

THE ECONOMY'S POTENTIAL DUALITY AND EQUILIBRIUM

Jacob K. Goeree¹

October 27, 2022

Abstract

I introduce a concave function of allocations and prices – the economy’s potential – which measures the difference between utilitarian social welfare and its dual. I show that Walrasian equilibria correspond to roots of the potential: allocations maximize weighted utility and prices minimize weighted indirect utility. Walrasian prices are “utility clearing” in the sense that the utilities consumers expect at Walrasian prices are just feasible. I discuss the implications of this simple duality for equilibrium existence, the welfare theorems, and the interpretation of Walrasian prices.

Keywords: *Walrasian equilibrium, Pareto optimality, duality, potential, roots*

1. Introduction

A landmark of economic theory concerns the determination of prices for all goods in the economy. General equilibrium theory originated with Walras “... whose system of equations, defining equilibria in a system of interdependent quantities, is the Magna Carta of economic theory” (Schumpeter, 1954). The modern approach to general equilibrium theory is due to Arrow and Debreu (1954) and McKenzie (1954) who established existence of Walrasian equilibria. Duffie and Sonnenschein (1989) describe the history and importance of this existence proof, which allowed general equilibrium theory to gain the central role it now occupies in economics and finance.

Arrow and Debreu’s proof pertains to “abstract economies” or “generalized games” and builds on Nash’s (1950) existence proof for normal-form games. Their abstract approach establishes existence of a solution to a system of equations but does not reveal if, or why, it has desirable properties. This is the content of the welfare theorems, the modern versions of which are also due to Arrow (1951) and Debreu (1951). The first welfare theorem – that the price system results in a Pareto optimal allocation of resources – is perhaps the central result in price theory. The second welfare theorem states the converse, i.e. that every Pareto optimal allocation is Walrasian.

Despite their dual formulations, the proofs of the two welfare theorems are very different in nature. The first welfare theorem requires only positive marginal utility of income while the second welfare theorem hinges on the assumption of convexity. Duffie and Sonnenschein (1989) note that as a result of Arrow and Debreu’s work “... the separateness of the two welfare theorems was brought into sharp focus.”

I demonstrate that the welfare theorems encapsulate a simple duality property of Walrasian equilibria. To this end, I introduce the *economy’s potential*, which is a weighted sum of consumers’ utilities of their allocations minus their indirect utilities at given prices. I show that, for any welfare weights, the potential is a non-positive and strictly concave function with a unique root corresponding to the Walrasian equilibrium. The intuition is that allocations solve the primal problem of maximizing weighted utilities and prices solve the dual problem of minimizing weighted indirect utilities. Walrasian prices are “utility clearing” in that the utilities consumers expect are just feasible, i.e. the potential vanishes at the Walrasian equilibrium.

Usually, the economy is parameterized by initial endowments rather than welfare weights. While the set of endowments is of higher dimension than the set of welfare weights,¹ no additional equilibria are introduced. The reason is that any endowments and resulting Walrasian price imply some set of welfare weights. Moreover, existence of Walrasian equilibrium for arbitrary endowments follows if there is at least one vector of “equilibrium weights” that produce the correct incomes. I show that existence of such equilibrium weights readily follows from the Poincare–Hopf theorem.

The next section presents a graphical illustration of duality for a simple exchange economy. Section 3 introduces the economy’s potential, generalizes the duality result to any exchange economy, and shows that existence and the welfare theorems are direct corollaries of duality. Furthermore, duality provides a novel interpretation of the Walrasian price vector as the gradient of utilitarian social welfare. Section 4 discusses possible applications of the potential to non-convex economies. Proofs can be found in the Appendix.

2. An Example

Consider an exchange economy with two consumers with Cobb–Douglas preferences $u_1(x, y) = 2 \log(x) + \log(y)$ and $u_2(x, y) = \log(x) + 2 \log(y)$. Suppose there are three units of each good in the economy. Welfare maximization

$$\max_{\substack{0 \leq x_1 + x_2 \leq 3 \\ 0 \leq y_1 + y_2 \leq 3}} \alpha u_1(x_1, y_1) + (1 - \alpha) u_2(x_2, y_2) \quad (1)$$

yields the Pareto-optimal allocations $(x_1(\alpha), y_1(\alpha)) = (\frac{6\alpha}{1+\alpha}, \frac{3\alpha}{2-\alpha})$ and $(x_2(\alpha), y_2(\alpha)) = (\frac{3-3\alpha}{1+\alpha}, \frac{6-6\alpha}{2-\alpha})$. The red curve in Figure 1 shows the resulting utility pairs $(u_1(\alpha), u_2(\alpha))$ for $\alpha \in (0, 1)$. The shaded area corresponds to the utility possibility set.

The dual of (1) entails minimizing a weighted sum of indirect utilities with respect to prices. If prices are normalized to sum to one, i.e. the price vector is $(p, 1 - p)$, then the indirect utility functions can be written as $v_1(p, m_1) = 2 \log(\frac{2m_1}{3p}) + \log(\frac{m_1}{3(1-p)})$ and

¹With $N > 1$ consumers and $K > 1$ goods the set of endowments is NK dimensional while the set of welfare weights is N dimensional.

Figure 1: Illustration of duality. The shaded area is the utility possibility set and the red curve its frontier. The blue curves depict indirect utilities for given welfare weights as functions of prices. For $\alpha = \frac{1}{2}$, weighted utility is constant on the dashed lines and increases to the North-East while weighted indirect utility is constant on the dotted lines and decreases to the South-West. The unique point where weighted utility and weighted indirect utility match corresponds to the Walrasian equilibrium.

$v_2(p, m_2) = \log\left(\frac{m_2}{3p}\right) + 2\log\left(\frac{2m_2}{3(1-p)}\right)$. The economy's total income is $3p + 3(1-p) = 3$ and a consumer's welfare weight determines her share:² $m_1 = 3\alpha$ and $m_2 = 3(1-\alpha)$. The dual of (1) is thus

$$\min_{0 \leq p \leq 1} \alpha v_1(p, 3\alpha) + (1-\alpha)v_2(p, 3(1-\alpha)) \quad (2)$$

The blue curves show the indirect utility pairs $(v_1(p, 3\alpha), v_2(p, 3(1-\alpha)))$ for different values of α and $p \in (0, 1)$. For $\alpha = \frac{1}{2}$, the weighted sum of utilities is constant on the dashed lines and increasing in the North-East direction. The weighted sum of indirect utilities is constant on the dotted lines and decreasing in the South-West direction. There is a unique point where weighted utility is maximized and weighted indirect utility minimized and their values are equal. This point corresponds to the Walrasian equilibrium.

To see this, note that the solution to (2) is $p(\alpha) = \frac{1}{3}(1+\alpha)$ and it is readily verified

²More generally, a consumer's welfare weight is equal to the inverse of her marginal utility of income, see Theorem 1 below. For the economy studied here this yields $\alpha = m_1/3$ and $1-\alpha = m_2/3$.

that the price ratio

$$\frac{p(\alpha)}{1-p(\alpha)} = \frac{1+\alpha}{2-\alpha}$$

is equal to consumers' marginal rates of substitution at $(x_1(\alpha), y_1(\alpha))$ and $(x_2(\alpha), y_2(\alpha))$. Hence, these allocations maximize consumers' utilities given prices $(p(\alpha), 1-p(\alpha))$. In other words, the Pareto-optimal allocations that follow from (1) form a Walrasian equilibrium together with the price that follows from the dual program in (2).

3. The Economy's Potential

Consider an exchange economy with $\mathcal{N} = \{1, \dots, N\}$ consumers and $\mathcal{K} = \{1, \dots, K\}$ goods. For $i \in \mathcal{N}$, let $u_i : \mathbb{R}_{\geq 0}^K \rightarrow \mathbb{R}$ denote consumer i 's utility function and $\omega_i \in \mathbb{R}_{> 0}^K$ consumer i 's endowment. I assume the utility functions are strictly increasing, strictly concave, and differentiable.³ For $k \in \mathcal{K}$, let $w_k = \sum_{i \in \mathcal{N}} \omega_{ik}$ denote the total amount of good k in the economy. The set of feasible allocations is

$$F(w) = \{x \in \mathbb{R}_{\geq 0}^{NK} \mid \sum_{i \in \mathcal{N}} x_{ik} \leq w_k \ \forall k \in \mathcal{K}\}$$

For vectors $v, v' \in \mathbb{R}^K$ let $\langle v | v' \rangle = \sum_{k \in \mathcal{K}} v_k v'_k$ denote the usual inner product. The Fenchel dual of $u_i(x_i)$ is defined as

$$\bar{v}_i(p) = \max_{x_i \geq 0} u_i(x_i) - \langle p | x_i \rangle \quad (3)$$

which is a strictly convex function of prices. An envelope-theorem argument establishes that the solution to (3) satisfies $\bar{x}_i(p) = -\nabla_p \bar{v}_i(p)$, which is a simplified version of Roy's identity. The solution $\bar{x}_i(p)$ is strictly decreasing in each price and further satisfies $\lim_{p_k \downarrow 0} \bar{x}_{ik}(p) = \infty$ and $\lim_{p_k \rightarrow \infty} \bar{x}_{ik}(p) = 0$.

The next lemma relates $\bar{v}_i(p)$ and $\bar{x}_i(p)$ to the traditional indirect utility $v_i(p, m_i)$ and the Marshallian demand $x_i(p, m_i)$ respectively.

³The usual assumption is that the utility functions are quasi-concave, which can be made concave by a monotone transformation. Intuitively, this construction implies that among utility functions with the same indifference curves there is one with non-increasing marginal utility. Concave functions are differentiable almost everywhere. For ease of presentation, I assume differentiability everywhere.

Lemma 1 For $i \in \mathcal{N}$, let $\lambda_i(p, m_i)$ solve $\langle p | \bar{x}_i(\lambda_i p) \rangle = m_i$, then

$$v_i(p, m_i) = \lambda_i(p, m_i) m_i + \bar{v}_i(\lambda_i(p, m_i) p) \quad (4)$$

$$x_i(p, m_i) = \bar{x}_i(\lambda_i(p, m_i) p) \quad (5)$$

Moreover, $\lambda_i(p, m_i)$ equals the marginal utility of income, $\lambda_i(p, m_i) = \partial v_i(p, m_i) / \partial m_i$, and for any price vector, $\lambda_i(p, m_i)$ is strictly positive and strictly decreasing in m_i with $\lim_{m_i \downarrow 0} \lambda_i(p, m_i) = \infty$ and $\lim_{m_i \rightarrow \infty} \lambda_i(p, m_i) = 0$.

Example 1 (CES utility) For $i \in \mathcal{N}$ and $\rho_i < 1$, consider the CES utilities

$$u_i(x_i) = \frac{1}{\rho_i} \log \left(\sum_{k \in \mathcal{K}} a_{ik} x_{ik}^{\rho_i} \right)$$

with Fenchel duals

$$\bar{v}_i(p) = \frac{1 - \rho_i}{\rho_i} \log \left(\sum_{k \in \mathcal{K}} a_{ik} (p_k / a_{ik})^{\frac{\rho_i}{\rho_i - 1}} \right) - 1$$

Roy's identity yields

$$\bar{x}_{ik}(p) = \frac{(p_k / a_{ik})^{\frac{1}{\rho_i - 1}}}{\sum_{\ell \in \mathcal{K}} a_{i\ell} (p_\ell / a_{i\ell})^{\frac{\rho_i}{\rho_i - 1}}}$$

which satisfies $\bar{x}_{ik}(p/m_i) = m_i \bar{x}_{ik}(p)$ and $\langle p | \bar{x}_i(p) \rangle = 1$ so $\lambda_i(p, m_i) = \frac{1}{m_i}$. Marshallian demand is $x_i(p, m_i) = m_i \bar{x}_i(p)$ and indirect utility is $v_i(p, m_i) = 1 + \bar{v}_i(p) + \log(m_i)$. ■

Let $U_\alpha(x) = \sum_{i \in \mathcal{N}} \alpha_i u_i(x_i)$ denote weighted aggregate utility for some positive weight vector $\alpha \in \mathbb{R}_{>0}^N$. The welfare-maximization program

$$W_\alpha(w) = \max_{x \in F(w)} U_\alpha(x) \quad (6)$$

is equivalent to the saddle-point problem

$$W_\alpha(w) = \min_{p \geq 0} \max_{x \geq 0} \sum_{i \in \mathcal{N}} \alpha_i u_i(x_i) - \langle p | x_i - \omega_i \rangle$$

where the multiplier for the feasibility constraint $\sum_{i \in \mathcal{N}} (x_i - \omega_i) \leq 0$ is denoted p on purpose. The maximization over allocations is solved by $\bar{x}_i(p/\alpha_i)$ and using the

Fenchel duals \bar{v}_i we can write the result as

$$W_\alpha(w) = \min_{p \geq 0} V_\alpha(p, w) \quad (7)$$

where

$$V_\alpha(p, w) = \langle p | w \rangle + \sum_{i \in \mathcal{N}} \alpha_i \bar{v}_i(p/\alpha_i) \quad (8)$$

is strictly convex in prices.

The *economy's potential* is defined as

$$Y_\alpha(x, p, w) = U_\alpha(x) - V_\alpha(p, w) \quad (9)$$

From (6) and (7) it follows that the potential is non-positive for all feasible allocations and non-negative prices. Moreover, it is a strictly concave function of allocations and prices since $U_\alpha(x)$ is strictly concave and $V_\alpha(p, w)$ is strictly convex.

Let $\lambda_i^{(-1)}(p, \cdot)$ denote the inverse of $\lambda_i(p, m_i)$ with respect to the income m_i .

Theorem 1 *If (x, p) is a Walrasian equilibrium of the economy with incomes m_i for $i \in \mathcal{N}$ then $Y_\alpha(x, p, w) = 0$ for $\alpha_i = 1/\lambda_i(p, m_i)$ and $i \in \mathcal{N}$. Conversely, for any $\alpha \in \mathbb{R}_{>0}^N$, $Y_\alpha(x, p, w)$ has a unique root $(x(\alpha), p(\alpha))$, which is the Walrasian equilibrium of the economy with incomes $m_i(\alpha) = \lambda_i^{(-1)}(p(\alpha), \frac{1}{\alpha_i})$ for $i \in \mathcal{N}$ and $\sum_{i \in \mathcal{N}} m_i(\alpha) = \langle p(\alpha) | w \rangle$.*

Evaluated at the equilibrium price, (8) can also be expressed in terms of the standard indirect utilities

$$V_\alpha(p(\alpha), w) = \sum_{i \in \mathcal{N}} \alpha_i v_i(p(\alpha), m_i(\alpha))$$

which follows from (4) together with $\lambda_i(p(\alpha), m_i(\alpha)) = \frac{1}{\alpha_i}$ and $\sum_{i \in \mathcal{N}} m_i(\alpha) = \langle p(\alpha) | w \rangle$.

3.1. Welfare Theorems

A necessary condition for the pair (x, p) to be a root of the potential is that x maximizes welfare, i.e. it is Pareto optimal. The first part of Theorem 1 thus implies the first welfare theorem and the converse part implies the second welfare theorem.

Corollary 1 *Theorem 1 implies that any Walrasian allocation is Pareto-optimal and vice versa.*

Figure 2: Illustration of duality for the economy in Example 2.

For the economy in Section 2, the Walrasian equilibrium price and allocation can be obtained from either the primal welfare-maximization program or the dual program of minimizing weighted indirect utility. For instance, the primal program yields the allocations and the price follows from consumers' marginal rates of substitution. Alternatively, the dual program yields the price and the allocations follow from Roy's identity. This is a consequence of the strict concavity assumption. If we relax this assumption to concavity, the tangency in Figure 1 does not necessarily occur. Nonetheless, Walrasian prices are "utility clearing," i.e. they force a zero potential.

Example 2 (Linear utility) Consider an exchange economy with two consumers with linear preferences $u_1(x, y) = \log(2x + y)$ and $u_2(x, y) = \log(x + 2y)$. Suppose there is one unit of each good in the economy. Welfare maximization yields the Pareto-optimal allocations

$$(x_1(\alpha), y_1(\alpha)) = \begin{cases} (3\alpha, 0) & \text{if } \alpha \leq \frac{1}{3} \\ (1, 0) & \text{if } \frac{1}{3} \leq \alpha \leq \frac{2}{3} \\ (1, 3\alpha - 2) & \text{if } \alpha \geq \frac{2}{3} \end{cases}$$

and $(x_2(\alpha), y_2(\alpha)) = (1 - x_1(\alpha), 1 - y_1(\alpha))$. The frontier of the utility-possibility set, depicted by the red curve in Figure 2, corresponds to the resulting utility pairs (u_1, u_2) .

The Pareto optimal allocations lie on the boundary of the Edgeworth box for any welfare weight and the Walrasian price does not follow from consumers' marginal rates of substitution. Instead it follows from minimizing $V_\alpha(p, w)$, which yields

$$\frac{p(\alpha)}{1-p(\alpha)} = \begin{cases} \frac{1}{2} & \text{if } \alpha \leq \frac{1}{3} \\ \frac{\alpha}{1-\alpha} & \text{if } \frac{1}{3} \leq \alpha \leq \frac{2}{3} \\ 2 & \text{if } \alpha \geq \frac{2}{3} \end{cases}$$

This outcome is illustrated by the blue curves in Figure 2. ■

3.2. The Greedy Invisible Hand

An envelope-theorem argument applied to (7) establishes the Walrasian price vector as the gradient of utilitarian social welfare.

Corollary 2 *If (x, p) is a Walrasian equilibrium then*

$$p = \nabla_w W_\alpha(w) \tag{10}$$

for $\alpha_i = 1/\lambda_i(p, m_i)$ and $x_i = \bar{x}_i(\lambda_i(p, m_i)p)$ for $i \in \mathcal{N}$.

The characterization of the Walrasian equilibrium price as the gradient of utilitarian social welfare is surprising – Adam Smith's "invisible hand" steers market participants to a state of greatest happiness in a simple greedy manner. Yet, the characterization is intuitive as it implies a balance of individual and social incentives:

$$\frac{\partial_k W_\alpha(w)}{\partial_\ell W_\alpha(w)} = \frac{\partial_k u_i(x_i)}{\partial_\ell u_i(x_i)} \tag{11}$$

for $i \in \mathcal{N}$, $k, \ell \in \mathcal{K}$ and $\alpha_i = 1/\lambda_i(p, m_i)$. In other words, individuals' marginal rates of substitution match the social marginal rate of substitution. Corollary 2 provides a simple-yet-powerful way to analytically characterize Walrasian equilibria.

Example 3 (Homogeneous CES) Suppose there are K goods and N consumers with CES utilities

$$u_i(x) = \frac{1}{\rho} \log\left(\sum_{k \in \mathcal{K}} a_k x_k^\rho\right)$$

for $\rho < 1$. Consumers' endowments are ω_i and the total endowments are $w = \sum_{i \in \mathcal{N}} \omega_i$. Aggregate utility $U_\alpha(x) = \sum_{i \in \mathcal{N}} \alpha_i u_i(x_i)$ is maximized at $x_i = (\alpha_i / \sum_{j \in \mathcal{N}} \alpha_j) w$. The social weights are $\alpha_i = 1 / (\partial v_i / \partial m_i) = m_i$, so the gradient of utilitarian social welfare is

$$\nabla_w W_\alpha(w) = \frac{\sum_{i \in \mathcal{N}} m_i}{\sum_{k \in \mathcal{K}} w_k^\rho} w^{\rho-1} = p$$

resulting in price ratios $p_k / p_\ell = (w_k / w_\ell)^\rho$. Using $m_i = \langle p | \omega_i \rangle$ and $x_i = (\alpha_i / \sum_{j \in \mathcal{N}} \alpha_j) w$ yields the Walrasian equilibrium allocations

$$x_i = \frac{\sum_{k \in \mathcal{K}} \omega_{ik} w_k^{\rho-1}}{\sum_{k \in \mathcal{K}} w_k^\rho} w$$

for $i \in \mathcal{N}$. Note that I did not need to solve any individual consumer's maximization problem to derive the Walrasian equilibrium price and allocations. ■

3.3. Existence of Walrasian Equilibria

Theorem 1 shows there is a unique Walrasian equilibrium for any welfare weights. No fixed-point arguments are needed. A simple duality result establishes the Walrasian equilibrium as the unique maximum, and root, of a strictly concave potential.

Usually, the economy is parameterized by endowments $\omega_i \in \mathbb{R}_{>0}$ for $i \in \mathcal{N}$ rather than welfare weights. Theorem 1 shows that if there is a Walrasian equilibrium (x, p) then it is a root of the potential for weights that equal the inverse of the marginal utility of income: $\alpha_i = 1 / \lambda_i(p, \langle p | \omega_i \rangle)$. Hence, despite the set of endowments being of higher dimension (NK) than the set of welfare weights (N), no additional Walrasian equilibria are added when parameterizing the economy by endowments.

Do Walrasian equilibria exist for any endowments? Arrow and Debreu (1954) have answered this question affirmatively by extending Nash's (1950) existence proof. Here I present a simpler argument by showing that for any initial endowments there are "equilibrium weights" that produces the correct incomes. Since $Y_{\kappa\alpha}(x, \kappa p, w) = \kappa Y_\alpha(x, p, w)$ for any $\kappa > 0$ we can, without loss of generality, scale the weight vector α so its entries sum to one, i.e. α belongs to the simplex Σ_N . For $i \in \mathcal{N}$, consider the fixed-point equations

$$\langle p(\alpha) | \omega_i \rangle - m_i(\alpha) = 0 \tag{12}$$

By Theorem 1, $\sum_{i \in \mathcal{N}} m_i(\alpha) = \langle p|w \rangle$, so the left side of (12) defines a vector field on Σ_N . Moreover, $\lim_{\alpha_i \downarrow 0} m_i(\alpha) = 0$ by Lemma 1, so the vector field points inward on the boundary of Σ_N . By the Poincaré–Hopf theorem such a vector field has at least one zero in the interior of Σ_N .

Corollary 3 *For any economy parametrized by endowments $\omega_i \in \mathbb{R}_{>0}$, $i \in \mathcal{N}$ there exists a weight vector $\alpha \in \Sigma_N$ such that the root of $Y_\alpha(x, p, w)$ is a Walrasian equilibrium.*

The solution to (12) is not necessarily unique as the next example shows.

Example 4 Consider an exchange economy with two goods and two consumers with utilities $u_1(x, y) = \frac{3}{2}x^{\frac{2}{3}} - \frac{1}{2}y^{-2}$ and $u_2(x, y) = \frac{3}{2}y^{\frac{2}{3}} - \frac{1}{2}x^{-2}$ and endowments $\omega_1 = (\frac{11}{6}, \frac{1}{6})$ and $\omega_2 = (\frac{1}{6}, \frac{11}{6})$. The Fenchel duals are

$$\bar{v}_1(p_1, p_2) = \frac{1}{2} \left(\frac{1}{p_1^2} - 3p_2^{\frac{2}{3}} \right)$$

and $\bar{v}_2(p_1, p_2) = \bar{v}_1(p_2, p_1)$. The prices $(p_1(\alpha), p_2(\alpha))$ that minimize $V_\alpha(p, w)$ solve

$$\left(\frac{\alpha}{p_1(\alpha)} \right)^3 + \left(\frac{1-\alpha}{p_1(\alpha)} \right)^{\frac{1}{3}} = 2$$

and the equation for $p_2(\alpha)$ follows by interchanging α and $1-\alpha$, i.e. $p_2(\alpha) = p_1(1-\alpha)$. The incomes are $m_1(\alpha) = \alpha^3/p_1(\alpha)^2 + \alpha^{\frac{1}{3}}p_2(\alpha)^{\frac{2}{3}}$ and $m_2(\alpha) = m_1(1-\alpha)$. The fixed-point condition (12) for the equilibrium weight can be written as

$$p_1(\alpha) \left(\left(\frac{1-\alpha}{p_1(\alpha)} \right)^{\frac{1}{3}} - \frac{1}{6} \right) = p_1(1-\alpha) \left(\left(\frac{\alpha}{p_1(1-\alpha)} \right)^{\frac{1}{3}} - \frac{1}{6} \right)$$

An obvious solution is $\alpha = \frac{1}{2}$ and prices $(p_1, p_2) = (\frac{1}{2}, \frac{1}{2})$. Two other solutions are, approximately, $\alpha \approx 0.09$, $(p_1, p_2) \approx (0.16, 0.79)$ and $\alpha \approx 0.91$, $(p_1, p_2) \approx (0.79, 0.16)$. ■

To summarize, parameterizing the economy using welfare weights is economical in two ways. First, there is exactly one Walrasian equilibrium for every welfare weight. Second, this unique Walrasian equilibrium follows from duality rather than from a system of fixed-point conditions. In contrast, parameterizing the economy using endowments is *uneconomical* for three reasons. First, if (x, p) is a Walrasian equilibrium

for the endowments ω_i then it is also a Walrasian equilibrium for any endowments ω'_i that satisfy $\langle p|\omega_i\rangle = \langle p|\omega'_i\rangle$ for $i \in \mathcal{N}$. Second, there may exist multiple Walrasian equilibria for some endowments as Example 4 shows. Third, computing Walrasian equilibria necessarily involves solving a system of fixed-point conditions, see (12). It should be noted that, since the number of goods (K) is typically assumed to be far larger than the number of consumers (N), (12) provides a computationally efficient alternative to solving fixed-point conditions for the equilibrium prices.

Importantly, even if the economy is parameterized by endowments there are no additional Walrasian equilibria with possibly different features than the potential's roots. The Paretian–Walrasian duality derived above thus applies to *all* Walrasian equilibria (even when computed using standard fixed-point conditions).

4. Outlook

The potential provides a litmus test for equilibrium existence. Given preferences and endowments it is a mechanical exercise to compute the potential's maximum value. A Walrasian equilibrium exists if and only if this exercise returns nil.

If not, general equilibrium theory is quiet about the allocations and prices that ensue even when there are obvious gains from trade. For instance, suppose two consumers have $\max(x, y)$ preferences and endowments $\omega_1 = (2, 2)$ and $\omega_2 = (1, 1)$. At any price vector $(p, 1 - p)$ consumer 1 demands at least four units of one of the goods, ruling out Walrasian equilibrium. Yet, consumers can exchange one unit of either good for one unit of the other and both be better off.

Non-existence of equilibrium usually stops any further analysis, but that does not mean that gains from trade will not be seized – the economy continues to operate after all. Goeree and Roger (2022) demonstrate that the outcome in which one unit is exchanged corresponds to a maximum of the potential, albeit not a root. They term these maxima “Y equilibria” and show they exist in *any* economy, including non-convex ones. As such, the potential complements general equilibrium's incomplete toolkit and provides a compass to navigate economics' terra incognita of non-convex economies.

A. Proofs

Proof of Lemma 1. The indirect utility $v_i(p, m_i)$ follows from the saddle-point problem

$$v_i(p, m_i) = \min_{\lambda_i \geq 0} \max_{x_i \geq 0} u_i(x_i) - \lambda_i(\langle p|x_i \rangle - m_i) \quad (\text{A.1})$$

and is related to the Fenchel dual as follows

$$v_i(p, m_i) = \min_{\lambda_i \geq 0} \lambda_i m_i + \bar{v}_i(\lambda_i p)$$

Let $\lambda_i(p, m_i)$ be the solution to the minimization problem then

$$v_i(p, m_i) = \lambda_i(p, m_i)m_i + \bar{v}_i(\lambda_i(p, m_i)p) \quad (\text{A.2})$$

where the $\lambda_i(p, m_i)$ for $i \in \mathcal{N}$ are such that budget constraints are binding:

$$\langle p|\bar{x}_i(\lambda_i(p, m_i)p) \rangle = m_i \quad (\text{A.3})$$

From (A.1), $\nabla_p v_i(p, m_i) = \lambda_i(p, m_i)(\omega_i - x_i)$ since $m_i = \langle p|\omega_i \rangle$. In addition, from (A.2), $\nabla_p v_i(p, m_i) = \lambda_i(p, m_i)(\omega_i + \nabla_p \bar{v}_i(\lambda_i(p, m_i)p))$. Combining these results yields a simplified version of Roy's identity: $x_i(p, m_i) = \bar{x}_i(\lambda_i(p, m_i)p) = -\nabla_p v_i(\lambda_i(p, m_i)p)$. From (A.2) it follows that $\partial v_i / \partial m_i = \lambda_i(p, m_i)$. The budget constraints (A.3) imply that $\lambda_i(p, m_i) > 0$ and that $\bar{x}_i(\lambda_i(p, m_i)p)$ is strictly decreasing in p and strictly increasing in m_i . The latter implies that $\lambda_i(p, m_i)$ is strictly decreasing in m_i . From (A.3) it further follows that $\bar{x}_i(\lambda_i(p, m_i)p)$ vanishes when $m_i = 0$ and $\bar{x}_i(\lambda_i(p, m_i)p)$ diverges when $m_i = \infty$. Hence, $\lim_{m_i \downarrow 0} \lambda_i(p, m_i) = \infty$ and $\lim_{m_i \rightarrow \infty} \lambda_i(p, m_i) = 0$. \blacksquare

Proof of Theorem 1. If (x, p) is a Walrasian equilibrium the Marshallian demands satisfy $x_i = -\nabla \bar{v}_i(\lambda_i(p, m_i)p)$, see Lemma 1. This can be inverted to $\lambda_i(p, m_i)p = \nabla u_i(x_i)$, see e.g. Rockafellar (1970, Th. 26.5).⁴ When $\alpha_i = 1/\lambda_i(p, m_i)$ we thus have $p = \alpha_i \nabla u_i(x_i)$, so the x_i satisfy the first-order conditions for maximizing U_α . Hence, $x = \operatorname{argmax}_{x'} U_\alpha(x')$ as U_α is strictly concave. The Walrasian price p is market clearing so $0 = \sum_{i \in \mathcal{N}} (\omega_i - x_i(p, m_i)) = \nabla_p V_\alpha(p, w)$ when $\alpha_i = 1/\lambda_i(p, m_i)$ for $i \in \mathcal{N}$. So p satisfies the first-order condition for minimizing V_α and $p = \operatorname{argmin}_{p'} V_\alpha(p', w)$ as V_α is strictly convex. Since $\max_x U_\alpha(x) = \min_p V_\alpha(p, w)$ the potential vanishes at (x, p) .

⁴Theorem 26.5 in Rockafellar (1970) relates the gradient of a strictly convex function to the gradient of its dual, which is also a strictly convex function. To apply the theorem use $-u$ and \bar{v} .

For the converse part, since $p(\alpha)$ minimizes $V_\alpha(p, w)$ it follows that $\nabla_p V_\alpha(p, w) = \sum_{i \in \mathcal{N}} (\omega_i - \bar{x}_i(p(\alpha)/\alpha_i)) = 0$, i.e. the $\bar{x}_i(p(\alpha)/\alpha_i)$ satisfy feasibility. The unique solution $x(\alpha)$ to $\max_{x \in F(w)} U_\alpha(x)$ satisfies $\alpha_i \nabla u_i(x_i(\alpha)) = q(\alpha)$ for $i \in \mathcal{N}$ and some price vector $q(\alpha)$. This can be inverted as $x_i(\alpha) = -\nabla \bar{v}_i(q(\alpha)/\alpha_i) = \bar{x}_i(q(\alpha)/\alpha_i)$. Since $x(\alpha)$ is feasible by construction, $q(\alpha)$ also minimizes $V_\alpha(p, w)$. Strict convexity of $V_\alpha(p, w)$ implies $q(\alpha) = p(\alpha)$. By Lemma 1 the $\bar{x}_i(p(\alpha)/\alpha_i)$ are optimal Marshallian demands at $p(\alpha)$ and incomes m_i if $\alpha_i = 1/\lambda_i(p(\alpha), m_i)$, which can be inverted as $m_i = \lambda_i^{(-1)}(p(\alpha), \frac{1}{\alpha_i})$. Taking the inner product of the feasibility condition with the price vector yields $\langle p(\alpha) | w \rangle = \sum_{i \in \mathcal{N}} \langle p(\alpha) | \bar{x}_i(p(\alpha)/\alpha_i) \rangle = \sum_{i \in \mathcal{N}} m_i(\alpha)$. To summarize, $(x(\alpha), p(\alpha))$ is a Walrasian equilibrium of the economy with incomes $m_i(\alpha)$. ■
