Keywords: Portfolio, Marčenko-Pastur distribution, financial correlations, factor model Received (Day Month Year) Revised (Day Month Year)

Given an  $N$ -dimensional sample of size  $T$  and form a sample correlation matrix  $C$ . Suppose that N and T tend to infinity with  $T/N$  converging to a fixed finite constant  $Q > 0$ . If the population is a factor model, then the eigenvalue distribution of C almost surely converges weakly to Marc̆enko-Pastur distribution such that the index is  $Q$  and the scale parameter is the limiting ratio of the specific variance to the *i*-th variable  $(i \rightarrow \infty)$ . For an N-dimensional normal population with equi-correlation coefficient  $\rho$ , which is a one-factor model, for the largest eigenvalue  $\lambda$  of C, we prove that  $\lambda/N$  converges to the equi-correlation coefficient  $\rho$  almost surely. These results suggest an important role of an equi-correlated normal population and a factor model in (Laloux et al. Random matrix theory and financial correlations, *Int. J. Theor. Appl. Finance*, 2000): the histogram of the eigenvalue of sample correlation matrix of the returns of stock prices fits the density of Marčenko-Pastur distribution of index  $T/N$  and scale parameter  $1 - \lambda/N$ . Moreover, we provide the limiting distribution of the largest eigenvalue of a sample covariance matrix of an equi-correlated normal population. We discuss the phase transition as to the decay rate of the equi-correlation coefficient in N.

#### 1. Introduction

For risk management and asset allocation, a sample correlation matrix is essential. One of the pillars of Markowitz portfolio theory [\(Markowitz 1959,](#page-24-0) [Elton](#page-24-1) et al. [2014\)](#page-24-1) is the study of correlation (or covariance) matrices, e.g., the optimal weight of each financial asset, given a set of assets with average returns and risks, so that the overall portfolio offers the best return for a fixed level of risk or, alternatively, the smallest risk for a given overall return. For these optimizations, the eigenvalues of covariance/correlating matrices are important. However, the eigenvalues of a sample covariance matrix/correlation matrix in finance are dispersed with noise, so various ways to eliminate noisy eigenvalues from them are studied by [Laloux](#page-24-2) [et al.](#page-24-2) [\(2000\)](#page-24-2), [El Karoui](#page-24-3) [\(2008\)](#page-24-3), [Ledoit & Wolf](#page-24-4) [\(2004,](#page-24-4) [2012\)](#page-24-5), Ledoit & Péché [\(2011\)](#page-24-6), [Donoho](#page-24-7) et al. [\(2018\)](#page-24-7), to cite a few. For this purpose, [Laloux](#page-24-2) et al. [\(2000\)](#page-24-2) proposed to approximate heuristically the distribution of noisy eigenvalues of a sample covariance/correlation matrix, with Marc̆enko-Pastur distribution (Marc̆enko & Pastur

[1967\)](#page-24-8) of random matrix theory. Their idea influenced on the statistical methods on vaccine design [\(Quadeer](#page-25-0) et al. [2018\)](#page-25-0). We will discuss the heuristic of [Laloux](#page-24-2) et al. [\(2000\)](#page-24-2) mathematically, with an equi-correlated normal population, which plays an important role in various risk models such as *dynamic equicorrelation* (Engle  $\&$ [Kelly 2012\)](#page-24-9) and constant correlation model [\(Elton](#page-24-1) et al. [2014\)](#page-24-1).

First of all, we fix the notation. Let  $X_1, \ldots, X_T \in \mathbb{R}^N$  be a random sample. By the *data matrix*, we mean  $\mathbf{X} = [\mathbf{X}_1, \dots, \mathbf{X}_T] \in \mathbb{R}^{N \times T}$ . Let  $1 \leq i \leq N$  and  $1 \leq t \leq T$ . The *it*-entry of **X** is denoted by  $x_{it}$ , and the *i*-th row by  $\mathbf{x}_i \in \mathbb{R}^{1 \times T}$ . For the sample average of  $x_i$ , write  $\overline{x}_i = T^{-1} \sum_{t=1}^T x_{it}$ . Let  $\overline{x}_i := [\overline{x}_i, \ldots, \overline{x}_i] \in \mathbb{R}^{1 \times T}$ and  $\overline{\mathbf{X}} := [\overline{x}_1, \ldots, \overline{x}_N]^\top [1, \ldots, 1] \in \mathbb{R}^{N \times T}$ . The sample correlation matrix is, by definition,

$$
\mathbf{C} = \mathbf{Y} \mathbf{Y}^{\top} \in \mathbb{R}^{N \times N} \text{ where } \mathbf{Y}^{\top} = \left[ \frac{(\boldsymbol{x}_1 - \overline{\boldsymbol{x}}_1)^{\top}}{\|\boldsymbol{x}_1 - \overline{\boldsymbol{x}}_1\|}, \dots, \frac{(\boldsymbol{x}_N - \overline{\boldsymbol{x}}_N)^{\top}}{\|\boldsymbol{x}_N - \overline{\boldsymbol{x}}_N\|} \right]
$$

Here, the notation  $\|.\|$  is the Euclidean norm. The *sample covariance matrix* is denoted by  $\mathbf{S} = T^{-1} \mathbf{X} \mathbf{X}^{\top} \in \mathbb{R}^{N \times N}$ . By a *distribution function*, we mean a nondecreasing, right-continuous function  $F : \mathbb{R} \to [0, 1]$  such that  $\lim_{x \to -\infty} F(x) = 0$  and  $\lim_{x\to+\infty} F(x) = 1.$ 

We review the results on eigenvalue distributions from random matrix theory. The *empirical spectral distribution* of a symmetric matrix  $\mathbf{P} \in \mathbb{R}^{N \times N}$  is, by definition,

$$
F^{\mathbf{P}}(x) = \frac{1}{N} \# \{ i : 1 \le i \le N, \ \lambda_i(\mathbf{P}) \le x \} \quad (x \in \mathbb{R})
$$

where  $\lambda_1(\mathbf{P}), \ldots, \lambda_N(\mathbf{P})$  are the eigenvalues of **P**, indexed in nonincreasing order. According to (Yao [et al.](#page-25-1) [2015,](#page-25-1) [Bai & Silverstein 2010,](#page-23-0) p. 10), Marčenko-Pastur distribution with the sample size to dimension ratio index  $Q > 0$  and scale parameter  $\sigma^2 \in (0, \infty)$  has a density

$$
\frac{Q}{2\pi\sigma^2 x} \sqrt{(\sigma^2 b_Q - x)(x - \sigma^2 a_Q)} 1_{x \in [\sigma^2 a_Q, \sigma^2 b_Q]} \tag{1.1}
$$

<span id="page-1-1"></span>.

and has a point mass of value  $1-Q$  at the origin if  $Q < 1$ . Here,  $a_Q = (1 - \sqrt{1/Q})^2$ ,

<span id="page-1-0"></span>
$$
b_Q = (1 + \sqrt{1/Q})^2,
$$

and 1... denotes the indicator function. Marc̆enko-Pastur distribution has expectation  $\sigma^2$ . The distribution function of Marc̆enko-Pastur distribution of the sample to dimension ratio index Q and scale parameter  $\sigma^2$  is denoted by  $MP_{Q,\sigma^2}$ . We write  $MP_Q$  for  $MP_{Q,1}$ . Clearly,  $MP_{Q,\sigma^2}(x) = MP_Q(x/\sigma^2)$  for all  $x \in \mathbb{R}$ . We say a sequence  $(F_i)_i$  of distribution functions *converges weakly* to a function F, if  $F_i(x) \to F(x)$ for every  $x \in \mathbb{R}$  where F is continuous.

**Proposition 1.1.** Let  $\{x_{it}: i, t \geq 1\}$  be a double array of i.i.d. random variables with  $E|x_{11}|^2 = \sigma^2 \in (0, \infty)$ . Suppose  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ . Then, almost surely,

- <span id="page-2-2"></span>(1)  $F^{\mathbf{S}}$  converges weakly to  $\text{MP}_{Q,\sigma^2}$ . (Yao [et al.](#page-25-1) [2015,](#page-25-1) p. 12)
- (2)  $F<sup>C</sup>$  converges weakly to MP<sub>Q</sub>. [\(Jiang 2004,](#page-24-10) Theorem 1.2)

However, the eigenvalues of financial correlation matrices distribute similarly as the random matrix theory suggests, but somehow differently. [Laloux](#page-24-2) et al. [\(2000\)](#page-24-2) considered a sample correlation matrix C "associated to the time series of the different stocks of the  $S\&P500$  (or other major markets)" where N is the number of assets and  $T$  is the number of observations. [Laloux](#page-24-2) *et al.* [\(2000\)](#page-24-2) found that the histogram of the eigenvalues of the financial, sample correlation matrix **C** fits not the density of  $MP_{T/N}$ , but a *scaled* density, specifically, the density of

<span id="page-2-0"></span>
$$
\text{MP}_{\frac{T}{N}, 1 - \frac{\lambda_1(\mathbf{C})}{N}}.\tag{1.2}
$$

In addition to the fitting result, for the first eigenvalue  $\lambda_1(\mathbf{C})$  of **C**, Laloux et al. remarked the following:

The corresponding eigenvector is, as expected, the "market" itself, i.e., it has roughly equal components on all the N stocks.

[Laloux](#page-24-2) *et al.*  $(2000)$  interpreted the support of the density function of the fitting Marc̆enko-Pastur distribution, as the interval of noisy eigenvalues of the sample correlation matrix  $\bf{C}$ . Based on the findings of [Laloux](#page-24-2) *et al.* [\(2000\)](#page-24-2), in order to improve risk management, Bun [et al.](#page-24-11) [\(2017\)](#page-24-11) proposed "eigenvalue clipping: all eigenvalues in bulk of the fitting Marc̆enko-Pastur spectrum are deemed as noise and thus replaced by a constant value whereas the principal components outside of the bulk (the spikes) are left unaltered." As portfolios of hundreds or thousands of assets becomes the target of research, many approaches have been proposed to deal with the problem of dimensionality. By the limiting regime  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ of Proposition [1.1,](#page-1-0) we would like to understand mathematically why the heuristic of [Laloux](#page-24-2) et al. [\(2000\)](#page-24-2) is meaningful.

Let us hypothesize about the population of the stock prices Laloux et al. considered, from their remark on the eigenvector that "has roughly equal components on all the N stocks." It is comparable to an eigenvector  $[1, \ldots, 1]^\top$  corresponding to the largest eigenvalue  $\lambda_1(\Sigma_\rho)$  of an *equi-correlation matrix* 

<span id="page-2-1"></span>
$$
\mathbf{\Sigma}_{\rho} = \begin{bmatrix} 1 & \rho & \cdots & \rho \\ \rho & 1 & \cdots & \rho \\ \vdots & \vdots & & \vdots \\ \rho & \rho & \cdots & 1 \end{bmatrix} \in \mathbb{R}^{N \times N} \qquad (0 \le \rho < 1),
$$

where

$$
\lambda_1(\Sigma_\rho) = (N-1)\rho + 1 \ge \lambda_2(\Sigma_\rho) = \dots = \lambda_N(\Sigma_\rho) = 1 - \rho. \tag{1.3}
$$

[SenGupta](#page-25-2) [\(1988\)](#page-25-2) studied hypothesis tests on  $\rho = 0$  vs.  $\rho > 0$ . Ishii *[et al.](#page-24-12)* [\(2021\)](#page-24-12) developed nonparametric tests of the high-dimensional covariance structures such as a scaled identity matrix, a diagonal matrix and  $\Sigma_{\rho}$  for  $N > T$  cases.

In particular, when  $\rho > 0$ ,  $\lambda_1(\Sigma_\rho)$  is unbounded with respect to N, and thus there is a 'spectral gap' between  $\lambda_1(\Sigma_\rho) = (N-1)\rho + 1$  and  $\lambda_2(\Sigma_\rho) = 1 - \rho$ . We presume that the population is a normal population with the population correlation matrix  $\Sigma_o$ .

<span id="page-3-0"></span>Then, for an equi-correlated normal population, we established the following scaling theorem for the limiting distribution of the *bulk eigenvalues* of the sample correlation matrix C:

**Proposition 1.2 [\(Akama & Husnaqilati](#page-23-1) [\(2022\)](#page-23-1)).** Let  $C$  be a sample correlation matrix formed from an N-dimensional normal population such that the population correlation matrix is  $\Sigma_{\rho}$  with deterministic  $\rho \in [0, 1)$ . Suppose  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ . Then, almost surely, the empirical spectral distribution  $F^{\mathbf{C}}$  converges weakly to

$$
MP_{Q, 1-\rho}.
$$

It is worth noting that the limiting spectral distribution (LSD) MP $_{Q, 1-\rho}$  is sim-ilar to Marčenko-Pastur distribution [\(1.2\)](#page-2-0) MP<sub>T/N, 1</sub>- $\lambda_1(C)/N$  where the histogram of the eigenvalues of a financial correlation matrix fits to the density of [\(1.2\)](#page-2-0). The index Q and the scale parameter  $1 - \rho$  correspond to  $T/N$  and  $1 - \lambda_1(\mathbf{C})/N$ , respectively.

By comparing [\(1.2\)](#page-2-0) to Proposition [1.2,](#page-3-0) we will show that the largest eigenvalue  $\lambda_1(\mathbf{C})$  of the sample correlation matrix **C** divided by the order N of **C** converges almost surely to the equi-correlation coefficient  $\rho$ , as follows. Hereafter,  $\stackrel{a.s.}{\rightarrow}$  and  $\stackrel{D}{\rightarrow}$ mean the almost sure convergence and the convergence in distribution respectively. Unless otherwise stated, the limiting regime is  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ .

Theorem 1.1. Suppose the assumptions of Proposition [1.2.](#page-3-0) Then,

<span id="page-3-3"></span>(1)  $\lambda_1(\mathbf{C})/N \stackrel{a.s.}{\rightarrow} \rho$ .

<span id="page-3-4"></span>(2) If, moreover, the population is  $N_N(0, \Sigma_o)$  and  $\rho > 0$ , then

<span id="page-3-2"></span><span id="page-3-1"></span>
$$
\frac{\lambda_1(\mathbf{S}) - \tau}{\varsigma} \stackrel{D}{\to} \text{N}(0, 1)
$$

where

$$
\tau = \frac{((N-1)\rho + 1)((1 + (T-1)N)\rho + N - 1)}{N T \rho}, \quad \varsigma = \frac{(N-1)\rho + 1}{\sqrt{2T}}.
$$

From the first assertion, i.e., the consistency of  $\lambda_1(\mathbf{C})/N$ , of Theorem [1.1,](#page-3-1) Proposition [1.2](#page-3-0) suggests that an equi-correlated normal population plays a role in Laloux et al.'s fitting result to the density of [\(1.2\)](#page-2-0):

Corollary 1.1. Assume the assumptions of Proposition [1.2.](#page-3-0) Then,

F

$$
F^{\mathbf{C}}(x) - \text{MP}_{\frac{T}{N}, 1 - \frac{\lambda_1(\mathbf{C})}{N}}(x) \stackrel{a.s.}{\to} 0 \quad (x \neq 0).
$$

Once the largest eigenvalue  $\lambda_1(C)$  of C is found, Corollary [1.1](#page-3-2) can suggest the support of the density of the fitting Marc̆enko-Pastur distribution to clean

up ("eigenvalue clipping"), and then we can eliminate the eigenvalues in the support to let a small, but important eigenvalue (e.g., Markowitz solution) show up. Moreover,  $\lambda_1(\mathbf{C})$  has been concerned by [Friedman & Weisberg](#page-24-13) [\(1981\)](#page-24-13).

The rest of the paper is organized as follows. In the next section, to generalize Proposition [1.2,](#page-3-0) we consider suitable factor models. Then, we establish the limiting spectral distribution of the sample correlation matrix  $C$  generated from such a factor model. In Section [3,](#page-5-0) for returns of S&P stock prices (2012-1-4/2021-12- 31), we compute the largest eigenvalues of financial correlation matrices C divided by the order, and estimate the time average  $\bar{\rho}$  of equi-correlation coefficient by GJR GARCH [\(Glosten](#page-24-14) et al. [1993\)](#page-24-14) with the correlation structure being 'equicor-relation' [\(Engle & Kelly 2012\)](#page-24-9). We show that  $\lambda_1(\mathbf{C})/N$  predicts very well  $\bar{\rho}$ . In Section [4,](#page-9-0) for a nonnormal population with equicorrelation coefficient  $\rho = \rho_N$  decaying in N, we review the consistency and the asymptotic normality of  $\lambda_1(\mathbf{S})$ , by citing [Yata & Aoshima](#page-25-3) [\(2009\)](#page-25-3). Then, for the limiting distribution of an appropriate scaling of a translation of  $\lambda_1(S)$  of equi-correlated normal population, we discuss the phase transition from the normal population to Tracy-Widom distribution [\(Baik](#page-23-2) *[et al.](#page-23-2)* [2005\)](#page-23-2), as to the decay rate of  $\rho_N$ . The proofs of Theorem [1.1,](#page-3-2) Corollary 1.1, and Theorem [2.1](#page-5-1) are postponed in Section [5,](#page-11-0) Section [6,](#page-16-0) and Section [7,](#page-17-0) respectively, for the sake of the presentation.

# 2. From equi-correlated normal population to factor models in limit

Proposition [1.2](#page-3-0) was proved by the following well-known fact [\(Fan & Jiang 2019,](#page-24-15) (3.21)): Assume that  $\mathbf{X}_1, \ldots, \mathbf{X}_T \stackrel{\text{i.i.d.}}{\sim} N_N(\mathbf{0}, \Sigma_\rho), 0 \leq \rho < 1$ , and  $[\mathbf{X}_1, \ldots, \mathbf{X}_T] =$  $[x_{it}]_{it} \in \mathbb{R}^{N \times T}$ . Then, there are independent standard normal random variables  $f_t$ ,  $e_{it}$   $(1 \leq i \leq N, 1 \leq t \leq T)$  such that

<span id="page-4-0"></span>
$$
x_{it} = \sqrt{\rho} f_t + \sqrt{1 - \rho} e_{it}.\tag{2.1}
$$

Actually, an equi-correlated normal population is a factor model [\(Bai 2003,](#page-23-3) [Mulaik](#page-25-4) [2009\)](#page-25-4) consisting of 1 factor. See Example [2.1.](#page-5-2) Beside this 1-factor model, a 3-factor model and a 5-factor model are employed by [Fama & French](#page-24-16) [\(1993,](#page-24-16) [2015\)](#page-24-17) to describe stock returns in asset pricing and portfolio management.

[Bai](#page-23-3) [\(2003\)](#page-23-3) studied an inferential theory for a general factor model of large dimensions to which classical factor analysis does not apply, by using limiting regime  $N, T \to \infty, \sqrt{N/T} \to 0$ . He derived the limiting distributions of the estimated factors and estimated factor loadings, the asymptotic normality of estimated common components, and their convergence rates. The convergence rate of the estimated factors and factor loadings can be faster than that of the estimated common components. These achievements are obtained under liberal conditions that allow for correlations and heteroskedasticities. Stronger results are obtained when the idiosyncratic errors are serially uncorrelated and homoskedastic. A necessary and

sufficient condition for consistency of the estimated factors is derived for large N but fixed T.

We will study a factor model in the limiting regime  $N, T \rightarrow \infty$ ,  $T/N \rightarrow Q$ . First, we recall a factor model [\(Bai 2003,](#page-23-3) [Mulaik 2009\)](#page-25-4):

<span id="page-5-4"></span>**Definition 2.1.** For a nonnegative integer  $K$ , by a  $K$ -factor model, we mean a data matrix

$$
[x_{it}]_{it} \in \mathbb{R}^{N \times T}
$$

such that

$$
x_{it} = \mu_i + \ell_i f_t + e_{it} \quad (1 \leq i \leq N, \ 1 \leq t \leq T),
$$
\n
$$
\mu_i
$$
 is a deterministic constant, 
$$
\ell_i = [\ell_{i1}, \dots, \ell_{iK}]
$$
 is a K-dimensional row vector, 
$$
(factor \, loadings)
$$
\n
$$
f_t = [f_{t1}, \dots, f_{tk}]^\top
$$
 is a K-dimensional column vector, 
$$
(common \, factors)
$$
\n
$$
f_{tk} \ (1 \leq t \leq T, \ 1 \leq k \leq K)
$$
 are centered, i.i.d. with Var  $f_{t1} = 1$ , 
$$
e_{it} \ (1 \leq t \leq T)
$$
 are centered, i.i.d., for each  $i \ (1 \leq i \leq N)$ , 
$$
f_{tk}
$$
 and  $e_{it} \ (1 \leq i \leq p, \ 1 \leq t \leq T, \ 1 \leq k \leq K)$  are independent, and 
$$
\psi_i := \text{Var } e_{it} < \infty
$$
\n
$$
(specific \, variance).
$$

 $e_{it}$ 's are called *idiosyncratic components*. K is the number of factors.

<span id="page-5-2"></span>**Example 2.1.** The decomposition [\(2.1\)](#page-4-0) is a factor model such that  $K = 1$ ,  $\mu_i := 0$ , **EXAMPLE 2.1.** The decomposition  $\{2.1\}$  is a factor model such that  $K = 1$ ,  $\ell_{i1} = \sqrt{\rho}$ ,  $\psi_i := 1 - \rho$ , and both of  $f_{t1}$  and  $e_{it}$  are independent and normal.

<span id="page-5-3"></span>**Assumption 2.1.**  $e_{it}$   $(i, t \ge 1)$  are i.i.d., and  $\ell_i \rightarrow \ell$  for some K-dimensional row vector  $\ell$ . In this case, define

$$
\sigma_{\infty}^2 := \lim_{i \to \infty} \text{Var}\, x_{it} = ||\ell||^2 + \psi_1 < \infty, \qquad \rho := \frac{||\ell||^2}{||\ell||^2 + \psi_1}.
$$

Then,  $1 - \rho$  is the portion of the specific variance to the limiting total variance  $\sigma_{\infty}^2$  of a variable  $x_{it}$   $(i \to \infty)$ .

The following generalizes Proposition [1.2.](#page-3-0) The LSD of a sample correlation matrix C generated from a factor model is as follows:

<span id="page-5-1"></span>**Theorem 2.1.** Given a factor model. Suppose  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ and Assumption [2.1.](#page-5-3) Then, almost surely,  $F^{\text{C}}$  converges weakly to  $\text{MP}_{Q, 1-\rho}$ .

By Example [2.1,](#page-5-2) this generalizes Proposition [1.2.](#page-3-0) Theorem [2.1](#page-5-1) is proved in Section [7.](#page-17-0)

#### <span id="page-5-0"></span>3. The largest eigenvalue of financial correlation matrix

For a dataset of returns of  $N$  S&P500 stocks (or other major markets) for  $T$  trading days, [Laloux](#page-24-2) *et al.* [\(2000\)](#page-24-2) fitted the histogram of the eigenvalues of the correlation matrix  $C$ , to the density function of a scaled Marc̆enko-Pastur distribution.

Naturally, the return of a stock is more correlated with the return of a stock of the same industry classification sector, than with the return of a stock of a different industry classification sector. We consider the 11 global industry classification standard (GICS) sectors of S&P500 stocks. For each GICS, for the dataset of the stock returns for the period 2012-01-04/2021-12-31, the time series of the equi-correlation coefficient is computed by GJR GARCH [\(Glosten](#page-24-14)  $et \ al.$  [1993\)](#page-24-14) with the correlation structure being dynamic equicorrelation [\(Engle & Kelly 2012\)](#page-24-9) (We abbreviate this model to 'GJR GARCH-DECO'). The program is due to [Candila](#page-24-18) [\(2021\)](#page-24-18).

However, the computation time of the time series of the equi-correlation coefficient by GJR GARCH-DECO is large, although we can quickly compute the estimator  $\lambda_1(\mathbf{C})/N$  of the equi-correlation coefficient by a power method. For each dataset, we compare the time series to  $\lambda_1(\mathbf{C})/N$  of the correlation matrix C.

Figure [1](#page-7-0) is the time series of equi-correlations for the 12 datasets. All the time series rise around March 2020, by the world-wide sudden crash after growing uncertainty due to the COVID-19 (Coronavirus disease 2019) pandemic. The time series of the equi-correlation coefficient of Energy sector kept high, even after the time series of the equi-correlation of the other 10 sectors of GICS as well as the total decrease. According to Figure [1,](#page-7-0) for each dataset, the time series is mostly smaller than  $\lambda_1(\mathbf{C})/N$ . Let us consider the time average  $\bar{\rho}$  of equi-correlation coefficients estimated by GJR GARCH-DECO. Table [1](#page-6-0) is the list of GICS,  $N/T$ ,  $\lambda_1(\mathbf{C})/N$ , N, and  $\bar{\rho}$ , for the period 2012-01-04/2021-12-31 (T = 2516=trading days −1). The rows of Table [1](#page-6-0) are ordered in the increasing order of  $\lambda_1(\mathbf{C})/N$ .

<span id="page-6-0"></span>

No	GICS	N/T	$\lambda_1({\bf C})/N$	N	$\overline{\rho}$
1	Communication Services	.0076	.3571	19	.2764

12	The total	.1705	.3819	429	.2939

Table 1: The stock return datasets of 11 GICS's and the total (2012-01-04/2021- 12-31), the largest eigenvalue of the correlation matrices and the time averages of equicorrelation coefficient.  $N/T$ ,  $\lambda_1(\mathbf{C})/N$  and  $\bar{\rho}$  are rounded.

The last row of Table [1](#page-6-0) is for the union dataset of the 11 GICS datasets. The

<span id="page-7-0"></span>

Fig. 1: Time series of  $\rho$  and  $\lambda_1(C)/N$  (red line) of the stock returns of the 12 datasets of Table [1.](#page-6-0)

union dataset is more 'heterogeneous' than the 11 GICS datasets. It has  $\lambda_1(\mathbf{C})/N$ and  $\bar{\rho}$  smaller than the corresponding  $\lambda_1(\mathbf{C})/N$  and  $\bar{\rho}$  for most of GICS. It means that correlations coefficients between different GICS's are very small. Figure [2](#page-8-0) are the heat maps with hierarchical clustering algorithms for the correlation matrices C of the 12 datasets. According to the last heat map of Figure [2,](#page-8-0) the correlation matrix of the returns of S&P500 stocks has diagonal block structures as well as an almost dominant background.

Although Figure [2](#page-8-0) shows the various structures of C for the 12 datasets,

<span id="page-8-0"></span>

Fig. 2: The correlation matrices of the stock returns of the 12 datasets of Table [1](#page-6-0) and the total.

 $\lambda_1(\mathbf{C})/N$  predicts well the time average  $\bar{\rho}$  of the time series of equi-correlation coefficients computed by GJR GARCH-DECO with much time. A regression anal-

ysis (Figure [3\)](#page-9-1) for Table [1](#page-6-0) shows:

$$
\bar{\rho} \sim 0.98488 \frac{\lambda_1(\mathbf{C})}{N} - 0.07190
$$
 (adjusted  $R^2$  being 0.9916).

<span id="page-9-1"></span>

Fig. 3: The regression analysis of  $\bar{\rho}$  by  $\lambda_1(\mathbf{C})/N$ .

# <span id="page-9-0"></span>4. Phase transition of limiting distribution of largest eigenvalue

In our setting, all the correlation coefficients among N variables being the positive constant  $\rho$ . It is, however, somehow unnatural in the limit  $N \to \infty$ . We assume that

$$
N > T
$$

and the equi-correlation coefficient  $\rho$  converges to 0 from above as  $N \to \infty$ .

For this setting with  $N > T$ , the consistency  $\lambda_1(\mathbf{S})/N \to \rho$  of the largest eigenvalue  $\lambda_1(S)$  and the asymptotic normality of  $\lambda_1(S)$  for a nonnormal population follows from [Yata & Aoshima](#page-25-3) [\(2009\)](#page-25-3). Moreover, the limiting distribution of  $\lambda_1(S)$ for an equi-correlated normal population seems to have a phase transition depending on the equi-correlation coefficient  $\rho$ , as the limiting distribution of the largest eigenvalue of S formed by a spiked population model does so with respect to the largest eigenvalue of the population covariance matrix (Baik [et al.](#page-23-2) [2005\)](#page-23-2).

# 4.1. Consistency and asymptotic normality of  $\lambda_1(S)$  of nonnormal population

In [\(Yata & Aoshima 2009\)](#page-25-3), the consistency and the asymptotic normality of  $\lambda_1(S)$ are proved without assuming the normality of the population.

<span id="page-10-1"></span>**Proposition 4.1.** Let a data matrix  $\mathbf{X} \in \mathbb{R}^{N \times T}$  be  $[X_1, \ldots, X_T]$  where  $X_t$  (1  $\leq$  $t \leq T$ ) are centered, i.i.d. and  $N > T$ . Suppose that the population covariance matrix  $\Sigma$  is  $H \text{ diag}(\lambda_1, ..., \lambda_N) H^{\top}$  for some orthogonal matrix  $H$ ,

<span id="page-10-2"></span>
$$
\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_N \geq 0,
$$
  
\n
$$
\lambda_i = c_i N^{\delta_i} \quad (i = 1, ..., m), \text{ and}
$$
  
\n
$$
\lambda_j \text{ are constants } (j = m+1, ..., N).
$$
\n(4.1)

Here m,  $c_i(> 0)$  and  $\delta_i$   $(\delta_1 \geq \cdots \geq \delta_m > 0)$  are constants.

Let  $\mathbf{Z} := [\mathbf{Z}_1,\ldots,\mathbf{Z}_N] := \text{diag}(\lambda_1,\ldots,\lambda_N)^{-1/2} \mathbf{H}^\top \mathbf{X}$ . Assume that  $\mathbf{Z}_1,\ldots,\mathbf{Z}_N$ are independent, the fourth moments of the entries of  $Z$  are uniformly bounded, and no  $Z_i$  is 0. Moreover suppose

(i)  $N, T \rightarrow \infty$  for i such that  $\delta_i > 1$ ; and

(ii)  $N, T \to \infty$  and  $N^{2-2\delta_i}/T \to 0$  for i such that  $\delta_i \in (0, 1]$ .

Then, we have

- (1)  $\lambda_1(\mathbf{S})/\lambda_1 = 1 + o_p(1)$ . [\(Yata & Aoshima 2009,](#page-25-3) Theorem 1)
- <span id="page-10-0"></span>(2) Assume also that the largest m eigenvalues of  $\Sigma$  are distinct and  $\text{Var}(z_{ij}^2)$  =  $M_i \ (< \infty$ ). Then,  $\sqrt{T/M_i} (\lambda_1(\mathbf{S})/\lambda_1 - 1) \overset{D}{\rightarrow} \text{N}(0, 1)$ . [\(Yata & Aoshima 2009,](#page-25-3) Theorem 2)

The condition (ii) is relieved for [\(Yata & Aoshima 2009,](#page-25-3) Theorem 2) if an independence condition is further assumed.

Proposition 4.2 ([\(Yata & Aoshima 2009,](#page-25-3) Corollary 1)). In the assertion [\(2\)](#page-10-0) of Proposition [4.1,](#page-10-1) assume further that  $z_{ij}$ ,  $1 \leq i \leq N(1 \leq t \leq T)$  are independent. Then, it holds that  $\lambda_1(S)/\lambda_1 = 1 + o_p(1)$  if the condition (i) and

(iii)  $N, T \to \infty$  and  $N^{1-2\delta_i}/T \to 0$  for i such that  $\delta_i \in (0, 1]$ .

By [\(1.3\)](#page-2-1),  $\Sigma_{\rho}$  does not meet the condition [\(4.1\)](#page-10-2). According to Kazuyoshi Yata, the conclusions of [\(Yata & Aoshima 2009,](#page-25-3) Theorem 1) and [\(Yata & Aoshima 2009,](#page-25-3) Theorem 2) indeed hold for  $\Sigma = \Sigma_{\rho}$ . Therefore, we get the following:

<span id="page-10-3"></span>Theorem 4.1. Suppose that a population is possibly nonnormal, the population covariance matrix is  $\Sigma_{\rho}$  ( $\rho > 0$ ), and  $N, T \to \infty, T/N \to Q \in (0, \infty)$ . Assume

<span id="page-10-4"></span>(1) the setting of [\(Yata & Aoshima 2009,](#page-25-3) Theorem 1) and  $\lim_{N\to\infty} N^{1/2} \rho = \infty$ ; or (2) the setting of [\(Yata & Aoshima 2009,](#page-25-3) Corollary 1) and  $\lim_{N\to\infty} N\rho = \infty$ .

Then, we have  $\lambda_1(S)/N \stackrel{P}{\rightarrow} \rho$  and the asymptotic normality of  $\lambda_1(S)$ .

# 4.2. Phase transition of limiting distribution of  $\lambda_1(S)$  for normal population as to decay rate of equi-correlation coefficient

The limiting distribution of an appropriate scaling of a translation of the largest eigenvalue  $\lambda_1(S)$  of a sample covariance matrix S is Tracy-Widom distribution if the equi-correlation coefficient  $\rho$  is 0, by [\(Johnstone 2001,](#page-24-19) [Soshnikov 2002\)](#page-25-5), and a normal distribution if  $\rho$  is a positive constant by Theorem [5.1.](#page-12-0) In view of Theorem [4.1](#page-10-3) [\(2\)](#page-10-4), we turn our attention to the case  $\lim_{N\to\infty}N\rho<\infty$ .

First, we recall (Baik [et al.](#page-23-2) [2005,](#page-23-2) Theorem 1.1 and Corollary 1.1).

**Proposition 4.3.** Assume  $Q > 1$  and the population is  $N_N(\mu, \Sigma)$ , and  $\lambda_1 \geq \lambda_2 \geq$  $\lambda_r \geq \lambda_{r+1} = \cdots = \lambda_N = 1$  be the eigenvalues of  $\Sigma$ .

(a) Suppose  $0 \leq k \leq r$ ,  $\lambda_1 = \cdots = \lambda_k = 1 + 1/\sqrt{Q}$ , and  $\{\lambda_{k+1}, \ldots, \lambda_r\} \subset$  $(0, 1 + 1/\sqrt{Q})$ . Then,

<span id="page-11-1"></span>
$$
\lambda_1(\mathbf{S}) \stackrel{P}{\to} (1 + \sqrt{1/Q})^2, \text{ and}
$$
  
\n
$$
P\left(\left(\lambda_1(\mathbf{S}) - (1 + \sqrt{1/Q})^2\right) \cdot \frac{\sqrt{Q}}{(1 + \sqrt{Q})^{4/3}} T^{2/3} \le x\right) \to F_{\text{TW},k}(x), \quad (4.2)
$$

where  $F_{\text{TW},k}(x)$  is the distribution function of a generalization of the Tracy-Widom distribution (Baik [et al.](#page-23-2) [2005,](#page-23-2) Definition 1.1).

(b) Suppose  $1 \leq k \leq r$ ,  $\lambda_1 = \cdots = \lambda_k > 1 + 1/\sqrt{Q}$ , and  $\{\lambda_{k+1}, \ldots, \lambda_r\} \subset (0, \lambda_1)$ . Then,

<span id="page-11-2"></span>
$$
\lambda_1(\mathbf{S}) \xrightarrow{P} \lambda_1 + \frac{Q^{-1}\lambda_1}{\lambda_1 - 1}, \text{ and}
$$
\n
$$
P\left(\left(\lambda_1(\mathbf{S}) - \left(\lambda_1 + \frac{Q^{-1}\lambda_1}{\lambda_1 - 1}\right)\right) \cdot \frac{\sqrt{T}}{\sqrt{\lambda_1^2 - Q^{-1}\lambda_1^2/(\lambda_1 - 1)^2}} \le x\right) \to F_{G,k}(x),\tag{4.3}
$$

where  $F_{G,k}(x)$  is the distribution function of a generalization of the Gaussian distribution (Baik [et al.](#page-23-2) [2005,](#page-23-2) Definition 1.2).

This proposition suggests the following phase transition: For a normal popula-√ tion, if  $\lim_{N\to\infty} N\rho > 1/\sqrt{Q}$ , then the largest eigenvalue  $\lambda_1(S)$  satisfies the asymp-totic normality in a sense of [\(4.2\)](#page-11-1), and if  $\lim_{N\to\infty} N\rho < 1/\sqrt{Q}$ , then an appropriate scaling of a translation of  $\lambda_1(S)$  converges to the Tracy-Widom distribution  $G_1$  in a sense of [\(4.3\)](#page-11-2). This holds for  $\lim_{N\to\infty} N\rho = \infty$  by Theorem [4.1.](#page-10-3)

<span id="page-11-3"></span>The detail of this phase transition will be studied elsewhere.

#### <span id="page-11-0"></span>5. Proof of Theorem [1.1](#page-3-1)

We also consider centered (noncentered, resp.) variant of the sample covariance matrix  $\mathbf{S} \in \mathbb{R}^{N \times N}$  (the sample correlation matrix  $\mathbf{C} \in \mathbb{R}^{N \times N}$ , resp.):

**Definition 5.1.** Let  $\tilde{\mathbf{Y}}$  be diag  $(\|\boldsymbol{x}_1\|^{-1}, \ldots, \|\boldsymbol{x}_N\|^{-1}) \mathbf{X} \in \mathbb{R}^{N \times T}$ . Define the following three matrices:

 $\tilde{\mathbf{C}}^- := \tilde{\mathbf{Y}} \tilde{\mathbf{Y}}^\top \in \mathbb{R}^{N \times N}$  $(noncentered sample correlation matrix),$  $\mathbf{E}$  =  $T^{-1/2}(\mathbf{X}-\overline{\mathbf{X}}) \in \mathbb{R}^{N \times T}$ ,  $\mathbf{S}^\circ~:= \mathbf{E} \mathbf{E}^\top \in \mathbb{R}$  $(centered sample covariance matrix).$ 

To prove Theorem [1.1](#page-3-1) [\(1\)](#page-3-3), we will prove:

**Theorem 5.1.** Assume that  $X_1, \ldots, X_T \stackrel{\text{i.i.d.}}{\sim} N_N(\mu, \Delta \Sigma_\rho \Delta)$ ,  $\mu \in \mathbb{R}^N$  is deterministic,  $\Delta$  is deterministic, nonsingular diagonal, and  $\rho \in [0, 1)$  is deterministic. Suppose  $(\mathbf{P} = \mathbf{S}, \ \boldsymbol{\mu} = \mathbf{0}, \ \boldsymbol{\Delta} = \mathbf{I}), (\mathbf{P} = \mathbf{S}^{\circ}, \ \boldsymbol{\Delta} = \mathbf{I}), (\mathbf{P} = \tilde{\mathbf{C}}, \ \boldsymbol{\mu} = \mathbf{0}), \ or \ \mathbf{P} = \mathbf{C}.$ Then,  $\lambda_1(\mathbf{P})/N \stackrel{a.s.}{\rightarrow} \rho$ .

**Proof.** First consider the case where  $P = S$ ,  $\mu = 0$ , and  $\Delta = I$ . Suppose  $\rho =$ 0. Then, all the entries of X are standard normal, so they are independent and  $E|x_{11}|^4 < \infty$ . Thus,

<span id="page-12-0"></span>
$$
\lim_{N,T \to \infty, T/N \to Q} \lambda_1(\mathbf{S}) = b_Q \quad (a.s.)
$$

by (Bai  $\&$  Yin 1993, Theorem 2). Hence, Theorem [5.1](#page-12-0) [\(1\)](#page-3-3) holds for this case when  $\rho = 0.$ 

Then, we prove  $\lambda_1(\mathbf{S})/N \stackrel{a.s.}{\rightarrow} \rho$  for  $\rho > 0$ . For this, we recall (Merlevède *et al.*) [2019,](#page-24-20) Proposition 2.1), which is due to [\(Ledoit & Wolf 2018,](#page-24-21) Proposition 7.3) and (Cai [et al.](#page-24-22) [2017,](#page-24-22) Theorem 2.1) according to Merlevède et al. [\(2019\)](#page-24-20). Following [\(Van der Vaart 2000,](#page-25-6) p. 8), we say a sequence  $(F_N)_N$  of distribution functions is tight on  $\mathbb{R}^+$ , if for every  $\epsilon \in (0, 1]$ , there is a constant  $M \geq 0$  such that

$$
\sup_N F_N(M) > 1 - \epsilon.
$$

#### <span id="page-12-1"></span>Proposition 5.1 (Merlevède et al. [\(2019,](#page-24-20) Proposition 2.1)). Assume

- (1)  $\mathbf{S} = T^{-1} \Sigma^{1/2} \mathbf{G} \mathbf{G}^{\top} \Sigma^{1/2} \in \mathbb{R}^{N \times N}$ , the entries of  $\mathbf{G} \in \mathbb{R}^{N \times T}$  are independent, standard normal, and  $\Sigma \in \mathbb{R}^{N \times N}$  is positive definite, symmetric, and deterministic.
- (2) A sequence  $(F^{\Sigma})_N$  of empirical spectral distributions is tight on  $\mathbb{R}^+$ , and  $\lim_{N\to\infty}\lambda_1(\Sigma)=\infty.$
- (3)  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ .
- Then,  $\lambda_1(\mathbf{S})/\lambda_1(\mathbf{\Sigma}) \stackrel{a.s.}{\rightarrow} 1.$

The sequence  $(F^{\Sigma_{\rho}})_N$  of the empirical spectral distribution function of  $\Sigma_{\rho} \in$  $\mathbb{R}^{N\times N}$  is a tight sequence on  $\mathbb{R}^+$ . To see it, consider  $\epsilon \in (0, 1]$  and  $M = (\epsilon^{-1} - \epsilon)$  $1/\rho + 1 > 0$ . For every integer  $N > M$ ,  $\lambda_1(\Sigma_\rho) > M$ , so  $F^{\Sigma_\rho}(M) = 1$ . Hence,  $\sup_N F^{\Sigma_\rho}(M) \geq 1 - \epsilon$ . Therefore, we have the tightness of the sequence.

Then, by Proposition [5.1](#page-12-1) with  $\Sigma := \Sigma_{\rho} \in \mathbb{R}^{N \times N}$ ,  $\lambda_1(\mathbf{S})/((N-1)\rho + 1) =$  $\lambda_1(\mathbf{S})/\lambda_1(\mathbf{\Sigma}_{\rho}) \stackrel{a.s.}{\rightarrow} 1$ . Thus, we have established  $\lambda_1(\mathbf{S})/N \stackrel{a.s.}{\rightarrow} \rho$  for every  $\rho \geq 0$ .

Now, we consider the case where  $\mathbf{P} = \mathbf{S}^{\circ}$  and  $\boldsymbol{\Delta} = \mathbf{I}$ . We will derive  $\lambda_1(\mathbf{S}^{\circ})/N \stackrel{a.s.}{\rightarrow}$  $\rho$  for every  $\rho \geq 0$ , by using the following:

Proposition 5.2 [\(Bai & Yin](#page-23-4) [\(1993,](#page-23-4) Lemma 2)). Let  $\{y_{kj}: k, j \geq 1\}$  be a double array of i.i.d. random variables and let  $\alpha > 1/2$ ,  $\beta \geq 0$  and  $M > 0$  be constants. Then,

<span id="page-13-0"></span>
$$
\max_{j \le MT^{\beta}} \left| \sum_{k=1}^{T} \frac{y_{kj} - m}{T^{\alpha}} \right| \stackrel{a.s.}{\to} 0 \quad (T \to \infty)
$$
  

$$
\iff E|y_{11}|^{\frac{1+\beta}{\alpha}} < \infty \ \& \ m = \begin{cases} E \ y_{11}, & (\alpha \le 1), \\ \text{any}, & (\alpha > 1). \end{cases}
$$

Proposition [5.2](#page-13-0) is also used to prove Theorem [2.1](#page-5-1) in Section [7.](#page-17-0)

The centered sample covariance matrix  $S^{\circ}$  is invariant with respect to the shifting of variables. By this invariance, we can assume  $\mu = 0$ . It suffices to assure

<span id="page-13-1"></span>
$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}}\left|\sqrt{\frac{\lambda_1(\mathbf{S}^\circ)}{N}}-\sqrt{\frac{\lambda_1(\mathbf{S})}{N}}\right|=0 \quad (a.s.).
$$

By the triangle inequality for the spectral norm,

$$
\left|\sqrt{\lambda_1(\mathbf{S}^\circ)} - \sqrt{\lambda_1(\mathbf{S})}\right| = \left|\|T^{-1/2}(\mathbf{X} - \overline{\mathbf{X}})\| - \|T^{-1/2}\mathbf{X}\|\right| \le \|T^{-1/2}\overline{\mathbf{X}}\|.
$$
 (5.1)

The last term  $||T^{-1/2}\overline{\mathbf{X}}||$  is  $\sqrt{\sum_{i=1}^{N} \overline{x}_i^2}$  (a.s.). To see it, note that the *it*-entry of  $T^{-1}\overline{\mathbf{X}}\overline{\mathbf{X}}$  is  $T^{-1}\sum_{k=1}^T \overline{x}_i\overline{x}_t = \overline{x}_i\overline{x}_t$ . Therefore,  $[\overline{x}_1,\ldots,\overline{x}_N]^{\top}$  is an eigenvector of  $T^{-1}\overline{\mathbf{X}}\overline{\mathbf{X}}^{\top}$ , corresponding to an eigenvalue  $\sum_{i=1}^{N} \overline{x}_{i}^{2}$ . Clearly, rank  $\overline{\mathbf{X}} \leq 1$  and almost surely rank  $\overline{X} = 1$ . Thus, it is also the case for rank  $T^{-1}\overline{X} \overline{X}^{\top}$ . Considering the eigenvalue  $\sum_{i=1}^{N} \overline{x}_i^2$  of  $T^{-1} \overline{\mathbf{X}} \overline{\mathbf{X}}^\top$  is positive almost surely, the other  $N-1$ eigenvalues are 0 almost surely.

hvalues are 0 almost surely.<br>By dividing [\(5.1\)](#page-13-1) with  $\sqrt{N}$ , it holds almost surely that

$$
\left| \sqrt{\frac{\lambda_1(\mathbf{S}^\circ)}{N}} - \sqrt{\frac{\lambda_1(\mathbf{S})}{N}} \right| \le \sqrt{\sum_{i=1}^N \frac{\overline{x}_i^2}{N}} \le \sqrt{\max_{1 \le i \le N} \left( \sum_{t=1}^T \frac{x_{it}}{T} \right)^2} = \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{x_{it}}{T} \right|.
$$
 (5.2)

By  $\Delta = I$  and  $\mu = 0$ ,  $x_{it}$   $(i, t \ge 1)$  are standard normal random variables equicorrelated with  $\rho \in [0, 1)$ . By decomposition [\(2.1\)](#page-4-0), there are independent standard normal random variables  $f_t$ ,  $e_{it}$  ( $i, t \ge 1$ ) such that  $x_{it} = \sqrt{\rho} f_t + \sqrt{1 - \rho} e_{it}$ . By the triangle inequality,

<span id="page-13-2"></span>
$$
\max_{1 \leq i \leq N} \left| \sum_{t=1}^T \frac{x_{it}}{T} \right| \leq \left| \sum_{t=1}^T \frac{\sqrt{\rho} f_t}{T} \right| + \max_{1 \leq i \leq N} \left| \sum_{t=1}^T \frac{\sqrt{1 - \rho} e_{it}}{T} \right|.
$$

The first term of the right side tends to 0 in  $T \to \infty$  almost surely, by the law of large numbers. The second term of the right side tends to 0 in  $N, T \to \infty$ ,  $T/N \to Q$ almost surely, by Proposition [5.2](#page-13-0) with  $\alpha = \beta = 1$  and  $M = Q$ . Thus,

$$
\max_{1 \le i \le N} |\overline{x}_i| = \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{x_{it}}{T} \right| \stackrel{a.s.}{\to} 0 \quad (N, T \to \infty, T/N \to Q). \tag{5.3}
$$

Hence,  $(5.2) \stackrel{a.s.}{\rightarrow} 0$  $(5.2) \stackrel{a.s.}{\rightarrow} 0$ . Since we have already established  $\lambda_1(\mathbf{S})/N \stackrel{a.s.}{\rightarrow} \rho$  for every  $\rho \geq 0$ , we then derived  $\lambda_1(\mathbf{S}^{\circ})/N \stackrel{a.s.}{\rightarrow} \rho$  for every  $\rho \geq 0$ .

We consider the case  $P = \tilde{C}$  and  $\mu = 0$ . Because the noncentered sample correlation matrix  $\tilde{\mathbf{C}}$  is invariant under the scaling, we can assume

<span id="page-14-3"></span><span id="page-14-1"></span>
$$
\Delta = \mathbf{I}.
$$

From  $\lambda_1(\mathbf{S})/N \stackrel{a.s.}{\rightarrow} \rho$  of Theorem [5.1,](#page-12-0) we will guarantee

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}}\left|\sqrt{\frac{\lambda_1(\tilde{\mathbf{C}})}{N}}-\sqrt{\frac{\lambda_1(\mathbf{S})}{N}}\right|=0 \quad (a.s.).\tag{5.4}
$$

For a diagonal matrix

$$
\tilde{\mathbf{D}} = \mathrm{diag}\left(\frac{\sqrt{T}}{\|\boldsymbol{x}_1\|}, \dots, \frac{\sqrt{T}}{\|\boldsymbol{x}_N\|}\right), \quad \|\boldsymbol{x}_i\| = \sqrt{\sum_{t=1}^T x_{it}^2}
$$

we have  $\tilde{\mathbf{Y}} = T^{-1/2} \tilde{\mathbf{D}} \mathbf{X}$ .

Recall that the *spectral norm* of a matrix  $\mathbf{M} \in \mathbb{R}^{m \times n}$  is

<span id="page-14-2"></span>
$$
\|\mathbf{M}\| = \sup_{\mathbf{X} \in \mathbb{R}^n, \|\mathbf{X}\| = 1} \|\mathbf{M}\mathbf{X}\|.
$$

Note  $\|\mathbf{M}\| = \sqrt{\lambda_1(\mathbf{M}^{\top}\mathbf{M})}$ . By the triangle inequality of the spectral norm and that  $||M_1M_2|| \le ||M_1|| ||M_2||$  for every  $M_1 \in \mathbb{R}^{N \times N}$  and  $M_2 \in \mathbb{R}^{N \times T}$ ,

$$
\left| \sqrt{\frac{\lambda_1(\tilde{\mathbf{C}})}{N}} - \sqrt{\frac{\lambda_1(\mathbf{S})}{N}} \right| \le \left\| \frac{1}{\sqrt{N}} \tilde{\mathbf{Y}} - \frac{1}{\sqrt{NT}} \mathbf{X} \right\| = \left\| (NT)^{-1/2} (\tilde{\mathbf{D}} - \mathbf{I}) \mathbf{X} \right\|
$$
 (5.5)

$$
\leq \|\tilde{\mathbf{D}} - \mathbf{I}\| \cdot \| (NT)^{-1/2} \mathbf{X} \| = \max_{1 \leq i \leq N} \left| \frac{T^{1/2}}{\|\mathbf{x}_i\|} - 1 \right| \cdot \sqrt{\frac{\lambda_1(\mathbf{S})}{N}}.
$$
(5.6)

Since we established  $\lambda_1(S)/N \stackrel{a.s.}{\rightarrow} \rho$  from  $\Delta = I$  and  $\mu = 0$ , it suffices to verify

<span id="page-14-0"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \max_{1 \le i \le N} \left| \frac{\sqrt{T}}{\|\mathbf{x}_i\|} - 1 \right| = 0 \quad (a.s.). \tag{5.7}
$$

By decomposition [\(2.1\)](#page-4-0), there are independent standard normal random variables  $f_t$ ,  $e_{it}$  (i, t  $\geq$  1) such that  $x_{it} = \sqrt{\rho} f_t + \sqrt{1 - \rho} e_{it}$ . Hence,

$$
\sum_{t=1}^{T} \frac{x_{it}^2}{T} = \rho \sum_{t=1}^{T} \frac{f_t^2}{T} + 2\sqrt{\rho(1-\rho)} \sum_{t=1}^{T} \frac{f_t e_{it}}{T} + (1-\rho) \sum_{t=1}^{T} \frac{e_{it}^2}{T}.
$$

Then

$$
\max_{1 \le i \le N} \left| \frac{\|\mathbf{x}_i\|^2}{T} - 1 \right| = \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{x_{it}^2}{T} - 1 \right|
$$
  
\n
$$
\le \rho \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{f_t^2}{T} - 1 \right| + 2\sqrt{\rho(1-\rho)} \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{f_t e_{it}}{T} \right| + (1-\rho) \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{e_{it}^2}{T} - 1 \right|.
$$

The right side converges almost surely to 0 by Proposition [5.2,](#page-13-0) because  $f_t^2$  ( $t \ge 1$ ) are i.i.d. of unit mean,  $f_t e_{it}$   $(i, t \ge 1)$  are centered i.i.d., and  $e_{it}^2$   $(i, t \ge 1)$  are i.i.d. of unit mean. Hence,

<span id="page-15-1"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \max_{1 \le i \le N} \left| \frac{\|\mathbf{x}_i\|^2}{T} - 1 \right| = 0 \quad (a.s.),\tag{5.8}
$$

from which  $\left| \lVert \boldsymbol{x}_i \rVert^2 / T - 1 \right| > \left| \lVert \boldsymbol{x}_i \rVert \right|$ √  $\left| \overline{T} - 1 \right|$  implies

<span id="page-15-0"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \max_{1 \le i \le N} \left| \frac{\|\boldsymbol{x}_i\|}{\sqrt{T}} - 1 \right| = 0 \quad (a.s.). \tag{5.9}
$$

Suppose  $\max_{1 \leq i \leq N} \Big| ||x_i||/$ √  $\left| \overline{T} - 1 \right| < \epsilon$  for sufficiently small  $\epsilon > 0$ . Then, for all i  $(1 \leq i \leq N), 1 - \epsilon < ||x_i||/$ √  $\overline{T}$  < 1 +  $\epsilon$ , which implies  $(1 + \epsilon)^{-1} - 1 < \sqrt{\epsilon}$  $T/\|\boldsymbol{x}_i\|$   $-$ 1 < (1 −  $\epsilon$ )<sup>-1</sup> − 1. Hence, for all *i* (1 ≤ *i* ≤ *N*),  $(1)$  $\left| \overline{T} / \|\boldsymbol{x}_i\| - 1 \right| \, < \, \max((1 - \frac{1}{n})$  $(\epsilon)^{-1} - 1, \|(1 + \epsilon)^{-1} - 1\|) < \epsilon + \epsilon^2 + \epsilon^3 + \cdots < 2\epsilon,$  because  $0 < \epsilon \ll 1$ . Thus,  $\max_{1 \leq i \leq N} \left| \sqrt{T/||x_i||} - 1 \right| < 2\epsilon$ . Therefore, from [\(5.9\)](#page-15-0), [\(5.7\)](#page-14-0) follows.

Thus, [\(5.4\)](#page-14-1) is guaranteed. Therefore,  $\lambda_1(\tilde{\mathbf{C}})/N \stackrel{a.s.}{\rightarrow} \rho$  follows because the assumption  $\mu = 0$  implies  $\lambda_1(S)/N \stackrel{a.s.}{\rightarrow} \rho$ .

At last, we will demonstrate  $\lambda_1(\mathbf{C})/N \stackrel{a.s.}{\rightarrow} \rho$  of Theorem [5.1.](#page-12-0) Because the sample correlation matrix C is invariant under the shifting and scaling, we can assume  $\mathbf{\Delta} = \mathbf{I}$  and  $\boldsymbol{\mu} = \mathbf{0}$ . For  $\mathbf{C} = \mathbf{YY}^{\top}$ , we have  $\mathbf{Y} = T^{-1/2} \mathbf{D} (\mathbf{X} - \overline{\mathbf{X}})$  where

$$
\mathbf{D} = \mathrm{diag}\left(\sqrt{T}/\|\mathbf{x}_1 - \overline{\mathbf{x}}_1\|, \ldots, \sqrt{T}/\|\mathbf{x}_N - \overline{\mathbf{x}}_N\|\right).
$$

Recall  $\mathbf{S}^{\circ} = T^{-1}(\mathbf{X} - \overline{\mathbf{X}})(\mathbf{X} - \overline{\mathbf{X}})^{\top}$ . By the same arguments as in [\(5.6\)](#page-14-2),

$$
\left|\sqrt{\frac{\lambda_1(\mathbf{C})}{N}} - \sqrt{\frac{\lambda_1(\mathbf{S}^\circ)}{N}}\right| \le \max_{1 \le i \le N} \left|\frac{\sqrt{T}}{\|\mathbf{x}_i - \overline{\mathbf{x}}_i\|} - 1\right| \cdot \sqrt{\frac{\lambda_1(\mathbf{S}^\circ)}{N}}.
$$

Because  $\lambda_1(\mathbf{S}^{\circ})/N \stackrel{a.s.}{\rightarrow} \rho$  follows from  $\mathbf{\Delta} = \mathbf{I}$  we assumed, it suffices to show

<span id="page-15-2"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \max_{1 \le i \le N} \left| \frac{\sqrt{T}}{\|\boldsymbol{x}_i - \overline{\boldsymbol{x}}_i\|} - 1 \right| = 0 \quad (a.s.). \tag{5.10}
$$

By 
$$
\|\mathbf{x}_i - \overline{\mathbf{x}}_i\|^2 = \|\mathbf{x}_i\|^2 - T|\overline{\mathbf{x}}_i|^2
$$
,  

$$
\max_{1 \leq i \leq N} \left| \frac{\|\mathbf{x}_i - \overline{\mathbf{x}}_i\|^2}{T} - 1 \right| \leq \max_{1 \leq i \leq N} \left| \frac{\|\mathbf{x}_i\|^2}{T} - 1 \right| + \max_{1 \leq i \leq N} |\overline{\mathbf{x}}_i|^2.
$$

The first (second, resp.) term of the right side converges almost surely to 0, by  $(5.8)$   $((5.3)$  $((5.3)$ , resp.). In a similar way as above,  $(5.10)$  is shown. Therefore,  $\lambda_1(\mathbf{C})/N \stackrel{a.s.}{\rightarrow} \rho$  for every  $\rho \geq 0$ . This completes the proof of Theorem [5.1.](#page-12-0)  $\Box$ 

To prove Theorem [1.1](#page-3-1) [\(2\)](#page-3-4), we employ:

Proposition 5.3 (Merlevède et al.  $(2019,$  Theorem 2.2)). Assume the three assumptions of Proposition [5.1.](#page-12-1) From a spectral gap condition on  $\Sigma$ :

<span id="page-16-1"></span>
$$
\limsup_{\substack{N,T \to \infty \\ T/N \to Q}} \frac{\lambda_2(\Sigma)}{\lambda_1(\Sigma)} < 1,\tag{5.11}
$$

it follows that

$$
\sqrt{T}\left(\frac{\lambda_1(\mathbf{S})}{\lambda_1(\mathbf{\Sigma})}-1-\frac{1}{T}\sum_{k=2}^N\frac{\lambda_k(\mathbf{\Sigma})}{\lambda_1(\mathbf{\Sigma})-\lambda_k(\mathbf{\Sigma})}\right)\stackrel{D}{\to}\mathrm{N}(0, 2).
$$

The spectral gap condition [\(5.11\)](#page-16-1) holds for  $\Sigma = \Sigma_{\rho}$  with  $\rho > 0$ , because [\(1.3\)](#page-2-1) implies

$$
\limsup_{\substack{N,T\to\infty\\T/N\to Q}}\frac{\lambda_2(\mathbf{\Sigma})}{\lambda_1(\mathbf{\Sigma})} = \limsup_{\substack{N,T\to\infty\\T/N\to Q}}\frac{1-\rho}{(N-1)\rho+1} = 0.
$$

Then,  $T^{-1} \sum_{k=2}^{N} \lambda_k(\mathbf{\Sigma})/(\lambda_1(\mathbf{\Sigma}) - \lambda_k(\mathbf{\Sigma})) = (N-1)(1-\rho)/(NT\rho)$ . This completes the proof of Theorem [1.1](#page-3-1) [\(2\)](#page-3-4).

# <span id="page-16-0"></span>6. Proof of Corollary [1.1](#page-3-2)

From Proposition [1.2,](#page-3-0)  $F^{\text{C}}(x)$  converges to  $MP_{Q, 1-\rho}(x)$  almost surely for every  $x \neq 0$ . It suffices to prove that  $\text{MP}_{T/N, 1-\lambda_1(\mathbf{C})/N}(x)$  converges almost surely to  $MP_{Q, 1-\rho}(x)$  for any  $x \neq 0$ . By Theorem [1.1,](#page-3-1)  $\lambda_1(\mathbf{C})/N \stackrel{a.s.}{\rightarrow} \rho$ , so  $x/(1-\rho(x))$  $\lambda_1(\mathbf{C})/N$ )  $\stackrel{a.s.}{\rightarrow} x/(1-\rho) > 0$ . The distribution function  $\text{MP}_Q(t)$  of a Marc̆enko-Pastur distribution is continuous with respect to  $t > 0$ . Thus,

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}}\left|\text{MP}_{T/N}\left(\frac{x}{1-\lambda_1(\mathbf{C})/N}\right)-\text{MP}_{T/N}\left(\frac{x}{1-\rho}\right)\right|=0\quad(a.s.).\tag{6.1}
$$

On the other hand,  $MP_Q(t)$  is continuous with respect to  $Q \in (0, \infty)$  for each  $t > 0$ , in view of the density function [\(1.1\)](#page-1-1). Therefore,

<span id="page-16-2"></span>
$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} \left| \text{MP}_{T/N}\left(\frac{x}{1-\rho}\right) - \text{MP}_Q\left(\frac{x}{1-\rho}\right) \right| = 0 \quad (a.s).
$$

By this, [\(6.1\)](#page-16-2), and the triangle inequality,

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}}\left|\text{MP}_{T/N}\left(\frac{x}{1-\lambda_1(\mathbf{C})/N}\right)-\text{MP}_Q\left(\frac{x}{1-\rho}\right)\right|=0\quad(a.s.).
$$

### <span id="page-17-0"></span>7. Proof of Theorem [2.1](#page-5-1)

### 7.1. LSD of sample covariance matrix generated from factor model

In this subsection, we provide the LSD of the sample covariance matrix S generated from a factor model (Definition [2.1\)](#page-5-4) in  $N, T \to \infty, T/N \to Q$  with Assumption [2.1.](#page-5-3) Let  $F_1$  and  $F_2$  be distribution functions. The Lévy distance between  $F_1$  and  $F_2$ is denoted by  $d_L(F_1, F_2)$ . For the definition, see [\(Huber & Ronchetti 2009,](#page-24-23) Definition 2.7). By [\(Huber & Ronchetti 2009,](#page-24-23) Theorem 2.9),

**Proposition 7.1.** For every sequence  $(F_n)_n$  of distribution functions, and every distribution function F,  $F_n$  converges weakly to F if and only if  $d_L(F_n, F) \to 0$ .

By [Huber & Ronchetti](#page-24-23) [\(2009,](#page-24-23) p. 36), the Kolmogorov distance between two  $F_1$ and  $F_2$  is defined as  $d_K(F_1, F_2) = \sup_{x \in \mathbb{R}} |F_1(x) - F_2(x)|$ , and satisfies

<span id="page-17-2"></span><span id="page-17-1"></span>
$$
d_{L}(F_{1}, F_{2}) \le d_{K}(F_{1}, F_{2}).
$$
\n(7.1)

<span id="page-17-3"></span>Proposition 7.2 [\(Bai](#page-23-5) [\(1999,](#page-23-5) Lemma 2.6, the rank inequality)).

$$
\mathrm{d}_{\mathrm{K}}\left(F^{\mathbf{A}\mathbf{A}^{\top}}, F^{\mathbf{B}\mathbf{B}^{\top}}\right) \leq \frac{1}{N} \ \mathrm{rank}(\mathbf{A} - \mathbf{B}), \qquad \left(\mathbf{A}, \mathbf{B} \in \mathbb{R}^{N \times T}\right).
$$

<span id="page-17-6"></span>**Theorem 7.1 (Scaling).** Given a factor model. Suppose  $N, T \to \infty$ ,  $T/N \to Q \in$  $(0, \infty)$  and Assumption [2.1.](#page-5-3) Then, the following two hold almost surely:

<span id="page-17-7"></span>(1)  $F^{\mathbf{S}}$  converges weakly almost surely to  $\text{MP}_{Q, \sigma^2_{\infty}(1-\rho)},$  if  $\mu_i = 0$   $(1 \leq i \leq N)$ . (2)  $F^{\text{EE}^{\top}}$  converges weakly almost surely to  $\text{MP}_{Q, \sigma^2_{\infty}(1-\rho)}$ .

Proof. By Definition [2.1,](#page-5-4) the data matrix is written as

<span id="page-17-4"></span>
$$
\mathbf{X} = \sum_{k=1}^{K} [\ell_{ik} f_{tk}]_{it} + \mathbf{\Psi}, \quad \mathbf{\Psi} := [e_{it}]_{it} \in \mathbb{R}^{N \times T}.
$$
 (7.2)

By Assumption [2.1](#page-5-3) and Proposition [1.1](#page-1-0) [\(1\)](#page-2-2), the ESD of  $T^{-1}\Psi\Psi^{\top}$  converges weakly to  $MP_{Q,\psi_1}$  almost surely. Then, Proposition [7.1](#page-17-1) implies

<span id="page-17-5"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} d_{\rm L} \left( F^{T^{-1} \Psi \Psi^{\top}}, \, \mathcal{M} \mathcal{P}_{Q, \psi_1} \right) = 0 \quad (a.s.) \tag{7.3}
$$

where  $\psi_1 = \sigma_{\infty}^2 (1 - \rho)$  by Assumption [2.1.](#page-5-3) Recall  $\mathbf{S} = T^{-1} \mathbf{X} \mathbf{X}^\top$ . Thus, by [\(7.1\)](#page-17-2), Proposition [7.2,](#page-17-3) [\(7.2\)](#page-17-4), and  $\text{rank}[\ell_{ik}f_{tk}]_{it} \leq 1$  ( $1 \leq k \leq K$ ), it holds almost surely

that

$$
d_{L}\left(F^{\mathbf{S}}, F^{T^{-1}\Psi\Psi^{\top}}\right) \leq d_{K}\left(F^{\mathbf{S}}, F^{T^{-1}\Psi\Psi^{\top}}\right) \leq \frac{1}{N} \operatorname{rank}\left(\frac{1}{\sqrt{T}}\mathbf{X} - \frac{1}{\sqrt{T}}\Psi\right)
$$
  
=  $\frac{1}{N} \operatorname{rank}\left(\frac{1}{\sqrt{T}} \sum_{k=1}^{K} \left[\ell_{ik} f_{tk}\right]_{it}\right) \leq \frac{1}{N} \sum_{k=1}^{K} \operatorname{rank}\left(\left[\ell_{ik} f_{tk}\right]_{it}\right) \leq \frac{K}{N} \to 0$   $(N \to \infty).$ 

By this, [\(7.3\)](#page-17-5), and the triangle inequality,

$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} d_{\mathcal{L}}\left(F^{\mathbf{S}}, \ \mathbf{MP}_{Q,\psi_1}\right) = 0 \quad (a.s.),\tag{7.4}
$$

which implies the first assertion of this theorem through Proposition [7.1.](#page-17-1) By the same proposition, the second assertion of this theorem follows by the triangle inequality from [\(7.4\)](#page-18-0) and

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} d_{\rm L} \left( F^{{\bf E} {\bf E}^{\top}},\ {\rm MP}_{Q,\psi_1} \right) = 0 \quad (a.s.).
$$

The last is because by [\(7.1\)](#page-17-2), Proposition [7.2,](#page-17-3) and  $rank(\mathbf{\overline{X}}) \leq 1$ , it holds almost surely that

$$
d_L(F^{\mathbf{EE}^{\top}}, F^{\mathbf{S}}) \le d_K\left(F^{\mathbf{EE}^{\top}}, F^{T^{-1}\mathbf{XX}^{\top}}\right) \le \frac{\operatorname{rank}\left(\overline{\mathbf{X}}\right)}{N} \le 1/N \to 0 \quad (N \to \infty).
$$

This completes the proof of Theorem [7.1.](#page-17-6)

<span id="page-18-2"></span><span id="page-18-1"></span><span id="page-18-0"></span>
$$
\sqcup
$$

# 7.2. LSD of sample correlation matrix generated from factor model

In this subsection, we provide the LSD of C generated from a factor model (Defi-nition [2.1\)](#page-5-4) in  $N, T \to \infty, T/N \to Q$  with Assumption [2.1.](#page-5-3) By Assumption [2.1,](#page-5-3)

$$
L := \sup \{ | \ell_{ik} | : 1 \le i, \ 1 \le k \le K \} < \infty. \tag{7.5}
$$

For  $\mu_i = 0$   $(1 \leq i \leq N)$ ,

$$
\sum_{t=1}^{T} \frac{x_{it}^2}{T} = \frac{\text{Tr}\left(\ell_i^{\top} \ell_i \sum_{t=1}^{T} f_t f_t^{\top}\right)}{T} + 2 \sum_{t=1}^{T} \frac{\ell_i f_t e_{it}}{T} + \sum_{t=1}^{T} \frac{e_{it}^2}{T}
$$
(7.6)

because

$$
\frac{1}{T}\sum_{t=1}^T f_t^\top \boldsymbol{\ell}_i^\top \boldsymbol{\ell}_i f_t = \text{Tr}\left(\boldsymbol{\ell}_i^\top \boldsymbol{\ell}_i \frac{\sum_{t=1}^T f_t f_t^\top}{T}\right).
$$

<span id="page-18-3"></span>**Lemma 7.1.** For a factor model with  $\mu_i = 0$   $(1 \leq i \leq N)$ , if Assumption [2.1,](#page-5-3) then

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}}\frac{1}{N}\operatorname{Tr}\mathbf{S}=\sigma_{\infty}^2\quad(a.s.).
$$

**Proof.** By (7.6), Tr 
$$
\mathbf{S}/N = \sum_{i=1}^{N} \sum_{t=1}^{T} x_{it}^2 / (NT)
$$
 is equal to  
\n
$$
\text{Tr}\left(\frac{\sum_{i=1}^{N} \ell_i^{\top} \ell_i}{N} \frac{\sum_{t=1}^{T} f_t f_t^{\top}}{T}\right) + 2 \frac{\sum_{i=1}^{N} \sum_{t=1}^{T} \ell_i f_t e_{it}}{NT} + \frac{\sum_{i=1}^{N} \sum_{t=1}^{T} e_{it}^2}{NT}.
$$
\n(7.7)

We will compute the almost sure limits of the three terms of [\(7.7\)](#page-19-0), in  $N, T \rightarrow$  $\infty, T/N \to Q.$ 

By the continuous mapping theorem [\(Van der Vaart 2000,](#page-25-6) Theorem 2.3) applied to the continuous function Tr, the limit of the first term of [\(7.7\)](#page-19-0) is

$$
\operatorname{Tr}\left(\lim_{\substack{N,T\to\infty\\T/N\to Q}}\frac{\sum_{i=1}^{N}\ell_{i}^{\top}\ell_{i}}{N}\frac{\sum_{t=1}^{T}f_{t}f_{t}^{\top}}{T}\right) = \operatorname{Tr}\left(\lim_{N\to\infty}\frac{\sum_{i=1}^{N}\ell_{i}^{\top}\ell_{i}}{N}\lim_{T\to\infty}\frac{\sum_{t=1}^{T}f_{t}f_{t}^{\top}}{T}\right).
$$
\n(7.8)

By Assumption [2.1,](#page-5-3)  $\lim_{i\to\infty} \ell_i^{\top} \ell_i = \ell^{\top} \ell$ , so the Cesàro sum [\(Abbott 2015\)](#page-23-6) satisfies  $\lim_{N\to\infty}\sum_{i=1}^N \ell_i^{\top}\ell_i/N = \ell^{\top}\ell.$  On other hand, by Definition [2.1,](#page-5-4)  $f_{tk}$   $(1 \leq t \leq t)$ T,  $1 \leq k \leq K$ ) are centered i.i.d. Thus,  $f_{tk}f_{tl}$   $(t = 1, 2, ...)$  are i.i.d., for each  $k, l \in \{1, \ldots, K\}$ . Since  $E(f_{tk}f_{tl}) = 1$   $(k = l); 0 \ (k \neq l)$ , the strong law of large numbers implies that

<span id="page-19-3"></span><span id="page-19-0"></span>
$$
\lim_{T \to \infty} \frac{\sum_{t=1}^{T} f_t f_t^{\top}}{T} = \mathbf{E} f_t f_t^{\top} = \mathbf{I}_K \quad (a.s.). \tag{7.9}
$$

By this, the limit of the first term of [\(7.7\)](#page-19-0) is:

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} \operatorname{Tr}\left(\frac{\sum_{i=1}^{N} \boldsymbol{\ell}_i^{\top} \boldsymbol{\ell}_i}{N} \frac{\sum_{t=1}^{T} \boldsymbol{f}_t \boldsymbol{f}_t^{\top}}{T}\right) = \operatorname{Tr}\left(\boldsymbol{\ell}^{\top} \boldsymbol{\ell} \mathbf{I}_K\right) = \|\boldsymbol{\ell}\|^2 \quad (a.s.).\tag{7.10}
$$

Next, we consider the second term of [\(7.7\)](#page-19-0). We will verify:

<span id="page-19-4"></span><span id="page-19-2"></span><span id="page-19-1"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} 2 \frac{\sum_{i=1}^{N} \sum_{t=1}^{T} \ell_i f_t e_{it}}{NT} = 0 \quad (a.s.). \tag{7.11}
$$

Let  $(i_j, t_j)$   $(j = 1, 2, 3, ...)$  be an enumeration of  $\{(i, t): i, t \in \mathbb{Z}_{\geq 1}\}.$  Because  $f_{t_j,k}$   $(j \geq 1, 1 \leq k \leq K)$  and  $e_{i_j,t_j}$   $(j \geq 1)$  are independent and centered, so are  $\ell_{i_j} f_{t_j}$  and  $e_{i_j,t_j}$ . Then,  $\sum_{j=1}^{\infty} j^{-2} \text{Var}(\ell_{i_j} f_{t_j} e_{i_j,t_j}) =$  $\sum_{j=1}^{\infty} j^{-2} \text{Var}(\ell_{i_j} f_{t_j}) \text{Var} e_{i_j,t_j} = \sum_{j=1}^{\infty} j^{-2} \text{Var}(\ell_{i_j} f_{t_j}) \psi_1.$  Because the K entries of  $f_{t_j} = [f_{t_j 1}, \ldots, f_{t_j K}]^\top$  are independent random variables with unit variance for each j, [\(7.5\)](#page-18-2) implies  $\sum_{j=1}^{\infty} \text{Var}(\ell_{i_j} f_{t_j})/j^2 = \sum_{j=1}^{\infty} ||\ell_{i_j}||^2 / j^2 < \infty$ . Moreover,  $E(\ell_i f_t e_{it}) = E(\ell_i f_t) E(e_{it}) = 0$ . Hence, [\(7.11\)](#page-19-1) follows from:

Proposition 7.3 (Kolmogorov sufficient condition [\(Gut 2013,](#page-24-24) Theorem 6.5.4)). Let  $X_1, X_2, \ldots$  be centered, independent random variables with finite variance. Then  $\sum_{j=1}^{\infty} \text{Var} X_j / j^2 < \infty$  implies  $\lim_{n \to \infty} \sum_{j=1}^{n} X_j / n = 0$  (a.s.).

The third term of [\(7.7\)](#page-19-0) tends almost surely to  $\psi_1$ , by the strong law of large numbers. Thus, by [\(7.10\)](#page-19-2) and [\(7.11\)](#page-19-1), we get  $(7.7) \stackrel{a.s.}{\rightarrow} ||\ell||^2 + \psi_1 = \sigma_{\infty}^2$  $(7.7) \stackrel{a.s.}{\rightarrow} ||\ell||^2 + \psi_1 = \sigma_{\infty}^2$ . This completes the proof of Lemma [7.1.](#page-18-3) $\Box$ 

Now, we prove Theorem [2.1.](#page-5-1)

Proof. The sample correlation matrix C and the noncentered sample correlation matrix  $\dot{C}$  (Definition [5.1\)](#page-11-3) are invariant under scaling of variables. To the factor model, we can assume

<span id="page-20-4"></span><span id="page-20-1"></span><span id="page-20-0"></span>
$$
\ell_{it} := \frac{\ell_{it}}{\sigma_{\infty}}, \quad \psi_1 := \frac{\psi_1}{\sigma_{\infty}^2}.
$$
\n(7.12)

without loss of generality. Moreover, we can safely assume that  $\mu_i = 0$  ( $1 \leq i \leq$ N) to prove that  $F^{\mathbf{C}}$  converges weakly to  $MP_{Q,1-\rho}$  almost surely, because C is invariant under shifting. It suffices to show that  $\lim_{\substack{N,T\to\infty\\T/N\to Q}} d_{\rm L} \left(F^{\rm C}, F^{{\rm E}{\rm E}^{\top}}\right) = 0$ (a.s.), because Theorem [7.1](#page-17-6) [\(2\)](#page-17-7) implies  $\lim_{\substack{N,T\to\infty\\T/N\to Q}} d_{\rm L} \left(F^{{\bf E} {\bf E}^{\top}}, {\,M} {\bf P}_{Q,1-\rho}\right) = 0$  (a.s.). By  $C = \mathbf{YY}^{\top}$ , [\(Bai 1999,](#page-23-5) Lemma 2.7) gives an upper bound on the fourth power

of the L´evy distance

$$
d_{L}^{4}\left(F^{\mathbf{C}}, F^{\mathbf{E}\mathbf{E}^{\top}}\right) \leq \frac{2}{N} \operatorname{Tr}\left(\mathbf{Y}\mathbf{Y}^{\top} + \mathbf{E}\mathbf{E}^{\top}\right) \times \frac{1}{N} \operatorname{Tr}\left(\left(\mathbf{Y} - \mathbf{E}\right)\left(\mathbf{Y} - \mathbf{E}\right)^{\top}\right). (7.13)
$$

On the right side of [\(7.13\)](#page-20-0),  $\text{Tr}(\mathbf{Y}\mathbf{Y}^{\top})/N = \text{Tr} \mathbf{C}/N = 1$ , and

$$
\frac{\text{Tr}(\mathbf{E}\mathbf{E}^{\top})}{N} = \sum_{i=1}^{N} \sum_{t=1}^{T} \frac{(x_{it} - \overline{x}_i)^2}{NT} = \sum_{i=1}^{N} \sum_{t=1}^{T} \frac{x_{it}^2}{NT} - \sum_{i=1}^{N} \frac{\overline{x}_i^2}{N} \le \sum_{i=1}^{N} \sum_{t=1}^{T} \frac{x_{it}^2}{NT}.
$$
 (7.14)

Since the rightmost term of [\(7.14\)](#page-20-1) converges almost surely to a finite deterministic value by Lemma [7.1,](#page-18-3)  $\limsup_{T \to \infty} N, T \to \infty$  $\left|\text{Tr}(\mathbf{E}\mathbf{E}^{\top})/N\right| \, < \, \infty \,$  (a.s.). Therefore, for the right side of [\(7.13\)](#page-20-0), we have only to assure the following:

<span id="page-20-3"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \frac{1}{N} \operatorname{Tr} \left( (\mathbf{Y} - \mathbf{E}) (\mathbf{Y} - \mathbf{E})^{\top} \right) = 0 \quad (a.s.). \tag{7.15}
$$

On the other hand, by  $\tilde{C} = T^{-1}XX$  and [\(Bai 1999,](#page-23-5) Lemma 2.7),  $d_L^4\left(F^{\tilde{\mathbf{C}}}, F^{T^{-1}\mathbf{X}\mathbf{X}^{\top}}\right)$  is at most the product of  $2N^{-1}\text{Tr}\left(\tilde{\mathbf{Y}}\tilde{\mathbf{Y}}^{\top}+T^{-1}\mathbf{X}\mathbf{X}^{\top}\right)$  and  $N^{-1}\,\text{Tr}\left(\left(\tilde{\mathbf{Y}}-T^{-1/2}\mathbf{X}\right)\left(\tilde{\mathbf{Y}}-T^{-1/2}\mathbf{X}\right)^\top\right)$ . Here,  $\text{Tr}\,\tilde{\mathbf{Y}}\tilde{\mathbf{Y}}^\top/N=\text{Tr}\,\tilde{\mathbf{C}}/N=1$  and  $\left|\text{Tr}\left((NT)^{-1}\mathbf{X}\mathbf{X}^{\top}\right)\right| < \infty$  (a.s.) by Lemma [7.1.](#page-18-3) Hence, to prove that  $F^{\tilde{\mathbf{C}}}$  converges weakly to  $MP_{Q,1-\rho}$  almost surely, it suffices to guarantee

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} \frac{1}{N} \operatorname{Tr}\left(\left(\tilde{\mathbf{Y}} - T^{-1/2}\mathbf{X}\right) \left(\tilde{\mathbf{Y}} - T^{-1/2}\mathbf{X}\right)^{\top}\right) = 0 \quad (a.s.),\tag{7.16}
$$

We will prove [\(7.16\)](#page-20-2), and then derive [\(7.15\)](#page-20-3) from it.

(a) The proof of [\(7.16\)](#page-20-2). The left side of (7.16) is  $\tilde{d}_1 - 2\tilde{d}_2$  where

<span id="page-20-5"></span><span id="page-20-2"></span>
$$
\tilde{d}_1 = \frac{1}{NT} \sum_{i=1}^{N} \sum_{t=1}^{T} x_{it}^2 - 1, \quad \tilde{d}_2 = \frac{1}{N} \sum_{i=1}^{N} \sqrt{\frac{1}{T} \sum_{t=1}^{T} x_{it}^2} - 1,\tag{7.17}
$$

because  $\text{Tr}(\tilde{\mathbf{Y}}\tilde{\mathbf{Y}}^{\top}) = \text{Tr}(\tilde{\mathbf{C}}) = N$  by the definition of  $\tilde{\mathbf{C}}$  and because  $\text{Tr}(\mathbf{X}\tilde{\mathbf{Y}}^\top) = \text{Tr}\left(\left[\mathbf{X}\boldsymbol{x}_1^\top/\|\boldsymbol{x}_1\|,\ldots,\mathbf{X}\boldsymbol{x}_N^\top/\|\boldsymbol{x}_N\|\right]\right) = \sum_{i=1}^N \boldsymbol{x}_i\boldsymbol{x}_i^\top/\|\boldsymbol{x}_i\| = \sum_{i=1}^N \|\boldsymbol{x}_i\|.$ Since Lemma [7.1](#page-18-3) implies

<span id="page-21-4"></span><span id="page-21-3"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \tilde{d}_1 = 0 \quad (a.s.),\tag{7.18}
$$

our goal [\(7.16\)](#page-20-2) follows from  $\lim_{N,T\to\infty} \tilde{d}_2 = 0$  (a.s.). Because of this, we will verify

<span id="page-21-0"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \frac{1}{T} \sum_{t=1}^{T} x_{it}^2 = 1 \quad (a.s.).
$$
\n(7.19)

By (7.6), 
$$
\sum_{t=1}^{T} x_{it}^2 / T
$$
 is  
\n
$$
\frac{\text{Tr}\left(\ell_i^{\top} \ell_i \sum_{t=1}^{T} f_t f_t^{\top}\right)}{T} + 2 \sum_{t=1}^{T} \frac{\ell_i f_t e_{it}}{T} + \sum_{t=1}^{T} \frac{e_{it}^2 - \psi_1}{T} + \psi_1.
$$
\n(7.20)

The first term of [\(7.20\)](#page-21-0) tends almost surely to  $||\ell_i||^2$  in  $N, T \to \infty$ ,  $T/N \to Q$ , by [\(7.9\)](#page-19-3) and the continuous mapping theorem for the continuous function Tr.

Next, we will verify that the second term of [\(7.20\)](#page-21-0) converges almost surely to 0, similarly as [\(7.11\)](#page-19-1). Because  $f_{tk}$   $(t \geq 1, 1 \leq k \leq K)$  and  $e_{it}$   $(t \geq 1)$  are independent and centered, so are  $\ell_i f_t$  and  $e_{it}$ . By Var  $f_{tk} = 1$   $(1 \leq k \leq K)$ , we then have  $\sum_{t=1}^{\infty} t^{-2} \text{Var}(\ell_i f_t e_{i,t}) = \sum_{t=1}^{\infty} t^{-2} \text{Var}(\ell_i f_t) \text{Var} e_{i,t} = \sum_{t=1}^{\infty} t^{-2} ||\ell_i||^2 \psi_1 < \infty$ by [\(7.5\)](#page-18-2). Moreover,  $\ell_i f_t e_{it}$  ( $t = 1, 2, 3, \ldots$ ) are centered independent. Hence, by Proposition [7.3,](#page-19-4) the second term of [\(7.20\)](#page-21-0) converges almost surely to 0:

$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} 2\sum_{t=1}^T \frac{\ell_i f_t e_{it}}{T} = 2\,\mathrm{E}(\ell_i f_t e_{it}) = 2\,\mathrm{E}(\ell_i f_t)\,\mathrm{E}(e_{it}) = 0 \quad (a.s.).
$$

For the third term of [\(7.20\)](#page-21-0), we will verify

<span id="page-21-2"></span><span id="page-21-1"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \max_{1 \le i \le N} \left| T^{-1} \sum_{t=1}^{T} (e_{it}^2 - \psi_1) \right| = 0 \quad (a.s.). \tag{7.21}
$$

Because we suppose  $N, T \to \infty$ ,  $T/N \to Q \in (0, \infty)$ , there exists  $T_1(m)$  such that for all  $T$ ,

$$
T > T_1(m) \implies (Q - 1/m)N < T < (Q + 1/m)N.
$$
 (7.22)

Since  $e_{it}^2$   $(1 \leq i \leq N, 1)$  are i.i.d. and  $E(e_{11}^2) = \psi_1$ , Proposition [5.2](#page-13-0) implies: for every constant  $M > 0$ , almost surely, there exists  $T_2(m, M)$  such that for all  $T \geq T_2(m, M)$  we have  $\left| \max_{1 \leq i \leq MT} \sum_{t=1}^T (e_{it}^2 - \psi_1)/T \right| < m^{-1}$ . Hence, by [\(7.22\)](#page-21-1), for all  $T \ge \max(T_1(m), T_2(m, (Q-1/m)^{-1}))$ , it holds

$$
\max_{1 \leq i \leq \frac{T}{Q+1/m}} \left| \sum_{t=1}^T \frac{e_{it}^2 - \psi_1}{T} \right| \leq \max_{1 \leq i \leq N} \left| \sum_{t=1}^T \frac{e_{it}^2 - \psi_1}{T} \right| \leq \max_{1 \leq i \leq \frac{T}{Q-1/m}} \left| \sum_{t=1}^T \frac{e_{it}^2 - \psi_1}{T} \right| < \frac{1}{m}.
$$

Consequently, [\(7.21\)](#page-21-2) has verified.

To sum up, by [\(7.12\)](#page-20-4) and  $\psi = 1$ . Hence, [\(7.19\)](#page-21-3) is verified. Thus

<span id="page-22-4"></span><span id="page-22-0"></span>
$$
\lim_{\substack{N,T \to \infty \\ T/N \to Q}} \tilde{d}_2 = 0 \quad (a.s.). \tag{7.23}
$$

Therefore [\(7.16\)](#page-20-2) is concluded.

(b) The proof of [\(7.15\)](#page-20-3). First, the left side of (7.15) is  $d_1 - 2d_2$  where

$$
d_1 = \frac{1}{NT} \sum_{i=1}^{N} \sum_{t=1}^{T} (x_{it} - \overline{x}_i)^2 - 1, \quad d_2 = \frac{1}{N} \sum_{i=1}^{N} \left( \frac{\|\mathbf{x}_i - \overline{\mathbf{x}}_i\|}{\sqrt{T}} - 1 \right). \tag{7.24}
$$

It is proved in a similar way for (a) as follows: By the definition,  $Tr(YY^{\top})$  = N. By Definition [5.1,](#page-11-3) the *i*-th column of  $Y^{\top}$  is  $(x_i - \overline{x}_i)^{\top}/||x_i - \overline{x}_i||$ , so that of  $\mathbf{E} \mathbf{Y}^{\top}$  is  $T^{-1/2}(\mathbf{X} - \overline{\mathbf{X}})$   $(x_i - \overline{x}_i)^{\top}/\Vert x_i - \overline{x}_i \Vert$ . Thus,  $\text{Tr}(\mathbf{E} \mathbf{Y}^{\top})$  =  $\sum_{i=1}^N (\bm{x}_i - \overline{\bm{x}}_i)(\bm{x}_i - \overline{\bm{x}}_i)^\top / \left(\sqrt{T} \|\bm{x}_i - \overline{\bm{x}}_i\|\right) = \sum_{i=1}^N \|\bm{x}_i - \overline{\bm{x}}_i\|/2$ √  $T$ .

Secondly, we will show  $d_1 \stackrel{a.s.}{\rightarrow} 0$  and  $d_2 \stackrel{a.s.}{\rightarrow} 0$ . From [\(7.17\)](#page-20-5) and [\(7.24\)](#page-22-0), it follows immediately

$$
\left| d_1 - \tilde{d}_1 \right| = \frac{1}{NT} \left| \sum_{i=1}^{N} \sum_{t=1}^{T} x_{it}^2 - \sum_{i=1}^{N} \sum_{t=1}^{T} (x_{it} - \overline{x}_i)^2 \right| = \frac{1}{N} \sum_{i=1}^{N} |\overline{x}_i|^2 \tag{7.25}
$$

Thus,

$$
\left| d_1 - \tilde{d}_1 \right| \le \left( \max_{1 \le i \le N} |\overline{x}_i| \right)^2 \le \left( \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{\ell_i f_t}{T} \right| + \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{e_{it}}{T} \right| \right)^2. \tag{7.26}
$$

As for the first term inside the right side,

<span id="page-22-3"></span><span id="page-22-2"></span><span id="page-22-1"></span>
$$
\max_{1 \leq i \leq N} \left| \sum_{t=1}^T \frac{\ell_i f_t}{T} \right| \leq \max_{1 \leq i \leq N} \left( \sum_{k=1}^K |\ell_{ik}| \left| \sum_{t=1}^T f_{tk}/T \right| \right).
$$

By [\(7.5\)](#page-18-2),

$$
\max_{1 \le i \le N} \left| \sum_{t=1}^{T} \frac{\ell_i f_t}{T} \right| \le KL \max_{1 \le k \le K} \left| \sum_{t=1}^{T} \frac{f_{tk}}{T} \right| \stackrel{a.s.}{\to} 0 \quad (N, T \to \infty, T/N \to Q), \quad (7.27)
$$

by the strong law of large numbers, because for each  $k$   $(1 \leq k \leq K)$ ,  $f_{tk} = 0$   $(t \geq 1)$ are centered i.i.d.

Next, we consider the second term  $\max_{1 \leq i \leq N} \left| \sum_{t=1}^T e_{it}/T \right|$  inside the right side of [\(7.26\)](#page-22-1). By Proposition [5.2,](#page-13-0) for every constant  $M > 0$ , almost surely, there exists  $T_3(m,M)$  such that for all  $T \geq T_3(m,M)$  we have  $\left|\max_{1 \leq i \leq MT} \sum_{t=1}^T e_{it}/T\right| < m^{-1}$ . Hence, by [\(7.22\)](#page-21-1), for all  $T \ge \max(T_1(m), T_3(m, (Q - 1/m)^{-1}))$ , it holds

$$
\max_{1 \le i \le \frac{T}{Q+1/m}} \left| \sum_{t=1}^T \frac{e_{it}}{T} \right| \le \max_{1 \le i \le N} \left| \sum_{t=1}^T \frac{e_{it}}{T} \right| \le \max_{1 \le i \le \frac{T}{Q-1/m}} \left| \sum_{t=1}^T \frac{e_{it}}{T} \right| < \frac{1}{m}.
$$

Consequently, 
$$
\lim_{\substack{N,T\to\infty\\T/N\to Q}} \max_{1\leq i\leq N} \left| T^{-1} \sum_{t=1}^T e_{it} \right| = 0
$$
 (a.s.). By this and (7.27),  

$$
\left| d_1 - \tilde{d}_1 \right| \leq \left( \max_{1\leq i\leq N} \left| \sum_{t=1}^T \frac{\ell_i f_t}{T} \right| + \max_{1\leq i\leq N} \left| \sum_{t=1}^T \frac{e_{it}}{T} \right| \right)^2 \stackrel{a.s.}{\to} 0 \quad (N,T\to\infty, T/N\to Q).
$$
(7.28)

Thus,  $d_1 \stackrel{a.s.}{\rightarrow} 0$ , by [\(7.18\)](#page-21-4).

In contrast, by [\(7.19\)](#page-21-3) and [\(7.24\)](#page-22-0),

$$
\left|d_2 - \tilde{d}_2\right| \le \frac{1}{N\sqrt{T}} \sum_{i=1}^N \left| \sqrt{\sum_{t=1}^T (x_{it} - \overline{x}_i)^2} - \sqrt{\sum_{t=1}^T x_{it}^2} \right|.
$$

Note  $|\sqrt{r} - \sqrt{s}| \le |r - s| / \sqrt{s}$   $(r, s \ge 0)$ . Let  $r = T^{-1} \sum_{t=1}^{T} (x_{it} - \overline{x}_{i})^{2}$  and  $s =$  $T^{-1} \sum_{t=1}^{T} x_{it}^2$ . Then,  $|r - s| = (\overline{x}_i)^2$ .

$$
\left| d_2 - \tilde{d}_2 \right| \le N^{-1} \sum_{i=1}^N |\overline{x}_i|^2 \cdot \left( \sum_{t=1}^T x_{it}^2 / T \right)^{-1/2}
$$

<span id="page-23-7"></span>.

On the right side,  $N^{-1}\sum_{i=1}^{N}|\overline{x}_i|^2$  is  $|d_1 - \tilde{d}_1|$  by [\(7.25\)](#page-22-3), which converges almost surely to 0 by [\(7.28\)](#page-23-7). Thus, [\(7.19\)](#page-21-3) implies  $|d_2 - \tilde{d}_2| \stackrel{a.s.}{\rightarrow} 0$ , from which  $d_2 \stackrel{a.s.}{\rightarrow} 0$ follows by [\(7.23\)](#page-22-4). Therefore, we have demonstrated [\(7.15\)](#page-20-3). This completes the proof of Theorem [2.1.](#page-5-1)  $\Box$
