Solving the Transmission Problem for Open Wave-Guides, I Fundamental Solutions and Integral Equations VERSION 5.1

Charles L. Epstein*

July 13, 2023

Abstract

We introduce a layer potential representation for the solution of the transmission problem defined by two dielectric channels, or open wave-guides, meeting along the straight-line interface, $\{x_1 = 0\}$. The main observation is that the outgoing fundamental solution for the operator $\Delta + k_1^2 + q(x_2)$, acting on functions defined in \mathbb{R}^2 , is easily constructed using the Fourier transform in the x_1 -variable and the elementary theory of ordinary differential equations. These fundamental solutions can then be used to represent the solution to the transmission problem in half planes. The transmission boundary conditions lead to integral equations along the intersection of the half planes, which, in our normalization, is the x_2 -axis. We show that, in appropriate Banach spaces, these integral equations are Fredholm equations of second kind, which are therefore generically solvable. We analyze the representation of the guided modes in our formulation.

1 Introduction

This paper is the first part of a three part series on scattering problems for open, or dielectric wave-guides. In these papers we focus on the scalar case, so that an open wave-guide is specified by perturbations of the background dielectric constant. We work in the time harmonic setting, i.e. solutions of the form $U(x,t) = e^{-i\omega t}u(x)$, where $\omega > 0$, and u solves an equation of the form

$$(\Delta + \omega^2 \epsilon(x))u = 0. \tag{1}$$

The permittivity function, $\epsilon(x)$, is assumed to be a positive constant outside of a compact set, union with tubular neighborhoods of a finite collection of semi-infinite rays, $\{\ell_1, \ldots, \ell_N\}$, see Figure 4. In each tubular neighborhood the permittivity is independent of the distance along the ray, depending only on variables in the orthogonal hyperplane. The solution is assumed to belong to $H^2_{loc}(\mathbb{R}^n)$, which means that it is continuous, and its gradient is continuous across jumps in the permittivity. Conceptually this is quite similar to the classical quantum-mechanical *N*-body problem, see [12, 10, 11, 14].

In the first 2 parts of this series we consider a very simple, 2-dimensional model case consisting of two semi-infinite strips of constant permittivity meeting along a common perpendicular line, see Figure 1. Outside the strips the permittivity is a

Figure 1: Two dielectric channels meeting along a straight interface. The x_3 -axis is orthogonal to the plane of the image.

constant. The goal of this paper is to produce a layer potential representation for the solution of this model problem, leading to Fredholm integral equations of second kind. We assume that the refractive index inside the wave-guide is larger than the surrounding space, which implies that wave-guide modes exist, see (12). Using the layer potential representation, which is practicably computable, we derive integral equations that lend themselves to numerical implementation for the approximate solution of this basic, model problem. In the second part of the series we show that our solution satisfies the natural outgoing radiation conditions, suggested by similar results in N-body theory.

Finally, in the third part of this series, which is joint with Rafe Mazzeo, we formulate the appropriate outgoing radiation conditions for the general n-dimensional, open wave-guide problem, show that they imply uniqueness, and are satisfied by the limiting absorption solution. Finally we show that the solutions found using our method satisfy these conditions, and therefore agree with the limiting absorption solutions. We refer to the subsequent parts of this series as Part II, and Part III, which are the papers [7], and [8].

This problem has already received a lot of attention in works of several authors, for example, see [2, 3, 4, 5]. As explained in [5], the fundamental electro-magnetic problem we are considering is that of scattering in \mathbb{R}^3 by a non-magnetic, dielectric sheet, which is independent of the x_3 -variable in the TM, or transverse magnetic mode. The electric field then takes the form $\boldsymbol{E} = (0, 0, u(x_1, x_2))$ where u satisfies

an appropriate Helmholtz-like equation

$$(\Delta + k^2(x))u = 0, \text{ with } k^2(x) = \omega^2 \epsilon(x).$$
(2)

For the case of two semi-infinite, dielectric channels meeting along a common perpendicular line, the precise formulation is in terms of a pair operators:

$$\Delta + k_1^2 + q_{l,r}(x_2), \tag{3}$$

see Figure 1. Here, and throughout the paper, l refers to $\{x_1 < 0\}$, and r refers to $\{x_1 > 0\}$. Though our method of solution applies to piecewise continuous $q(x_2)$ with bounded support, for simplicity we usually assume that

$$q_{l,r}(x_2) = (k_{2;l,r}^2 - k_1^2)\chi_{[d_{l,r}^-, d_{l,r}^+]}(x_2),$$
(4)

with $k_{2;l,r} \ge k_1$. This is essentially the same problem as that considered in [2], but rather different from that considered in [5]. Chandler-Wilde and Zhang consider more general potentials, but make assumptions that preclude the existence of waveguide modes. They also focus on incoming data similar to plane waves, whereas we consider incoming fields that decay as $|x_2| \to \infty$, which includes wave-guide modes as well as point sources and smooth wave packets formed from plane waves, see Section 6.

For time harmonic solutions, with time dependence $e^{-i\omega t}$, the wave numbers, $\{k_1, k_{2;l}, k_{2;r}\}$, are related to permittivity by $k_1 = \omega \sqrt{\epsilon_1}$, $k_{2;l,r} = \omega \sqrt{\epsilon_{2;l,r}}$, with ϵ denoting the permittivities of the materials, which we assume are positive, real numbers. We use a symmetric formulation of the transmission problem, which is suggested by the symmetry of the operator itself.

Suppose that there are incoming solutions $u_{l,r}^{in}$, which satisfy

$$(\Delta + k_1^2 + q_{l,r}(x_2))u_{l,r}^{\rm in} = 0,$$
(5)

in a neighborhood of $\{x_1 = 0\}$, we then look for "outgoing" solutions u^l, u^r , to the equations

$$(\Delta + k_1^2 + q_{l,r})u^{l,r} = 0 \text{ where } x_1 < 0, \text{ resp. } x_1 > 0,$$
(6)

with $u^l \in H^2_{\text{loc}}((-\infty, 0] \times \mathbb{R})$ and $u^r \in H^2_{\text{loc}}([0, \infty) \times \mathbb{R})$, satisfying the transmission boundary conditions

$$u^{r}(0^{+}, x_{2}) - u^{l}(0^{-}, x_{2}) = u^{\text{in}}_{l}(0, x_{2}) - u^{\text{in}}_{r}(0, x_{2}) = g(x_{2}),$$

$$\partial_{x_{1}}u^{r}(0^{+}, x_{2}) - \partial_{x_{1}}u^{l}(0^{-}, x_{2}) = \partial_{x_{1}}u^{\text{in}}(0, x_{2}) - \partial_{x_{1}}u^{\text{in}}_{r}(0, x_{2}) = h(x_{2}).$$
(7)

The regularity and boundary conditions then imply that the field

$$u^{\text{tot}}(x_1, x_2) = \begin{cases} u^l(x_1, x_2) + u^{\text{in}}_l(x_1, x_2) \text{ for } x_1 \le 0, \\ u^r(x_1, x_2) + u^{\text{in}}_r(x_1, x_2) \text{ for } x_1 > 0, \end{cases}$$
(8)

is a weak solution to

$$(\Delta + q(x_1, x_2) + k_1^2)u^{\text{tot}} = 0,$$

where $q(x_1, x_2) = q_l(x_2)\chi_{(-\infty,0]}(x_1) + q_r(x_2)\chi_{(0,\infty)}(x_1),$ (9)

which belongs to $H^2_{\text{loc}}(\mathbb{R}^2)$.

Our solutions are outgoing in a sense rather different from that in earlier papers on *this* problem. The outgoing condition we establish in Part III requires the scattered fields to satisfy more or less classical Sommerfeld radiation conditions outside the channels, with appropriate outgoing conditions within the channels, see (14). Among other things this implies that along the line $\{x_1 = 0\}$ the solutions must satisfy an estimate like

$$(\partial_{x_2} \mp ik_1)u^{l,r}(0,x_2) = O((\pm x_2)^{-\frac{3}{2}}).$$
(10)

The transmission boundary condition then implies that

$$(\partial_{x_2} \mp ik_1)g(x_2) = O((\pm x_2)^{-\frac{3}{2}}), \tag{11}$$

which shows that some conditions are required on the data for the solution to this problem to be outgoing. This is extensively discussed in Parts II and III.

Under a different definition of outgoing, the existence and uniqueness of solutions to this problem is established in [2]. We give a very different formulation of the solution that we believe is better suited to numerical approximation. That said, in this paper we only prove existence generically, and have not considered the relationship between our solution and that found in [2]. In Part III we consider radiation conditions for open wave-guides, and the problem of uniqueness using tools from microlocal analysis pioneered in [10, 11, 14]. Our solutions will turn out to satisfy the radiation conditions given in Part III, and are uniquely determined according to this notion of outgoing. This will also imply that our integral equations have a trivial null-space and are therefore always solvable.

For the applications of most immediate interest, the incoming field is a sum of *wave-guide modes*. A single wave-guide mode for $\Delta + k_1^2 + q_l(x_2)$, is given by $u_l^{\text{in}} = e^{i\xi_0 x_1} v_0(x_2), u_r^{\text{in}} = 0$ where $v_0(x_2)$ is an $H^2(\mathbb{R})$ -solution to

$$[\partial_{x_2}^2 - \xi_0^2 + k_1^2 + q_l(x_2)]v_0(x_2) = 0$$
(12)

that is exponentially decaying outside the channel, which is the supp q_l . If $\xi_0 > 0$ then this mode is rightward moving, and if $\xi_0 < 0$, leftward moving. For such a single mode, the jump data is given by

$$g(x_2) = v_0(x_2), \quad h(x_2) = i\xi_0 v_0(x_2).$$
 (13)

For the data of this type we show, in Part II, that the solution found using our method satisfies an analogue of the Sommerfeld radiation condition suggested by the analysis of the *N*-body Schrödinger equation given by Isozaki, Melrose, Vasy, et al., see [10, 11, 14]. We show that along rays $r\eta = r(\eta_1, \eta_2)$, with $\eta_1^2 + \eta_2^2 = 1$, $\eta_1 \cdot \eta_2 \neq 0$, the scattered fields satisfy

$$u^{l,r}(r\eta) = O(r^{-\frac{1}{2}}),$$

$$(\partial_r - ik_1)u^{l,r}(r\eta) = O(r^{-\frac{3}{2}}),$$
(14)

as $r \to \infty$, uniformly as $\eta_1, \eta_2 \to 0^{\pm}$. Within the channels ($\eta_2 = 0$) we also have contributions from the guided modes, which do not decay, but are outgoing in an appropriate sense: on the left a guided mode is outgoing if it is proportional to $v(x_2)e^{-i\xi_0x_1}$, with $\xi_0 > 0$, and outgoing to the right if is proportional to $v(x_2)e^{i\xi_0x_1}$, with $\xi_0 > 0$.

Section 2 introduces our approach, which uses the fundamental solutions for the perturbed operators, $\Delta + k_1^2 + q_{l,r}(x_2)$. In Sections 3 and 4 we provide details for the construction of, and estimates for the kernels introduced in Section 2. In Section 4.6 we show how these estimates extend to a half plane. In Section 5 we examine the integral equations we need to solve and prove mapping results on the operators defined by these kernels in Banach spaces of continuous functions with specified rates of decay: For $0 \le \alpha$, let $C_{\alpha}(\mathbb{R})$ denote the subspace of functions $f \in C^0(\mathbb{R})$ with

$$|f|_{\alpha} = \sup\{(1+|x|)^{\alpha}|f(x)|: x \in \mathbb{R}\} < \infty.$$
(15)

We show that the integral equations obtained in Section 5 make sense in the spaces $C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$ for $0 < \alpha < \frac{1}{2}$. If the contrast, $q_l - q_r$, is sufficiently small, then it easy to see these equations are solvable. We next show that, on these spaces, these equations are of the form Id + compact, and are therefore Fredholm equations of second kind, which are generically solvable. In a final section we show that the projections of the solutions onto the wave-guide modes are determined by the projections of the source terms onto these modes. In Section 6 we consider different kinds of physically interesting data that belong to $C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$ for an $0 < \alpha < \frac{1}{2}$. In Section 7 we derive equations that allow for the approximate

determination of the scattering relation from incoming wave-guide modes to transmitted and reflected modes, without solving the full system of equations. Several appendices give background material and proofs of ancillary results used at various points in the paper.

ACKNOWLEDGMENTS

I would like to thank Leslie Greengard for suggesting this problem and for many interesting conversations along the way. I would also like to thank Manas Rachh, Shidong Jiang, Felipe Vico, and Alex Barnett for many helpful discussions of this material and pointers to the literature on this problem. I am very grateful to Manas for carefully reading this manuscript and providing very useful comments. I would like to thank David Jerison, Rafe Mazzeo and Andras Vasy for useful discussions about these issues. I am finally very grateful for the support of the Flatiron Institute of the Simons Foundation, and for the support of Stanford University through the Bergman Visiting Scholarship.

2 A Layer Potential Approach

The starting point for our approach is the formula for the solution of the classical transmission problem: find a function u that solves

$$(\Delta + k^2)u = 0$$
, in $\mathbb{R}^2 \setminus \{x_1 = 0\}$,

and the transmission boundary condition

$$u(0^+, x_2) - u(0^-, x_2) = g(x_2)$$

$$\partial_{x_1} u(0^+, x_2) - \partial_{x_1} u(0^-, x_2) = h(x_2).$$
(16)

The outgoing solution to this problem is given by

$$u(x) = -\mathcal{D}_k g + \mathcal{S}_k h,\tag{17}$$

where the single and double layers are given by

$$\mathcal{S}_k f(x) = \int_{\{y_1=0\}} g_k(x-y) f(y_2) dy_2, \text{ and } \mathcal{D}_k f(x) = \int_{\{y_1=0\}} \partial_{y_1} g_k(x-y) f(y_2) dy_2,$$
(18)

with

$$g_k(x-y) = \frac{i}{4}H_0^{(1)}(k|x-y|)$$

the outgoing fundamental solution to $\Delta + k^2$. That this gives a solution follows from the classical jump formulæ for layer potentials, see [6].

Our method for solving the transmission problem for 2 wave guides (6), and (7), uses this general approach. Let $\mathfrak{E}^{l,r}(x;y)$ denote the outgoing fundamental solutions for the operators $\Delta + k_1^2 + q_{l,r}(x_2)$, acting on the *whole plane*. The kernels of these operators take a rather special form:

$$\mathfrak{E}^{l,r}(x;y) = \frac{i}{4} H_0^{(1)}(k_1|x-y|) + w^{l,r}(x;y), \tag{19}$$

where $w^{l,r}$ satisfies the equation

$$(\Delta_x + k_1^2 + q_{l,r}(x_2))w^{l,r}(x;y) = -\frac{i}{4}q_{l,r}(x_2)H_0^{(1)}(k_1|x-y|).$$
(20)

The right hand sides of (20) are compactly supported in the x_2 -variable. As we shall see, these equations can be solved quite explicitly by taking the Fourier transform in the x_1 -variable, and solving frequency-by-frequency. The correction terms, $w^{l,r}(x;y)$, are smooth away from the diagonal, and 2 orders smoother along the diagonal, as distributions, than $H_0^{(1)}(k|x-y|)$. Suppose that supp $q_{l,r} \subset [-d,d]$, then, where $x_1 = y_1 = 0$, the singularities of $w^{l,r}$ are contained within the compact set B_d , where, for d > 0,

$$B_d \stackrel{d}{=} [-d,d] \times [-d,d]. \tag{21}$$

Once the fundamental solutions are constructed we can express the right and left portions of the solution as

$$u^{l,r} = -\mathcal{E}^{l,r'}\sigma + \mathcal{E}^{l,r}\tau, \qquad (22)$$

where

$$\mathcal{E}^{l,r}f(x) = \int_{-\infty}^{\infty} \mathfrak{E}^{l,r}(x;0,y_2)f(y_2)dy_2 = \mathcal{S}_{k_1}f + \mathcal{W}^{l,r}f(x)$$

$$\mathcal{E}^{l,r'}f(x) = \int_{-\infty}^{\infty} [\partial_{y_1}\mathfrak{E}^{l,r}](x;0,y_2)f(y_2)dy_2 = \mathcal{D}_{k_1}f + \mathcal{W}^{l,r'}f(x),$$
(23)

with

$$\mathcal{W}^{l,r}f(x) = \int_{-\infty}^{\infty} w^{l,r}(x;0,y_2)f(y_2)dy_2,$$

$$\mathcal{W}^{l,r'}f(x) = \int_{-\infty}^{\infty} [\partial_{y_1}w^{l,r}](x;0,y_2)f(y_2)dy_2.$$
(24)

Using this representation we derive a system of equations for (σ, τ) , which are somewhat better behaved than usual in so far as the singularities of $w^{l,r}$ behave

like $|x - y|^2 \log |x - y|$. The restrictions to the boundary, $x_1 = y_1 = 0$, are given by

$$u^{r}(0, x_{2}) - u^{l}(0, x_{2}) = \sigma(x_{2}) + \int_{-\infty}^{\infty} [\partial_{y_{1}}w^{l} - \partial_{y_{1}}w^{r}](0, x_{2}; 0; y_{2})\sigma(y_{2})dy_{2} + \int_{-\infty}^{\infty} [w^{r} - w^{l}](0, x_{2}; 0; y_{2})\tau(y_{2})dy_{2} = g(x_{2}),$$

$$\partial_{x_{1}}u^{r}(0, x_{2}) - \partial_{x_{1}}u^{l}(0, x_{2}) = \tau(x_{2}) + \int_{-\infty}^{\infty} [\partial_{x_{1}}w^{r} - \partial_{x_{1}}w^{l}](0, x_{2}; 0; y_{2})\tau(y_{2})dy_{2} + \int_{-\infty}^{\infty} [\partial_{x_{1}y_{1}}w^{l} - \partial_{x_{1}y_{1}}w^{r}](0, x_{2}; 0; y_{2})\sigma(y_{2})dy_{2} = h(x_{2})$$
(25)

Only the $H_0^{(1)}$ -terms have jumps across $\{x_1 = 0\}$; as we show in Section 4.1

$$\partial_{y_1} w^{l,r}(0, x_2; 0, y_2) = \partial_{x_1} w^{l,r}(0, x_2; 0, y_2) = 0,$$
(26)

so these equations take the very simple form

$$\begin{pmatrix} \text{Id} & D \\ C & \text{Id} \end{pmatrix} \begin{pmatrix} \sigma \\ \tau \end{pmatrix} = \begin{pmatrix} g \\ h \end{pmatrix}.$$
 (27)

The behavior of these equations hinges on the analytic properties of the functions $w^{l,r}$ along the plane where $x_1 = y_1 = 0$, which we analyze in the following 2 sections. It is an interesting feature of this approach, via the fundamental solutions of $\Delta + k_1^2 + q_{l,r}(x_2)$, that if $q_l = q_r$, then these equations reduce to

$$u^{r}(0, x_{2}) - u^{l}(0, x_{2}) = \sigma(x_{2}) = g(x_{2})$$

$$\partial_{x_{1}}u^{r}(0, x_{2}) - \partial_{x_{1}}u^{l}(0, x_{2}) = \tau(x_{2}) = h(x_{2}),$$
(28)

exactly as in (17).

3 The Structure of the Perturbed Green's Function

In Sections 3–4 we simplify notation by dropping the l, r sub- and super-scripts. We use the resolvent kernel for $\Delta + k_1^2 + q(x_2) + i\delta$ to find the kernel functions needed to solve the transmission problem above; these functions are found by solving the equation

$$(\Delta + k_1^2 + q(x_2) + i\delta)w_\delta(x;y) = -\frac{i}{4}q(x_2)H_0^{(1)}(\sqrt{k_1^2 + i\delta}|x-y|), \text{ for } \delta > 0.$$
(29)

If $\delta > 0$, then, for fixed y, the right hand side belongs to $L^2(\mathbb{R}^2)$. We then let $\delta \to 0^+$, and denote this "limiting absorption solution" by $w_{0+}(x; y)$. This insures that we get the desired outgoing solution. To solve the limiting equation we simply take the Fourier transform in the x_1 -variable, and use the fact that, as $\delta \to 0^+$, we get

$$\mathcal{F}_{x_1}[(i/4)H_0^{(1)}(k_1|x-y|)](\xi) = \frac{ie^{i|x_2-y_2|\sqrt{k_1^2-\xi^2}}e^{-iy_1\xi}}{2\sqrt{k_1^2-\xi^2}}.$$
(30)

Let $\tilde{w}_{0+}(\xi, x_2; y)$ denote the Fourier transform of w_{0+} in the x_1 -variable. For $\xi \in \mathbb{R}$, it is the outgoing solution to the ordinary differential equation

$$L_{\xi}\tilde{w}_{0+} = (\partial_{x_2}^2 - \xi^2 + k_1^2 + q(x_2))\tilde{w}_{0+} = -q(x_2)\frac{ie^{i|x_2 - y_2|\sqrt{k_1^2 - \xi^2}}e^{-iy_1\xi}}{2\sqrt{k_1^2 - \xi^2}}.$$
 (31)

The spectral theory of $\Delta + q$ is reviewed in Appendix A, and we assume the reader is familiar with this material. Let $R_{\xi,0+}(x_2, z_2)$ denote the "outgoing" resolvent kernels for the 1-dimensional operators L_{ξ} . They are the limits of the resolvent kernels for $(L_{\xi} + i\delta)^{-1}$ as $\delta \to 0^+$, constructed out of the basic solutions, $\tilde{u}_{\pm}(\xi, 0+; x_2)$, of L_{ξ} and their Wronskian, $W(\xi)$, see (217), (218), (224). Using this kernel we can write:

$$\tilde{w}_{0+}(\xi, x_2; y) = -\frac{ie^{-iy_1\xi}}{2\sqrt{k_1^2 - \xi^2}} \int_{-d}^d R_{\xi, 0+}(x_2, z_2)q(z_2)e^{i|z_2 - y_2|\sqrt{k_1^2 - \xi^2}}dz_2, \quad (32)$$

where $\sqrt{k_1^2 - \xi^2} = i\sqrt{\xi^2 - k_1^2}$, if $|\xi| > k_1$.

Note that the integral in (32) extends over the *finite* interval $[-d, d] \supset \operatorname{supp} q$, which is extremely useful from the perspective of numerical solutions. Away from the diagonal in $[-d, d] \times [-d, d]$, it also decays exponentially as $|\xi| \to \infty$. We reconstruct w_{0+} as a contribution from the continuous spectrum of L_{ξ} , and a contribution from the wave-guide modes. The continuous spectrum contributes

$$w_{0+}^c(x;y) = \frac{1}{2\pi} \int_{\Gamma_{\nu}^+} \tilde{w}_{0+}(\xi, x_2; y) e^{ix_1\xi} d\xi \text{ for } x_1 > 0.$$
(33)

The integral in (33) is over the contour Γ_{ν}^+ , which is defined below, see Figure 2. In order to be able to deform the contour of integration and use (33) to represent

Figure 2: The portion of Γ^+_{ν} near to the positive wave-guide frequencies

 w_{0+} , it is necessary to assume that $\pm k_1$ are not roots of Wronskian, $W(\xi)$, of L_{ξ} , see (225) and (231)–(233). If

$$q(x_2) = (k_2^2 - k_1^2)\chi_{[-d,d]}(x_2),$$
(34)

then this amounts to the requirement that

$$2d\sqrt{k_2^2 - k_1^2} \neq n\pi \text{ for } n \in \mathbb{N}.$$
(35)

In this case, as shown in Theorem 2, the roots of the Wronskian, $\{\pm \xi_n : n = 1, \ldots, N\}$, lie in $(-k_2, -k_1) \cup (k_1, k_2)$. The contour Γ_{ν}^+ is defined by replacing the intervals $\{[\pm \xi_n - \nu, \pm \xi_n + \nu] : n = 1, \ldots, N\}$ in \mathbb{R} with the semi-circles in the upper half plane

$$\{\pm \xi_n + \nu e^{i\theta} : \ \theta \in [0,\pi]\},\tag{36}$$

with a clockwise orientation. We assume that $\nu > 0$ is small enough so these semicircles are disjoint and intersect \mathbb{R} within $(-k_2, -k_1) \cup (k_1, k_2)$. The contour $\Gamma_{\nu}^$ is obtained by reflecting Γ_{ν}^+ in the real axis.

To $w_{0+}^c(x; y)$ we add a contribution from the wave-guide modes:

$$w_{0+}^g(x;y) = \sum_{n=1}^N v_n(x_2)a_n(y_2)e^{i\xi_n(x_1-y_1)} \text{ for } x_1 > 0,$$
(37)

which is *i* times the sum of the residues of $\tilde{w}_{0+}(\xi, x_2; y)e^{ix_1\xi}$ at the $\{\xi_n\}$. The $\{v_n(x_2)\}$ are normalized to have L^2 -norm 1. The coefficients of the wave-guide

terms are given by

$$a_n(y_2) = -\frac{1}{2} \int_{-d}^d \frac{e^{-\sqrt{\xi_n^2 - k_1^2}|y_2 - z_2|}q(z_2)v_n(z_2)dz_2}{\sqrt{\xi_n^2 - k_1^2}}.$$
(38)

These contributions and their ∂_{x_1} -derivatives are in $\mathcal{C}^1(\mathbb{R})$. Using the fact that $(\partial_{x_2}^2 + k_1^2 - \xi_n^2)v_n(x_2) = -q(x_2)v_n(x_2)$, and integration by parts, we show that

$$a_n(y_2) = v_n(y_2),$$
 (39)

and therefore

$$w_{0+}^g(x;y) = \sum_{n=1}^N v_n(x_2)v_n(y_2)e^{i\xi_n(x_1-y_1)} \text{ for } x_1 > 0.$$
(40)

Hence this term and its x_1 -derivatives decay exponentially as $|x_2| + |y_2| \to \infty$. The fundamental solution for $\Delta + k_1^2 + q(x_2)$ is given by

$$\mathfrak{E}(x;y) = g_{k_1}(|x-y|) + w_{0+}^c(x;y) + w_{0+}^g(x;y); \tag{41}$$

the guided modes are entirely captured by w_{0+}^g . This and the following section describes the construction in the right half plane; the left half plane is obtained by replacing (x_1, y_1) with $(-x_1, -y_1)$, and Γ_{ν}^+ with Γ_{ν}^- .

We need to analyze w_{0+} , and certain of its derivatives, along the set $x_1 = y_1 = 0$. First observe that outside the strip $|x_2| \leq d$, this function satisfies the homogeneous elliptic equation $(\Delta_x + k_1^2)w_{0+} = 0$, and is therefore a \mathcal{C}^{∞} -function of x. From (30) and (33) it is clear that $\partial_{x_1}w_{0+}^c(x;y) = -\partial_{y_1}w_{0+}^c(x;y)$, hence it suffices to analyze the smoothness and decay properties of $\partial_{x_1}^j w_{0+}^c(x;y)$, for j = 0, 1, 2.

As noted, away from $x_2 = y_2$, the functions $\partial_{x_1}^j w_{0+}(0, x_2; 0, y_2)$ are \mathcal{C}^{∞} -functions provided $x_2 \neq \pm d$ or $y_2 \neq \pm d$. The function w_{0+} is \mathcal{C}^1 in a neighborhood of these points with higher regularity determined by the regularity of q. If q were a smooth function, then it would follow that

$$(\Delta_x + k_1^2 + q(x_2))q(x_2)|x - y|^2 H_0^{(1)}(k_1|x - y|) = 4q(x_2)H_0^{(1)}(k_1|x - y|) + O(1 + |x - y|\log|x - y|), \quad (42)$$

showing that the principal singularity along the diagonal would be given by

$$w_{0+}(x;y) = -i\frac{q(x_2)}{16}|x-y|^2H_0^{(1)}(k_1|x-y|) + O(|x-y|^3\log|x-y|).$$
(43)

Even with q given by (34) this is essentially correct.

4 Estimates for the Boundary Kernel

In this section we analyze the behavior of the functions

$$\mathfrak{w}^{[j]}(x_2, y_2) = \left[\frac{1}{i}\partial_{x_1}\right]^j w_{0+}^c(x_1, x_2; y_1, y_2) \upharpoonright_{x_1=y_1=0}, j = 0, 1, 2.$$
(44)

With these functions one can easily construct the kernel functions appearing in the equations in (25). In the following section we explain why similar estimates hold for $w_{0+}(x_1, x_2; 0, y_2)$, and its derivatives

$$\partial_{y_1} w_{0+}(x_1, x_2; 0, y_2), \partial_{x_1} w_{0+}(x_1, x_2; 0, y_2), \text{ and } \partial_{x_1} \partial_{y_1} w_{0+}(x_1, x_2; 0, y_2),$$

where $x_1 > 0$. These estimates require tedious, but rather standard analysis, using the properties of solutions to second order ODEs, stationary phase and integration by parts. A reader only interested in the final results can safely skip to Section 4.5.

4.1 Estimates on the Wronskian and Basic Solutions of L_{ξ}

We first spell out the properties of the basic solutions, $\tilde{u}_{\pm}(\xi, 0+; x_2)$, and their Wronskian, $W(\xi)$, in greater detail. For these calculations we assume that q is given in (34). Similar estimates hold for any piecewise continuous, bounded potential, which is supported in an interval, though we can no longer rely on explicit formulæ within the support of q.

The Wronskian is given by

$$W(\xi) = \begin{cases} -e^{2iBd} \left[(2\xi^2 - k_1^2 - k_2^2) \frac{\sin 2dA}{A} - 2iB\cos 2dA \right] \text{ for } |\xi| < k_1, \\ -e^{-2\widetilde{B}d} \left[(2\xi^2 - k_1^2 - k_2^2) \frac{\sin 2dA}{A} + 2\widetilde{B}\cos 2dA \right] \text{ for } k_1 < |\xi| < k_2, \\ -e^{-2\widetilde{B}d} \left[(2\xi^2 - k_1^2 - k_2^2) \frac{\sinh 2d\widetilde{A}}{\widetilde{A}} + 2\widetilde{B}\cosh 2d\widetilde{A} \right] \text{ for } k_2 < |\xi|, \end{cases}$$

$$(45)$$

where

$$A = \sqrt{k_2^2 - \xi^2}, B = \sqrt{k_1^2 - \xi^2},$$

$$\widetilde{A} = \sqrt{\xi^2 - k_2^2}, \widetilde{B} = \sqrt{\xi^2 - k_1^2}.$$
(46)

These formulæ and those for \tilde{u}_+ below are provided for the convenience of the reader, as all can be derived from the formula for $|\xi| < k_1$ by choosing the correct branch of the square root: \sqrt{z} is defined in $\mathbb{C} \setminus (-\infty, 0]$, with $\sqrt{x} \in (0, \infty)$ for $x \in (0, \infty)$.

The Wronskian is analytic in a neighborhood of $\pm k_2$, (where A, \widetilde{A} vanish), but has square root singularities at $\pm k_1$. It never vanishes at $\pm k_2$, and does not vanish at $\pm k_1$, provided that

$$2d\sqrt{k_2^2 - k_1^2} \neq n\pi \text{ for any } n \in \mathbb{Z}.$$
(47)

As $|\xi| \to \infty$, we have the lower bound

$$|W(\xi)| > M|\xi|. \tag{48}$$

Since q is supported in [-d,d] the asymptotics of \tilde{w}_{0+} as $|x_2|\to\infty$ are given by

$$\tilde{w}_{0+}(\xi, x_2; y) = -\frac{\tilde{u}_{+}(\xi, 0+; x_2)e^{-iy_1\xi}}{2W(\xi)\sqrt{\xi^2 - k_1^2}} \times \int_{-d}^{d} \tilde{u}_{+}(\xi, 0+; -z_2)q(z_2)e^{-|z_2 - y_2|\sqrt{\xi^2 - k_1^2}}dz_2, \text{ for } x_2 > d,$$

$$\tilde{w}_{0+}(\xi, x_2; y) = -\frac{\tilde{u}_{+}(\xi, 0+; -x_2)e^{-iy_1\xi}}{2W(\xi)\sqrt{\xi^2 - k_1^2}} \times \int_{-d}^{d} \tilde{u}_{+}(\xi, 0+; z_2)q(z_2)e^{-|z_2 - y_2|\sqrt{\xi^2 - k_1^2}}dz_2, \text{ for } x_2 < -d,$$
(49)

which shows that we need formulæ for $\tilde{u}_+(\xi, 0+; z_2)$ for all $z_2 \ge -d$. We include the formula for $z_2 < -d$, with $|\xi| < k_1$, as we need the analytic properties of $\tilde{u}_+(\xi, 0+; z_2)$ in the appendices. For $|\xi| < k_1$,

$$\widetilde{u}_{+}(\xi, 0+; z_{2}) = \begin{cases} e^{iBz_{2}}, \text{ for } z_{2} > d, \\ e^{iBd} \left[\cos A(d-z_{2}) - iB\frac{\sin A(d-z_{2})}{A} \right] \text{ for } |z_{2}| < d, \\ e^{iBd} \left[\left(\cos 2dA \cos B(d+z_{2}) + A \sin 2dA\frac{\sin B(d+z_{2})}{B} \right) + iB \left(\cos 2dA\frac{\sin B(d+z_{2})}{B} - \frac{\sin 2dA}{A} \cos B(d+z_{2}) \right) \right] \text{ for } z_{2} < -d. \end{cases}$$
(50)

Note that for all $z_2 < d$,

$$\widetilde{u}_{+}(\xi, 0+; z_2) = e^{i\sqrt{k_1^2 - \xi^2}d} \left[\theta(\xi, z_2) + \sqrt{k_1^2 - \xi^2} \varphi(\xi, z_2) \right],$$

where θ and φ are entire functions ξ . For the convenience of the reader we include certain formulæ for $k_1 < |\xi| < k_2$,

$$\widetilde{u}_{+}(\xi, 0+; z_{2}) = \begin{cases} e^{-\widetilde{B}z_{2}}, \text{ for } z_{2} > d \\ e^{-\widetilde{B}d} \left[\cos A(d-z_{2}) + \widetilde{B} \frac{\sin A(d-z_{2})}{A} \right] \text{ for } |z_{2}| < d; \end{cases}$$
(51)

and for $k_2 < |\xi|$,

$$\widetilde{u}_{+}(\xi, 0+; z_{2}) = \begin{cases} e^{-\widetilde{B}z_{2}}, \text{ for } z_{2} > d \\ e^{-\widetilde{B}d} \left[\cosh \widetilde{A}(d-z_{2}) + \widetilde{B} \frac{\sinh \widetilde{A}(d-z_{2})}{\widetilde{A}} \right] \text{ for } |z_{2}| < d. \end{cases}$$
(52)

If $\{\xi_n\}$ are the positive roots of the Wronskian, then

$$\gamma_n^- = \{-\xi_n + \nu e^{i\theta} : \theta \in [0, 2\pi)\} \text{ and } \gamma_n^+ = \{\xi_n + \nu e^{i\theta} : \theta \in [0, 2\pi)\}$$
 (53)

are circles of radius ν centered in these roots. We let $-\gamma_{n+}^{\pm}$ denote the intersection of these circles with the upper half plane, oriented from left to right. Before proceeding with this analysis, we observe that $\tilde{w}_{0+}(\xi, x_2; 0, y_2) = \tilde{w}_{0+}(-\xi, x_2; 0, y_2)$, which implies that, in the integral defining $\mathfrak{w}^{[1]}$, the contributions from $\Gamma_{\nu}^+ \cap \mathbb{R}$ cancel exactly, and therefore

$$\mathfrak{w}^{[1]} = \frac{1}{2\pi} \sum_{n=1}^{N} \left[\int_{-\gamma_{n+}^{-}} \xi \tilde{w}_{0+}(\xi, x_2; 0, y_2) d\xi + \int_{-\gamma_{n+}^{+}} \xi \tilde{w}_{0+}(\xi, x_2; 0, y_2) d\xi \right].$$
(54)

Using the symmetries of the integrand it is not difficult to show that

$$\mathfrak{w}^{[1]} = \frac{1}{2\pi} \sum_{n=1}^{N} \int_{-\gamma_n^+} \xi \tilde{w}_{0+}(\xi, x_2; 0, y_2) d\xi;$$
(55)

where $-\gamma_n^+$ indicates that the circles about the $\{\xi_n\}$ are oriented in the clockwise direction. This gives -i times the sum of the residues of $\xi \tilde{w}_{0+}(\xi, x_2; 0, y_2)$ at the $\{\xi_n\}$. It is not difficult to see that

$$i\mathfrak{w}^{[1]} + \partial_{x_1} w^g_{0+}(0, x_2; 0, y_2) = 0,$$
(56)

as the function $\partial_{x_1} w_{0+}^g$ is *i* times the sum of the residues of $i\xi \tilde{w}_{0+}(\xi, x_2; 0, y_2)$ at the $\{\xi_n\}$. Hence the kernel $\mathfrak{w}^{[1]}$ does not play any role in the integral equations derived in Section 5, nonetheless we include estimates for its behavior as we need these results for the representation formula, which involves $\partial_{y_1} w_{0+}(x; 0, y_2)$.

4.2 Asymptotics for $|x_2|, |y_2| > d$

For $x_2 > d$, we write these functions in the form

$$\mathfrak{w}^{[j]}(x_2, y_2) = \frac{1}{2\pi} \int_{\Gamma_{\nu}^+} \xi^j \tilde{w}_{0+}(\xi, x_2; 0, y_2) d\xi$$
$$= \frac{1}{2\pi} \int_{\Gamma_{\nu}^+} \xi^j \frac{\tilde{u}_+(\xi, 0+; x_2) \mathfrak{A}(\xi, \sqrt{\xi^2 - k_1^2}; y_2)}{\mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2}) \sqrt{k_1^2 - \xi^2}} d\xi, \quad (57)$$

where, for $|\xi| < k_1, \sqrt{\xi^2 - k_1^2} = -i\sqrt{k_1^2 - \xi^2}$ and we write

$$\mathfrak{A}(\xi,\eta;y_2) = \int_{-d}^{d} q(z_2) e^{-\eta |y_2 - z_2|} e^{-\eta d} \left[\cos A(d+z_2) + \eta \frac{\sin A(d+z_2)}{A} \right] dz_2.$$
(58)

We rewrite the Wronskian as $W(\xi) = \mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2})$, with

$$\mathfrak{W}(\xi,\eta) = -e^{2i\eta d} \left[(2\xi^2 - k_1^2 - k_2^2) \frac{\sin 2dA}{A} - 2i\eta \cos 2dA \right] \text{ for } |\xi| < k_1.$$
 (59)

These formulæ hold for other ranges of ξ by using the correct branch of $B = \sqrt{k_1^2 - \xi^2}$; as noted these formulæ do not depend on the choice of branch for $A = \sqrt{k_2^2 - \xi^2}$. We use this formulation, as $\mathfrak{A}(\xi, \eta; y_2)$, and $\mathfrak{W}(\xi, \eta)$ are entire functions of (ξ, η) , which allows us to better keep track of the square root singularities at $\pm k_1$ in our subsequent computations.

To analyze $\mathfrak{w}^{[j]}$ we split the integral over ξ into the segment where $|\xi| < k_1$, a segment with $k_1 < |\xi| < k_2$, and finally the segment where $k_2 < |\xi|$. The leading order behavior is largely determined, via stationary phase, by the integral over small neighborhood of $\xi = 0$; whereas the diagonal singularities come from large $|\xi|$.

We begin with $\xi \in [-k_1, k_1]$, and denote these contributions by $\mathfrak{w}_0^{[j]}(x_2, y_2)$:

$$\mathfrak{w}_{0}^{[j]}(x_{2}, y_{2}) = \frac{1}{2\pi} \int_{-k_{1}}^{k_{1}} \xi^{j} \tilde{w}_{0+}(\xi, x_{2}; 0, y_{2}) d\xi$$
$$= \frac{1}{2\pi} \int_{-k_{1}}^{k_{1}} \xi^{j} \frac{\tilde{u}_{+}(\xi, 0+; x_{2}) \mathfrak{A}(\xi, \sqrt{\xi^{2} - k_{1}^{2}}; y_{2})}{\mathfrak{W}(\xi, \sqrt{k_{1}^{2} - \xi^{2}}) \sqrt{k_{1}^{2} - \xi^{2}}} d\xi. \quad (60)$$

We first consider $x_2, y_2 > d$, so that

$$\mathfrak{w}_{0}^{[j]}(x_{2}, y_{2}) = \frac{1}{2\pi} \int_{-k_{1}}^{k_{1}} \xi^{j} \tilde{w}_{0+}(\xi, x_{2}; 0, y_{2}) d\xi$$
$$= \frac{i}{2\pi} \int_{-k_{1}}^{k_{1}} \xi^{j} \frac{e^{i\sqrt{k_{1}^{2} - \xi^{2}}(x_{2} + y_{2})} \mathfrak{A}_{0}(\xi, -i\sqrt{k_{1}^{2} - \xi^{2}})}{\mathfrak{W}(\xi, \sqrt{k_{1}^{2} - \xi^{2}})\sqrt{k_{1}^{2} - \xi^{2}}} d\xi, \quad (61)$$

where

$$\mathfrak{A}_0(\xi,\eta) = \int_{-d}^d q(z_2) e^{\eta z_2} e^{-\eta d} \left[\cos A(d+z_2) + \eta \frac{\sin A(d+z_2)}{A} \right] dz_2.$$
(62)

We split the integral in (61) into the part near to $\xi = 0$, denoted $\mathfrak{w}_{00}^{[j]}$, where the phase is stationary and the part near to $\xi = \pm k_1$, denoted $\mathfrak{w}_{01}^{[j]}$, where the integrand

appears to have a singularity. As we will see, this singularity is removable by changing variables. Let $\phi \in C_c^{\infty}((-\frac{1}{2}, \frac{1}{2}))$, be a non-negative, even function with $\phi(t) = 1$ for $|t| < \frac{1}{4}$. Using a standard stationary phase argument we see that there are complete asymptotic expansions

$$\mathfrak{w}_{00}^{[j]}(x_2, y_2) = \frac{i}{2\pi} \int_{-k_1}^{k_1} \xi^j \frac{e^{i\sqrt{k_1^2 - \xi^2}(x_2 + y_2)} \mathfrak{A}_0(\xi, -i\sqrt{k_1^2 - \xi^2})\phi(\xi/k_1)}{\mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2})\sqrt{k_1^2 - \xi^2}} \\ \sim \frac{e^{ik_1(x_2 + y_2)}}{(x_2 + y_2)^{\frac{j+1}{2}}} \left[M_{j0} + \sum_{l=1}^{\infty} \frac{M_{jl}}{(x_2 + y_2)^l} \right] \text{ for } j = 0, 1, 2.$$
(63)

To treat the other part of the integral we let $s = \sqrt{k_1^2 - \xi^2}$, to obtain a smooth integrand that can be integrated by parts giving

$$\begin{split} \mathfrak{w}_{01}^{[j]}(x_2, y_2) &= \\ \frac{i}{\pi} \int_0^{k_1} (k_1^2 - s^2)^{\frac{j}{2}} \frac{e^{is(x_2 + y_2)} \mathfrak{A}_0(\sqrt{k_1^2 - s^2}, -is)[1 - \phi(\sqrt{k_1^2 - s^2}/k_1)]}{\mathfrak{W}(\sqrt{k_1^2 - s^2}, s)\sqrt{k_1^2 - s^2}} ds = \\ - \frac{k_1^{j-1}}{\pi(x_2 + y_2)} \frac{\mathfrak{A}_0(k_1, 0)}{\mathfrak{W}(k_1, 0)} + O\left((x_2 + y_2)^{-2}\right). \end{split}$$
(64)

The leading term here will cancel with the leading contribution from this endpoint for the integrals over set $k_1 < |\xi| < k_2$. So overall, the contribution of this endpoint will be $O((x_2 + y_2)^{-2})$.

We next consider, $\mathfrak{w}_1^{[j]}$, the contributions from $k_1 < |\xi| < k_2$, which includes small semi-circles around the zeros of the Wronskian. We first consider the portions of these integrals from near to $\xi = \pm k_1$, which we denote $\mathfrak{w}_{10}^{[j]}(x_2, y_2)$. By evenness of the integrand it suffices to consider $\xi \in [k_1, k_1 + \mu]$. Let $\phi \in C_c^{\infty}([0, \mu))$, for an $0 < \mu \ll \xi_1 - k_1$, with $\phi(t) = 1$ for $t \in [0, \mu/2]$. Set $s = \sqrt{\xi^2 - k_1^2}$, and integrate by parts to get

$$\mathfrak{w}_{10}^{[j]}(x_2, y_2) = \frac{1}{\pi} \int_{k_1}^{k_1 + \mu} \xi^j \frac{e^{-\sqrt{\xi^2 - k_1^2 (x_2 + y_2)}} \mathfrak{A}_0(\xi, \sqrt{\xi^2 - k_1^2}) \phi(\sqrt{\xi^2 - k_1^2})}{\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})\sqrt{\xi^2 - k_1^2}} d\xi = \frac{1}{\pi} \int_0^{\sqrt{2k_1 \mu + \mu^2}} (s^2 + k_1^2)^{\frac{j}{2}} \frac{e^{-s(x_2 + y_2)}}{\mathfrak{W}(\sqrt{s^2 + k_1^2}, is)\sqrt{s^2 + k_1^2}} ds = \frac{k_1^{j-1}}{\pi(x_2 + y_2)} \frac{\mathfrak{A}_0(k_1, 0)}{\mathfrak{W}(k_1, 0)} + O\left((x_2 + y_2)^{-2}\right).$$
(65)

As stated above,

$$\mathfrak{w}_{10}^{[j]}(x_2, y_2) + \mathfrak{w}_{01}^{[j]}(x_2, y_2) = O\left((x_2 + y_2)^{-2}\right).$$
(66)

Figure 3: The blue contour is $\Gamma^+_{\nu,\epsilon}$ showing the smooth curves replacing intervals $[-\epsilon - k_1, \epsilon - k_1] \cup [-\epsilon + k_1, \epsilon + k_1]$. The roots of the Wronskian are shown as asterisks, and $\pm k_1$ as diamonds.

In fact the sum of these terms vanishes to all orders. This can be proved by using analyticity to deform the portions of the contour near to $\pm k_1$: we replace an interval $[-\epsilon - k_1, \epsilon - k_1]$ with a smooth contour meeting the real axis smoothly, lying in the upper half plane and an interval $[-\epsilon + k_1, \epsilon + k_1]$ with a smooth contour meeting the real axis smoothly, lying in the lower half plane. We call this contour $\Gamma^+_{\nu,\epsilon}$. An example is shown in Figure 3. On this contour the analytic continuation of $\sqrt{k_1^2 - \xi^2}$ is smooth, has a positive imaginary part, and no critical points. Hence $e^{i\sqrt{k_1^2 - \xi^2}(x_2 + y_2)}$ is exponentially decaying, and therefore

$$\mathfrak{w}_{10}^{[j]}(x_2, y_2) + \mathfrak{w}_{01}^{[j]}(x_2, y_2) = O\left((x_2 + y_2)^{-N}\right) \text{ for any } N > 0.$$
 (67)

A similar argument applies in all cases considered in the subsequent sections. To treat the right half plane we use the contour $\Gamma_{\nu,\epsilon}^-$, which is obtained by modifying Γ_{ν}^- is the same way, i.e. the change to the contour in the left half plane lies in Im $\xi > 0$, and that in the right half plane lies in Im $\xi < 0$. Note: deforming the contours from $\Gamma_{\nu,\epsilon}^{\pm}$ to $\Gamma_{\nu,\epsilon}^{\pm}$ does not change the value of the integral, and therefore it follows that all finite order contributions from near to $\pm k_1$ along Γ_{ν}^{\pm} also cancel.

Now we need to estimate the contributions from the remainder of $\Gamma_{\nu,\epsilon}^+$ lying over $[k_1 + \mu/2, k_2] \cup [-k_2, -(k_1 + \mu/2)]$. Other than the semi-circles centered on the roots of the Wronskian,

$$\bigcup_{n=1}^{N} \{ \pm \xi_n + \nu e^{i\theta} : \ \theta \in [\pi, 0] \} = \bigcup_{n=1}^{N} C_{n,\nu}^{\pm}, \tag{68}$$

we use the evenness of the integrand to restrict our attention to $[k_1 + \mu/2, k_2]$.

To estimate the contributions from the semi-circles we need to estimate both $|\mathfrak{A}_0(\xi, \sqrt{\xi^2 - k_1^2})|$, from above, and $|\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})|$, from below, on these arcs. As the roots of the Wronskian are all simple, there is a constant M so that

$$|\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})| \ge M\nu \text{ for } \xi \in C_{n,\nu}^{\pm}.$$
(69)

On the other hand, for $\xi \in C_{n,\nu}^{\pm}$,

$$|\mathfrak{A}_{0}(\xi,\eta)| \leq \int_{-d}^{d} q(z_{2})e^{\alpha(z_{2}-d)} \left[\exp\beta(d-z_{2}) + |\eta|\frac{\exp\beta(d-z_{2})}{|\sqrt{k_{2}^{2}-\xi^{2}}|}\right] dz_{2}, \quad (70)$$

where

$$\alpha = \operatorname{Re}\left[\sqrt{(\pm\xi_n + \nu e^{i\theta})^2 - k_1^2}\right] \text{ and } \beta = \left|\operatorname{Im}\left[\sqrt{k_2^2 - (\pm\xi_n + \nu e^{i\theta})^2}\right]\right|.$$
(71)

There is a constant, m so that, for $\theta \in [0, 2\pi]$, we have

$$\alpha > \sqrt{\xi_n^2 - k_1^2} (1 - m\nu) \text{ and } \beta < m\nu.$$
(72)

These inequalities rely on the fact that $k_1 < \xi_j < k_2$. If we choose $0 < \nu$ sufficiently small so that

$$m\nu - \sqrt{\xi_n^2 - k_1^2}(1 - m\nu) < 0 \text{ for } n = 1, \dots, N,$$
 (73)

then it follows that there exists a constant, M, so that

$$|\mathfrak{A}_0(\xi,\eta)| \le M \text{ for } \xi \in C^{\pm}_{n,\nu} \text{ for } n = 1,\dots,N.$$
(74)

For sufficiently small ν we therefore have the estimates

$$\left|\sum_{n=1}^{N} \int_{C_{n,\nu}^{\pm}} \xi^{j} \frac{e^{-\sqrt{\xi^{2}-k_{1}^{2}}(x_{2}+y_{2})} \mathfrak{A}_{0}(\xi,\sqrt{\xi^{2}-k_{1}^{2}})}{\mathfrak{W}(\xi,i\sqrt{\xi^{2}-k_{1}^{2}})\sqrt{\xi^{2}-k_{1}^{2}}} d\xi\right| \leq M \sum_{n=1}^{N} \frac{e^{-\sqrt{\xi_{n}^{2}-k_{1}^{2}}(1-m\nu)(x_{2}+y_{2})}}{\nu}.$$
 (75)

To treat $\Gamma^+_{\nu} \cap [k_1 + \mu/2, k_2]$, we see that $|\mathfrak{A}_0(\xi, \eta)|$ is bounded by a constant on this set and therefore

$$\left| \int_{\Gamma_{\nu}^{+} \cap [k_{1}+\mu/2,k_{2}]} \xi^{j} \frac{e^{-\sqrt{\xi^{2}-k_{1}^{2}}(x_{2}+y_{2})} \mathfrak{A}_{0}(\xi,\sqrt{\xi^{2}-k_{1}^{2}})}{\mathfrak{W}(\xi,i\sqrt{\xi^{2}-k_{1}^{2}})\sqrt{\xi^{2}-k_{1}^{2}}} d\xi \right| \leq M \frac{e^{-\mu k_{1}(x_{2}+y_{2})/2}}{\nu}.$$
(76)

To summarize, we have shown that for $x_2, y_2 > d$, the contributions to the integrals defining $\mathfrak{w}^{[j]}(x_2, y_2)$, from frequencies $\xi \in [-k_2, k_2]$ are given by the asymptotic expansions in (63), with errors $O((x_2 + y_2)^{-N})$, for any N > 0. We conclude the discussion of this case by estimating the contribution from $|\xi| > k_2$, which we denote by $\mathfrak{w}_2^{[j]}(x_2, y_2)$. As before, by evenness, it suffices to consider $[k_2, \infty)$. Using the formulæ above we see that

$$\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2}) = \int_{k_{2}}^{\infty} \xi^{j} \frac{e^{-\sqrt{\xi^{2} - k_{1}^{2}}(x_{2} + y_{2})} \mathfrak{A}_{0}(\xi, \sqrt{\xi^{2} - k_{1}^{2}})}{\mathfrak{W}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}})\sqrt{\xi^{2} - k_{1}^{2}}} d\xi,$$
(77)

where

$$\mathfrak{A}_{0}(\xi,\sqrt{\xi^{2}-k_{1}^{2}}) = \int_{-d}^{d} q(z_{2})e^{\sqrt{\xi^{2}-k_{1}^{2}}(z_{2}-d)} \times \left[\cosh\sqrt{\xi^{2}-k_{2}^{2}}(d+z_{2}) + \sqrt{\xi^{2}-k_{1}^{2}}\frac{\sinh\sqrt{\xi^{2}-k_{2}^{2}}(d+z_{2})}{\sqrt{\xi^{2}-k_{2}^{2}}}\right] dz_{2}.$$
 (78)

From this formula we can easily show that there is a constant M so that

$$|\mathfrak{A}_0(\xi, \sqrt{\xi^2 - k_1^2})| \le \frac{M e^{2d\sqrt{\xi^2 - k_1^2}}}{1 + |\xi|} \text{ for } \xi \in [k_2, \infty),$$
(79)

and therefore, for $x_2, y_2 > d$, $|\xi| > k_2$ we have the estimate

$$|\tilde{w}_{0+}(\xi, x_2; 0, y_2)| \le M \frac{e^{-\sqrt{\xi^2 - k_1^2}(x_2 + y_2 - 2d)}}{(1 + |\xi|)^3}.$$
(80)

Hence

$$\begin{aligned} |\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2})| &\leq M \int_{k_{2}}^{\infty} \frac{\xi^{j} e^{-\sqrt{\xi^{2} - k_{1}^{2}(x_{2} + y_{2} - 2d)}}{(1 + |\xi|)^{3}} d\xi \\ &\leq \begin{cases} M e^{-\sqrt{k_{2}^{2} - k_{1}^{2}(x_{2} + y_{2})} \text{ for } j = 0, 1 \\ M e^{-\sqrt{k_{2}^{2} - k_{1}^{2}(x_{2} + y_{2})} \log\left(\frac{2(x_{2} + y_{2})}{x_{2} + y_{2} - 2d}\right) \text{ for } j = 2. \end{aligned}$$

$$(81)$$

The calculation above indicates that the diagonal singularity should be $|x-y|^2 \log |x-y|$, and this implies that we should expect a log-singularity in $\mathfrak{w}^{[2]}$ where $x_2 + y_2 = 2d$.

Altogether we have shown that, for $x_2, y_2 > d$ we have the asymptotic formulæ

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1(x_2+y_2)}}{(x_2+y_2)^{\frac{j+1}{2}}} \left[M_{j0} + \sum_{l=1}^{\infty} \frac{M_{jl}}{(x_2+y_2)^l} \right] \text{ for } j = 0, 1, 2.$$
 (82)

We can also analyze

$$\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) - ik_1 \mathfrak{w}^{[j]}(x_2, y_2), \text{ and } \partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) - ik_1 \mathfrak{w}^{[j]}(x_2, y_2),$$
 (83)

which are only significantly different in the contribution from $\xi \in [-k_1, k_1]$. In this interval we get an additional factor of $i(\sqrt{k_1^2 - \xi^2} - k_1) = O(\xi^2)$ in the integrand. From the usual stationary phase argument it will follow that, for j = 0, 1, 2,

$$\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) - ik_1 \mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1(x_2+y_2)}}{(x_2+y_2)^{\frac{j+3}{2}}} \left[M'_{j0} + \sum_{l=1}^{\infty} \frac{M'_{jl}}{(x_2+y_2)^l} \right],\\ \partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) - ik_1 \mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1(x_2+y_2)}}{(x_2+y_2)^{\frac{j+3}{2}}} \left[M''_{j0} + \sum_{l=1}^{\infty} \frac{M''_{jl}}{(x_2+y_2)^l} \right].$$
(84)

It is not difficult to see that the same arguments apply if $\pm x_2, \pm y_2 > d$ to show that the same expansions hold with (x_2, y_2) replaced with $(|x_2|, |y_2|)$, for example:

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1(|x_2| + |y_2|)}}{(|x_2| + |y_2|)^{\frac{j+1}{2}}} \left[M_{j0}^{\pm, \pm} + \sum_{l=1}^{\infty} \frac{M_{jl}^{\pm, \pm}}{(|x_2| + |y_2|)^l} \right], \text{ for } j = 0, 1, 2.$$
(85)

We can also show

$$\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2), \text{ for } \pm x_2 > d, \text{ and}$$

 $\partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2) \text{ for } \pm y_2 > d,$ (86)

have asymptotic expansions like those in (84), with (x_2, y_2) replaced by $(|x_2|, |y_2|)$, obtained by applying the appropriate operator, $\partial_{x_2} \mp ik_1$, or $\partial_{y_2} \mp ik_1$, to the expansions in (85). The function $\mathfrak{w}^{[0]}(x_2, y_2)$ is continuous as $(x_2, y_2) \rightarrow (\pm d, \pm d)$, and

$$|\mathfrak{w}^{[2]}(x_2, y_2)| \le M |\log(|x_2 + y_2| - 2d)|, \text{ as } |x_2 + y_2| \to 2d.$$
 (87)

There is no singularity as $(x_2, y_2) \rightarrow (\pm d, \mp d)$. Similar conclusions hold for $w_{0+} = w_{0+}^c + w_{0+}^g$, as the contribution of the wave-guide modes is exponentially decaying as $|x_2| + |y_2| \rightarrow \infty$.

4.3 Asymptotics for $|x_2|$ or $|y_2| < d$

We now consider what happens if either $|x_2| < d$, or $|y_2| < d$. We start by assuming that $y_2 > d$, but $|x_2| < d$. For this case the integrals defining $\mathfrak{w}^{[j]}$ take the form

$$\mathfrak{w}^{[j]}(x_2, y_2) = \frac{i}{2\pi} \int_{\Gamma_{\nu,\epsilon}^+} \xi^j \frac{e^{i\sqrt{k_1^2 - \xi^2}(y_2 + 2d)} \mathfrak{B}(\xi, \sqrt{k_1^2 - \xi^2}; x_2)}{\mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2})\sqrt{k_1^2 - \xi^2}} d\xi, \qquad (88)$$

where

$$\mathfrak{B}(\xi,\eta;x_2) = \int_{-d}^{x_2} \left[\cos A(d-x_2) \cos A(d+z_2) - i\frac{\eta}{A} \sin A(2d+z_2-x_2) - \frac{\eta^2}{A^2} \sin A(d-x_2) \sin A(d+z_2) \right] e^{-iz_2\eta} q(z_2) dz_2 + \int_{x_2}^{d} \left[\cos A(d+x_2) \cos A(d-z_2) - i\frac{\eta}{A} \sin A(2d-z_2+x_2) - \frac{\eta^2}{A^2} \sin A(d+x_2) \sin A(d-z_2) \right] e^{-iz_2\eta} q(z_2) dz_2.$$
(89)

Again $\mathfrak{B}(\xi, \eta; x_2)$ is an entire function of (ξ, η) . In the integral over $\Gamma^+_{\nu,\epsilon}$ we take $\eta = \sqrt{k_1^2 - \xi^2} = i\sqrt{\xi^2 - k_1^2}$ for $k_1 < |\xi|$.

As before the principal contribution to $\mathfrak{w}^{[j]}(x_2, y_2)$, as $y_2 \to \infty$, comes from the stationary phase at $\xi = 0$. The function $|\mathfrak{B}(\xi, \sqrt{k_1^2 - \xi^2}; x_2)|$ is easily seen to be uniformly bounded where $|\xi| < k_1, |x_2| < d$. We separate the contributions from the stationary point at zero, and the contributions from endpoints $\pm k_1$. The leading contributions from the stationary point are

$$\mathfrak{w}_{00}^{[j]}(x_2, y_2) = C'_j k_1^{\frac{j-1}{2}} \frac{e^{ik_1 y_2} \mathfrak{B}(0, k_1; x_2)}{\mathfrak{W}(0, k_1) y_2^{\frac{j+1}{2}}} + O\left(|y_2|^{-\frac{j+3}{2}}\right) \text{ for } j = 0, 1, 2.$$
(90)

As before, there are complete asymptotic expansions of the form

$$\mathfrak{w}_{00}^{[j]}(x_2, y_2) = k_1^{\frac{j-1}{2}} \frac{e^{ik_1 y_2}}{\mathfrak{W}(0, k_1) y_2^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{b_{jl}(x_2)}{y_2^l} \right], \text{ for } j = 0, 1, 2.$$
(91)

The contributions from near to $\pm k_1$ are estimated as before by using the deformed contour $\Gamma^+_{\nu,\epsilon}$. The portions from $\delta > 0$ to $k_1 + \mu$, and from $-k_1 - \mu$ to $-\delta$ are easily seen to be $O(y_2^{-N})$, for any N > 0. We leave the details to the reader.

We next consider the integral over $\Gamma^+_{\nu,\epsilon}$ lying above $k_1 + \mu < |\xi| < k_2$, which is of the form

$$\mathfrak{w}_{11}^{[j]}(x_2, y_2) = \frac{1}{2\pi} \int_{\{k_1+\mu<|\xi|< k_2\}\cap\Gamma_{\nu,\epsilon}^+} \xi^j \frac{e^{-\sqrt{\xi^2-k_1^2}(y_2+2d)}\mathfrak{B}(\xi, i\sqrt{\xi^2-k_1^2}; x_2)\widetilde{\phi}(\xi)}{\mathfrak{W}(\xi, i\sqrt{\xi^2-k_1^2})\sqrt{\xi^2-k_1^2}} d\xi, \quad (92)$$

for a suitable cut-off function $\tilde{\phi}$. As before we use the lower bound on the Wronskian, $|\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})| > m\nu$. We also need to bound $\mathfrak{B}(\xi, i\sqrt{\xi^2 - k_1^2}; x_2)$ from above. For $|x_2| < d$, we can easily show that there is a constant M so that

$$|\mathfrak{B}(\xi, i\sqrt{\xi^2 - k_1^2}; x_2)| \le M e^{\rho(\xi)d}$$
, where $\rho(\xi) = \operatorname{Re}\left(\sqrt{\xi^2 - k_1^2}\right)$. (93)

It then follows that

$$|\mathfrak{w}_{11}^{[j]}(x_2, y_2)| \le \frac{M}{\nu} \int_{k_1 + \mu < |\xi| < k_2} e^{-\rho(\xi)(y_2 + d)} d\xi \tag{94}$$

If we set

$$\alpha = \min\{\rho(\xi) : \xi \in \Gamma_{\nu}^{+} \text{ with } k_{1} + \mu < |\xi| < k_{2}\},$$
(95)

then $\alpha > 0$, provided that ν is sufficiently small, from which it follows easily that

$$|\mathfrak{w}_{11}^{[j]}(x_2, y_2)| \le \frac{M e^{-\alpha y_2}}{\nu}.$$
(96)

This leaves the integral over the set $\{|\xi| > k_2\}$. In this set we can prove the estimate

$$\left|\mathfrak{B}(\xi, i\sqrt{\xi^2 - k_1^2}; x_2)\right| \le M e^{(2d + x_2)\sqrt{\xi^2 - k_1^2}} \left[\frac{1}{1 + |\xi|} + (d - x_2)\right], \quad (97)$$

and therefore, if either $|x_2| < d$ or $|y_2| < d$, and $|\xi| > k_2$, we have the estimate

$$|\tilde{w}_{0+}(\xi, x_2; 0, y_2)| < M \frac{e^{-\sqrt{\xi^2 - k_2^2}|x_2 - y_2|}}{(1 + |\xi|)^2} \left[\frac{1}{(1 + |\xi|)} + |y_2 - x_2|\right],$$
(98)

and therefore for $|x_2| < d < y_2$, we have

$$\begin{aligned} |\mathfrak{w}_{2}^{[j]}(x_{2},y_{2})| &= \left| \frac{1}{2\pi} \int_{k_{2} < |\xi|} \xi^{j} \frac{e^{\sqrt{\xi^{2} - k_{1}^{2}(y_{2} + 2d)} \mathfrak{B}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}}; x_{2})}}{\mathfrak{W}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}})\sqrt{\xi^{2} - k_{1}^{2}}} d\xi \right| \\ &\leq M \int_{k_{2}}^{\infty} e^{-\sqrt{\xi^{2} - k_{1}^{2}}(y_{2} - x_{2})} \left[\frac{1}{(1 + |\xi|)^{3-j}} + \frac{y_{2} - x_{2}}{(1 + |\xi|)^{2-j}} \right] d\xi. \end{aligned}$$

$$\tag{99}$$

An elementary calculation now shows that

$$|\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2})| \leq \begin{cases} Me^{-\sqrt{k_{2}^{2} - k_{1}^{2}}(y_{2} - x_{2})} \text{ for } j = 0, 1\\ Me^{-\sqrt{k_{2}^{2} - k_{1}^{2}}(y_{2} - x_{2})} \log\left(\frac{2y_{2}}{y_{2} - x_{2}}\right) \text{ for } j = 2. \end{cases}$$
(100)

We can again show that this analysis applies equally well if $|x_2| < d, y_2 < -d$, and therefore we have the asymptotic expansions

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim k_1^{\frac{j-1}{2}} \frac{e^{ik_1|y_2|}}{|y_2|^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{b_{jl}^{\pm}(x_2)}{|y_2|^l} \right], \text{ for } \pm y_2 > d, \ j = 0, 1, 2.$$
(101)

The functions $\mathfrak{w}^{[0]}(x_2, y_2), \mathfrak{w}^{[1]}(x_2, y_2)$ are continuous as $y_2 \to x_2$, and

$$|\mathfrak{w}^{[2]}(x_2, y_2)| \le M |\log |y_2 - x_2||, \text{ as } y_2 \to x_2.$$
 (102)

As before we can show that

$$\partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2) = O\left(|y_2|^{-\frac{j+3}{2}}\right), \tag{103}$$

in fact these functions have complete asymptotic expansion obtained by applying the operator $\partial_{y_2} \mp i k_1$ to the expansions above.

The final case we need to treat is $|y_2| < d$, $|x_2| > d$. We begin with $x_2 > d$. For this case we write

$$\mathfrak{w}^{[j]}(x_2, y_2) = \frac{1}{2\pi} \int_{\Gamma_{\nu,\epsilon}^+} \frac{\xi^j e^{i\sqrt{k_1^2 - \xi^2} x_2} \mathfrak{C}(\xi, \sqrt{k_1^2 - \xi^2}; y_2)}{\mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2})\sqrt{k_1^2 - \xi^2}} d\xi,$$
(104)

where

$$\mathfrak{C}(\xi,\eta;y_2) = e^{i\eta(y_2+d)} \int_{-d}^{y_2} e^{-i\eta z_2} \left[\cos A(d+z_2) - i\eta \frac{\sin A(d+z_2)}{A} \right] q(z_2) dz_2 + e^{i\eta(d-y_2)} \int_{y_2}^{d} e^{i\eta z_2} \left[\cos A(d+z_2) - i\eta \frac{\sin A(d+z_2)}{A} \right] q(z_2) dz_2, \text{ with } A = \sqrt{k_2^2 - \xi^2}.$$
(105)

As in the earlier cases, there is a stationary phase contribution from $\xi = 0$, which we denote by $\mathfrak{w}_{00}^{[j]}(x_2, y_2)$. The function $\mathfrak{C}(\xi, \sqrt{k_1^2 - \xi^2}; y_2)$ is an analytic function of ξ in $|\xi| < k_1 - \epsilon$, for any $\epsilon > 0$. The stationary phase contributions are

$$\mathfrak{w}_{00}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1 x_2}}{\mathfrak{W}(0, k_1) x_2^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{c_{jl}(y_2)}{x_2^l} \right] \text{ for } j = 0, 1, 2.$$
(106)

The analysis for the contribution from $\delta < |\xi| < \sqrt{k_1^2 + \epsilon^2}$ is as before, and can be shown to be $O(x_2^{-N})$, for any N > 0.

The remaining portion for $\sqrt{k_1^2+\epsilon^2} < |\xi| < k_2$ is given by

$$\mathfrak{w}_{11}^{[j]}(x_2, y_2) = \frac{1}{i\pi} \int_{\{\sqrt{k_1^2 + \epsilon^2} < |\xi| < k_2\} \cap \Gamma_{\nu, \epsilon}^+} \frac{e^{-\sqrt{\xi^2 - k_1^2} x_2} \xi^j \mathfrak{C}(\xi, i\sqrt{\xi^2 - k_1^2}; y_2)(1 - \widetilde{\phi}(\sqrt{\xi^2 - k_1^2}))}{\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})\sqrt{\xi^2 - k_1^2}} d\xi,$$
(107)

where

$$\mathfrak{C}(\xi, i\sqrt{\xi^2 - k_1^2}; y_2) = e^{-\sqrt{\xi^2 - k_1^2}(y_2 + d)} \times \int_{-d}^{y_2} e^{\sqrt{\xi^2 - k_1^2}z_2} \left[\cos A(d + z_2) + \sqrt{\xi^2 - k_1^2} \frac{\sin A(d + z_2)}{A} \right] q(z_2)dz_2 + e^{-\sqrt{\xi^2 - k_1^2}(d - y_2)} \times \int_{y_2}^{d} e^{-\sqrt{\xi^2 - k_1^2}z_2} \left[\cos A(d + z_2) + \sqrt{\xi^2 - k_1^2} \frac{\sin A(d + z_2)}{A} \right] q(z_2)dz_2 + with A = \sqrt{k_2^2 - \xi^2}.$$
 (108)

It is easy to see that for $|y_2| < d$, $|\mathfrak{C}(\xi, i\sqrt{\xi^2 - k_1^2}; y_2)|$ is bounded, and the Wronskian satisfies $|\mathfrak{W}(\xi, i\sqrt{\xi^2 - k_1^2})| > M\nu$, on the part of Γ_{ν}^+ lying over $\sqrt{k_1^2 + \epsilon^2} < |\xi| < k_2$. Moreover $\operatorname{Re} \sqrt{\xi^2 - k_1^2} > \alpha > 0$, therefore

$$|\mathfrak{w}_{11}^{[j]}(x_2, y_2)| \le \frac{M e^{-\alpha x_2}}{\nu}.$$
(109)

Where $|\xi| > k_2$ we have

$$\mathfrak{C}(\xi, i\sqrt{\xi^2 - k_1^2}; y_2) = e^{-\sqrt{\xi^2 - k_1^2}(y_2 + d)} \times \int_{-d}^{y_2} e^{\sqrt{\xi^2 - k_1^2}z_2} \left[\cosh A(d + z_2) + \sqrt{\xi^2 - k_1^2} \frac{\sinh A(d + z_2)}{A} \right] q(z_2) dz_2 + e^{-\sqrt{\xi^2 - k_1^2}(d - y_2)} \times \int_{y_2}^{d} e^{-\sqrt{\xi^2 - k_1^2}z_2} \left[\cosh A(d + z_2) + \sqrt{\xi^2 - k_1^2} \frac{\sinh A(d + z_2)}{A} \right] q(z_2) dz_2 \\ \text{with } A = \sqrt{\xi^2 - k_2^2}.$$
(110)

The first term in (110) is bounded by

$$M\frac{e^{\sqrt{\xi^2 - k_2^2 y_2}}}{1 + |\xi|};\tag{111}$$

the other term requires somewhat more care. It is bounded by

$$Me^{\sqrt{\xi^2 - k_1^2}y_2} \int_{y_2}^{d} e^{(\sqrt{\xi^2 - k_2^2} - \sqrt{\xi^2 - k_1^2})z_2} dz_2 = Me^{\sqrt{\xi^2 - k_1^2}y_2} \left[\frac{e^{(\sqrt{\xi^2 - k_2^2} - \sqrt{\xi^2 - k_1^2})d} - e^{(\sqrt{\xi^2 - k_2^2} - \sqrt{\xi^2 - k_1^2})y_2}}{\sqrt{\xi^2 - k_2^2} - \sqrt{\xi^2 - k_1^2}} \right].$$
 (112)

An elementary argument then shows that the expression in the bracket is bounded by $|d - y_2|$ and therefore

$$|\mathfrak{C}(\xi, i\sqrt{\xi^2 - k_1^2}; y_2)| \le M e^{\sqrt{\xi^2 - k_1^2}y_2} \left[\frac{1}{1 + |\xi|} + |d - y_2|\right].$$
(113)

These estimates show that

$$\begin{aligned} |\mathfrak{w}_{2}^{[j]}(x_{2},y_{2})| &= \frac{1}{\pi} \left| \int_{k_{2} < |\xi|} \frac{e^{-\sqrt{\xi^{2} - k_{1}^{2} x_{2}} \, \xi^{j} \mathfrak{C}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}}; y_{2})}{\mathfrak{W}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}})\sqrt{\xi^{2} - k_{1}^{2}}} d\xi \right| \\ &\leq M \int_{k_{2}}^{\infty} e^{-\sqrt{\xi^{2} - k_{1}^{2}} (x_{2} - y_{2})} \xi^{j-2} \left[\frac{1}{\xi} + (x_{2} - y_{2}) \right] d\xi. \end{aligned}$$
(114)

In the second line we use the fact that $x_2 - y_2 > d - y_2$. It is easy to show that the second term is bounded by $Me^{\sqrt{k_2^2 - k_1^2(x_2 - y_2)}}$ for j = 0, 2. We estimate the contribution from the first term, as before, to obtain that for $|y_2| < d, x_2 > d$, we have

$$|\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2})| \leq \begin{cases} Me^{-\sqrt{k_{2}^{2}-k_{1}^{2}}(x_{2}-y_{2})} \text{ for } j=0,1\\ Me^{-\sqrt{k_{2}^{2}-k_{1}^{2}}(x_{2}-y_{2})} \cdot \log \frac{2x_{2}}{x_{2}-y_{2}} \text{ for } j=2. \end{cases}$$
(115)

It is not difficult to show that the analogous estimates hold with $x_2 < -d$, so that

$$|\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2})| \leq \begin{cases} Me^{-\sqrt{k_{2}^{2}-k_{1}^{2}}|x_{2}-y_{2}|} \text{ for } j=0,1\\ Me^{-\sqrt{k_{2}^{2}-k_{1}^{2}}|x_{2}-y_{2}|} \cdot \log \frac{2|x_{2}|}{|x_{2}-y_{2}|} \text{ for } j=2. \end{cases}$$
(116)

Altogether we have, for $|y_2| < d$, $|x_2| > d$,

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1|x_2|}}{|x_2|^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{c_{jl}^{\pm}(y_2)}{|x_2|^l} \right], \text{ for } \pm x_2 > d, \ j = 0, 1, 2.$$
(117)

The function $\mathfrak{w}^{[0]}(x_2, y_2)$ is continuous as $|x_2 - y_2| \to 0$, and

$$|\mathfrak{w}^{[2]}(x_2, y_2)| \le M |\log |x_2 - y_2||.$$
(118)

As before we can show that

$$\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2) = O\left(|x_2|^{-\frac{j+3}{2}}\right) \text{ as } \pm x_2 \to \infty,$$
 (119)

have asymptotic expansions obtained by applying $\partial_{x_2} \mp ik_1$ to the expansions in (117).

4.4 The Diagonal Singularity

The singularities of the function w(x; y) are confined to the set x = y where $|x_2|, |y_2| \le d$. In this section we use the Fourier representation to study the nature of this singularity. As expected from the discussion surrounding (42), the principal singularity behaves like $(x_2 - y_2)^2 \log |x_2 - y_2|$. Note that the discussion leading to (42) assumed that the potential $q(x_2)$ is smooth, whereas here we continue working with q as defined in (34).

We start by assuming that $-d < y_2 < x_2 < d$, so that

$$\mathfrak{w}^{[j]}(x_2, y_2) = \int_{\Gamma^+_{\nu}} \frac{\xi^j \mathfrak{D}(\xi, \sqrt{\xi^2 - k_1^2}; x_2, y_2)}{\mathfrak{W}(\xi, \sqrt{k_1^2 - \xi^2}) \sqrt{k_1^2 - \xi^2}} d\xi,$$
(120)

where

$$\begin{aligned} \mathfrak{D}(\xi,\eta;x_{2},y_{2}) &= \int_{-d}^{x_{2}} \widetilde{u}_{+}(x_{2},0+;\xi) \widetilde{u}_{+}(-z_{2},0+;\xi) e^{-\eta|z_{2}-y_{2}|} q(z_{2}) dz_{2} + \\ &\int_{x_{2}}^{d} \widetilde{u}_{+}(-x_{2},0+;\xi) \widetilde{u}_{+}(z_{2},0+;\xi) e^{-\eta|z_{2}-y_{2}|} q(z_{2}) dz_{2} \\ &= \int_{-d}^{y_{2}} e^{-2\eta d} \left[\cosh A(d-x_{2}) + \eta \frac{\sinh A(d-x_{2})}{A} \right] \times \\ & \left[\cosh A(d+z_{2}) + \eta \frac{\sinh A(d+z_{2})}{A} \right] e^{-\eta(y_{2}-z_{2})} q(z_{2}) dz_{2} + \\ &\int_{y_{2}}^{x_{2}} e^{-2\eta d} \left[\cosh A(d-x_{2}) + \eta \frac{\sinh A(d-x_{2})}{A} \right] \times \\ & \left[\cosh A(d+z_{2}) + \eta \frac{\sinh A(d+z_{2})}{A} \right] e^{-\eta(z_{2}-y_{2})} q(z_{2}) dz_{2} + \\ &\int_{x_{2}}^{d} e^{-2\eta d} \left[\cosh A(d+x_{2}) + \eta \frac{\sinh A(d+x_{2})}{A} \right] e^{-\eta(z_{2}-y_{2})} q(z_{2}) dz_{2}, \end{aligned}$$

$$(121)$$

with $A = \sqrt{\xi^2 - k_2^2}$. As usual $\mathfrak{D}(\xi, \eta; x_2, y_2)$ is an entire function of (ξ, η) ; we use $\eta = -i\sqrt{k_1^2 - \xi^2}$, for $|\xi| < k_1$, and $\eta = \sqrt{\xi^2 - k_1^2}$, for $|\xi| > k_1$. In the second, more explicit expression, we use the conditions that $-d < y_2 < x_2 < d$, and $|\xi| > k_2$. The parts of the integrals in (120) where $|\xi| < k_2$, defines \mathcal{C}^2 -functions of (x_2, y_2) , so we focus our attention on $|\xi| \ge k_2$. In this set we have

$$\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2}) = -i \int_{|\xi| > k_{2}} \frac{\xi^{j} \mathfrak{D}(\xi, \sqrt{\xi^{2} - k_{1}^{2}}; x_{2}, y_{2})}{\mathfrak{W}(\xi, i\sqrt{\xi^{2} - k_{1}^{2}})\sqrt{\xi^{2} - k_{1}^{2}}} d\xi.$$
(122)

Using the definition of \mathfrak{D} we see that, with $B = \sqrt{\xi^2 - k_1^2}$,

$$\left|\mathfrak{D}(\xi, B; x_2, y_2)\right| \le M \left[e^{-(Ax_2 + By_2)} \int_{-d}^{y_2} e^{(A+B)z_2} dz_2 + e^{-(Ax_2 - By_2)} \int_{y_2}^{x_2} e^{(A-B)z_2} dz_2 + e^{Ax_2 + By_2} \int_{x_2}^{d} e^{-(A+B)z_2} dz_2 \right].$$
(123)

Performing these integrals and using elementary estimates we see that

$$|\mathfrak{D}(\xi, B; x_2, y_2)| \le M e^{-\sqrt{\xi^2 - k_2^2} |x_2 - y_2|} \left[\frac{1}{1 + |\xi|} + |x_2 - y_2| \right].$$
(124)

and therefore (98) holds if both $|x_2| < d$, and $|y_2| < d$. Inserting this into (122), we see that

$$\begin{aligned} |\mathfrak{w}_{2}^{[j]}(x_{2}, y_{2})| &\leq M \int_{k_{2}}^{\infty} \xi^{j-2} e^{-\sqrt{\xi^{2}-k_{2}^{2}}|x_{2}-y_{2}|} \left[\frac{1}{1+|\xi|} + |x_{2}-y_{2}| \right] d\xi \\ &\leq \begin{cases} M \text{ for } j = 0, 1 \\ M|\log(x_{2}-y_{2})| \text{ for } j = 2. \end{cases} \end{aligned}$$
(125)

It is straightforward to see that $|\mathfrak{D}(\xi, B; x_2, y_2)|$ satisfies the same estimate if $-d < x_2 < y_2 < d$, and therefore the estimates in (125) hold in this case as well. It is easy to see that differentiating $\mathfrak{w}^{[j]}(x_2, y_2)$ with respect to x_2 or y_2 has the effect of increasing j by 1. Thus we see that $\partial_{x_2}\mathfrak{w}^{[0]}(x_2, y_2), \partial_{y_2}\mathfrak{w}^{[0]}(x_2, y_2)$, are uniformly bounded, and $\partial_{x_2}\mathfrak{w}^{[1]}(x_2, y_2), \partial_{y_2}\mathfrak{w}^{[1]}(x_2, y_2)$, along with the second derivatives of $\mathfrak{w}^{[0]}(x_2, y_2)$ have a $\log |x_2 - y_2|$ -singularity along the diagonal.

4.5 Summary

Thus we see that the kernels that appear in the integral equations in (25) have a very particular form. These kernels are smooth outside of $B_d = [-d, d] \times [-d, d]$; the kernel $\mathfrak{w}^{[j]}(x_2, y_2)$ has an $(x_2 - y_2)^{2-j} \log |x_2 - y_2|$ -singularity in B_d .

1. Asymptotically, for $\pm x_2 > d, \pm y_2 > d, j = 0, 1, 2,$

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1(|x_2| + |y_2|)}}{(|x_2| + |y_2|)^{\frac{j+1}{2}}} \left[M_{j0}^{\pm, \pm} + \sum_{l=1}^{\infty} \frac{M_{jl}^{\pm, \pm}}{(|x_2| + |y_2|)^l} \right], \quad (126)$$

we also have

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1|y_2|}}{|y_2|^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{b_{jl}^{\pm}(x_2)}{|y_2|^l} \right], \text{ where } \pm y_2 > d, \ |x_2| < d;$$

$$\mathfrak{w}^{[j]}(x_2, y_2) \sim \frac{e^{ik_1|x_2|}}{|x_2|^{\frac{j+1}{2}}} \left[\sum_{l=0}^{\infty} \frac{c_{jl}^{\pm}(y_2)}{|x_2|^l} \right], \text{ where } \pm x_2 > d, \ |y_2| < d.$$
(127)

2. The kernels are outgoing: $\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2), \partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2)$ have asymptotic expansions obtained by applying $\partial_{x_2} \mp i k_1$, or $\partial_{y_2} \mp i k_1$ to the appropriate expansion in (126), or (127). In particular

$$\partial_{x_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2) = O\left((|x_2| + |y_2|)^{-\frac{j+3}{2}}\right) \text{ as } \pm x_2 \to \infty,$$
(128)

$$\partial_{y_2} \mathfrak{w}^{[j]}(x_2, y_2) \mp i k_1 \mathfrak{w}^{[j]}(x_2, y_2) = O\left((|x_2| + |y_2|)^{-\frac{j+3}{2}}\right) \text{ as } \pm y_2 \to \infty.$$
(129)

3. The kernel $i\mathfrak{w}^{[1]}(x_2, y_2) + \partial_{x_1} w^g_{0+}(0, x_2; 0, y_2) = 0.$

4.6 Estimates in the Right Half Plane

In this section we extend the estimates derived in the previous sections to $|x_1| > 0$, with x_1 bounded. These estimates are essentially the same as those in the previous section, as the principal term is a stationary phase contribution arising from $\xi = 0$. The estimates for $w_c(x; 0, y_2)$, $\partial_{y_1} w_c(x; 0, y_2)$, with bounded x_1 , suffice to show that the representations of $u^{l,r}$ in terms of $(\sigma, \tau) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$ with $0 < \alpha < \frac{1}{2}$, make sense, see (15). Using (33) we express the derivatives of w_{0+}^c as the contour integrals:

$$\partial_{x_1}^j w_{0+}^c(x;0,y_2) = \frac{1}{2\pi} \int_{\Gamma_{\nu}^+} (i\xi)^j \tilde{w}_{0+}(\xi,x_2;0,y_2) e^{ix_1\xi} d\xi \text{ for } x_1 > 0.$$
(130)

The only difference between these integrals and those estimated in Section 4 is the factor of $e^{i\xi x_1}$ in the integrand. Recalling that $\partial_{x_1}^j w_{0+}^c(x;y) = (-1)^j \partial_{y_1}^j w_{0+}^c(x;y)$; it suffices to consider these expressions to estimate $\partial_{x_1} w_{0+}^c$, $\partial_{y_1} w_{0+}^c$ and $\partial_{x_1} \partial_{y_1} w_{0+}^c$.

The contribution from the guided modes is clearly infinitely differentiable in the x_1 -variable for all x_1 , and satisfies the same estimates as for $x_1 = 0$. It is easy to see that the estimates derived in Section 4.2 for $\mathfrak{w}^{[j]}$, j = 0, 1, 2 hold equally well for bounded x_1 , as the principal contribution comes from the stationary phase at $\xi = 0$. The addition of the factor $e^{i\xi x_1}$ does not change the contribution from the semi-circular components, $\{C_{j,\nu}^{\pm}\}$, as $\operatorname{Im} \xi \ge 0$, and therefore $|e^{ix_1\xi}| \le 1$ on this part of the contour. Where $|x_2|, |y_2| > d$, for bounded x_1 , the extension to the right half plane satisfies the asymptotic expression

$$\partial_{x_1}^j w_{0+}^c(x_1, x_2; 0, y_2) = C_j \frac{e^{ik_1(|x_2| + |y_2|)}}{(|x_2| + |y_2|)^{\frac{j+1}{2}}} + O\left((|x_2| + |y_2|)^{-\frac{j+3}{2}}\right) \text{ for } j = 0, 1, 2.$$
(131)

It is similarly straightforward to handle the estimates where either $|x_2| < d$, or $|y_2| < d$. Again, since the principal contribution comes from $\xi = 0$, for bounded $x_1 > 0$, we have

$$\partial_{x_{1}}^{j} w_{0+}^{c}(x_{1}, x_{2}; 0, y_{2}) = \frac{e^{ik_{1}|y_{2}|} b_{\pm}^{[j]}(x_{2})}{|y_{2}|^{\frac{j+1}{2}}} + O(|y_{2}|^{-\frac{j+3}{2}}) \text{ where } \pm y_{2} > d, \ |x_{2}| < d,$$

$$\partial_{x_{1}}^{j} w_{0+}^{c}(x_{1}, x_{2}; 0, y_{2}) = \frac{e^{ik_{1}|x_{2}|} c_{\pm}^{[j]}(y_{2})}{|x_{2}|^{\frac{j+1}{2}}} + O(|x_{2}|^{-\frac{j+3}{2}}) \text{ where } \pm x_{2} > d, \ |y_{2}| < d;$$

(132)

From ellipticity it follows that $w_{0+}^c(x_1, x_2; 0, y_2)$ is a \mathcal{C}^{∞} -function if $x_1 > 0$, away from $x_2, y_2 = \pm d$. It clear that if $f(y_2)$ is a bounded continuous function, then for any finite L we have

$$\lim_{x_1 \to 0^+} \partial_{x_1}^j \int_{-L}^{L} w_{0+}^c(x_1, x_2; 0, y_2) f(y_2) dy_2 = \int_{-L}^{L} \partial_{x_1}^j w_{0+}^c(0, x_2; 0, y_2) f(y_2) dy_2 \text{ for } j = 0, 1, 2.$$
(133)

From the Fourier representations it is clear that the asymptotics, for $|x_2| + |y_2|$ large, hold uniformly as $x_1 \to 0^+$. Hence if f is continuous and

$$|f(y_2)| \le M \frac{(1+|y_2|)^{\frac{1}{2}}}{(1+|y_2|)^{\frac{1}{2}+\epsilon}},$$
(134)

for an $\epsilon > 0$, then, for j = 0, 1, 2,

$$\lim_{x_1 \to 0^+} \partial_{x_1}^j \int_{-\infty}^{\infty} w_{0+}^c(x_1, x_2; 0, y_2) f(y_2) dy_2 = \\
\lim_{x_1 \to 0^+} \int_{-\infty}^{\infty} \partial_{x_1}^j w_{0+}^c(x_1, x_2; 0, y_2) f(y_2) dy_2 \\
= \int_{-\infty}^{\infty} \partial_{x_1}^j w_{0+}^c(0, x_2; 0, y_2) f(y_2) dy_2 \\
= \left[\partial_{x_1}^j \int_{-\infty}^{\infty} w_{0+}^c(x_1, x_2; 0, y_2) f(y_2) dy_2 \right]_{x_1 = 0}.$$
(135)

With these observations we can now show that the representation in (22) can be used with solutions of the corresponding boundary integral equations to find and represent the scattered fields, $u^{l,r}(x)$.

5 The Integral Equations

With the computations we have completed we now express the kernels appearing in the integral equations, (25), in terms of $\mathfrak{w}^{[j]}$ and the guided modes for the relevant equations. We reintroduce the l, r sub- and superscripts, letting $\mathfrak{w}^{[j]}_{l,r}$ denote the kernels defined by $q_{l,r}$ and $w^g_{l,r}$ the contributions of the guided modes $\{v^{l,r}_n(x_2)e^{\pm i\xi^{l,r}_n}: n = 1, \ldots, N^{l,r}\}$, from (40). With this notation we have

$$W_{l,r}^{0} = w^{l,r}(0, x_{2}; 0, y_{2}) = \mathfrak{w}_{l,r}^{[0]}(x_{2}, y_{2}) + w_{l,r}^{g}(0, x_{2}; 0; y_{2}),$$

$$\partial_{x_{1}}w^{l,r}(0, x_{2}; 0, y_{2}) = \partial_{y_{1}}w^{l,r}(0, x_{2}; 0, y_{2}) = 0,$$

$$W_{l,r}^{2} = \partial_{x_{1}y_{1}}^{2}w^{l,r}(0, x_{2}; 0, y_{2}) = \mathfrak{w}_{l,r}^{[2]}(x_{2}, y_{2}) + \partial_{x_{1}y_{1}}^{2}w_{l,r}^{g}(0, x_{2}; 0; y_{2}).$$
(136)

The integral equations therefore can be written

$$\begin{pmatrix} \mathrm{Id} & W_r^0 - W_l^0 \\ W_l^2 - W_r^2 & \mathrm{Id} \end{pmatrix} \begin{pmatrix} \sigma \\ \tau \end{pmatrix} = \begin{pmatrix} g \\ h \end{pmatrix},$$
(137)

which, to simplify notation, we rewrite as

$$\begin{pmatrix} \mathrm{Id} & D \\ C & \mathrm{Id} \end{pmatrix} \begin{pmatrix} \sigma \\ \tau \end{pmatrix} = \begin{pmatrix} g \\ h \end{pmatrix}.$$
 (138)

The analysis of $\mathfrak{w}_{l,r}^{[2]}$ shows that the operator $W_l^2 - W_r^2$ is compact on $L^2(\mathbb{R})$, amongst other spaces. While $W_r^0 - W_l^0$ is smoothing, the $(|x_2| + |y_2|)^{-\frac{1}{2}}$ asymptotic behavior of $\mathfrak{w}_{l,r}^{[0]}$ prevents it from being defined on $L^2(\mathbb{R})$, let alone compact. In the sequel we work with subspaces of $\mathcal{C}^0(\mathbb{R})$.

Definition 1. For $\alpha \in \mathbb{R}$, let $\mathcal{C}_{\alpha}(\mathbb{R})$ denote continuous functions on \mathbb{R} with

$$|f|_{\alpha} = \sup\{(1+|x|)^{\alpha}|f(x)|: x \in \mathbb{R}\} < \infty.$$
(139)

These spaces are somewhat like Hölder spaces, in that, for $\alpha > 0$, $C_c^{\infty}(\mathbb{R})$ is not dense in $\mathcal{C}_{\alpha}(\mathbb{R})$ with respect to the $|\cdot|_{\alpha}$ -norm. A usable replacement is the fact that $\mathcal{C}_c^{\infty}(\mathbb{R})$ is dense in $\mathcal{C}_{\alpha}(\mathbb{R})$ with respect to the $|\cdot|_{\alpha'}$ -norm, for any $0 < \alpha' < \alpha$. It is important to have a criterion for when a bounded linear operator $A : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha}(\mathbb{R})$ is compact. We give a simple sufficient condition.

Proposition 1. Let $0 < \alpha < \beta$, and let $A : C_{\alpha}(\mathbb{R}) \to C_{\beta}(\mathbb{R})$ be a bounded linear operator. Let $B_r = \{f \in C_{\alpha}(\mathbb{R}) : |f|_{\alpha} < r\}$. If, for any 0 < X, the image AB_r restricted to [-X, X] is a uniformly equicontinuous family of functions, then $A : C_{\alpha}(\mathbb{R}) \to C_{\alpha}(\mathbb{R})$ is a compact operator.

Proof. To prove the proposition we need to show that if $\{f_n\} \subset C_{\alpha}(\mathbb{R})$ is a bounded sequence, then $\{Af_n\}$ has a $C_{\alpha}(\mathbb{R})$ -convergent subsequence. The hypotheses of the proposition imply that there are positive constants M, r so that $\{f_n\} \subset B_r$ and

$$|Af|_{\beta} \le M |f|_{\alpha} \text{ for all } f \in \mathcal{C}_{\alpha}(\mathbb{R}).$$
(140)

The restriction of $\{Af_n\}$ to any interval [-X, X] is a bounded, uniformly equicontinuous family. Hence a simple diagonal argument using the Arzela-Ascoli theorem produces a subsequence $\{f_{n_j}\}$ so that $\{Af_{n_j}\}$ converges to $g \in C^0(\mathbb{R})$ uniformly on any interval [-X, X]. In fact this sequence also converges in $C_{\alpha}(\mathbb{R})$.

For the terms of the sequence we have the estimate

$$|Af_{n_i}(x)|(1+|x|)^{\beta} \le Mr.$$
(141)

Letting $j \to \infty$ shows that

$$|g(x)|(1+|x|)^{\beta} \le Mr$$
(142)

as well. These estimates and the triangle inequality show that

$$|Af_{n_j}(x) - g(x)|(1+|x|)^{\alpha} \le 2Mr \frac{(1+|x|)^{\alpha}}{(1+|x|)^{\beta}}.$$
(143)

For an $\epsilon > 0$, we can therefore choose X so that

$$|Af_{n_j}(x) - g(x)|(1+|x|)^{\alpha} \le \epsilon \text{ if } |x| > X.$$
(144)

As $\{Af_{n_j} \upharpoonright_{[-X,X]}\}$ converges uniformly to $g \upharpoonright_{[-X,X]}$, there is a J so that if j > J, then

$$|Af_{n_j}(x) - g(x)|(1+|x|)^{\alpha} \le \epsilon \text{ if } |x| \le X.$$
(145)

Together these estimates show that

$$|Af_{n_j} - g|_{\alpha} < \epsilon \text{ if } j > J, \tag{146}$$

which completes the proof of the proposition.

In the estimates below the function $m(q_l, q_r)$ is a continuous function of the norms $||q_l||_{L^{\infty}}$, $||q_r||_{L^{\infty}}$, and $||q_l - q_r||_{L^{\infty}}$, which satisfies:

$$m(q,q) = 0.$$
 (147)

The estimates on the kernels follow from the analysis in Section 4. The kernel, $k_D(x_2, y_2)$, of D is at least C^1 and satisfies an estimate of the form,

$$|k_D(x_2, y_2)| \le \frac{m(q_l, q_r)}{(1 + |x_2| + |y_2|)^{\frac{1}{2}}}.$$
(148)

The kernel, $k_C(x_2, y_2)$, of C is singular on the diagonal in B_d , with a singularity of the form $m(q_l, q_r) \log |x_2 - y_2| \chi_{B_d}(x_2, y_2)$ and

$$|(1 - \varphi(x_2, y_2))k_C(x_2, y_2)| \le \frac{m(q_l, q_r)}{(1 + |x_2| + |y_2|)^{\frac{3}{2}}}.$$
(149)

Here $\varphi \in \mathcal{C}_c^{\infty}(B_{d+2\epsilon})$ for an $\epsilon > 0$, with

$$\varphi(x_2, y_2) = 1 \text{ for } (x_2, y_2) \in B_{d+\epsilon}.$$
 (150)

We begin with the following boundedness result for the operator appearing in (138).

Proposition 2. For $0 < \alpha < \frac{1}{2}$, there is a constant M_{α} so that if $(\sigma, \tau) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$, then

$$|D\tau|_{\alpha} + |C\sigma|_{\alpha + \frac{1}{2}} \le M_{\alpha} m(q_l, q_r) \left[|\tau|_{\alpha + \frac{1}{2}} + |\sigma|_{\alpha} \right].$$
(151)

The proof relies on the following lemma

Lemma 1. If $0 < \alpha < 1$, and $\alpha + \beta > 1$, then, for $x_2 > 0$, we have the estimate

$$\int_{0}^{\infty} \frac{dy_2}{y_2^{\alpha} (x_2 + y_2)^{\beta}} \le \frac{M_{\alpha,\beta}}{x_2^{\alpha+\beta-1}}.$$
(152)

Proof of Lemma. If we let $y_2 = x_2 t$, then the integral becomes

$$\frac{1}{x_2^{\alpha+\beta-1}} \int_0^\infty \frac{dt}{t^{\alpha}(1+t)^{\beta}} \le \frac{M_{\alpha,\beta}}{x_2^{\alpha+\beta-1}}.$$
(153)

Proof of Proposition. We first consider $C\sigma$, splitting it into a compactly supported part, C_0 , whose kernel is given by $\varphi(x_2, y_2)k_C(x_2, y_2)$, and a part, C_1 , with kernel $(1 - \varphi(x_2, y_2))k_C(x_2, y_2)$. It is clear that the compactly supported part satisfies

$$|C_0 f(x_2)| \le m(q_l, q_r) |\sigma|_{\alpha} \chi_{[-(d+2\epsilon), d+2\epsilon]}(x_2).$$
(154)

To estimate the other part we observe that, if $0<\alpha<1,$ then applying the lemma gives

$$|C_{1}\sigma(x_{2})| \leq \int_{\mathbb{R}} (1 - \varphi(x_{2}, y_{2})) |k_{C}(x_{2}, y_{2})| |\sigma(y_{2})| dy_{2}$$

$$\leq \int_{\mathbb{R}} \frac{m(q_{l}, q_{r}) |\sigma|_{\alpha} dy_{2}}{|y_{2}|^{\alpha} (|x_{2}| + |y_{2}|)^{\frac{3}{2}}}$$

$$\leq K_{\alpha}' \frac{m(q_{l}, q_{r}) |\sigma|_{\alpha}}{|x_{2}|^{\alpha + \frac{1}{2}}}.$$
(155)

Which shows that

$$|C\sigma|_{\alpha+\frac{1}{2}} \le Mm(q_l, q_r)|\sigma|_{\alpha}.$$
(156)

We now estimate $|D\tau|_{\alpha}$, assuming that $0 < \alpha < \frac{1}{2}$; applying the lemma gives

$$|D\tau(x_{2})| \leq m(q_{l},q_{r})|\tau|_{\alpha+\frac{1}{2}} \int_{\mathbb{R}} \frac{dy_{2}}{(1+|y_{2}|)^{\alpha+\frac{1}{2}}(1+|x_{2}|+|y_{2}|)^{\frac{1}{2}}} \leq K_{\alpha} \frac{m(q_{l},q_{r})|\tau|_{\alpha+\frac{1}{2}}}{|x_{2}|^{\alpha}}.$$
(157)

The estimate in (151) follows from this and (156).

If $M_{\alpha}m(q_l, q_r) < 1$, then the Neumann series,

$$\begin{pmatrix} \text{Id} & D \\ C & \text{Id} \end{pmatrix}^{-1} = \text{Id} + \sum_{j=1}^{\infty} (-1)^j \begin{pmatrix} 0 & D \\ C & 0 \end{pmatrix}^j$$
(158)

converges uniformly in the space of bounded operators on $\mathcal{C}_{\alpha}(\mathbb{R}) \oplus \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$. This proves:

Theorem 1. For $0 < \alpha < \frac{1}{2}$, if $M_{\alpha}m(q_l, q_r) < 1$, and $(g, h) \in \mathcal{C}_{\alpha}(\mathbb{R}) \oplus \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$, then the equations in (137) (or (138)) have a unique solution $(\sigma, \tau) \in \mathcal{C}_{\alpha}(\mathbb{R}) \oplus \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$.

Remark 1. As m(q,q) = 0, the smallness hypothesis is satisfied if the contrast between the left and right channels is sufficiently small.

In fact we do not need to require the channels to have small contrast to prove the generic solvability of (138). To prove this it is easier to use the single equation formulation

$$(\mathrm{Id} - DC)\sigma = (g - Dh) \tag{159}$$

obtained by multiplying (138) by $\begin{pmatrix} \mathrm{Id} & -D \\ 0 & \mathrm{Id} \end{pmatrix}$. If $h \in \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$, then $Dh \in \mathcal{C}_{\alpha}(\mathbb{R})$. In the table below we show the leading order asymptotics for the kernels of $W_{l,r}^j$, for j = 0, 2, assuming the channel is centered at $x_2 = \gamma$. The differences between $W_{l,r}^j$, and the leading terms, shown in Table 1, are $O((|x_2| + |y_2|)^{-\frac{j+3}{2}})$; these differences are smoothing and improve decay and therefore Proposition 1 implies that they define compact operators from $\mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R}) \to \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$, resp. for any $\alpha < \frac{1}{2}$.

$$\begin{array}{c|c} c_{-+}^{j} \frac{e^{ik_{1}(|y_{2}-\gamma|+|x_{2}-\gamma|)}}{(|y_{2}-\gamma|+|x_{2}-\gamma|)^{\frac{j+1}{2}}} & \frac{e^{ik_{1}|y_{2}-\gamma|}b_{+}^{j}(x_{2}-\gamma)}{|y_{2}-\gamma|^{\frac{j+1}{2}}} & c_{++}^{j} \frac{e^{ik_{1}(|x_{2}-\gamma|+|y_{2}-\gamma|)}}{(|y_{2}-\gamma|+|x_{2}-\gamma|)^{\frac{j+1}{2}}} \\ \hline \frac{e^{ik_{1}|y_{2}-\gamma|}c_{-}^{j}(y_{2}-\gamma)}{|x_{2}-\gamma|^{\frac{j+1}{2}}} & c_{00}^{j}(x_{2}-\gamma,y_{2}-\gamma) & \frac{e^{ik_{1}|x_{2}-\gamma|}c_{+}^{j}(y_{2}-\gamma)}{|x_{2}-\gamma|^{\frac{j+1}{2}}} \\ \hline c_{--}^{j} \frac{e^{ik_{1}(|x_{2}-\gamma|+|y_{2}-\gamma|)}}{(|y_{2}-\gamma|+|x_{2}-\gamma|)^{\frac{j+1}{2}}} & \frac{e^{ik_{1}|y_{2}-\gamma|}b_{-}^{j}(x_{2}-\gamma)}{|y_{2}-\gamma|^{\frac{j+1}{2}}} & c_{+-}^{j} \frac{e^{ik_{1}(|x_{2}-\gamma|+|y_{2}-\gamma|)}}{(|x_{2}-\gamma|+|y_{2}-\gamma|)^{\frac{j+1}{2}}} \end{array}$$

Table 1: Schematic for the structure of the leading terms of $W_{l,r}^j$ assuming the channel is centered on γ . If the channel has width 2δ , then + is the requirement that a variable is greater than $\gamma + \delta$, and - is the requirement that a variable is less than $\gamma - \delta$.

To analyze the kernel of composition DC, we choose d > 0 so that the supports of q_l and q_r are contained in (-d, d). As above we choose a function $\varphi \in C_c^{\infty}(B_{d+4\epsilon})$, which equals 1 in $B_{d+2\epsilon}$. We let C_0 (resp. D_0) have the kernel $\varphi(x_2, y_2)k_C(x_2, y_2)$, (resp. $\varphi(x_2, y_2)k_D(x_2, y_2)$), and C_1 (resp. D_1) have kernel $(1 - \varphi(x_2, y_2))k_C(x_2, y_2)$, (resp. $(1 - \varphi(x_2, y_2))k_D(x_2, y_2)$). The composition then splits into the terms

$$DC = D_0 C_0 + D_0 C_1 + D_1 C_0 + D_1 C_1.$$
(160)

As the kernels of D_0 and C_0 are compactly supported and smoothing, and the kernels of D_1, C_1 are smooth and have specified rates of decay it is not difficult to show that

$$D_0C_0 + D_0C_1 + D_1C_0 : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha}(\mathbb{R}) \text{ is compact for any } 0 < \alpha < \frac{1}{2}.$$
 (161)

Using smooth cut-off functions, we now divide D_1, C_1 into operators D_{11}, C_{11} , with kernels supported in the set $\{(x_2, y_2) : |x_2| > d + \epsilon, |y_2| > d + \epsilon\}$, and the remainders $D_{10} = D_1 - D_{11}, C_{10} = C_1 - C_{11}$. This additional splitting is useful as the kernels for D_{11}, C_{11} have simpler asymptotics outside of the channels centered on the x_2 and y_2 axes. It is again not difficult to show that

$$D_{10}C_{10} + D_{10}C_{11} + D_{11}C_{10} : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha}(\mathbb{R}) \text{ is compact for any } 0 < \alpha < \frac{1}{2}.$$
(162)

This leaves just the $D_{11}C_{11}$ term. If we suppose that the left channel is centered at 0 and the right at γ , then, from Table 1, it follows that the leading terms of $k_{C_{11}}, k_{D_{11}}$ are given by

$$\tilde{k}_{j}^{0} = \sum_{\chi_{0},\chi_{1} \in \{-,+\}} \psi(\chi_{0}x_{2})\psi(\chi_{1}y_{2}) \left[c_{\chi_{0}\chi_{1}}^{l,j} \frac{e^{ik_{1}(|x_{2}|+|y_{2}|)}}{(|x_{2}|+|y_{2}|)^{\frac{j+1}{2}}} - c_{\chi_{0}\chi_{1}}^{r,j} \frac{e^{ik_{1}(|x_{2}-\gamma|+|y_{2}-\gamma|)}}{(|x_{2}-\gamma|+|y_{2}-\gamma|)^{\frac{j+1}{2}}} \right], \quad (163)$$

with j = 0 for D and j = 2 for C, and $\psi(z) \in C^{\infty}(\mathbb{R})$ is a non-negative, even function supported where $|z| \ge d + \epsilon$ and equal to 1 where $|z| > d + 4\epsilon$. Note that d is selected so that supp q_l , supp q_r are compact subsets of (-d, d). The very simple form of these kernels allows us to estimate the leading order part of the kernel of the composition, $D_{11}C_{11}$.

Proposition 3. There are positive constants m, M so that

$$\left| \int_{-\infty}^{\infty} \tilde{k}_0^0(x_2, z) \tilde{k}_2^0(z, y_2) dz \right| \le \frac{M}{(|x_2| + m)^{\frac{1}{2}} (|y_2| + m)^{\frac{3}{2}}}.$$
 (164)

Proof. From (163) it follows that the integral in (164) is a sum of integrals over either $(-\infty, -d]$ or $[d, \infty)$ consisting of terms of the form

$$e^{ik_1(|x_2-a|+|y_2-b|)} \frac{\psi(|z|)e^{ik_1(|z-a|+|z-b|)}}{(|x_2-a|+|z-a|)^{\frac{1}{2}}(|y_2-b|+|z-b|)^{\frac{3}{2}}},$$
(165)

where a and b equal either 0 or γ . Within the domain of integration neither z - a, nor z - b changes sign. All of the various terms are estimated by integrating by parts. For example, in case a = b = 0, an integration by parts shows that the integral over $[d, \infty)$ equals

$$\int_{d}^{\infty} \frac{\psi(z)e^{2ik_{1}z}}{(|x_{2}|+z)^{\frac{1}{2}}(|y_{2}|+z)^{\frac{3}{2}}} = \frac{1}{2ik_{1}} \left[\int_{d}^{\infty} \frac{-e^{2ik_{1}z}\psi'(z)}{(|x_{2}|+z)^{\frac{1}{2}}(|y_{2}|+z)^{\frac{3}{2}}} + \frac{1}{2} \int_{d}^{\infty} \frac{e^{2ik_{1}z}\psi(z)}{(|x_{2}|+z)^{\frac{1}{2}}(|y_{2}|+z)^{\frac{3}{2}}} \left(\frac{1}{|x_{2}|+z} + \frac{3}{|y_{2}|+z} \right) dz \right].$$
 (166)

The first integral on the right is easily seen to satisfy an estimate like that in (164). Integrating by parts one more time in the other terms gives a similar formula from which the estimates follows easily. All other types of terms appearing in (165) are estimated using the same integrations by parts. \Box

We have the following corollary.

Corollary 1. For any $0 < \alpha < \frac{1}{2}$, the operator $D_{11}C_{11} : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\frac{1}{2}}(\mathbb{R})$ is bounded, and therefore $DC : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha}(\mathbb{R})$ is a compact operator.

Proof. The first statement is an immediate consequence of the estimate in (164), and the fact that the differences between $k_{D_{11}}$ and $k_{C_{11}}$ and their leading parts are bounded by $\frac{M}{(1+|x_2|+|y_2|)^{\frac{3}{2}}}$ and $\frac{M}{(1+|x_2|+|y_2|)^{\frac{5}{2}}}$, respectively. The x_2 -derivative of the kernel of $D_{11}C_{11}$ is easily seen to satisfy the same type of estimates, hence Proposition 1 applies to show that $D_{11}C_{11} : C_{\alpha}(\mathbb{R}) \to C_{\alpha}(\mathbb{R})$ is a compact operator. The second statement follows from this observation along with (161) and (162).

This corollary immediately implies:

Corollary 2. $(\mathrm{Id} - DC) : \mathcal{C}_{\alpha}(\mathbb{R}) \to \mathcal{C}_{\alpha}(\mathbb{R})$ is a Fredholm operator of index 0.

Remark 2. To prove the solvability for arbitrary data we would still need to show that the operator (Id - DC) has a trivial null-space, which we leave to Part III. It will follow from the uniqueness of the outgoing solution to the scattering problem.

Suppose that $(g,h) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$, and $(\mathrm{Id} - DC)\sigma = g - Dh$ is solvable for $\sigma \in C_{\alpha}(\mathbb{R})$, if we set $\tau = h - C\sigma \in C_{\alpha+\frac{1}{2}}(\mathbb{R})$, then the pair (σ, τ) solves (138). In this case the solution to the transmission problem is given by (23),

$$u^{l,r} = -\mathcal{E}^{l,r'}\sigma + \mathcal{E}^{l,r}\tau, \tag{167}$$

which implies that

$$u^{l,r}(x) = S_{k_1}\tau(x) + \int_{-\infty}^{\infty} w^{l,r}(x;0,y_2)\tau(y_2)dy_2 - \mathcal{D}_{k_1}\sigma(x) - \int_{-\infty}^{\infty} \partial_{y_1} w^{l,r}(x;0,y_2)\sigma(y_2)dy_2,$$
(168)

where $\mp x_2 > 0$. The kernel for single layer satisfies the estimate

$$\left|\frac{H_0^{(1)}(k_1|x-(0,y_2)|)}{4}\right| \le \frac{M}{[x_1^2+(x_2-y_2)^2]^{\frac{1}{4}}}.$$
(169)

The kernel of the double layer is given by

$$\partial_{y_1} \frac{iH_0^{(1)}(k_1|x-y|)}{4} \upharpoonright_{y_1=0} = -i\frac{k_1x_1}{4|x-(0,y_2)|} \partial_z H_0^{(1)}(k_1|x-(0,y_2)|).$$
(170)

For $x_1 \neq 0$, as $y_2 \rightarrow \infty$, it satisfies the estimate

$$\left|\partial_{y_1} \frac{H_0^{(1)}(k_1|x-y|)}{4} \right|_{y_1=0} \le \frac{Mx_1}{[x_1^2 + (x_2 - y_2)^2]^{\frac{3}{4}}}.$$
 (171)

The estimates proved for $w^{l,r}(0, x_2; 0, y_2)$, $\partial_{y_1} w^{l,r}(0, x_2; 0, y_2)$ also hold where $x_1 \neq 0$, which, along with Proposition 2, shows that representations for $u^{l,r}(x_1, x_2)$ in (168) are given by absolutely convergent integrals.

Remark 3. One can imagine other uses for the fundamental solution, \mathfrak{E} , of operators like $(\Delta + q(x_2) + k_1^2)$ constructed above. A simple example would be to change the electrical properties of the wave-guide in a compact set replacing $q(x_2)$ by $q(x_2) + Q(x_1, x_2)$, with Q a compactly supported function. Suppose that u^{in} is a solution to $(\Delta + q + k_1^2)u^{\text{in}} = 0$, and we seek an outgoing solution, u^{out} , to

$$(\Delta + q + k_1^2 + Q)[u^{\rm in} + u^{\rm out}] = 0.$$
(172)

Using the fundamental solution this can be rewritten as a Lipmann-Schwinger type equation:

$$(\mathrm{Id} + \mathfrak{E}Q)u^{\mathrm{out}} = -\mathfrak{E}Qu^{\mathrm{in}}.$$
 (173)

At least for small Q, this equation can be solved using a Neumann series

$$u^{\text{out}} = -\mathfrak{E}Q\sum_{j=0}^{\infty} (-1)^j (\chi_Q \mathfrak{E}Q)^j u^{\text{in}},$$
(174)

Figure 4: Three dielectric channels meeting in a compact interaction zone, D, showing sectors S_1, S_2, S_3 .

where χ_Q is the characteristic function of supp Q. To compute the terms of the sum only requires a knowledge of the kernel of \mathfrak{E} on supp $Q \times \text{supp } Q$.

A similar approach can be used to study the effect of placing an non-transparent obstacle in the channel. For these cases the scattered field can be represented in terms of the sum of a single and double layer with respect to the kernel of \mathfrak{E} over the boundary of the obstacle. This will lead to a second kind Fredholm equation on the boundary of the obstacle.

A more ambitious application might be to study a network of channels meeting in a compact set. Using an idea similar to that employed in [1] one can decompose \mathbb{R}^2 into a collection of truncated sectors, $\{S_1, \ldots, S_N\}$ each containing a single semi-infinite channel

$$\{x: |\langle x, v_j^{\perp} \rangle - c_j| \le d_j, \langle x, v_j \rangle > e_j\}, \text{ for } v_j \in \mathbb{R}^2 \text{ unit vectors,}$$

with electrical properties modeled by an operator of the form

$$L_j = (\Delta + q_j(\langle x, v_j^{\perp} \rangle - c_j) + k_1^2).$$

Here $\langle \cdot, \cdot \rangle$ is the Euclidean inner product in \mathbb{R}^2 . The channels meet in a compact interaction zone, D. See Figure 4. Using our construction we can build a fundamental solution, $\mathfrak{E}_j = \mathcal{S}_{k_1} + W_j$, for each operator L_j .

Solutions to $L_j u_j = 0$ in S_j can then be written as sums of single and double layers w.r.t. \mathfrak{E}_j integrated over ∂S_j . Imposing jump conditions across the common

boundaries of the sectors would then lead to systems of integral equations over $\cup \partial S_j$, analogous to (25). These would be supplemented with boundary conditions on ∂D . As before, the kernels of the various W_j decay like $(|s| + |t|)^{-\frac{1}{2}}$ as one goes out to infinity along components of the ∂S_j . Unfortunately, unless the ∂S_j is orthogonal to the channel lying in S_j , the normal derivatives of these kernels will also decay at this rate. Thus it seems unlikely that these integral equations will be well posed in any useful function space. Adding a little dissipation does lead to tractable integral equations.

6 Admissible Data

In general, our method for solving the transmission problem specified in (6)–(7) is applicable to data $(g,h) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$, for some $0 < \alpha < \frac{1}{2}$. If the incoming fields $u_{l,r}^{\text{in}}$ are sums of wave-guides modes, then they decay exponentially as $|x_2| \to \infty$, and are therefore admissible as data for our method. In general, there are two other types of incoming data that naturally arise in this context: plane waves, and point sources.

In this setting, point sources will arise from taking a fundamental solution for a bi-infinite strip, $\mathfrak{E}^{l,r}(x;y)$, which is precisely what we have constructed above. Using our representation, we have

$$\mathfrak{E}^{l,r}(x;y) = g_{k_1}(x-y) + w^{l,r}(x:y).$$
(175)

If we fix a point y_0 with $y_{01} < 0$, then we can use $u_l^{\text{in}}(x) = \mathfrak{E}^l(x; y_0)$ as point source in the left half plane at y_0 ; we can let $u_r^{\text{in}} = 0$. The data for the transmission problem is then

$$g(x_2) = \mathfrak{E}^l(0, x_2; y_0), \ h(x_2) = \partial_{x_1} \mathfrak{E}^l(0, x_2; y_0).$$
(176)

The analysis in Section 4.6 is easily adapted to show that $g(x_2) = O(|x_2|^{-\frac{1}{2}})$, and $h(x_2) = O(|x_2|^{-1})$. In fact, these functions are "outgoing," and have complete asymptotic expansions, as $\pm x_2 \to \infty$, of the form

$$g(x_2) \sim \frac{e^{ik_1|x_2|}}{\sqrt{|x_2|}} \sum_{j=0}^{\infty} \frac{a_j^{\pm}}{|x_2|^j},$$

$$h(x_2) \sim \frac{e^{ik_1|x_2|}}{|x_2|} \sum_{j=0}^{\infty} \frac{b_j^{\pm}}{|x_2|^j}.$$
(177)

This sort of asymptotic behavior is needed in order for the solutions we obtain to be outgoing. As we show in Parts II and III, this would imply

$$(\partial_{x_2} \mp ik_1)g(x_2) = (\partial_{x_2} \mp ik_1)u^l(0^-, x_2) - (\partial_{x_2} \mp ik_1)u^r(0^+, x_2) = O((\pm x_2)^{-\frac{3}{2}}).$$
(178)

The case of incoming plane waves is similar. In the case that the wave-guide is a bi-infinite channel, with $k_1 < k_2$, as described by (4), the scattering problem for an incoming plane wave "from above" has an elementary solution: Let $\kappa = (\kappa_1, \kappa_2)$ satisfy

$$\kappa_1^2 + \kappa_2^2 = k_1^2, \quad \kappa_2 < 0, \tag{179}$$

then the function $v^{\text{in}} = e^{i\boldsymbol{\kappa}\cdot\boldsymbol{x}}$ is a reasonable incoming field "from above" for the single channel modeled by $(\Delta + q(x_2) + k_1^2)$, with $q(x_2) = \chi_{[-d,d]}(x_2)(k_2^2 - k_1^2)$. We would like to find the outgoing scattered wave, v^{sc} , produced by this incoming field. We let $\boldsymbol{\kappa}' = (\kappa_1, -\kappa_2)$, and $\tilde{\boldsymbol{\kappa}} = (\kappa_1, \hat{\kappa}_2), \tilde{\boldsymbol{\kappa}}' = (\kappa_1, -\hat{\kappa}_2)$, where $\hat{\kappa}_2 = \sqrt{k_2^2 - \kappa_1^2} > 0$. The scattered field can be found using the jump conditions directly and takes the form predicted by the Fresnel relations

$$v^{\rm sc}(\boldsymbol{\kappa};\boldsymbol{x}) = \begin{cases} \alpha^+(\boldsymbol{\kappa})e^{i\boldsymbol{\kappa}\cdot\boldsymbol{x}} \text{ where } x_2 > d, \\ \alpha^0(\boldsymbol{\kappa})e^{i\boldsymbol{\tilde{\kappa}}\cdot\boldsymbol{x}} + \beta^0(\boldsymbol{\kappa})e^{i\boldsymbol{\tilde{\kappa}}\cdot\boldsymbol{x}} \text{ where } |x_2| < d, \\ \alpha^-(\boldsymbol{\kappa})e^{i\boldsymbol{\kappa}\cdot\boldsymbol{x}} \text{ where } x_2 < -d. \end{cases}$$
(180)

The determinant of the linear system that defines the coefficients, $(\alpha^+(\kappa), \alpha^0(\kappa), \beta^0(\kappa), \alpha^-(\kappa))$, is a non-zero multiple of $2\kappa_2\hat{\kappa}_2\cos 2\hat{\kappa}_2d + i(k_2^2 - k_1^2)\sin 2\hat{\kappa}_2d$, which does not vanish provided that $\kappa_2 \neq 0$. Hence if $\kappa = k_1(\cos\theta, -\sin\theta)$, then these coefficients depend smoothly on $\theta \in (0, \pi)$. A general field incoming "from above" takes the form

$$v_{\mu}^{\rm in}(x) = \int_0^{\pi} e^{ik_1(\cos\theta, -\sin\theta) \cdot \boldsymbol{x}} d\mu(\theta), \tag{181}$$

with $d\mu$ a finite measure on $(0, \pi)$. By linearity, it produces an "outgoing" scattered field of the form

$$v_{\mu}^{\text{out}} = \int_0^{\pi} v^{\text{sc}}(k_1(\cos\theta, -\sin\theta); \boldsymbol{x}) d\mu(\theta).$$
(182)

While our method for analyzing a pair of intersecting semi-infinite wave-guides does not apply to incoming fields that do not decay as $|x_2| \to \infty$, if $d\mu(\theta) = m(\theta)d\theta$, with $m \in \mathcal{C}_c^{\infty}((0,\pi))$, then

$$v_{\mu}^{\text{tot}}(x_1, x_2) = v_{\mu}^{\text{in}}(x_1, x_2)\chi_{[d,\infty)}(x_2) + v_{\mu}^{\text{out}}(x_1, x_2)$$

satisfies the transmission boundary conditions and is a weak solution of the PDE $(\Delta + q(x_2) + k_1^2)v_{\mu}^{\text{tot}} = 0$. A stationary phase computation shows that $v_{\mu}^{\text{out}}(\kappa; r\eta)$ satisfies the Sommerfeld radiation conditions if either η , or $-\eta$ belongs to the supp m, and is rapidly vanishing at infinity otherwise. Moreover we have asymptotic expansions

$$v_{\mu}^{\text{tot}}(0, x_{2}) \sim \begin{cases} \frac{e^{-ik_{1}x_{2}}}{\sqrt{x_{2}}} \sum_{j=0}^{\infty} \frac{a_{j}^{-}}{x_{2}^{j}} + \frac{e^{ik_{1}x_{2}}}{\sqrt{x_{2}}} \sum_{j=0}^{\infty} \frac{a_{j}^{+}}{x_{2}^{j}} \text{ for } x_{2} > 0, \\ \frac{e^{-ik_{1}x_{2}}}{\sqrt{|x_{2}|}} \sum_{j=0}^{\infty} \frac{b_{j}^{+}}{x_{2}^{j}} \quad \text{for } x_{2} < 0, \\ \partial_{x_{1}}v_{\mu}^{\text{tot}}(0, x_{2}) \sim \begin{cases} \frac{e^{-ik_{1}x_{2}}}{x_{2}} \sum_{j=0}^{\infty} \frac{a_{j}^{-}}{x_{2}^{j}} + \frac{e^{ik_{1}x_{2}}}{x_{2}} \sum_{j=0}^{\infty} \frac{a_{j}^{+}}{x_{2}^{j}} \text{ for } x_{2} > 0, \\ \frac{e^{-ik_{1}x_{2}}}{x_{2}} \sum_{j=0}^{\infty} \frac{a_{j}^{-}}{x_{2}^{j}} + \frac{e^{ik_{1}x_{2}}}{x_{2}} \sum_{j=0}^{\infty} \frac{a_{j}^{+}}{x_{2}^{j}} \text{ for } x_{2} > 0, \\ \frac{e^{-ik_{1}x_{2}}}{x_{2}} \sum_{j=0}^{\infty} \frac{b_{j}^{+}}{x_{2}^{j}} \quad \text{for } x_{2} < 0. \end{cases} \end{cases}$$
(183)

and therefore our method of solution, with $q_l = q$, and data determined by $u_l^{\text{in}} = v_{\mu}^{\text{tot}}, u_r^{\text{in}} = 0$ does apply to this case. To obtain the needed estimates for our approach to apply it suffices for $m \in \mathcal{C}_c^2((0,\pi))$.

Unfortunately, as is clear from (183), data of this type is not outgoing along the ray $\{x_1 = 0, x_2 > 0\}$, hence, from (178), it is clear that the solution found by our method cannot be outgoing. This is where the symmetric formulation of the transmission problem proves its worth. If we let $v_{\mu;l}^{\text{out}}$, $v_{\mu;r}^{\text{out}}$, denote the scattered fields obtained using the foregoing method with $q = q_l$, $q = q_r$, respectively, then we can let

$$u_{l,r}^{\rm in}(x_1, x_2) = \begin{cases} & v_{\mu}^{\rm in}(x_1, x_2)\chi_{[d_l^+, \infty)}(x_2) + v_{\mu;l}^{\rm out}(x_1, x_2), \text{ for } l, x_1 < 0, \\ & v_{\mu}^{\rm in}(x_1, x_2)\chi_{[d_r^+, \infty)}(x_2) + v_{\mu;r}^{\rm out}(x_1, x_2), \text{ for } r, x_1 > 0, \end{cases}$$
(184)

where $\operatorname{supp} q_{l,r} = [d_{l,r}^-, d_{l,r}^+]$. These two fields have the same incoming component where $x_2 \gg 0$, given by v_{μ}^{in} . Hence the data for the transmission problem has no incoming part and, for $x_2 \gg 0$, is given by

$$g(x_2) = \int_0^{\pi} (\alpha_l^+(\theta) - \alpha_r^+(\theta)) e^{ik_1 \sin \theta} d\mu(\theta),$$

$$h(x_2) = ik_1 \int_0^{\pi} (\alpha_l^+(\theta) - \alpha_r^+(\theta)) \cos \theta e^{ik_1 \sin \theta} d\mu(\theta).$$
(185)

If $d\mu = m(\theta)d\theta$, with $m \in C_c^{\infty}((0, \pi))$, then g and h have asymptotic expansions like those in (183), but with $a_j^- = a_j'^- = 0$, for all j. This data is therefore outgoing, and the solution to the transmission problem produced by our method can also

expected to be. It is worth mentioning that if $m \in C_c^{\infty}((0,\pi))$, with $\operatorname{supp} m \subset [\theta_0, \pi - \theta_0]$, for a $\theta_0 > 0$, then the incoming wave packet $v_{\mu}^{\operatorname{in}}(r\eta) = O(r^{-N})$ for any N > 0, if $0 < \eta_2 < \sin \theta_0$.

Remark 4. I want to thank Manas Rachh for explaining the trick used here for removing the incoming part of the data in a transmission problem.

7 The Projections onto Wave-Guide Modes

In the foregoing pages we have explained a method to find and represent solutions to the transmission problem that results from two semi-infinite wave-guides meeting along a common perpendicular line. The solution is represented in each half plane by layer potentials along this line, with sources (σ, τ) , see (168). The solutions in each half plane can be split into a contribution from the wave-guide modes and "radiation,"

$$u^{l,r}(x) = u_g^{l,r}(x) + u_{\rm rad}^{l,r}(x).$$
 (186)

If $\{(v_n^{l,r}, \xi_n^{l,r}) : n = 1, \dots, N_{l,r}\}$ are the guided modes, normalized to have L^2 -norms 1, then the projection into the guided modes is given by

$$u_g^{l,r}(x_1, x_2) = \sum_{n=1}^{N_{l,r}} v_n^{l,r}(x_2) \int_{-\infty}^{\infty} u^{l,r}(x_1, y_2) v_n^{l,r}(y_2) dy_2$$
(187)

This has a very simple expression in terms of our representation, coming entirely from the w_{0+}^g -term in the expression for $\mathfrak{E}^{l,r}$, see (41). We assume that $u^{l,r}$ is given by (168), with sources $(\sigma, \tau) \in \mathcal{C}_{\alpha}(\mathbb{R}) \oplus \mathcal{C}_{\alpha+\frac{1}{2}}(\mathbb{R})$.

We assume that $u^{l,r}$ is given by (168), with sources $(\sigma, \tau) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$. As noted in Section 5 the representations for $u^{l,r}$ and $\partial_{x_1} u^{l,r}$ are in terms of absolutely convergent integrals. The key observation is the following

Proposition 4. Let $(\sigma, \tau) \in C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$ and let $v_n^{l,r}(x_2)e^{i\xi_n^{l,r}x_1}$ be a waveguide mode for $\Delta + k_1^2 + q_{l,r}(x_2)$, then, for all $\pm x_1 > 0$,

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [g_{k_1}(|(x_1, x_2 - y_2)|) + w_{0+}^{c;l,r}(x_1, x_2; 0, y_2)]\tau(y_2)v_n^{l,r}(x_2)dy_2dx_2 = 0,$$

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \partial_{y_1}[g_{k_1}(|(x_1 - y_1, x_2 - y_2)|) + w_{0+}^{c;l,r}(x_1, x_2; y_1, y_2)]_{y_1=0}\sigma(y_2)v_n^{l,r}(x_2)dy_2dx_2 = 0.$$

(188)

Proof. We give the details for the right half plane. The estimates proved in the previous sections show that these integrals are absolutely convergent and therefore we can change the order of the integrations. To prove the proposition we show that, for each y_2 and $x_1 > 0$, we have

$$\int_{-\infty}^{\infty} [g_{k_1}(|(x_1, x_2 - y_2)|) + w_{0+}^{c;r}(x_1, x_2; 0, y_2)]v_n^r(x_2)dx_2 = 0,$$

$$\int_{-\infty}^{\infty} \partial_{y_1}[g_{k_1}(|(x_1 - y_1, x_2 - y_2)|) + w_{0+}^{c;r}(x_1, x_2; y_1, y_2)]_{y_1 = 0}v_n^r(x_2)dx_2 = 0.$$
(189)

To prove these statements we use the Sommerfeld integral representation for the free space fundamental solution, see (30).

We begin with the single layer term, which can be written as the iterated integral:

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} \frac{ie^{i|x_2-y_2|\sqrt{k_1^2-\xi^2}}}{2\sqrt{k_1^2-\xi^2}} + \int_{\Gamma_{\nu}^+} \tilde{w}_{0+}^{c;r}(\xi, x_2; y_2) \right] e^{ix_1\xi} d\xi \, v_n^r(x_2) dx_2.$$
(190)

We would like to change the order of integrations in this integral, which would be easily justified if the integral in ξ were over any finite interval. Note that

$$\int_{k_1+1}^{\infty} \left| \frac{ie^{-|x_2-y_2|\sqrt{\xi^2-k_1^2}}e^{-iy_1\xi}}{2\sqrt{\xi^2-k_1^2}} \right| d\xi \le M[1+|\log|x_2-y_2|].$$
(191)

Combining this with the estimates (80) and (98), and the fact that $|v_n^r(x_2)| \leq Me^{-|x_2|\sqrt{\xi_n^{r_2}-k_1^2}}$ shows that these integrals are absolutely convergent and therefore we can interchange the order of the integrations. By analyticity we can also replace the integral in the first term with an integral over Γ_{ν}^+ , to obtain

$$\frac{1}{2\pi} \int_{\Gamma_{\nu}^{+}} \left[\int_{-\infty}^{\infty} \frac{ie^{i|x_2 - y_2|\sqrt{k_1^2 - \xi^2}}}{2\sqrt{k_1^2 - \xi^2}} + \tilde{w}_{0+}^{c;r}(\xi, x_2; y_2) \right] e^{ix_1\xi} v_n^r(x_2) dx_2 d\xi.$$
(192)

Using the fact that $\xi_n^{r\,2}v_n^r = (\partial_{x_2}^2 + k_1^2 + q_r(x_2))v_n^r$ and integrating by parts it follows that

$$\int_{-\infty}^{\infty} \left[\frac{ie^{i|x_2 - y_2|\sqrt{k_1^2 - \xi^2}}}{2\sqrt{k_1^2 - \xi^2}} + \tilde{w}_{0+}^{c;r}(\xi, x_2; y_2) \right] e^{ix_1\xi} v_n^r(x_2) dx_2 = \frac{ie^{ix_1\xi} v_n^r(y_2)}{\xi_n^{r\,2} - \xi^2}.$$
(193)

Hence the double integral is

$$\frac{1}{2\pi i} \int_{\Gamma_{\nu}^{+}} \frac{i e^{i x_{1} \xi} v_{n}^{r}(y_{2}) d\xi}{\xi^{2} - \xi_{n}^{r \, 2}},\tag{194}$$

which, using Cauchy's theorem, is easily seen to vanish for $x_1 > 0$.

The double layer is almost the same; the double integral in (190) is replaced by

$$\frac{i}{2\pi} \int_{-\infty}^{\infty} \left[\int_{\Gamma_{\nu}^{+}} \left[\frac{ie^{i|x_2 - y_2|\sqrt{k_1^2 - \xi^2}}}{2\sqrt{k_1^2 - \xi^2}} + \tilde{w}_{0+}^{c;r}(\xi, x_2; y_2) \right] \xi e^{ix_1\xi} d\xi \right] v_n^r(x_2) dx_2.$$
(195)

The integral involving $\tilde{w}_{0+}^{c;r}(\xi, x_2; y_2)$ is again easily seen to be absolutely convergent, but the additional factor of ξ makes the other term more subtle. We need an estimate for this term that takes account of the fact that $x_1 > 0$.

Lemma 2. For $x_1 > 0, \lambda > 0$ and $R > k_1$ let

$$f_R^{\pm}(x_1,\lambda) = \pm \int_{\pm R}^{\pm \infty} \frac{e^{ix_1\xi - \lambda\sqrt{\xi^2 - k_1^2}} \xi d\xi}{\sqrt{\xi^2 - k_1^2}}.$$
 (196)

These functions satisfy the estimates

$$|f_R^{\pm}(x_1,\lambda)| \le \frac{Me^{-\lambda\sqrt{R^2 - k_1^2}}}{x_1}$$
(197)

Proof. As $f_R^-(x_1,\lambda) = \overline{f_R^+(x_1,\lambda)}$ it suffices to do the +-case. If we let $s = \sqrt{\xi^2 - k_1}$, then

$$f_R^+(x_1,\lambda) = \int_{\sqrt{R^2 - k_1^2}}^{\infty} e^{ix_1\sqrt{s^2 + k_1^2} - \lambda s} ds.$$
 (198)

Noting that

$$\partial_{s} \left[\frac{\sqrt{s^{2} + k_{1}^{2}}}{s} e^{ix_{1}\sqrt{s^{2} + k_{1}^{2}}} \right] = ix_{1}e^{ix_{1}\sqrt{s^{2} + k_{1}^{2}}} - \frac{k_{1}^{2}}{s^{2}\sqrt{s^{2} + k_{1}^{2}}}e^{ix_{1}\sqrt{s^{2} + k_{1}^{2}}}, \quad (199)$$

integration by parts shows that

$$f_{R}^{+}(x_{1},\lambda) = \frac{1}{ix_{1}} \left[\frac{k_{1}e^{-\lambda\sqrt{R^{2}-k_{1}^{2}}+ix_{1}R}}{\sqrt{R^{2}-k_{1}^{2}}} + \int_{\sqrt{R^{2}-k_{1}^{2}}}^{\infty} \left[\frac{\lambda\sqrt{s^{2}+k_{1}^{2}}}{s} + \frac{k_{1}^{2}}{s^{2}\sqrt{s^{2}+k_{1}^{2}}} \right] e^{ix_{1}\sqrt{s^{2}+k_{1}^{2}}-\lambda s} ds \right].$$
 (200)

The integral is easily seen to be $O(e^{-\lambda\sqrt{R^2-k_1^2}})$, which completes the proof of the lemma.

We rewrite the integral in (195) as

$$\frac{i}{2\pi} \int_{-\infty}^{\infty} \int_{\Gamma_{\nu}^{+}} \left[\frac{ie^{i|x_{2}-y_{2}|\sqrt{k_{1}^{2}-\xi^{2}}}}{2\sqrt{k_{1}^{2}-\xi^{2}}} \right] \xi e^{ix_{1}\xi} d\xi \, v_{n}^{r}(x_{2}) dx_{2} = \\ \frac{i}{2\pi} \int_{-\infty}^{\infty} \left[\int_{\Gamma_{\nu}^{+}\cap D_{R}} \left[\frac{ie^{i|x_{2}-y_{2}|\sqrt{k_{1}^{2}-\xi^{2}}}}{2\sqrt{k_{1}^{2}-\xi^{2}}} \right] \xi e^{ix_{1}\xi} d\xi + f_{R}^{+}(x_{1},|x_{2}-y_{2}|) + f_{R}^{-}(x_{1},|x_{2}-y_{2}|) \right] v_{n}^{r}(x_{2}) dx_{2}.$$

$$(201)$$

In the part of the integral over $\Gamma^+_{\nu} \cap D_R$ we can interchange the order of the integrations. We use the lemma to estimate the other terms

$$\left| \int_{-\infty}^{\infty} [f_R^+(x_1, |x_2 - y_2|) + f_R^-(x_1, |x_2 - y_2|)] v_n^r(x_2) dx_2 \right|$$

$$\leq \frac{M}{x_1} \int_{-\infty}^{\infty} e^{-\sqrt{R^2 - k_1^2} |x_2 - y_2|} e^{-\sqrt{\xi_n^{r^2} - k_1^2} |x_2|} dx_2 \quad (202)$$

$$\leq \frac{M}{x_1(\sqrt{R^2 - k_1^2} - \sqrt{\xi_n^{r^2} - k_1^2})}.$$

Thus we see that

$$\int_{-\infty}^{\infty} \left[\int_{\Gamma_{\nu}^{+}} \left[\frac{ie^{i|x_{2}-y_{2}|\sqrt{k_{1}^{2}-\xi^{2}}}}{2\sqrt{k_{1}^{2}-\xi^{2}}} + \tilde{w}_{0+}^{c;r}(\xi, x_{2}; y_{2}) \right] \xi e^{ix_{1}\xi} d\xi \right] v_{n}^{r}(x_{2}) dx_{2} = \lim_{R \to \infty} \int_{\Gamma_{\nu}^{+} \cap D_{R}} \int_{-\infty}^{\infty} \left[\left[\frac{ie^{i|x_{2}-y_{2}|\sqrt{k_{1}^{2}-\xi^{2}}}}{2\sqrt{k_{1}^{2}-\xi^{2}}} + \tilde{w}_{0+}^{c;r}(\xi, x_{2}; y_{2}) \right] v_{n}^{r}(x_{2}) dx_{2} \right] \xi e^{ix_{1}\xi} d\xi.$$

$$(203)$$

The x_2 -integral is computed in (193), giving

$$\int_{-\infty}^{\infty} \left[\int_{\Gamma_{\nu}^{+}} \left[\frac{ie^{i|x_{2}-y_{2}|\sqrt{k_{1}^{2}-\xi^{2}}}}{2\sqrt{k_{1}^{2}-\xi^{2}}} + \tilde{w}_{0+}^{c;r}(\xi, x_{2}; y_{2}) \right] \xi e^{ix_{1}\xi} d\xi \right] v_{n}^{r}(x_{2}) dx_{2} = \lim_{R \to \infty} v_{n}(y_{2}) \int_{\Gamma_{\nu}^{+} \cap D_{R}} \frac{i\xi e^{ix_{1}\xi}}{\xi_{n}^{r^{2}}-\xi^{2}} d\xi = 0.$$
(204)

The last equality follows from Cauchy's theorem. It completes the proof of (189) and also of the proposition. $\hfill \Box$

Using this proposition we can compute the projections of $u^{l,r}$ to the respective right and left wave-guide modes given in (187). In our representation

$$u^{l,r}(x) = \int_{-\infty}^{\infty} \mathfrak{E}^{l,r}(x;0,y_2)\tau(y_2)dy_2 - \int_{-\infty}^{\infty} \partial_{y_1} \mathfrak{E}^{l,r}(x;0,y_2)\sigma(y_2)dy_2.$$
(205)

We give the details for $\{x_1 > 0\}$; Proposition 4 and (40) show that

$$u_{g}^{r}(x_{1}, x_{2}) = \sum_{n=1}^{N_{r}} [\langle \tau, v_{n}^{r} \rangle + i\xi_{n}^{r} \langle \sigma, v_{n}^{r} \rangle] v_{n}^{r}(x_{2}) e^{i\xi_{n}^{r}x_{1}},$$
(206)

where

$$\langle f,g\rangle = \int_{-\infty}^{\infty} f(x)\overline{g(x)}dx.$$
 (207)

Hence the projections of $u^{l,r}$ onto the wave-guide modes are completely determined by the projections, $\{\langle \tau, v_n^{l,r} \rangle, \langle \sigma, v_n^{l,r} \rangle : n = 1, \ldots, N_{l,r}\}$, of the source terms onto these modes.

If these projections could be determined directly from the data, then we could determine the scattering relation, from incoming wave-guide modes to outgoing modes, without having to solve the complete problem. Starting with the equation (138) we can almost find equations for the coefficients in (206). Projecting these equations into span of the wave-guide modes we obtain

$$P_g^{l,r}\sigma + P_g^{l,r}D\tau = P_g^{l,r}g$$

$$P_g^{l,r}C\sigma + P_g^{l,r}\tau = P_g^{l,r}h,$$
(208)

where we let

$$P_g^{l,r}f = \sum_{n=1}^{N_{l,r}} \langle f, v_n^{l,r} \rangle v_n^{l,r}(x_2).$$
(209)

These equations can be rewritten as

$$P_{g}^{l,r}\sigma + P_{g}^{l,r}DP_{g}^{l,r}\tau = P_{g}^{l,r}g - P_{g}^{l,r}D(\mathrm{Id} - P_{g}^{l,r})\tau$$

$$P_{g}^{l,r}CP_{g}^{l,r}\sigma + P_{g}^{l,r}\tau = P_{g}^{l,r}h - P_{g}^{l,r}C(\mathrm{Id} - P_{g}^{l,r})\sigma.$$
(210)

While this is not quite a system of equations for the projections $(P_g^{l,r}\sigma, P_g^{l,r}\tau)$, the facts that $P_g^{l,r}(\mathrm{Id}-P_g^{l,r})=0$, and the norms of ||D|| and ||C|| are proportional to $m(q_l, q_r)$ suggests that, at least for two channels with small contrast, dropping these terms leads to equations

$$P_g^{l,r}\widetilde{\sigma} + P_g^{l,r}DP_g^{l,r}\widetilde{\tau} = P_g^{l,r}g$$

$$P_g^{l,r}CP_g^{l,r}\widetilde{\sigma} + P_g^{l,r}\widetilde{\tau} = P_g^{l,r}h,$$
(211)

whose solutions, $(P_g^{l,r}\widetilde{\sigma}, P_g^{l,r}\widetilde{\tau})$, should be very close to $(P_g^{l,r}\sigma, P_g^{l,r}\tau)$.

8 Some Concluding Remarks

In the foregoing pages we have constructed outgoing fundamental solutions for operators of the form $\Delta + k_1^2 + q(x_2)$, and shown how to use them to represent the solution to the transmission problem defined by two semi-infinite wave-guides meeting along a common perpendicular line. The construction of the "outgoing" fundamental solution is in a form that should lend itself to numerical implementation. We have shown that the resultant system of integral equations is Fredholm of second kind on the spaces $C_{\alpha}(\mathbb{R}) \oplus C_{\alpha+\frac{1}{2}}(\mathbb{R})$, with $0 < \alpha < \frac{1}{2}$, and are therefore generically solvable.

We have only presented a detailed analysis of this problem for the case of potentials given by (4), though it is clear that our approach will apply, *mutatis mutandis*, if $q(x_2)$ is a bounded, measurable function with bounded support. The principal difference will be that the basic solutions, $\tilde{u}_{\pm}(\xi, 0^+; x_2)$, of the ODE, and their Wronskian no longer have explicit formulæ in terms of elementary functions within the support of q. These formulæ need to be replaced by (standard) estimates. To implement the method numerically, the functions \tilde{u}_{\pm} have to be computed numerically within the support of q. The problem of having 2 open wave-guides that are of the form considered here outside a compact set, is a relatively compact perturbation which, while requiring further analysis, should not pose serious additional difficulties.

In Part II we show that under reasonable hypotheses on the data, which are satisfied by wave-guide modes, points sources and wave-packets, the sources found by solving the integral equations along $\{x_1 = 0\}$ satisfy many additional estimates and even admit asymptotic expansions, that is

$$\sigma(x_2) \sim \frac{e^{ik_1|x_2|}}{|x_2|^{\frac{1}{2}}} \sum_{l=0}^{N} \frac{a_l^{\pm}}{|x_2|^l} + O\left(|x_2|^{-N-\frac{3}{2}}\right),$$

$$\tau(x_2) \sim \frac{e^{ik_1|x_2|}}{|x_2|} \sum_{l=0}^{N} \left[\frac{b_l^{\pm}}{|x_2|^{l+\frac{1}{2}}} + \frac{c_l^{\pm}}{|x_2|^l}\right] + O\left(|x_2|^{-N-2}\right), \text{ as } |x_2| \to \infty.$$
(212)

In some cases the coefficients $c_l^{\pm} = 0$.

Using these asymptotic expansions we show that the solutions given by $u^{l,r}$ also have complete expansions that are uniformly correct as $\eta_1, \eta_2 \rightarrow 0^{\pm}$. The existence of these expansions implies that the solutions satisfy precisely the sort of outgoing radiation condition that one expects from the work of Isozaki, Melrose, Vasy et al. The proofs of the asymptotic expansions use fairly classical techniques, combined with a novel contour deformation argument. To complete this analysis, and prove the uniqueness of the solutions found using our method, requires a much more sophisticated, microlocal analysis of this class of problems, which is given in Part III.

Appendix

In these appendices we collect a variety of background results, and study the outgoing properties of the limiting absorption solution in the case of a bi-infinite channel.

A The Planar Case

In order to estimate the correction terms $w^{l,r}(x;y)$ we need to have a good description of the limit of the kernels for $(D_q + i\delta)^{-1}$ as $\delta \to 0^+$, where

$$D_q = \Delta + k_1^2 + q(x_2). \tag{213}$$

We are employing the limiting absorption principle limit, which, more or less by definition, gives the outgoing solution to

$$(\Delta + k_1^2 + q)u = f, (214)$$

for certain functions f, which includes, but is not limited to compactly supported functions.

In this section we use the Fourier transform in the x_1 -variable and basic ODE theory to construct the kernels for these operators where we usually take

$$q(x_2) = (k_2^2 - k_1^2)\chi_{[-d,d]}(x_2).$$
(215)

It would be more standard to consider the spectral theory and resolvent of the operator $\Delta + q(x_2)$. However our analysis relies on detailed analyticity properties of the kernel of $(\Delta + q + k_1^2 + i\delta)$ for $\delta > 0$, which is why we consider the shifted operator. The substance of these results generalizes easily to piecewise continuous functions, $q(x_2)$, with support in [-d, d].

With $H^2(\mathbb{R}^2)$ as the domain, D_q defines an unbounded self adjoint operator on $L^2(\mathbb{R}^2)$. The spectrum of this operator, $\sigma(D_q)$, is well known to lie in the interval $(-\infty, k_2^2]$. In this section we present a construction for the resolvent kernel of this operator, which allows for the construction of the perturbation terms $w^{l,r}$, by taking for q either q_l or q_r . To that end we need compute the kernel of the limit

$$\lim_{\delta \to 0^+} (D_q + i\delta)^{-1}$$

which we denote by $\mathcal{R}_{0+}(x; y)$. This is the operator arising from limiting absorption principle applied to this case. By a small abuse of terminology, in the sequel we refer to \mathcal{R}_{0+} as the *resolvent kernel*, or outgoing resolvent kernel.

Our construction of the resolvent kernel uses the partial Fourier transform in the x_1 -variable, which we denote by

$$\widetilde{u}(\xi, x_2) = \int_{-\infty}^{\infty} u(x_1, x_2) e^{-i\xi x_1} dx_1.$$
(216)

To construct the resolvent kernel we the need kernels for inverses of the operators

$$L_{\xi} + i\delta = \partial_{x_2}^2 + k_1^2 + q(x_2) - \xi^2 + i\delta, \ \xi \in \mathbb{R},$$

with domain $H^2(\mathbb{R})$. These kernels are constructed from the *basic solutions* to

$$\partial_{x_2}^2 \widetilde{u}_{\pm}(\xi,\delta;x_2) + (k_1^2 + q(x_2) - \xi^2 + i\delta)\widetilde{u}_{\pm}(\xi,\delta;x_2) = 0, \qquad (217)$$

which satisfy

$$\widetilde{u}_{\pm}(\xi,\delta;x_2) = e^{\pm ix_2\sqrt{k_1^2 - \xi^2 + i\delta}} \text{ for } \pm x_2 > d.$$
 (218)

The \sqrt{z} is defined on $\mathbb{C} \setminus (-\infty, 0]$, to be positive on $(0, \infty)$; for $\delta, \xi \in \mathbb{R}$,

$$\operatorname{sgn}\operatorname{Im}\sqrt{k^2-\xi^2+i\delta}=\operatorname{sgn}\delta,$$

and therefore, for $\delta > 0$, and $\xi^2 > k_1^2$,

$$\sqrt{k_1^2 - \xi^2 + i\delta} = i\sqrt{\xi^2 - k_1^2 - i\delta}.$$
(219)

Hence, for $\delta > 0$, $\tilde{u}_+(\xi, \delta; x_2)$ decays exponentially as $x_2 \to \infty$, whereas $\tilde{u}_-(\xi, \delta; x_2)$ decays exponentially as $x_2 \to -\infty$. Taking $\delta \to 0^+$ we get the basic solutions that satisfy

$$\widetilde{u}_{\pm}(\xi, 0^+; x_2) = \begin{cases} e^{\pm i x_2 \sqrt{k_1^2 - \xi^2}} \text{ for } |\xi| \le k_1, \\ e^{\pm x_2 \sqrt{\xi^2 - k_1^2}} \text{ for } |\xi| > k_1, \text{ as } \pm x_2 \to \infty. \end{cases}$$
(220)

The solutions $\tilde{u}_+(\xi, 0; x_2)$ are outgoing as $x_2 \to \infty$, and $\tilde{u}_-(\xi, 0; x_2)$ are outgoing as $x_2 \to -\infty$. If $q(-x_2) = q(x_2)$, then it is easy to show that

$$\widetilde{u}_{-}(\xi,\delta;x_2) = \widetilde{u}_{+}(\xi,\delta;-x_2).$$
(221)

Remark 5. It should be noted that while the families $\tilde{u}_{\pm}(\xi, \delta; x_2)$ are analytic as functions of ξ^2 , their analyticity properties as functions of ξ are more complicated. This is because, with our choice of square-root, the composition $\xi \mapsto \sqrt{k_1^2 - \xi^2}$ is

analytic and single-valued in $\mathbb{C} \setminus (-\infty, -k_1] \cup [k_1, \infty)$. We see that letting $\delta \to 0^+$ implies that, for ξ real with for $|\xi| > k_1$,

$$\sqrt{k_1^2 - \xi^2} = i\sqrt{\xi^2 - k_1^2},$$

where $\sqrt{\xi^2 - k_1^2} \in (0, \infty)$. Fortunately our applications only require analyticity for ξ in small neighborhoods of the intervals $(k_1, k_2), (-k_2, -k_1) \subset \mathbb{R}$. Since this avoids the branch points at $\pm k_1$, the $\sqrt{\xi^2 - k_1^2}$ has a single valued, analytic determination in a neighborhood of these open intervals.

As solutions to an ODE, the functions $\tilde{u}_{\pm}(\xi, 0^+; x_2)$ are specified by their behavior for $\pm x_2 > d$, and therefore have analytic extensions to $\tilde{u}_{\pm}(\zeta, 0^+; x_2)$, for ζ in a neighborhood, $\mathcal{U} \subset \mathbb{C}$, of $(k_1, k_2) \cup (-k_2, -k_1)$. As these solutions are also determined by their asymptotics, for small enough δ , these extensions satisfy

$$\widetilde{u}(\xi,\delta;x_2) = \widetilde{u}(\sqrt{\xi^2 - i\delta}, 0^+;x_2).$$

Note also that $\tilde{u}_{\pm}(\zeta, 0^+; x_2) = \tilde{u}_{\pm}(-\zeta, 0^+; x_2)$, for $\zeta \in \mathcal{U}$. This does not require $q(x_2) = q(-x_2)$.

The simple case of the $\Delta + k^2$ is instructive. Constructing the outgoing solution to $(\Delta + k^2)u = f$, via a 1-dimensional Fourier transform gives the formula

$$u(x_1, x_2) = -\frac{1}{4\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{e^{-\sqrt{\xi^2 - k^2}|x_2 - y_2|} e^{i\xi x_1} \tilde{f}(\xi, y_2) dy_2 d\xi}{\sqrt{\xi^2 - k^2}}, \qquad (222)$$

where $\sqrt{\xi^2 - k^2} = -i\sqrt{k^2 - \xi^2}$ if $|\xi| < k$. The resolvent kernel of $\partial_{x_2}^2 - \xi^2 + k^2$ is an even function of ξ , and has an analytic extension to a neighborhood of $(-\infty, -k) \cup (k, \infty)$. This is *not* the restriction of its analytic extension to the upper, or lower half plane.

In order to satisfy the equation and boundary conditions at $x_2 = \pm d$, implied by $\text{Dom}(L_{\xi}) = H^2(\mathbb{R})$, it is necessary for \tilde{u}_+ to have the form

$$\widetilde{u}_{+}(\xi,\delta;x_{2}) = \begin{cases} a_{0}e^{ix_{2}\sqrt{k_{2}^{2}-\xi^{2}+i\delta}} + b_{0}e^{-ix_{2}\sqrt{k_{2}^{2}-\xi^{2}+i\delta}} \text{ for } |x_{2}| < d, \\ a_{-}e^{ix_{2}\sqrt{k_{1}^{2}-\xi^{2}+i\delta}} + b_{-}e^{-ix_{2}\sqrt{k_{1}^{2}-\xi^{2}+i\delta}} \text{ for } x_{2} < -d. \end{cases}$$
(223)

The claim for $|x_2| < d$ assumes that q is given by (215), which we assume for the remainder of this section. If $\delta = 0^+$, and $|\xi| < k_1$, then \tilde{u}_+ oscillates as $|x_2| \to \infty$, whereas if $|\xi| > k_1$, then this solution decays exponentially as $x_2 \to \infty$, but typically grows exponentially as $x_2 \to -\infty$.

Using the solutions described in (218)–(223), we now construct the inverse for $L_{\xi} + i\delta$. The inverse is given by

$$R_{\xi,\delta}(\tilde{f})(x_2) = \frac{1}{W(\xi,\delta)} \left[\int_{-\infty}^{x_2} \tilde{u}_+(\xi,\delta;x_2)\tilde{u}_-(\xi,\delta;y_2)\tilde{f}(y_2)dy_2 + \int_{x_2}^{\infty} \tilde{u}_-(\xi,\delta;x_2)\tilde{u}_+(\xi,\delta;y_2)\tilde{f}(y_2)dy_2 \right], \quad (224)$$

where

$$W(\xi,\delta) = u_{-}(\xi,\delta;x_{2})\partial_{x_{2}}u_{+}(\xi,\delta;x_{2}) - u_{+}(\xi,\delta;x_{2})\partial_{x_{2}}u_{-}(\xi,\delta;x_{2}), \quad (225)$$

is the Wronskian, which is independent of x_2 . This operator agrees with the bounded inverse of $L_{\xi} + i\delta$, where it is defined, but is also defined as an operator from $L^2_{\text{comp}}(\mathbb{R}) \to H^2_{\text{loc}}(\mathbb{R})$, even for $\delta = 0^+, |\xi| < k_1$. We denote the operator by $R_{\xi,\delta}$, with

$$R_{\xi,0^+} = \lim_{\delta \to 0^+} R_{\xi,\delta}.$$
 (226)

The operator $\partial_{x_2}^2 + k_1^2 + q(x_2)$, acting on $H^2(\mathbb{R})$ is self adjoint and its spectrum is easily shown lie in the interval $(-\infty, k_2^2]$. Thus $L_{\xi} + i\delta$ is invertible on $L^2(\mathbb{R})$ provided $\delta \neq 0$, and also if $\delta = 0$, but $|\xi| > k_2$. Indeed it is also invertible with $\delta = 0$, for all but finitely ξ with $k_1 < |\xi| < k_2$. Because it is self adjoint we have the norm estimate for $(L_{\xi} + i\delta)^{-1} = R_{\xi,\delta}$

$$||R_{\xi,\delta}|| \le \frac{1}{\operatorname{dist}(\xi^2 - i\delta, (-\infty, k_2^2])} \le \begin{cases} \frac{1}{|\delta|} \text{ for } |\xi| < k_2, \\ \frac{1}{\sqrt{(\xi^2 - k_2^2)^2 + \delta^2}} \text{ for } |\xi| \ge k_2. \end{cases}$$
(227)

If $f \in L^2(\mathbb{R}^2)$, then the L^2 -solution to $(D_q + i\delta)u = f$ is given by

$$u(x_1, x_2) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{i\xi x_1} R_{\xi,\delta}(\tilde{f})(x_2) d\xi,$$
(228)

where

$$\tilde{f}(\xi, x_2) = \int_{-\infty}^{\infty} f(x_1, x_2) e^{-i\xi x_1} dx_1.$$
(229)

Using Plancherel's formula and (227) we see that, for $\delta \neq 0$,

$$\int_{\mathbb{R}^2} |u(x_1, x_2)|^2 dx \le \frac{1}{2\pi} \int_{\mathbb{R}^2} \frac{|\tilde{f}(\xi, x_2)|^2}{\delta^2 + (\xi^2 - k_2^2)_+^2} dx_2 d\xi \le \frac{1}{\delta^2} \int_{\mathbb{R}^2} |f(x_1, x_2)|^2 dx.$$
(230)

If q = 0, then the limit of (228) as $\delta \to 0^+$, is just Sommerfeld's integral expressing the outgoing fundamental solution to $\Delta + k_1^2$ as a Fourier transform in the x_1 -variable.

Relation (221) shows that

$$W(\xi, \delta) = 2u_{+}(\xi, \delta; 0)\partial_{x_{2}}u_{+}(\xi, \delta; 0);$$
(231)

from (223) we conclude that

$$W(\xi,\delta) = 2i(a_0^2 - b_0^2)\sqrt{k_2^2 - \xi^2 + i\delta}.$$
(232)

It follows from Remark 5 and (231) that $W(\xi, 0^+) = \lim_{\delta \to 0^+} W(\xi, \delta)$ has an analytic extension to the open set, \mathcal{U} , and, for $\pm \sqrt{\xi^2 - i\delta} \in \mathcal{U}$,

$$W(\xi,\delta) = W(\sqrt{\xi^2 - i\delta}, 0^+).$$
(233)

Suppose that $W(\xi_0, \delta) = 0$; this happens if and only if

$$\widetilde{u}_{+}(\xi_{0},\delta;x_{2}) = c\widetilde{u}_{-}(\xi_{0},\delta;x_{2}) = c\widetilde{u}_{+}(\xi_{0},\delta;-x_{2}),$$
(234)

for some non-zero constant c. For $x_2 < 0$, this shows

$$\widetilde{u}_{-}(\xi_0,\delta;x_2) = e^{-ix_2\sqrt{k_1^2 - \xi_0^2 + i\delta}}.$$
(235)

If $\delta > 0$, then $\operatorname{Im} \sqrt{k_1^2 - \xi_0^2 + i\delta} > 0$, and therefore $\widetilde{u}_+(\xi_0, \delta; x_2) \in L^2(\mathbb{R})$, would be an L^2 -eigenvector with eigenvalue $k_1^2 - \xi_0^2 + i\delta$. As $\partial_{x_2}^2 + k_1^2 + q(x_2)$ is self-adjoint, its spectrum is real, and therefore such roots cannot exist. If a relation like (234) holds, then $\delta = 0$.

If $k_1^2 - \xi_0^2 < 0$, then

$$\operatorname{Im} \sqrt{k_1^2 - \xi_0^2} = \lim_{\delta \to 0^+} \operatorname{Im} \sqrt{k_1^2 - \xi_0^2 + i\delta} > 0.$$
(236)

hence

$$\widetilde{u}_{-}(\xi_0, 0^+; x_2) = e^{x_2\sqrt{\xi_0^2 - k_1^2}},$$
(237)

which decays exponentially as $x_2 \to -\infty$. The function, $\tilde{u}_+(\xi_0, 0^+; x_2)$ is an L^2 -eigenfunction of $\partial_{x_2}^2 + k_1^2 + q(x_2)$ with eigenvalue ξ_0^2 .

Definition 2. A *wave-guide* solution is a function $v \in H^2(\mathbb{R})$ that is a solution to

$$\partial_{x_2}^2 v - \xi^2 v + (k_1^2 + q(x_2))v = 0, (238)$$

which satisfies the estimate

$$|v(x_2)| \le Ce^{-\sqrt{\xi^2 - k_1^2}|x_2|}$$
 for $|x_2| > d$. (239)

The functions $e^{\pm i\xi x_1}v(x_2)$ are solutions to the homogeneous equation $D_q u = 0$. These solutions are strongly localized within the channel $|x_2| < d$. The solution with $0 < \xi$ is a right-ward moving wave, and that with $\xi < 0$ is left-ward moving. In Appendix A.1 we prove the following theorem.

Theorem 2. If $0 < k_1 < k_2$, for $\xi \in \mathbb{R}$, and $\delta \ge 0$, there are finitely many simple solutions, $\{\pm \xi_n : n = 1, ..., N\}$, to the equation

$$W(\xi,\delta) = 0, \tag{240}$$

all of which satisfy $\delta = 0^+$, and

$$k_1 < |\xi_n| < k_2. \tag{241}$$

These are the only solutions to equation (240). For $0 < k_1 < k_2$, and any d > 0, there is at least one non-trivial solution to $W(\xi, 0^+) = 0$.

The number of solutions, N, is a non-decreasing function of d, the width of the channel.

Remark 6. In the sequel we assume that $0 < k_1 < \xi_n < k_2$, for n = 1, ..., N. We can show that

$$\lim_{\delta \to 0^+} (\xi - \xi_n) R_{\xi_n, \delta} \tilde{f}(x_2) = \frac{\widetilde{u}_+(\xi_n, 0^+; x_2) \langle \widetilde{u}_+(\xi_n, 0^+; \cdot), \tilde{f} \rangle}{cW_{\xi}(\xi_n)},$$
(242)

where c is defined in (234). Following §2.6 of [13], we conclude that

$$v_n(x_2) = \frac{\widetilde{u}_+(\xi_n, 0^+; \cdot)}{\sqrt{|cW_{\xi}(\xi_n)|}}$$
(243)

has L^2 -norm 1.

Our main interest is in analyzing the behavior of solutions to $(D_q + i\delta)u_{\delta} = f$ as $\delta \to 0^+$. In general, the limiting solution does not belong to $L^2(\mathbb{R}^2)$ and will not exist unless f satisfies certain conditions. In Appendix A.2 we prove the following estimates on the limits of the kernels of $(L_{\xi} + i\delta)^{-1}$ as $\delta \to 0^+$.

Theorem 3. For $|\xi| > k_2$, we have the following estimates for the resolvent kernel:

$$|R_{\xi,0^{+}}(x_{2}, y_{2})| \leq C \cdot (1 + |\xi|)^{-1} \times \begin{cases} e^{-\tilde{B}|x_{2}-y_{2}|} \text{ if both } d < |x_{2}| \text{ and } d < |y_{2}|, \\ e^{-\tilde{A}|x_{2}-y_{2}|} \text{ otherwise;} \end{cases}$$
(244)

for $k_1 < |\xi| < k_2$, we have the following estimate

$$|R_{\xi,0^+}(x_2, y_2)| \le C \frac{e^{-\widetilde{B}|x_2 - y_2|}}{\sqrt{|\xi^2 - k_1^2|} \prod_{n=1}^N |\xi^2 - \xi_n^2|},$$
(245)

with analogous estimates for $x_2 < y_2$. If $|\xi| < k_1$, then

$$|R_{\xi,0^+}(x_2, y_2)| \le \frac{C}{\sqrt{|\xi^2 - k_1^2|}}.$$
(246)

Here C are constants independent of x_2, y_2, ξ *, and*

$$\widetilde{A} = \sqrt{\xi^2 - k_2^2}, \ \widetilde{B} = \sqrt{\xi^2 - k_1^2}.$$
 (247)

Remark 7. Somewhat more precise estimates are used in Section 4.

For $\delta \neq 0, u_{\delta} \in H^2(\mathbb{R}^2)$, and the PDE, $(D_q + i\delta)u_{\delta} = f$, is equivalent to

$$(L_{\xi} + i\delta)\widetilde{u}_{\delta} = f, \text{ for } \xi \in \mathbb{R},$$
 (248)

which implies that

$$\widetilde{u}_{\delta}(\xi, \cdot) = R_{\xi,\delta} \widetilde{f}(\xi, \cdot).$$
(249)

We consider what happens where the Wronskian vanishes. Using (234), we see that at such a root the limit of $W(\xi,\delta)R_{\xi,\delta}\tilde{f}$ satisfies

$$\lim_{\delta \to 0^+} W(\xi_0, \delta) R_{\xi_0, \delta}(\tilde{f}) = \frac{1}{c} \int_{-\infty}^{\infty} \widetilde{u}_+(\xi_0, 0^+; x_2) \widetilde{u}_+(\xi_0, 0^+; y_2) \widetilde{f}(\xi_0, y_2) dy_2.$$
(250)

From this relation it is clear that in order for $\lim_{\delta \to 0^+} R_{\xi_0,\delta} \tilde{f}(\xi_0,\cdot)$ to exist, where $W(\xi_0, 0^+) = 0$, it would be necessary for

$$\int_{-\infty}^{\infty} \tilde{u}_{+}(\xi_0, 0^+; y_2) \tilde{f}(\xi_0, y_2) dy_2 = 0.$$
(251)

In fact, we are only interested in the inverse Fourier transform,

$$\lim_{\delta \to 0^+} \frac{1}{2\pi} \int_{-\infty}^{\infty} R_{\xi,\delta}(\tilde{f})(\xi, x_2) e^{i\xi x_1} d\xi,$$
(252)

which may well have a limit even if $\lim_{\delta \to 0^+} R_{\xi,\delta}(\tilde{f})(\xi, x_2)$ does not exist for all real ξ . This is because for data analytic in ξ we can deform the contour and avoid the singularities at $\{\pm \xi_n\}$.

Proposition 5. Suppose that $\pm k_1$ are not roots of $W(\xi, 0^+)$. If f satisfies the following properties:

- *1.* The supp $f \subset \mathbb{R} \times [-L, L]$ for some finite L.
- 2. For each $x_2 \in [-L, L]$, the distributional partial Fourier transform of f in the x_1 -variable, $\tilde{f}(\cdot, x_2)$, is in $L^1_{loc}(\mathbb{R})$, and in $L^2(\mathbb{R} \setminus [-k_2, k_2])$.
- 3. The function $\xi \to \tilde{f}(\xi, x_2)$ has an analytic extension to \mathcal{U} , a complex neighborhood of $(-k_2, -k_1) \cup (k_1, k_2)$.
- 4. $\tilde{f}(\xi, x_2) \in L^1_{\text{loc}}(\mathbb{R}^2)$.

In this case the limit

$$v_{0+}(x_1, x_2) = \lim_{\delta \to 0^+} \frac{1}{2\pi} \int_{-\infty}^{\infty} R_{\xi,\delta}(\tilde{f})(\xi, x_2) e^{i\xi x_1} d\xi$$
(253)

exists in $H^2_{loc}(\mathbb{R}^2)$ and defines an outgoing solution to $D_q v_{0+} = f$.

Proof. For $\delta > 0$, the integral on the right hand side of (253), which we denote v_{δ} , satisfies

$$(D_q + i\delta)v_\delta = f. \tag{254}$$

Under the hypotheses on f we can express the Fourier transform in x_1 as

$$R_{\xi,\delta}[\tilde{f}(\xi,\cdot)](x_2) = \frac{U_{\xi,\delta}[\tilde{f}(\xi,\cdot)](x_2)}{W(\xi,\delta)} = \frac{U_{\sqrt{\xi^2 - i\delta},0^+}[f(\xi,\cdot)](x_2)}{W(\sqrt{\xi^2 - i\delta},0^+)}.$$
 (255)

In light of Remark 5, and the fact that the integrals defining $U_{\sqrt{\xi^2 - i\delta}, 0^+}[\tilde{f}(\xi, \cdot)](x_2)$ extend over a compact interval, this function has an analytic extension as a function of ξ to the neighborhood, \mathcal{U} , of $(-k_2, -k_1) \cup (k_1, k_2)$. The denominator also has an analytic extension, with simple zeroes at $\{\pm \sqrt{\xi_n^2 + i\delta} : n = 1, \ldots, N\}$. Those with +-signs lie in the upper half plane near to $\{|\xi_n|\}$.

Let $\nu > 0$ be a small number so that, for all small enough δ , tending to 0^+ , the numerator, $U_{\xi,\delta}[\tilde{f}(\xi,\cdot)](x_2)$, is analytic in

$$\mathcal{B}_{2\nu} = \bigcup_{n=1}^{N} D_{2\nu}(\xi_n) \cup D_{2\nu}(-\xi_n).$$
(256)

Furthermore, assume that $\nu > 0$ is less than 1/4 the minimum distance between successive values of $\{\pm \xi_n\} \cup \{\pm k_1, \pm k_2\}$. Let Γ_{ν}^+ be the contour, which lies along the real axis, except for semi-circles, in the upper half plane, of radius ν centered

on the zeros (both positive and negative) of $W(\xi, 0^+)$. See Figure 2. For $\delta > 0$, the numerator of the integrand is analytic in the region between the real axis and Γ_{ν}^+ , and the denominator has simple zeroes at $\{\pm \sqrt{\xi_n^2 + i\delta} : n = 1, ..., N\}$, which, for small enough δ , lie in \mathcal{B}_{ν} .

For small enough $\delta > 0$, we can therefore replace the integration along \mathbb{R} in (253) with an integral over the contour Γ^+_{ν} . The residue theorem implies that

$$v_{\delta}(x_{1}, x_{2}) = \frac{1}{2\pi} \int_{-\infty}^{\infty} R_{\xi,\delta}(\tilde{f})(\xi, x_{2}) e^{i\xi x_{1}} d\xi = \frac{1}{2\pi} \int_{\Gamma_{\nu}^{+}} R_{\xi,\delta}(\tilde{f})(\xi, x_{2}) e^{i\xi x_{1}} d\xi + i\sum_{n=1}^{N} \frac{U_{\xi_{n},0^{+}}(\tilde{f})(\sqrt{\xi_{n}^{2} + i\delta}, x_{2}) e^{i\sqrt{\xi_{n}^{2} + i\delta} x_{1}}}{W_{\xi}(\xi_{n}, 0^{+})}.$$
(257)

From this expression it is quite clear that we can let $\delta \to 0^+$, and v_{δ} and its derivatives converge locally uniformly to $v_{0+} = \mathcal{R}_{0+}f$ and its derivatives, with

$$v_{0+}(x_1, x_2) = \frac{1}{2\pi} \int_{\Gamma_{\nu}^+} R_{\xi, 0^+}(\tilde{f})(\xi, x_2) e^{i\xi x_1} d\xi + i \sum_{n=1}^N v_n(x_2) \langle \tilde{f}(\xi_n, \cdot), v_n \rangle e^{i\xi_n x_1},$$
(258)

where the $\{v_n\}$ are defined in Remark 6. Taking the limit in (254) in the weak sense we deduce that $D_q v_{0+} = f$, weakly. The fact that $v_{0+} \in H^2_{loc}$ follows easily from (258), and the estimates in Theorem 3. By elliptic regularity it follows that $D_q v_{0+} = f$ holds in the H^2_{loc} -sense.

As Γ_{ν}^{+} lies in the closed upper half plane, along the semi-circles $e^{i\xi x_{1}}$ is exponentially decaying as $x_{1} \to \infty$. Hence this gives the correct asymptotics as $x_{1} \to \infty$, showing that the guided modes are outgoing to the right. To get the asymptotics as $x_{1} \to -\infty$ we need to replace the contour with Γ_{ν}^{-} , its reflection across the real axis into the lower half plane. Using the analyticity properties of the integrand in the set \mathcal{B}_{ν} , we see that this replaces the sum in (258) with

$$-i\sum_{n=1}^{N}v_n(x_2)\langle \tilde{f}(-\xi_n,\cdot),v_n\rangle e^{-i\xi_nx_1},$$
(259)

which shows that the guided wave contributions are also outgoing to the left.

A.1 Proof of Theorem 2

In this appendix we prove:

Theorem 1. If $0 < k_1 < k_2$, for $\xi \in \mathbb{R}$, and $\delta \ge 0$, there are finitely many simple solutions, $\{\pm \xi_n : n = 1, ..., N\}$, to the equation

$$W(\xi,\delta) = 0, \tag{260}$$

all of which satisfy $\delta = 0^+$, and

$$k_1 < |\xi_n| < k_2. \tag{261}$$

These are the only solutions to equation (260). For $0 < k_1 < k_2$, and any d > 0, there is at least one non-trivial solution to $W(\xi, 0^+) = 0$.

Proof. From the discussion preceding the statement of the theorem in the previous section, it is clear that we only need to consider the case that $k_1^2 < \xi^2 < k_2^2$; we let

$$A = \sqrt{k_2^2 - \xi^2}, \widetilde{B} = \sqrt{\xi^2 - k_1^2}.$$
 (262)

Both A and \widetilde{B} are positive real numbers. To find a_0, b_0 we need to solve the linear system:

$$\begin{pmatrix} e^{iAd} & e^{-iAd} \\ iAe^{iAd} & -iAe^{-iAd} \end{pmatrix} \begin{pmatrix} a_0 \\ b_0 \end{pmatrix} = \begin{pmatrix} e^{-\widetilde{B}d} \\ -\widetilde{B}e^{-\widetilde{B}d} \end{pmatrix}.$$
 (263)

Solving we see that

$$\begin{pmatrix} a_0 \\ b_0 \end{pmatrix} = \frac{ie^{-\widetilde{B}d}}{2A} \begin{pmatrix} (A+i\widetilde{B})e^{-iAd} \\ (A-i\widetilde{B})e^{iAd} \end{pmatrix}.$$
 (264)

Since $W(\xi, 0^+) = 2iA(a_0^2 - b_0^2)$; we have

$$2iA(a_0^2 - b_0^2) = 2ie^{-2\widetilde{B}d}[(A^2 - \widetilde{B}^2)\frac{\sin 2dA}{2A} - \widetilde{B}\cos 2dA].$$
 (265)

But for the points $\xi = \pm k_2, \pm \sqrt{(k_1^2 + k_2^2)/2}$ the equation $a_0^2 - b_0^2 = 0$ is equivalent to

$$\tan 2d\sqrt{k_2^2 - \xi^2} = \frac{2\sqrt{(k_2^2 - \xi^2)(\xi^2 - k_1^2)}}{k_1^2 + k_2^2 - 2\xi^2}.$$
 (266)

Since this is an analytic equation (at least on a Riemann surface covering \mathbb{C}) the set of solutions is discrete. Indeed, for a given d, there is a finite set of points

$$\{k_1 \le \xi_j \le k_2 : j = 1, \dots, N\},\$$

which solve this equation. Clearly $\{-\xi_j\}$ are also solutions.

(a) Plot showing left and right sides (b) Plot showing left and right sides of (266) with d = 0.05. (b) Plot showing left and right sides of (266) with d = 0.8.

Figure 5: Zeros of the Wronskian with $k_1 = 16, k_2 = 18$.

The right hand side of (266) goes from 0 to $+\infty$ for $\xi \in [k_1, \sqrt{(k_1^2 + k_2^2)/2})$, and from $-\infty$ to $0 \xi \in (\sqrt{(k_1^2 + k_2^2)/2}, k_2]$. The left hand side of (266) vanishes at $\xi = k_2$, and therefore, no matter how small $d\sqrt{k_2^2 - k_1^2}$ is, the graph of the left hand side crosses that of the right hand side for some value of $\xi \in (k_1, k_2)$. See Figure 5(a).

If

$$d\sqrt{2(k_2^2 - k_1^2)} = \frac{\pi}{2} + (n - 1)\pi, \text{ for some } n \in \mathbb{N},$$
 (267)

then $\xi = \pm \sqrt{(k_1^2 + k_2^2)/2}$ are roots of $A(a_0^2 - b_0^2) = 0$. It is easy to see that $\xi = \pm k_2$ are never solutions to $A(a_0^2 - b_0^2) = 0$. It is possible that $\xi = \pm k_1$ are roots, but only if

$$2d\sqrt{k_2^2 - k_1^2} = n\pi \text{ for some } n \in \mathbb{N}.$$
(268)

That (266) has no positive solutions less than k_1 follows from the observation that, for $|\xi| < k_1$, the right hand side is a non-zero imaginary number, and the left hand side is real. For $\xi > k_2$, the left and right hand sides of (266) are purely imaginary numbers with opposite signs. Hence, all roots of $W(\xi)$ lie in the intervals $(-k_2, -k_1] \cup [k_1, k_2)$.

Figure 5 shows plots of the two sides of (266) (left in blue, right in red) on a single graph, with $k_1 = 16$, $k_2 = 18$ and d = 0.05 and 0.8.

A.2 Proof of Theorem 3

In this appendix we prove:

Theorem 2. For $|\xi| > k_2$, we have the following estimates for the resolvent kernel:

$$|R_{\xi,0^{+}}(x_{2}, y_{2})| \leq C \cdot (1 + |\xi|)^{-1} \times \begin{cases} e^{-\tilde{B}|x_{2}-y_{2}|} \text{ if both } d < |x_{2}| \text{ and } d < |y_{2}|, \\ e^{-\tilde{A}|x_{2}-y_{2}|} \text{ otherwise;} \end{cases}$$
(269)

for $k_1 < |\xi| < k_2$, we have the following estimate

$$|R_{\xi,0^+}(x_2, y_2)| \le C \frac{e^{-B|x_2 - y_2|}}{\sqrt{|\xi^2 - k_1^2|} \prod_{n=1}^N |\xi^2 - \xi_n^2|},$$
(270)

with analogous estimates for $x_2 < y_2$. If $|\xi| < k_1$, then

$$|R_{\xi,0^+}(x_2, y_2)| \le \frac{C}{\sqrt{|\xi^2 - k_1^2|}}.$$
(271)

Here C are constants independent of x_2, y_2, ξ *, and*

$$\widetilde{A} = \sqrt{\xi^2 - k_2^2}, \ \widetilde{B} = \sqrt{\xi^2 - k_1^2}.$$
 (272)

Proof. Since $R_{\xi,0^+}(x_2, y_2) = \overline{R_{\xi,0^+}(y_2, x_2)}$, it suffices to consider the case $y_2 < x_2$. Using the calculations above we see that the Wronskian is given by (265):

$$W(\xi, 0^{+}) = e^{2id\sqrt{k_{1}^{2} - \xi^{2}}} \left[(k_{1}^{2} + k_{2}^{2} - 2\xi^{2}) \frac{\sin 2Ad}{A} + 2i\sqrt{k_{1}^{2} - \xi^{2}} \cos 2dA \right]$$
for $|\xi| < k_{1}$, (273)

along with $\sqrt{k_1^2 - \xi^2} = i\sqrt{\xi^2 - k_1^2}$ for $|\xi| > k_1$. We see that the Wronskian has square root singularities at $\pm k_1$, though not at $\pm k_2$. For $|\xi| > k_2$

$$W(\xi, 0^{+}) = \frac{(3k_{1}^{2} + k_{2}^{2} - 4\xi^{2})e^{2d(\sqrt{\xi^{2} - k_{2}^{2}} - \sqrt{\xi^{2} - k_{1}^{2}})}}{\sqrt{\xi^{2} - k_{1}^{2}}} + O(e^{-2d(\sqrt{\xi^{2} - k_{2}^{2}} + \sqrt{\xi^{2} - k_{1}^{2}})}).$$
(274)

Since

$$\sqrt{\xi^2 - k_2^2} - \sqrt{\xi^2 - k_1^2} = \frac{k_1^2 - k_2^2}{\sqrt{\xi^2 - k_2^2} + \sqrt{\xi^2 - k_1^2}},$$
(275)

we see that there is a constant C > 0 so that

$$|W(\xi, 0^+)| > C|\xi| \text{ for } |\xi| > k_2.$$
(276)

As we are principally interested in the behavior of these solutions as $|\xi| \rightarrow \infty$, we begin by assuming that $|\xi| > k_2$, and rewrite the relations defining these coefficients as

$$\widetilde{u}_{+}(\xi, , 0^{+}; x_{2}) = \begin{cases} e^{-x_{2}\widetilde{B}} \text{ for } x_{2} > d, \\ a_{0}e^{-x_{2}\widetilde{A}} + b_{0}e^{x_{2}\widetilde{A}} \text{ for } |x_{2}| < d, \\ a_{-}e^{-x_{2}\widetilde{B}} + b_{-}e^{x_{2}\widetilde{B}} \text{ for } x_{2} < -d. \end{cases}$$
(277)

As $|\xi| > k_2$,

$$\widetilde{A} = \sqrt{\xi^2 - k_2^2}, \ \widetilde{B} = \sqrt{\xi^2 - k_1^2}.$$
 (278)

are positive real numbers. The jump relations imply

$$\begin{pmatrix} a_0 \\ b_0 \end{pmatrix} = -\frac{1}{2\widetilde{A}} \begin{pmatrix} (\widetilde{A} + \widetilde{B})e^{(\widetilde{A} - \widetilde{B})d} \\ (\widetilde{A} - \widetilde{B})e^{-(\widetilde{A} + \widetilde{B})d} \end{pmatrix},$$
(279)

and

$$\binom{a_{-}}{b_{-}} = \frac{1}{4\widetilde{A}\widetilde{B}} \begin{pmatrix} (\widetilde{A}^{2} - \widetilde{B}^{2})e^{-2(\widetilde{A} + \widetilde{B})d} - (\widetilde{A} + \widetilde{B})^{2}e^{2(\widetilde{A} - \widetilde{B})d} \\ (\widetilde{A}^{2} - \widetilde{B}^{2})e^{2\widetilde{A}d} - (\widetilde{A} - \widetilde{B})^{2}e^{-2\widetilde{A}d} \end{pmatrix}.$$
(280)

From (279)–(280) we see that these coefficients are functions asymptotically homogeneous of degree 0, as $|\xi| \to \infty$, times exponentials, which together with $1/W(\xi, 0^+)$, are bounded by the function on the first line of (269). Below we refer to these sorts of algebraic terms as "prefactors."

We need to consider the products $u_+(\xi, , 0^+; x_2)u_+(\xi, , 0^+; -y_2)$ for $y_2 < x_2$ in various ranges. To simplify the notation we largely suppress explicit mention of ξ in the computations below. We start with 2 observations:

- 1. $\widetilde{A} < \widetilde{B}$.
- 2. $0 < \widetilde{B} \widetilde{A} = \frac{(k_2^2 k_1^2)}{\widetilde{A} + \widetilde{B}} \le \frac{K}{|\xi|}$, for a positive constant K.

We start with the case $y_2 < x_2 < -d$, where

$$u_{+}(x_{2})u_{+}(-y_{2}) = e^{y_{2}\widetilde{B}}(a_{-}e^{-x_{2}\widetilde{B}} + b_{-}e^{x_{2}\widetilde{B}}),$$
(281)

which gives

$$\frac{1}{4\widetilde{A}\widetilde{B}} \Big[e^{-(x_2 - y_2)\widetilde{B}} [(\widetilde{A}^2 - \widetilde{B}^2) e^{-2(\widetilde{A} + \widetilde{B})d} - (\widetilde{A} + \widetilde{B})^2 e^{2(\widetilde{A} - \widetilde{B})d}] + e^{(x_2 + y_2)\widetilde{B}} [(\widetilde{A}^2 - \widetilde{B}^2) e^{2\widetilde{A}d} - (\widetilde{A} - \widetilde{B})^2 e^{-2\widetilde{A}d}] \Big].$$
(282)

Since $x_2 - y_2 > 0$, $x_2 + y_2 < -2d$, it follows easily from 1. and 2. that, away from $x_2 = y_2$, all terms are bounded by a prefactor times $e^{-\tilde{B}(x_2-y_2)}$.

We now consider $y_2 < -d < x_2 < d$:

$$u_{+}(x_{2})u_{+}(-y_{2}) = e^{y_{2}\widetilde{B}}(a_{0}e^{-x_{2}\widetilde{A}} + b_{0}e^{x_{2}\widetilde{A}}) = -\frac{1}{2\widetilde{A}} \Big[e^{-x_{2}\widetilde{A}+y_{2}\widetilde{B}}(\widetilde{A}+\widetilde{B})e^{(\widetilde{A}-\widetilde{B})d} + e^{x_{2}\widetilde{A}+y_{2}\widetilde{B}}(\widetilde{A}-\widetilde{B})e^{-(\widetilde{A}+\widetilde{B})d} \Big]$$
(283)

The first term is exponentially decaying away from $x_2 = y_2 = -d$, as $\widetilde{A} < \widetilde{B}$ and $d - x_2 \leq 2d$, $y_2 - d \leq -2d$. The second term is exponentially decaying as $x_2 - d \leq 0$. Indeed all terms are bounded by a prefactor times $e^{-\widetilde{A}(x_2-y_2)}$.

Next we consider $-d < y_2 < x_2 < d$:

$$u_{+}(x_{2})u_{+}(-y_{2}) = (a_{0}e^{-x_{2}\tilde{A}} + b_{0}e^{x_{2}\tilde{A}})(a_{0}e^{y_{2}\tilde{A}} + b_{0}e^{-y_{2}\tilde{A}})$$

$$= a_{0}^{2}e^{-(x_{2}-y_{2})\tilde{A}} + a_{0}b_{0}[e^{(x_{2}+y_{2})\tilde{A}} + e^{-(x_{2}+y_{2})\tilde{A}}] + b_{0}^{2}e^{(x_{2}-y_{2})\tilde{A}}.$$

(284)

Inserting the coefficients gives

$$\frac{1}{4\tilde{A}^{2}} \Big[(\tilde{A} + \tilde{B})^{2} e^{2(\tilde{A} - \tilde{B})d} e^{-(x_{2} - y_{2})\tilde{A}} + (\tilde{A}^{2} - \tilde{B}^{2}) e^{-2\tilde{B}d} \Big[e^{(x_{2} + y_{2})\tilde{A}} + e^{-(x_{2} + y_{2})\tilde{A}} \Big] + (\tilde{A} - \tilde{B})^{2} e^{-2(\tilde{A} + \tilde{B})d} e^{(x_{2} - y_{2})\tilde{A}} \Big].$$
(285)

A careful examination shows that this term remains bounded as $\widetilde{A} \to 0$. Fact 2. above and $y_2 < x_2$ shows that first term is exponentially decreasing away from $x_2 = y_2$. As $|x_2 \pm y_2| \le d$ and $\widetilde{A} < \widetilde{B}$ the second term is exponentially decaying, as is the third term. All terms are bounded by a prefactor times $e^{-\widetilde{A}(x_2-y_2)}$.

In case $y_2 < -d < d < x_2$, $u_+(x_2)u_+(-y_2) = e^{-\tilde{B}(x_2-y_2)}$, which obviously satisfies the desired estimate.

Next we turn to $-d < y_2 < d < x_2$ which gives

$$u_{+}(x_{2})u_{+}(-y_{2}) = e^{-x_{2}\widetilde{B}}(a_{0}e^{y_{2}\widetilde{A}} + b_{0}e^{-y_{2}\widetilde{A}})$$

$$= -\frac{1}{2\widetilde{A}} \Big[e^{-x_{2}\widetilde{B}+y_{2}\widetilde{A}}(\widetilde{A}+\widetilde{B})e^{(\widetilde{A}-\widetilde{B})d} + e^{-x_{2}\widetilde{B}-y_{2}\widetilde{A}}(\widetilde{A}-\widetilde{B})e^{-(\widetilde{A}+\widetilde{B})d} \Big].$$
(286)

The first term decays exponentially as $\widetilde{A} < \widetilde{B}$ and $x_2 + d > y_2 + d$; as does the second term since $y_2 + d \ge 0$. Indeed all terms are bounded by a prefactor times $e^{-\widetilde{A}|x_2-y_2|}$.

This leaves the final case $d < y_2 < x_2$:

$$u_{+}(x_{2})u_{+}(-y_{2}) = e^{-x_{2}\widetilde{B}}(a_{-}e^{y_{2}\widetilde{B}} + b_{-}e^{-y_{2}\widetilde{B}})$$

$$= \frac{1}{4\widetilde{A}\widetilde{B}} \left[e^{-(x_{2}-y_{2})\widetilde{B}}[(\widetilde{A}^{2}-\widetilde{B}^{2})e^{-2(\widetilde{A}+\widetilde{B})d} - (\widetilde{A}+\widetilde{B})^{2}e^{2(\widetilde{A}-\widetilde{B})d}] + e^{-(x_{2}+y_{2})\widetilde{B}}[(\widetilde{A}^{2}-\widetilde{B}^{2})e^{2\widetilde{A}d} - (\widetilde{A}-\widetilde{B})^{2}e^{-2\widetilde{A}d}] \right]$$
(287)

The first term is exponentially decaying away from $x_2 = y_2$; the second term is as well because $\widetilde{A} < \widetilde{B}$ and $2d \le x_2 + y_2$. Indeed all terms are bounded by a prefactor times $e^{-\widetilde{B}|x_2-y_2|}$.

Altogether we have shown that $u_+(\xi, , 0^+; x_2)u_+(\xi, , 0^+; -y_2)\chi(\{y_2 < x_2\})$ satisfies the estimates in (269). The estimate for the other term in the resolvent kernel, $u_+(\xi, , 0^+; -x_2)u_+(\xi, , 0^+; y_2)\chi(\{y_2 > x_2\})$, follows from the symmetry of the kernel. Using these formulæ we easily establish the estimate in (270). The estimate for $|\xi| < k_1$ follows easily from the fact the eigenfunctions \tilde{u}_{\pm} are bounded and oscillatory in this range.
