)\overset{\text{a.s.}}{\to}0$$
(228)

for all $\tau' \in \{0, \ldots, \tau\}$ hold, with

$$\tilde{\xi}_{A,t',\tau}[\ell] = \frac{1}{N_{c}[\ell]} \sum_{n=1}^{N_{c}[\ell]} \partial_{(\tau+1)\ell+t'}[\tilde{\phi}_{\tau}]_{n}.$$
 (229)

- almost surely to some constant $\pi_{\tau',\tau}[\ell] \in \mathbb{R}$ for all $\tau' \in$ $\{0, \ldots, \tau\}.$
- (A5) For some $\epsilon > 0$ and C > 0,

$$\mathbb{E}\left[|\vec{m}_{n,\tau}^{\text{ext}}[\ell]|^{2+\epsilon}\right] < \infty, \tag{230}$$

$$\lambda_{\min}\left(\frac{1}{N_{c}[\ell]}(\vec{\boldsymbol{M}}_{\tau+1}^{\text{ext}}[\ell])^{\mathrm{T}}\vec{\boldsymbol{M}}_{\tau+1}^{\text{ext}}[\ell]\right) \stackrel{\text{a.s.}}{>} C \qquad (231)$$

in the large system limit.

The following properties in module B hold for all τ = $0, 1, \ldots$ in the large system limit.

(B1) Suppose that $\{ ilde{m{V}}[\ell] \in \mathcal{O}_{N_{\mathrm{c}}[\ell]-(2 au+1)}\}$ are independent Haar-distributed orthogonal matrices. Let $\vec{\alpha}_{\tau}[\ell] =$ $\begin{array}{lll} (\vec{M}_{\tau}^{\text{ext}}[\ell])^{\dagger}\vec{m}_{\tau}^{\text{ext}}[\ell], \ \vec{m}_{0}^{\text{ext},\perp}[\ell] &= \ \vec{m}_{0}^{\text{ext}}[\ell], \ \vec{\omega}_{\text{B},0}[\ell] &= \\ \tilde{V}[\ell] (\boldsymbol{\Phi}_{\vec{b}_{0}[\ell]}^{\perp})^{\text{T}} \vec{m}_{0}^{\text{ext}}[\ell], \ \vec{m}_{\tau}^{\text{ext},\perp}[\ell] &= \ \boldsymbol{P}_{\vec{M}_{\tau}^{\text{ext}}[\ell]}^{\perp} \vec{m}_{\tau}^{\text{ext}}[\ell], \end{array}$ and $\vec{\boldsymbol{\omega}}_{\mathrm{B},\tau}[\ell] = \tilde{\boldsymbol{V}}[\ell] (\boldsymbol{\Phi}_{(\vec{\boldsymbol{M}}_{\tau}^{\mathrm{ext}}[\ell],\vec{\boldsymbol{B}}_{\tau+1}[\ell])}^{\perp})^{\mathrm{T}} \vec{\boldsymbol{m}}_{\tau}^{\mathrm{ext}}[\ell]$ for $\tau >$ 0. Then, we have

$$\vec{\boldsymbol{h}}_0[\ell] \sim o(1) \vec{\boldsymbol{q}}_0^{\text{ext}}[\ell] + \boldsymbol{\Phi}_{\vec{\boldsymbol{q}}_0^{\text{ext}}[\ell]}^{\perp} \vec{\boldsymbol{\omega}}_{\text{B},0}[\ell]$$
(232)

conditioned on \mathfrak{F} and $\mathfrak{E}_{0,1} = \{ \vec{b}_0, \vec{m}_0^{\text{ext}}, \vec{q}_0^{\text{ext}} \}$ in the large system limit. For $\tau > 0$

$$\vec{\boldsymbol{h}}_{\tau}[\ell] \sim \vec{\boldsymbol{H}}_{\tau}[\ell] \vec{\boldsymbol{\alpha}}_{\tau}[\ell] + \Phi^{\perp}_{(\vec{\boldsymbol{H}}_{\tau}[\ell], \vec{\boldsymbol{Q}}_{\tau+1}^{\text{ext}}[\ell])} \vec{\boldsymbol{\omega}}_{\text{B}, \tau}[\ell] + \vec{\boldsymbol{Q}}_{\tau+1}^{\text{ext}}[\ell] \boldsymbol{o}(1) + \vec{\boldsymbol{H}}_{\tau}[\ell] \boldsymbol{o}(1)$$
(233)

conditioned on \mathfrak{F} and $\mathfrak{E}_{\tau,\tau+1}$ in the large system limit, with

$$\frac{1}{N_{\rm c}[\ell]} \left\{ \|\vec{\boldsymbol{\omega}}_{{\rm B},\tau}[\ell]\|^2 - \|\vec{\boldsymbol{m}}_{\tau}^{\rm ext,\perp}[\ell]\|^2 \right\} \stackrel{\rm a.s.}{\to} 0.$$
(234)

(B2) Suppose that $\tilde{\psi}_{\tau}(\mathcal{H}_{\tau+1},\mathcal{X})$: $\mathbb{R}^{N_{c}\times(\tau+2)|\mathcal{L}_{W}|} \to \mathbb{R}^{N_{c}}$ is a separable and proper pseudo-Lipschitz function of order 2. If $N_c^{-1}[\ell](\vec{m}_{t'}^{ext}[\ell])^T \vec{m}_t^{ext}[\ell]$ converges almost surely to some constant $\pi_{t',t}[\ell] \in \mathbb{R}$ in the large system limit for all $t', t \in \{0, \ldots, \tau\}$, then

$$\langle \tilde{\boldsymbol{\psi}}_{\tau}(\mathcal{H}_{\tau+1}, \mathcal{X}) \rangle - \mathbb{E} \left[\langle \tilde{\boldsymbol{\psi}}_{\tau}(\mathcal{Z}_{\mathrm{B}, \tau+1}, \mathcal{X}) \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0, \quad (235)$$

with the set of independent random matrices $\mathcal{Z}_{B,\tau+1} =$ $\{[\vec{\boldsymbol{Z}}_{\mathrm{B},\tau+1}^{\mathrm{T}}[\ell], \boldsymbol{O}]^{\mathrm{T}} \in \mathbb{R}^{N_{\mathrm{c}} \times (\tau+1)} : \ell \in \mathcal{L}_{W}\}.$ Here, each $\vec{\boldsymbol{Z}}_{\mathrm{B},\tau+1}[\ell] = (\vec{\boldsymbol{z}}_{\mathrm{B},0}[\ell], \dots, \vec{\boldsymbol{z}}_{\mathrm{B},\tau}[\ell])$ has zero-mean Gaussian random vectors with covariance $\mathbb{E}[\vec{z}_{\mathrm{B},t}[\ell]\vec{z}_{\mathrm{B},t'}^{\mathrm{T}}[\ell]] =$ $\pi_{t',t}[\ell] \boldsymbol{I}_{N_{c}[\ell]} \text{ for all } t', t \in \{0, \dots, \tau\}.$ (B3) Suppose that $\tilde{\boldsymbol{\psi}}_{\tau}(\mathcal{H}_{\tau+1}, \mathcal{X}) : \mathbb{R}^{N_{c} \times (\tau+2)|\mathcal{L}_{W}|} \to \mathbb{R}^{N_{c}} \text{ is }$

separable and proper Lipschitz-continuous. Then,

$$\langle \partial_{\tau'} \tilde{\psi}_{\tau}(\mathcal{H}_{\tau+1}, \mathcal{X}) \rangle - \mathbb{E} \left[\langle \partial_{\tau'} \tilde{\psi}_{\tau}(\mathcal{Z}_{\mathrm{B}, \tau+1}, \mathcal{X}) \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0$$
(236)

for all $\tau' \in \{0, ..., (\tau + 1) | \mathcal{L}_W | - 1\}$ and

$$\frac{1}{N_{c}[\ell]}\vec{\boldsymbol{h}}_{\tau'}^{\mathrm{T}}[\ell]\left((\boldsymbol{I}_{N_{c}[\ell]},\boldsymbol{O})\tilde{\boldsymbol{\psi}}_{\tau}-\sum_{t'=0}^{\tau}\tilde{\xi}_{\mathrm{B},t',\tau}[\ell]\vec{\boldsymbol{h}}_{t'}[\ell]\right) \stackrel{\mathrm{a.s.}}{\to} 0$$
(237)

for all $\tau' \in \{0, \ldots, \tau\}$ hold, with

$$\tilde{\xi}_{\mathrm{B},t',\tau}[\ell] = \frac{1}{N_{\mathrm{c}}[\ell]} \sum_{n=1}^{N_{\mathrm{c}}[\ell]} \partial_{(\tau+1)\ell+t'} [\tilde{\psi}_{\tau}]_n.$$
(238)

- (B4) The inner product $N_{\rm c}^{-1}[\ell](\vec{q}_{\tau'}^{\rm ext}[\ell])^{\rm T}\vec{q}_{\tau+1}^{\rm ext}[\ell]$ converges almost surely to some constant $\kappa_{ au', au+1}[\ell] \in \mathbb{R}$ for all $\tau' \in \{0, \ldots, \tau + 1\}.$
- (B5) For some $\epsilon > 0$ and C > 0,

$$\mathbb{E}\left[|\bar{q}_{n,\tau+1}^{\text{ext}}[\ell]|^{2+\epsilon}\right] < \infty, \tag{239}$$

$$\lambda_{\min}\left(\frac{1}{N_{c}[\ell]}(\vec{\boldsymbol{Q}}_{\tau+2}^{\text{ext}}[\ell])^{\mathrm{T}}\vec{\boldsymbol{Q}}_{\tau+2}^{\text{ext}}[\ell]\right) \stackrel{\text{a.s.}}{>} C \qquad (240)$$

in the large system limit.

Proof: The proof is by induction. In a first step, we prove the properties of module A for $\tau = 0$ in Appendix G-E. In a second step, the properties of module B are proved for $\tau = 0$ in Appendix G-F. In a third step, for some t we assume that Theorem 8 is correct for all $\tau < t$ and prove the properties of module A for $\tau = t$ in Appendix G-G. The last step is a proof for the properties of module B for $\tau = t$ under induction hypotheses where the properties of modules A and B are correct for all $\tau \leq t$ and $\tau < t$, respectively. The proof in the last step is omitted since it is the same as that in the third step. By induction, we arrive at Theorem 8 for all τ .

The second and third properties in Theorem 8 are regarded as evaluation tools. The property (A2) allows us to replace the non-tractable vector $\vec{b}_t[\ell]$ with a tractable zero-mean Gaussian vector. The property (A3) is useful for reducing evaluation for the inner product of $b_t[\ell]$ and its nonlinear mapping to that for the squared norm of $\vec{b}_t[\ell]$. The properties (B2) and (B3) play the same roles as for $h_t[\ell]$.

As the last step, we prove Theorem 5.

Proof of Theorem 5: We only prove Theorem 5 for LM-OAMP since the theorem for OAMP can be proved in the same manner as for LM-OAMP. For any t, we prove the identity

$$\frac{1}{N_{c}[\ell]} (\vec{\boldsymbol{q}}_{\tau'}^{ext}[\ell])^{T} \vec{\boldsymbol{q}}_{\tau+1}^{ext}[\ell] \stackrel{\text{a.s.}}{=} \bar{v}_{\mathrm{B}\to\mathrm{A},\tau',\tau+1}[\ell] + o(1) \quad (241)$$

for all $\tau \in \{0, ..., t\}$ and $\tau' \in \{0, ..., \tau + 1\}$, with (100). To use Lemma 13, we need Properties (A3) and (B3) in Theorem 8 to prove the almost sure convergence of $\eta_{A,t}[\ell]$ and $\eta_{B,t}[\ell]$. On the other hand, we need Lemma 13 to use Theorem 8. To resolve this dilemma, we prove $\vec{\boldsymbol{h}}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} \vec{\boldsymbol{x}}_{\mathrm{A}\to\mathrm{B},\tau}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{\boldsymbol{x}}[\ell] + o(1) \text{ and } \vec{\boldsymbol{q}}_{\tau+1}^{\mathrm{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{\boldsymbol{x}}_{\mathrm{B}\to\mathrm{A},\tau+1}[\ell] - \vec{\boldsymbol{x}}[\ell] + o(1) \text{ for all } \tau \in \{0,\ldots,t\} \text{ by induction,}$ as well as the identity (241).

The proof for t = 0 is omitted since it is the same as that for general t. For some t > 0, assume $\vec{h}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A \to B,\tau}[\ell] -$
$$\begin{split} &|\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1) \text{ and } \vec{q}_{\tau+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{\mathrm{B}\to\mathrm{A},\tau+1}[\ell] - \vec{x}[\ell] + o(1), \text{ and } (241) \text{ for all } \tau \in \{0, \dots, t-1\} \text{ and } \tau' \in \{0, \dots, \tau+1\}. \end{split}$$
 $\begin{aligned} &\text{We need to prove } \vec{h}_t[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] - o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}[\ell] + o(1), \text{ and } \vec{x}_{\mathrm{A}\to\mathrm{B},t}$ o(1) and $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell] + o(1)$, and (241) for $\tau = t$ and all $\tau' \in \{0, \dots, t+1\}.$

The induction hypotheses imply that the error model for LM-OAMP is included in the general error model as long as at most t-1 iterations are considered. Thus, we can use the properties of module A in Theorem 8 for $\tau = t$.

We first evaluate $N_{\rm c}^{-1}[\ell](\vec{\boldsymbol{x}}_{{\rm A},t'}^{\rm post}[\ell] - \vec{\boldsymbol{x}}[\ell])^{\rm T}(\vec{\boldsymbol{x}}_{{\rm A},t}^{\rm post}[\ell] -$ $\vec{x}[\ell]) \stackrel{\text{a.s.}}{\to} \bar{v}_{A,t',t}^{\text{post}}[\ell]$ for all $t' \in \{0, \dots, t\}$. From the induction hypothesis $\vec{q}_t^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{\mathrm{B}\to\mathrm{A},t}[\ell] - \vec{x}[\ell] + o(1)$, we use the definitions of $\vec{m}_t^{\text{post}}[\ell]$ in (208) and (212) to obtain

$$\boldsymbol{V}^{\mathrm{T}}[\ell](\boldsymbol{\vec{x}}_{\mathrm{A},t}^{\mathrm{post}}[\ell] - \boldsymbol{\vec{x}}[\ell]) \stackrel{\mathrm{a.s.}}{=} (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell]) \boldsymbol{\vec{b}}_{t}[\ell] \\ + \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{U}^{\mathrm{T}}[\ell] \boldsymbol{n}[\ell] + o(1).$$
(242)

Applying Property (A2) in Theorem 8 yields

$$\begin{split} \bar{v}_{\mathrm{A},t',t}^{\mathrm{post}}[\ell] &\stackrel{\mathrm{a.s.}}{=} o(1) + \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathbb{E} \left[\mathrm{Tr} \left(\boldsymbol{\Sigma}_{\boldsymbol{F}_{t'}[\ell]} \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \right) \right] \\ &+ \frac{\bar{v}_{\mathrm{B} \to \mathrm{A},t',t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathbb{E} \left[\mathrm{Tr} (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell]) (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t'}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell])^{\mathrm{T}} \right] \\ &= o(1) + \frac{\sigma^2}{N_{\mathrm{c}}[\ell]} \mathbb{E} \left[\mathrm{Tr} \left(\boldsymbol{F}_{t}^{\mathrm{T}}[\ell] \boldsymbol{F}_{t'}[\ell] \right) \right] \\ &+ \frac{\bar{v}_{\mathrm{B} \to \mathrm{A},t',t}[\ell]}{N_{\mathrm{c}}[\ell]} \mathbb{E} \left[\mathrm{Tr} (\boldsymbol{I} - \boldsymbol{F}_{t}^{\mathrm{T}}[\ell] \boldsymbol{A}[\ell]) (\boldsymbol{I} - \boldsymbol{F}_{t'}^{\mathrm{T}}[\ell] \boldsymbol{A}[\ell])^{\mathrm{T}} \right]. \end{split}$$

$$(243)$$

In the derivation of the first equality, we have used the induction hypothesis (241) for all $\tau \in \{0, \ldots, t-1\}$ and $\tau' \in \{0, \dots, \tau + 1\}$. The last expression is equivalent to the state evolution recursion (96).

Let us prove $\vec{h}_t[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A \to B,t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$. Since $\vec{m}_t^{\text{post}}[\ell]$ in (212) is a separable and proper-Lipschitz function of $b_t[\ell]$, we can use Property (A3) in Theorem 8 for $\tau = t$ to obtain $\eta_{A,t}[\ell] \stackrel{\text{a.s.}}{\to} \bar{\eta}_{A,t}[\ell]$. Under the induction hypothesis $\vec{q}_t^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B \to A,t}[\ell] - \vec{x}[\ell] + o(1)$, thus, Lemma 13 implies $\vec{h}_t[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A \to B,t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$.

We next evaluate $N_c^{-1}[\ell](\vec{x}_{A\to B,t'}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell])^T$ $(\vec{x}_{A\to B,t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell]) \xrightarrow{a.s.} \vec{v}_{A\to B,t',t}[\ell]$. Using $\vec{h}_t[\ell] \stackrel{a.s.}{=} \vec{x}_{A\to B,t}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ and the definition of $\vec{m}_t^{\text{ext}}[\ell]$ in (203) yields

$$\bar{v}_{\mathrm{A}\to\mathrm{B},t',t}[\ell] \stackrel{\mathrm{a.s.}}{=} \frac{1}{N_{\mathrm{c}}[\ell]} (\vec{\boldsymbol{m}}_{t'}^{\mathrm{ext}}[\ell])^{\mathrm{T}} \vec{\boldsymbol{m}}_{t}^{\mathrm{ext}}[\ell].$$
(244)

Applying Property (A2) in Theorem 8 to the expression of $\vec{m}_t^{\text{ext}}[\ell]$ in (213) yields

$$\begin{split} \bar{v}_{A\to B,t',t}[\ell] &\stackrel{\text{a.s.}}{=} \frac{1}{N_{c}[\ell]} (\vec{m}_{t'}^{\text{post}}[\ell])^{\mathrm{T}} \vec{m}_{t}^{\text{ext}}[\ell] + o(1) \\ \underset{a.s.}{\overset{\text{a.s.}}{=}} \frac{\bar{v}_{A,t',t}^{\text{post}}[\ell] - \eta_{A,t}[\ell] N_{c}^{-1}[\ell] \vec{b}_{t'}^{\mathrm{T}}[\ell] (\boldsymbol{I} - \boldsymbol{\Sigma}_{\boldsymbol{F}_{t'}[\ell]}^{\mathrm{T}} \boldsymbol{\Sigma}[\ell])^{\mathrm{T}} \vec{b}_{t}[\ell]}{|\mathcal{W}[\ell]| (1 - \bar{\eta}_{A,t'}[\ell]) (1 - \bar{\eta}_{A,t}[\ell])} \\ + o(1) \stackrel{\text{a.s.}}{\to} \frac{\bar{v}_{A,t',t}^{\text{post}}[\ell] - \bar{\eta}_{A,t'}[\ell] \bar{\eta}_{A,t}[\ell] \bar{v}_{B\to A,t',t}[\ell]}{|\mathcal{W}[\ell]| (1 - \bar{\eta}_{A,t'}[\ell]) (1 - \bar{\eta}_{A,t'}[\ell])}, \quad (245) \end{split}$$

which is equivalent to the state evolution recursion (97). Here, the first equality follows from the asymptotic orthogonality $N_c^{-1}[\ell] \vec{b}_t^{\mathrm{T}}[\ell] \vec{m}_t^{\mathrm{ext}}[\ell] \stackrel{\mathrm{a.s.}}{=} o(1)$. The second equality is due to the definitions of $\vec{m}_t^{\mathrm{post}}[\ell]$ and $\vec{m}_t^{\mathrm{ext}}[\ell]$ in (212) and (213), as well as the expression of $\vec{m}_t^{\mathrm{post}}[\ell]$ in (208). The last follows from Property (A2) in Theorem 8.

Let us prove $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell] + o(1)$. We have already proved that the covariance message $v_{A\to B,t',t}[\ell]$ in (84) is a consistent estimator of the error covariance $\vec{v}_{A\to B,t',t}[\ell]$ in the large system limit. Furthermore, we use Property (A5) in Theorem 8 to confirm that the covariance matrix $\vec{V}_{A\to B,t',t}[\ell]$ is positive definite. Using the definition of $\vec{q}_{t+1}^{\text{post}}[\ell]$ in (216) and $\vec{h}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{A\to B,\tau}[\ell] - |\mathcal{W}[\ell]|^{-1/2}\vec{x}[\ell] + o(1)$ for all $\tau \in \{0, \ldots, t\}$, we find that $\vec{q}_{t+1}^{\text{post}}[\ell]$ is a separable and proper-Lipschitz function of $\{\vec{h}_{\tau}[\ell]: \tau \in \{0, \ldots, t\}\}$. Thus, we can utilize Property (B3) in Theorem 8 for $\tau = t$ to obtain $\eta_{B,t}[\ell] \stackrel{\text{a.s.}}{\to} \bar{\eta}_{B,t}[\ell]$, which implies that $\vec{q}_{t+1}^{\text{ext}}[\ell] \stackrel{\text{a.s.}}{=} \vec{x}_{B\to A,t+1}[\ell] - \vec{x}[\ell] + o(1)$ holds from Lemma 13.

We derive the state evolution recursions (98) and (99) with respect to $\bar{v}_{A\to B,t',t}^{suf}[l]$ and $\bar{v}_{B,t'+1,t+1}^{post}[l]$, respectively. The almost sure convergence $V_{A\to B,t}[\ell] \xrightarrow{a.s.} \bar{V}_{A\to B,t}[\ell]$ implies that the covariance message $v_{A\to B,t',t}^{suf}[l]$ in (86) converges almost surely to $\bar{v}_{A\to B,t',t}^{suf}[l]$ in (98) in the large system limit. Since $v_{A\to B,t',t}^{suf}[l]$ is a consistent estimator of the error covariance $N^{-1}[l]\mathbb{E}[(\boldsymbol{x}[l] - \boldsymbol{x}_{A\to B,t'}^{suf}[l])^{T}(\boldsymbol{x}[l] - \boldsymbol{x}_{A\to B,t}^{suf}[l])]$ in the large system limit, we use Property (B2) in Theorem 8 to arrive at the almost sure convergence $N^{-1}[l]\mathbb{E}[(\boldsymbol{x}[l] - \boldsymbol{x}_{B,t'+1}^{suf}[l])] \xrightarrow{a.s.} \bar{v}_{B,t'+1}^{post}[l]$ given in (99).

Finally, we evaluate $\overline{v}_{B\to A,t'+1,t+1}[\ell]$ in (241) for all $t' \in \{-1,\ldots,t\}$ Consider the case $t' \geq 0$. Using $\overline{q}_{t+1}^{ext}[\ell] = \overline{x}_{B\to A,t+1}[\ell] - \overline{x}[\ell]$, the definition of $\overline{x}_{B\to A,t+1}[\ell]$ in (222), and

the asymptotic orthogonality $N_c^{-1}[\ell] \vec{\boldsymbol{h}}_{t'}^{\mathrm{T}}[\ell] \vec{\boldsymbol{q}}_{t+1}^{\mathrm{next}}[\ell] \stackrel{\mathrm{a.s.}}{=} o(1)$ yields

$$\bar{v}_{B\to A,t'+1,t+1}[\ell] \stackrel{\text{a.s.}}{=} \frac{(\vec{q}_{t'+1}^{\text{post}}[\ell])^{\mathrm{T}} \vec{q}_{t+1}^{\text{ext}}[\ell]}{N_{\mathrm{c}}[\ell]} + o(1) \\
= \frac{(\vec{q}_{t'+1}^{\text{post}}[\ell])^{\mathrm{T}} \vec{q}_{t+1}^{\text{post}}[\ell]}{N_{\mathrm{c}}[\ell]} - \frac{|\mathcal{W}[\ell]|^{-1/2}}{1 - \bar{\eta}_{B,t}[\ell]/|\mathcal{W}[\ell]|} \\
\cdot \sum_{\tau=0}^{t} \eta_{B,\tau,t}[\ell] \frac{(\vec{q}_{t'+1}^{\text{post}}[\ell])^{\mathrm{T}} \vec{h}_{\tau}[\ell]}{N_{\mathrm{c}}[\ell]} + o(1), \quad (246)$$

where we have used $\eta_{\mathrm{B},t}[\ell] \xrightarrow{\mathrm{a.s.}} \bar{\eta}_{\mathrm{B},t}[\ell]$. From the definition of $\vec{q}_{t+1}^{\mathrm{post}}[\ell]$ in (216), we find that the first term reduces to

$$\frac{(\vec{q}_{t'+1}^{\text{post}}[\ell])^{\mathrm{T}}\vec{q}_{t+1}^{\text{post}}[\ell]}{N_{\mathrm{c}}[\ell]} = \frac{1}{N_{\mathrm{c}}[\ell]} \sum_{w \in \mathcal{W}[\ell]} (\vec{q}_{t'+1}^{\text{post}}[\ell][w])^{\mathrm{T}}\vec{q}_{t+1}^{\text{post}}[\ell][w]
\stackrel{\text{a.s.}}{=} \sum_{w \in \mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} \frac{|\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{B},t'+1,t+1}^{\text{post}}[\ell-w]}{(1-\bar{\eta}_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)(1-\bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)}
+o(1).$$
(247)

For the second term, on the other hand, we use the expression of $\vec{q}_{t+1}^{\text{ext}}[\ell] = \vec{x}_{\text{B}\to\text{A},t+1}[\ell] - \vec{x}[\ell]$ in (222) and the asymptotic orthogonality $N_{\text{c}}^{-1}[\ell](\vec{q}_{t'+1}^{\text{ext}}[\ell])^{\text{T}}\vec{h}_{\tau}[\ell] \stackrel{\text{a.s.}}{=} o(1)$ to obtain

$$\frac{|\mathcal{W}[\ell]|^{-1/2}}{1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau,t}[\ell] \frac{(\vec{q}_{t'+1}^{\mathrm{post}}[\ell])^{\mathrm{T}} \vec{h}_{\tau}[\ell]}{N_{\mathrm{c}}[\ell]}$$

$$\stackrel{\mathrm{a.s.}}{=} \frac{|\mathcal{W}[\ell]|^{-1}}{(1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)(1 - \bar{\eta}_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)}$$

$$\cdot \sum_{\tau'=0}^{t'} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau',t'}[\ell] \eta_{\mathrm{B},\tau,t}[\ell] \bar{v}_{\mathrm{A}\to\mathrm{B},\tau',\tau}[\ell] + o(1). (248)$$

Using the following identity obtained from (51), (89), and (91):

$$\eta_{\mathrm{B},\tau,t}[\ell] = \eta_{\mathrm{B},t}[\ell] \frac{\boldsymbol{e}_{\tau}^{\mathrm{T}} \boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell] \mathbf{1}}{\mathbf{1}^{\mathrm{T}} \boldsymbol{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell] \mathbf{1}},$$
(249)

as well as the expression $\sum_{\tau'=0}^{t'} \sum_{\tau=0}^{t} \bar{v}_{A \to B, \tau', \tau}[\ell] \boldsymbol{e}_{\tau'} \boldsymbol{e}_{\tau}^{T} = (\boldsymbol{I}_{t'+1}, \boldsymbol{O}) \bar{\boldsymbol{V}}_{A \to B, t}[\ell] \text{ for } t' \leq t \text{ and } \boldsymbol{V}_{A \to B, t}[\ell] \xrightarrow{a.s.} \bar{\boldsymbol{V}}_{A \to B, t}[\ell]$, we find that the last factor reduces to

$$\sum_{\tau'=0}^{t'} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau',t'}[\ell] \eta_{\mathrm{B},\tau,t}[\ell] \bar{v}_{\mathrm{A}\to\mathrm{B},\tau',\tau}[\ell]$$

$$\stackrel{\mathrm{a.s.}}{=} \frac{\bar{\eta}_{\mathrm{B},t'}[\ell] \bar{\eta}_{\mathrm{B},t}[\ell]}{\mathbf{1}^{\mathrm{T}} \mathbf{V}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell] \mathbf{1}} + o(1),$$
(250)

with

$$\bar{\eta}_{\mathrm{B},t}[\ell] = \sum_{w \in \mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} \bar{\eta}_{\mathrm{B},t}[\ell][w], \qquad (251)$$

where we have used the fact that $\eta_{B,t}[\ell][w]$ in (90) converges almost surely to $\bar{\eta}_{B,t}[\ell][w]$ in (102), because of $V_{A\to B,t}[\ell] \xrightarrow{a.s.}$ $\bar{V}_{A\to B,t}[\ell], v_{A\to B,t,t}^{suf}[l] \xrightarrow{a.s.} \bar{v}_{A\to B,t,t}^{suf}[l]$, and Property (B3) in Theorem 8 for $\tau = t$. Combining these results, we arrive at

$$\frac{|\mathcal{W}[\ell]|^{-1/2}}{1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|} \sum_{\tau=0}^{t} \eta_{\mathrm{B},\tau,t}[\ell] \frac{(\vec{q}_{t'+1}^{\mathrm{post}}[\ell])^{\mathrm{T}} \vec{h}_{\tau}[\ell]}{N_{\mathrm{c}}[\ell]} \\
\stackrel{\mathrm{a.s.}}{=} \frac{|\mathcal{W}[\ell]|^{-1}}{(1 - \bar{\eta}_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)(1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)} \frac{\bar{\eta}_{\mathrm{B},t'}[\ell] \bar{\eta}_{\mathrm{B},t}[\ell]}{\mathbf{1}^{\mathrm{T}} \bar{\mathbf{V}}_{\mathrm{A} \to \mathrm{B},t}^{-1}[\ell] \mathbf{1}} \\
+ o(1). \tag{252}$$

We are ready to prove (241) for $\tau' > 0$. Substituting (247) and (252) into (246) yields

$$(1 - \bar{\eta}_{\mathrm{B},t'}[\ell]/|\mathcal{W}[\ell]|)(1 - \bar{\eta}_{\mathrm{B},t}[\ell]/|\mathcal{W}[\ell]|)\bar{v}_{\mathrm{B}\to\mathrm{A},t'+1,t+1}[\ell] \stackrel{\mathrm{a.s.}}{=} \sum_{w\in\mathcal{W}[\ell]} \frac{N[\ell-w]}{N_{\mathrm{c}}[\ell]} |\mathcal{W}[\ell]|\gamma^{2}[\ell][\ell-w]\bar{v}_{\mathrm{B},t'+1,t+1}^{\mathrm{post}}[\ell-w] - \frac{1}{|\mathcal{W}[\ell]|} \frac{\bar{\eta}_{\mathrm{B},t'}[\ell]\bar{\eta}_{\mathrm{B},t}[\ell]}{\mathbf{1}^{\mathrm{T}}\bar{\boldsymbol{V}}_{\mathrm{A}\to\mathrm{B},t}^{-1}[\ell]\mathbf{1}} + o(1),$$
(253)

which is equivalent to the state evolution recursion (100).

In the case of t' = -1, for $f_{-1}[l] = 0$ we repeat the same proof as that for the case $t' \ge 0$ to find that $\bar{v}_{B\to A,0,t+1}[\ell]$ is equivalent to (103). Thus, Theorem 5 holds.

E. Module A for $\tau = 0$

Proof of (A2): We first prove the strong law of large numbers with respect to $\vec{b}_0[0]$. Consider

$$\langle \tilde{\phi}_0(\mathcal{B}_1,\Omega,\Lambda) \rangle = \frac{1}{N_c} \sum_{n=1}^{N_c[0]} \tilde{\phi}_{n,0} + \frac{1}{N_c} \sum_{n=N_c[0]+1}^{N_c} \tilde{\phi}_{n,0}.$$
 (254)

By definition, the second term is independent of $\vec{b}_0[0]$.

Let us evaluate the first term. Under Assumptions 2 and 7, for some $\kappa_{0,0}[\ell] > 0$ we find $N_c^{-1}[\ell] \| \vec{q}_0^{\text{ext}}[\ell] \|^2 \overset{\text{a.s.}}{\longrightarrow} \kappa_{0,0}[\ell]$ for the initial condition $\vec{q}_0^{\text{ext}}[\ell] = (I_{N_c[\ell]}, \mathbf{O})\psi_{-1}[\ell](\mathcal{X})$. Consider $A_{3|\mathcal{L}_W|-1} = \{\{[\vec{b}_0^{\text{T}}[\ell], \mathbf{0}]^{\text{T}}\}_{\ell=1}^{|\mathcal{L}_W|-1}, \Omega, \Lambda\}, a_{3|\mathcal{L}_W|-1} = \epsilon = \mathbf{0}, \Phi_E^{\perp} = \mathbf{I}, \text{ and } \omega = \vec{b}_0[0] \text{ in } [54, \text{ Lemma 3}].$ Since $\vec{b}_0[0] = \mathbf{V}^{\text{T}}[0]\vec{q}_0^{\text{ext}}[0]$ is orthogonally invariant and $\mathbf{V}[0]$ is independent of the other matrices $\{\mathbf{V}[\ell] : \ell \neq 0\}$, we can use [54, Lemma 3] to obtain

$$\langle \tilde{\boldsymbol{\phi}}_{0}(\mathcal{B}_{1},\Omega,\Lambda) \rangle$$

= $\mathbb{E}_{\vec{\boldsymbol{z}}_{\mathrm{A},0}[0]} \left[\langle \tilde{\boldsymbol{\phi}}_{0}([\vec{\boldsymbol{z}}_{\mathrm{A},0}^{\mathrm{T}}[0],\mathbf{0}]^{\mathrm{T}},\boldsymbol{A}_{3|\mathcal{L}_{W}|-1}) \rangle \right] + o(1),(255)$

with $\vec{z}_{A,0}[\ell] \sim \mathcal{N}(\mathbf{0}, \kappa_{0,0}[\ell] \boldsymbol{I}_{N_{c}[\ell]}).$

We next prove the strong law of large numbers with respect to the remaining vectors in the same manner. Since ϕ_0 is separable and proper pseudo-Lipschitz, $\mathbb{E}_{\vec{z}_{A,0}[0]}[\langle \tilde{\phi}_0([\vec{z}_{A,0}^T[0], \mathbf{0}]^T, \mathbf{A}_{3|\mathcal{L}_W|-1})]$ is also separable and proper pseudo-Lipschitz from Proposition 6. Thus, we can repeat the same derivation for $\{\vec{b}_0[\ell]\}_{\ell=1}^{|\mathcal{L}_W|-1}$ and $\{n[\ell]\}_{\ell=1}^{|\mathcal{L}_W|-1}$ to arrive at

$$\langle \tilde{\phi}_0(\mathcal{B}_1,\Omega,\Lambda) \rangle \stackrel{\text{a.s.}}{=} \mathbb{E}\left[\langle \tilde{\phi}_0(\mathcal{Z}_{\mathrm{A},1},\tilde{\Omega},\Lambda) \rangle \right] + o(1), \quad (256)$$

where the strong law of large numbers with respect to $\{\lambda[\ell]\}$ follows from Assumption 3. Thus, the former property (226) holds for $\tau = 0$.

Proof of (A3): The former property (227) for $\tau = 0$ follows from Property (A2) and a technical result in [8, Lemma 5]. Thus, we only prove the latter property for $\tau = 0$.

Without loss of generality, we focus on $\ell = 0$. We use Property (A2) and (227) for $\tau = 0$ to find that the LHS of (228) reduces to its expectation

$$\frac{1}{N_{c}[0]} \mathbb{E}\left[\vec{\boldsymbol{z}}_{A,0}^{T}[0]\left((\boldsymbol{I}_{N_{c}[0]},\boldsymbol{O})\tilde{\boldsymbol{\phi}}_{0} - \mathbb{E}[\tilde{\boldsymbol{\xi}}_{A,0,0}[0]]\vec{\boldsymbol{z}}_{A,0}[0]\right)\right]$$
(257)

in the large system limit, with $\tilde{\phi}_0 = \tilde{\phi}_0(\mathcal{Z}_{A,0}, \tilde{\Omega}, \Lambda)$. Using [54, Lemma 2] yields

LHS of (228)

$$\stackrel{\text{a.s.}}{=} \frac{1}{N_{c}[0]} \sum_{n=1}^{N_{c}[0]} \mathbb{E}[\vec{z}_{A,n,0}^{2}[0]] \mathbb{E}[\langle \partial_{0}\tilde{\phi}_{n,0}\rangle] \\ -\mathbb{E}[\tilde{\xi}_{A,0,0}[0]] \frac{\mathbb{E}[\|\vec{z}_{A,0}[0]\|^{2}]}{N_{c}[0]} + o(1) = o(1), \quad (258)$$

where the last equality follows from the definition of $\tilde{\xi}_{A,0,0}[0]$ in (229). Thus, Property (A3) holds for $\tau = 0$.

Proofs of (A4) and (A5): The proofs are omitted since they are the same as in [54, p. 4419].

F. Module B for $\tau = 0$

Proof of (B1): The proof is omitted since it is the same as in [54, pp. 4419-4420].

Proof of (B2): We prove the strong law of large numbers with respect to $\vec{h}_0[0]$. Consider

$$\langle \tilde{\psi}_0(\mathcal{H}_1, \mathcal{X}) \rangle = \frac{1}{N_{\rm c}} \sum_{n=1}^{N_{\rm c}[0]} \tilde{\psi}_{n,0} + \frac{1}{N_{\rm c}} \sum_{n=N_{\rm c}[0]+1}^{N_{\rm c}} \tilde{\psi}_{n,0}.$$
 (259)

By definition, the second term is independent of $\vec{h}_0[0]$.

To evaluate the first term, we utilize [54, Lemma 3] with $a_{2|\mathcal{L}_W|-1} = 0$, $A_{2|\mathcal{L}_W|-1} = \{\{[\vec{h}_0^{\mathrm{T}}[\ell], O]^{\mathrm{T}}\}_{\ell=1}^{|\mathcal{L}_W|-1}, \mathcal{X}\}, \epsilon = o(1)\vec{q}_0^{\mathrm{ext}}[0], E = \vec{q}_0^{\mathrm{ext}}[0], \text{ and } \omega = \vec{\omega}_{\mathrm{B},0}[0].$ Using Property (B1) for $\tau = 0$ and [54, Lemma 3] yields

$$\langle \tilde{\psi}_{0}(\mathcal{H}_{1}, \mathcal{X}) \rangle - \mathbb{E}_{\vec{z}_{\mathrm{B},0}[0]} \left[\langle \tilde{\psi}_{0}([\vec{z}_{\mathrm{B},0}^{\mathrm{T}}[0], \mathbf{0}]^{\mathrm{T}}, \mathbf{A}_{2|\mathcal{L}_{W}|-1}) \rangle \right]$$
^{a.s.}

$$\rightarrow 0,$$
(260)

with $\vec{z}_{B,0}[0] \sim \mathcal{N}(\mathbf{0}, \pi_{0,0}[0] \boldsymbol{I}_{N_c[0]})$, where Property (A4) for $\tau = 0$ implies the existence of $\pi_{0,0}[0]$.

The strong law of large numbers with respect to the remaining vectors can be proved in the same manner. Repeating the application of [54, Lemma 3] for $\ell = 1, \ldots, |\mathcal{L}_W| - 1$, we arrive at

$$\langle \tilde{\boldsymbol{\psi}}_{0}(\mathcal{H}_{1},\mathcal{X}) \rangle - \mathbb{E}\left[\langle \tilde{\boldsymbol{\psi}}_{0}(\mathcal{Z}_{\mathrm{B},0},\mathcal{X}) \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0,$$
 (261)

where the strong law of large numbers for \mathcal{X} follows from Assumption 2. Thus, Property (B2) holds for $\tau = 0$.

Proofs of (B3) and (B4): The proofs are omitted since they are the same as in Properties (A3) and (A4) for $\tau = 0$, respectively.

Proof of (B5): The proof is omitted since it is the same as in [54, p. 4420].

G. Module A by Induction

Assume that Theorem 8 is correct for all $\tau < t$. We prove Theorem 8 for $\tau = t$. Since the properties for module B can be proved in the same manner as for module A, we only prove the properties for module A.

Proof of (A1) for $\tau = t$: The proof is omitted since it is the same as in [54, p. 4420].

Proof of (A2) for $\tau = t$: The proof is essentially the same as in the proof of Property (A2) for $\tau = 0$. We prove the strong law of large numbers with respect to $\{\vec{b}_{\tau}[0]\}$ in the order $\tau = t, \ldots, 0$. Consider

$$\langle \tilde{\phi}_t(\mathcal{B}_{t+1},\Omega,\Lambda) \rangle = \frac{1}{N_c} \sum_{n=1}^{N_c[0]} \tilde{\phi}_{n,t} + \frac{1}{N_c} \sum_{n=N_c[0]+1}^{N_c} \tilde{\phi}_{n,t}.$$
(262)

By definition, the second term is independent of $\vec{b}_t[0]$.

To evaluate the first term, we utilize [54, Lemma 3] under Property (A1) for $\tau \leq t$. Let $\boldsymbol{a}_{(t+3)|\mathcal{L}_W|-1} = \boldsymbol{B}_t[0]\boldsymbol{\beta}_t[0]$, $\boldsymbol{A}_{(t+3)|\mathcal{L}_W|-1} = \{[\boldsymbol{B}_t^{\mathrm{T}}[0], \boldsymbol{O}]^{\mathrm{T}}, \{[\boldsymbol{B}_{t+1}^{\mathrm{T}}[\ell], \boldsymbol{O}]^{\mathrm{T}}\}_{\ell=1}^{|\mathcal{L}_W|-1}, \Omega, \Lambda\}, \boldsymbol{\epsilon} = \boldsymbol{M}_t^{\mathrm{ext}}[0]\boldsymbol{o}(1) + \boldsymbol{B}_t[0]\boldsymbol{o}(1), \boldsymbol{E} = (\boldsymbol{B}_t[0], \boldsymbol{M}_t^{\mathrm{ext}}[0]),$ and $\boldsymbol{\omega} = \boldsymbol{\omega}_{\mathrm{A},t}[0]$. Using Property (A1) for $\tau = t$ and [54, Lemma 3] yields

$$\langle \tilde{\boldsymbol{\phi}}_t(\boldsymbol{\mathcal{B}}_{t+1}, \Omega, \Lambda) \rangle - \mathbb{E}_{\vec{\boldsymbol{z}}_{\mathrm{A}, t}[0]} \left[\langle \tilde{\boldsymbol{\phi}}_t([(\vec{\boldsymbol{B}}_t[0]\vec{\boldsymbol{\beta}}_t[0] + \vec{\boldsymbol{z}}_{\mathrm{A}, t}[0])^{\mathrm{T}}, \mathbf{0}]^{\mathrm{T}}, \mathbf{A}_{(t+3)|\mathcal{L}_W|-1} \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0.$$
 (263)

Repeating this argument, we follow [54, p. 4420] to arrive at

$$\langle \tilde{\boldsymbol{\phi}}_{t}(\mathcal{B}_{t+1},\Omega,\Lambda) \rangle - \mathbb{E}_{\vec{\boldsymbol{Z}}_{\mathrm{A},t+1}[0]} \left[\langle \tilde{\boldsymbol{\phi}}_{t}([\vec{\boldsymbol{Z}}_{\mathrm{A},t+1}^{\mathrm{T}}[0],\boldsymbol{0}]^{\mathrm{T}}, \\ \boldsymbol{A}_{(t+3)|\mathcal{L}_{W}|-t-1}) \rangle \right] \stackrel{\mathrm{a.s.}}{\to} 0,$$
 (264)

with $\boldsymbol{A}_{(t+3)|\mathcal{L}_W|-(t+1)} = \{\{[\vec{\boldsymbol{B}}_{t+1}^{\mathrm{T}}[\ell], \boldsymbol{O}]^{\mathrm{T}}\}_{\ell=1}^{|\mathcal{L}_W|-1}, \Omega, \Lambda\}.$

The strong law of large numbers with respect to the remaining vectors can be proved in the same manner. Repeating the application of [54, Lemma 3] for $\ell = 1, \ldots, |\mathcal{L}_W| - 1$, we obtain

$$\langle \tilde{\boldsymbol{\phi}}_t(\mathcal{B}_{t+1},\Omega,\Lambda) \rangle - \mathbb{E}\left[\langle \tilde{\boldsymbol{\phi}}_t(\mathcal{Z}_{\Lambda,t+1},\tilde{\Omega},\Lambda) \rangle \right] \stackrel{\text{a.s.}}{\to} 0, \quad (265)$$

where the strong law of large numbers for Ω and Λ follows from Assumptions 3 and 4. Thus, Property (A2) holds for $\tau = t$.

Proof of (A3) for $\tau = t$: The former property (227) for $\tau = t$ follows from Property (A2) for $\tau = t$ and a technical result in [8, Lemma 5]. Thus, we only prove the latter property for $\tau = t$.

Without loss of generality, we focus on $\ell = 0$. We use Property (A2) and (227) for $\tau = t$ to find that the LHS of (228) reduces to its expectation

$$\mathbb{E}\left[\frac{\vec{\boldsymbol{z}}_{\mathrm{A},\tau'}^{\mathrm{T}}[0]}{N_{c}[0]}\left((\boldsymbol{I}_{N_{c}[0]},\boldsymbol{O})\tilde{\boldsymbol{\phi}}_{t}-\sum_{t'=0}^{t}\mathbb{E}[\tilde{\xi}_{\mathrm{A},t',t}[0]]\vec{\boldsymbol{z}}_{\mathrm{A},t'}[0]\right)\right]$$
(266)

in the large system limit, with $\tilde{\phi}_t = \tilde{\phi}_t(\mathcal{Z}_{A,t+1}, \tilde{\Omega}, \Lambda)$. Using [54, Lemma 2] yields

LHS of (228)
^{a.s.}

$$= o(1) + \frac{1}{N_{c}[0]} \sum_{n=1}^{N_{c}[0]} \sum_{t'=0}^{t} \mathbb{E}[\vec{z}_{A,n,\tau'}[0]\vec{z}_{A,n,t'}[0]]\mathbb{E}[\langle \partial_{t'}\tilde{\phi}_{n,t}\rangle] - \sum_{t'=0}^{t} \mathbb{E}[\tilde{\xi}_{A,t',t}[0]] \frac{\mathbb{E}[\vec{z}_{A,\tau'}^{T}[0]\vec{z}_{A,t'}[0]]}{N_{c}[0]} = o(1)$$
(267)

where the last equality follows from the definition of $\xi_{A,t',t}[0]$ in (229). Thus, Property (A3) holds for $\tau = t$.

Proofs of (A4) and (A5) for $\tau = t$: The proofs are omitted since they are the same as in [54, p. 4420].

APPENDIX H Proof of Lemma 8

A. Proof of (121)

The former property (121) follows from the latter (122). We first evaluate an upper bound on $\tilde{s}_{\tau}[l]$. From Lemma 3 and the assumption (72) in Theorem 4, we have R(0) = 1. Using this result, the definition of g(z) in (116), and the non-decreasing assumption for R(z) on $(-\infty, 0]$, we have the upper bound $g(z) \leq 1/\sigma^2$ for all $z \geq 0$. Thus, from the definition of $\tilde{s}_{\tau}[l]$ in (115) we arrive at $\tilde{s}_{\tau}[l] \leq 1/\sigma^2$. We next evaluate $s_{\tau}[l]$. From the latter property (122),

We next evaluate $s_{\tau}[l]$. From the latter property (122), the difference $|\tilde{s}_{\tau}[l] - s_{\tau}[l]|$ is bounded for fixed τ and all $l \in \mathcal{L}_0$, i.e. $|\tilde{s}_{\tau}[l] - s_{\tau}[l]| < d$ for some d > 0, which implies $s_{\tau}[l] < \tilde{s}_{\tau}[l] + d \leq 1/\sigma^2 + d$. Thus, we can restrict the domain of MMSE(s) to the interval $[0, 1/\sigma^2 + d]$. Since Proposition 2 implies the continuous differentiability of MMSE(s) for all $s \geq 0$, MMSE(s) is Lipschitz-continuous for all $s \in [0, 1/\sigma^2 + d]$.

Let us prove the former property (121). From the definitions of $E_{\tau+1}[\ell]$ and $\tilde{E}_{\tau+1}$ in (105) and (114), we use the triangle inequality and the Lipschitz-continuity of MMSE(s) to obtain

$$|E_{\tau+1}[\ell] - E_{\tau+1}[\ell]| \le \frac{1}{W+1} \sum_{w \in \mathcal{W}[\ell]} |\mathrm{MMSE}(\tilde{s}_{\tau}[\ell-w]) - \mathrm{MMSE}(s_{\tau}[\ell-w])| \le \frac{C}{W+1} \sum_{w \in \mathcal{W}[\ell]} |\tilde{s}_{\tau}[\ell-w] - s_{\tau}[\ell-w]| = \mathcal{O}(a_W^{-1}), \quad (268)$$

with some constant C > 0, where the last follows from the latter property (122) and $|\mathcal{W}[\ell]| \leq W+1$ for all $\ell \in \mathcal{L}_W$. Thus, the former property (121) holds if the latter property (122) is correct.

B. Proof of (122)

We prove the latter property (122) by induction. The proof of (122) for $\tau = 0$ is trivial from the initial condition $\tilde{s}_0[l] = s_0[l]$. For some $t \in \mathbb{N}$, suppose that (122) is correct for $\tau = t - 1$. We need to prove (122) for $\tau = t$.

From the definitions of $s_t[l]$ and $\tilde{s}_t[l]$ in (106) and (115), respectively, we use the triangle inequality to obtain

$$|\tilde{s}_t[l] - s_t[l]| < \frac{1}{W+1} \sum_{\ell=l}^{l+W} \left(T_t^{(1)}[\ell] + T_t^{(2)}[\ell] + T_t^{(3)}[\ell] \right),$$
(269)

where $T_t^{(i)}[\ell]$ for $i \in \{1, 2, 3\}$ is given by

$$T_t^{(1)}[\ell] = |g(\tilde{E}_t[\ell]) - g(E_t[\ell])|, \qquad (270)$$

$$T_t^{(2)}[\ell] = |g(\nu_t[\ell]E_t[\ell]) - g[\ell](\nu_t[\ell]E_t[\ell])|, \qquad (271)$$

$$T_t^{(3)}[\ell] = |g(E_t[\ell]) - g(\nu_t[\ell]E_t[\ell])|, \qquad (272)$$

with

$$\nu_t[\ell] = \frac{\bar{\eta}_{\mathrm{A},t}[\ell]}{1 - \bar{\eta}_{\mathrm{B},t-1}[\ell]/|\mathcal{W}[\ell]|} > 0.$$
(273)

We evaluate the first term. The induction hypothesis (122) for $\tau = t - 1$ implies the former property (121) for $\tau = t - 1$,

$$|\tilde{E}_t[\ell] - E_t[\ell]| = \mathcal{O}(a_W^{-1}).$$
 (274)

The continuous-differentiability assumption of R(z) in Lemma 8 implies that g(z) in (116) is also continuously differentiable for all $z \ge 0$. Furthermore, from the upper bound $\text{MMSE}(s) \le 1$ in (5) and the induction hypothesis (274) we find that both $\tilde{E}_t[\ell]$ and $E_t[\ell]$ are bounded. Repeating the same proof as that for the former property (121) in Appendix H-A, we obtain

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(1)}[\ell] = \mathcal{O}(a_W^{-1}).$$
(275)

In evaluating the remaining terms, we use the following lemma on $\mathcal{O}(W/a_W)$ sections in both ends:

Lemma 14: Suppose that $\mathbb{E}[x_1^2[l]] = 1$ holds. Let $\{a_W > 0\}_{W=1}^{\infty}$ denote a positive and diverging sequence at a sublinear speed in W: $\lim_{W\to\infty} a_W = \infty$ and $\lim_{W\to\infty} a_W/W = 0$. For all t and $\ell \in \{0, \ldots, \lceil W/a_W \rceil\} \cup \{L + W - 1 - \lceil W/a_W \rceil, \ldots, L + W - 1\}, E_t[\ell] = \mathcal{O}(a_W^{-1})$ and $\tilde{E}_t[\ell] = \mathcal{O}(a_W^{-1})$ hold in the continuum limit $L, W \to \infty$ with $\Delta = W/L$ kept constant.

Proof: Without loss of generality, we focus on $E_t[\ell]$ given in (114) and only consider the case of $\ell \in \{0, \ldots, \lceil W/a_W \rceil\}$ since the case of $\ell \in \{L+W-1-\lceil W/a_W \rceil, \ldots, L+W-1\}$ can be proved in the same manner.

For all $\ell \in \{0, \ldots, \lceil W/a_W \rceil\}$, we use the definition of $\mathcal{W}[\ell]$ in (30) and the upper bound $\text{MMSE}(\tilde{s}_t[l]) \leq \mathbb{E}[x_1^2] = 1$ in (5) to have

$$\tilde{E}_{t}[\ell] = \frac{1}{W+1} \sum_{w=0}^{\ell} \text{MMSE}(\tilde{s}_{t-1}[\ell-w])$$
$$\leq \frac{\ell+1}{W+1} < \frac{2+W/a_{W}}{W+1} = \mathcal{O}(a_{W}^{-1})$$
(276)

in the continuum limit.

We arrive at the latter property (122) for $\tau = t$, by proving

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(2)}[\ell] = \mathcal{O}(a_W^{-1}), \qquad (277)$$

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(3)}[\ell] = \mathcal{O}(a_W^{-1})$$
(278)

for all $l \in \mathcal{L}_0$. They are proved in Appendices H-C, and H-D, respectively.

C. Proof of (277)

1) Case 1: We evaluate the summation (277) in the case of $l \in \{\lceil W/a_W \rceil, \ldots, L-1-\lceil W/a_W \rceil\}$. In this case, we can use the assumption (72) in Theorem 4 for all $\ell \in \{l, \ldots, l+W\}$. Applying $g[\ell](z)$ in (107) and g(z) in (116) to (72), we have $|g[\ell](z) - g(z)| = \mathcal{O}(a_W^{-1})$ in the continuum limit for all $\ell \in \{l, \ldots, l+W\}$. Thus,

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(2)}[\ell] = \mathcal{O}(a_W^{-1}).$$
(279)

2) Case 2: In the case of $l \in \{0, ..., \lceil W/a_W \rceil - 1\}$, we decompose the summation (277) into two terms,

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(2)}[\ell] = \frac{1}{W+1} \sum_{\ell=l}^{\lceil W/a_W \rceil - 1} T_t^{(2)}[\ell] + \frac{1}{W+1} \sum_{\ell=\lceil W/a_W \rceil}^{l+W} T_t^{(2)}[\ell].$$
(280)

Repeating the derivation of (279) for the second term yields

$$\frac{1}{W+1} \sum_{\ell=\lceil W/a_W \rceil}^{l+W} T_t^{(2)}[\ell] = \mathcal{O}(a_W^{-1})$$
(281)

in the continuum limit.

For the first term, we use the triangle inequality to obtain

$$T_t^{(2)}[\ell] < \left| g(\nu_t[\ell] E_t[\ell]) - \frac{1}{\sigma^2} \right| + \left| \frac{1}{\sigma^2} - g[\ell](\nu_t[\ell] E_t[\ell]) \right|.$$
(282)

From $g[\ell](z)$ in (107) and Lemma 3, we have $|g[\ell](z) - \sigma^{-2}| = o(1)$ for all $\ell \in \mathcal{L}_W$ as $z \to 0$. Similarly, we use the definition of g(z) in (116), the assumption (72) in Theorem 4, and the continuity assumption of R(z) to obtain $|g(z) - \sigma^{-2}| = o(1)$. Furthermore, Lemma 14 implies $E_t[\ell] \to 0$ for $\ell \in \{l, \ldots, \lceil W/a_W \rceil - 1\}$. Combining these results, we arrive at

$$\frac{1}{W+1} \sum_{\ell=l}^{\lceil W/a_W \rceil - 1} T_t^{(2)}[\ell] = \mathcal{O}(a_W^{-1})$$
(283)

in the continuum limit. Thus, (277) holds.

3) Case 3: The proof in the case of $l \in \{L - \lceil W/a_W \rceil, \ldots, L-1\}$ is omitted since it is the same as that in the case of $l \in \{0, \ldots, \lceil W/a_W \rceil - 1\}$.

D. Proof of (278)

1) Case 1: We evaluate the summation (278) in the case of $l \in \{ \lceil W/a_W \rceil, \ldots, L-1 - \lceil W/a_W \rceil \}$. Since we have already proved the boundedness of $E_t[\ell]$, we use Lemma 7 for all $\ell \in \{l, \ldots, l+W\}$ to find the boundedness of $\nu_t[\ell]E_t[\ell]$. We repeat the proof in Appendix H-A to arrive at

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(3)}[\ell] < \frac{C}{W+1} \sum_{\ell=l}^{l+W} |1-\nu_t[\ell]| E_t[\ell] = \mathcal{O}(a_W/W)$$
(284)

for some constant C > 0, where the last equality follows from Lemma 7.

2) Case 2: In the case of $l \in \{0, ..., \lceil W/a_W \rceil - 1\}$, we decompose the summation (278) into two terms,

$$\frac{1}{W+1} \sum_{\ell=l}^{l+W} T_t^{(3)}[\ell] = \frac{1}{W+1} \sum_{\ell=l}^{\lceil W/a_W \rceil - 1} T_t^{(3)}[\ell] + \frac{1}{W+1} \sum_{\ell=\lceil W/a_W \rceil}^{l+W} T_t^{(3)}[\ell].$$
(285)

Since we have already proved $|g(z) - \sigma^{-2}| = o(1)$, for the first term we use Lemma 14 to obtain

$$\frac{1}{W+1} \sum_{\ell=l}^{|W/a_W|-1} T_t^{(3)}[\ell] = \mathcal{O}(a_W^{-1}).$$
(286)

Repeating the derivation of (284) for the second term, we have

$$\frac{1}{W+1} \sum_{\ell=\lceil W/a_W \rceil}^{l+W} T_t^{(3)}[\ell] = \mathcal{O}(a_W/W).$$
(287)

Thus, (278) holds.

3) Case 3: The proof in the case of $l \in \{L - \lceil W/a_W \rceil, \ldots, L-1\}$ is omitted since it is the same as that in the case of $l \in \{0, \ldots, \lceil W/a_W \rceil - 1\}$.

ACKNOWLEDGMENT

The author thanks the anonymous reviewers for their suggestions that have improved the quality of the manuscript greatly.
