# Approximating the density of states for Poisson distributed random Schrödinger operators 

David Hasler ${ }^{1 *}$ Jannis Koberstein ${ }^{1 \dagger}$<br>1. Department of Mathematics, Friedrich Schiller University Jena<br>Jena, Germany

#### Abstract

We consider a Schrödinger operator with random potential distributed according to a Poisson process. We show that expectations of matrix elements of the resolvent as well as the density of states can be approximated to arbitrary precision in powers of the coupling constant. The expansion coefficients are given in terms of expectations obtained by Neumann expanding the potential around the free Laplacian. One can control these expansion coefficients in the infinite volume limit. We show that for this limit the boundary value as the spectral parameter approaches the real axis exists as well. Our results are valid for arbitrary strength of the disorder parameter, including the small disorder regime.

## 1 Introduction

Random Schrödinger operators are a class of mathematical models describing transport properties in solids, which are subject to some form of disorder. Starting with the seminal paper of Anderson [PW58] in 1958 such models have intensively been investigated. Various physical as well as mathematical properties have been shown for this model. In particular various localization properties have been established mathematically rigorous, starting with [FS83] see also [AM93]. Specifically, for large disorder existence of dense pure point spectrum with exponentially localized eigenfunctions has been proven. In this paper we focus on the small disorder regime. In this regime much less is known. One conjectures

[^0]that this regime exhibits extended states, i.e., absolutely continuous spectrum. A few results have been obtained supporting this conjecture, cf. AK92; Kle98; FHS06; ASW06; FHS07; AW13] for results on the Bethe lattice. Nevertheless, the common belief is that there is a phase transition of some form between the regime of large disorder and small disorder.

The density of states has been studied intensively for such operators. The boundedness of the density of states follows from a so called optimal Wegner estimate. A Wegner estimate [Weg81] gives an upper bound on the number of expected eigenvalues in an interval. It is optimal if the bound is proportional to the volume and the interval length. Wegner estimates have been obtained for various models, cf. KM82; CHK03; CHK07; KM07; EH12]. In particular, for Poisson distributed random Potential a Wegner estimate has been obtained which is optimal in the interval size but not in the volume [CH94]. Note that it is possible to turn Wegner estimates which are not optimal in the volume into an optimal in the volume estimate in exchange for optimality in the interval length, cf. [HL13]. For typical Wegner estimates, the proportionality constant is of the magnitude of the inverse disorder strength. This gives a good estimate for large disorder. However for small disorder, such estimates do not seem optimal. For this reason we follow a different approach.

In this paper, we study a Laplacian in $\mathbb{R}^{d}$ with a Poisson distributed random potential. Such random potentials are used to model amorphous materials like glass or rubber. We consider expansions of the expectation value of the interacting resolvent in terms of the free resolvent. In particular, we show that the expectation of the interacting resolvent can be approximated in terms of expectations involving the free resolvent with arbitrary precision. We then show that the density of states can be approximated to arbitrary precision using this expansion as well. The estimates are uniform in the disorder strength in a bounded interval around zero. Finally, we show that the expansion coefficients have infinite volume limits which are finite as the spectral parameter approaches the real axis within the spectrum of the free Laplacian.

The present paper complements the work [HK22]. While the main result, Theorem 2.3 stands completely on its own, Corollary 2.5 uses results from HK22]. To obtain our result, we expand the resolvent in a Neumann Series by treating the random potential as a perturbation of the free Laplacian. Then we calculate the expectation and show that these expansion coefficients are finite in an infinite volume limit. The techniques which we use are inspired by [ESY07a; ESY07b; ESY08]. A related expansion method of the resolvent has been used in [MPR97; MPR98; Poi99]. A typical challenge in such an analysis is to obtain a suitable estimate on the combinatorics of the expansion terms.

In this paper we focus directly on the error term. The error estimate of our main result shows that this expansion technique gives the correct answer to arbitrary order.

This manuscript is structured as follows. In the next section we introduce the model and state the main results. The proofs are given in Section 3. In the appendix we collect a few results, which we need for the proofs.

## 2 Model and Statement of Main Results

In this section we introduce the model and state the main results on the expectation of the resolvent. We note that the definition of the model follows the one given in [ESY08] closely. We consider a finite box of size $L>0$ and define the box $\Lambda_{L}:=\left[-\frac{1}{2} L, \frac{1}{2} L\right)^{d} \subset \mathbb{R}^{d}$, where $d \in \mathbb{N}$ denotes the spacial dimension. Let $\langle\cdot, \cdot\rangle_{L^{2}\left(\Lambda_{L}\right)}$ and $\|\cdot\|_{L^{2}\left(\Lambda_{L}\right)}$ denote the canonical scalar product and the norm of the Hilbert space $L^{2}\left(\Lambda_{L}\right)$. If it is clear from the context what the inner product or the norm is, we shall occasionally drop the subscript $L^{2}\left(\Lambda_{L}\right)$. To introduce the periodic Laplacian operator on this space it is convenient to work in terms of Fourier series. For this, let $\Lambda_{L}^{*}=\left(\frac{1}{L} \mathbb{Z}\right)^{d}=\left\{\left(k_{1}, \ldots, k_{d}\right): \forall j=1, \ldots, d, \exists m_{j} \in\right.$ $\left.\mathbb{Z},: k_{j}=\frac{m_{j}}{L}\right\}$ denote the so-called dual lattice. We introduce the notation

$$
\begin{equation*}
\int_{\Lambda_{L}^{*}} f(p) d p:=\frac{1}{\left|\Lambda_{L}\right|} \sum_{p \in \Lambda_{L}^{*}} f(p) . \tag{2.1}
\end{equation*}
$$

The sum $\int_{\Lambda_{L}^{*}} f(p) d p$ can be interpreted as a Riemann-sum, which converges to the integral $\int f(p) d p$ as $L \rightarrow \infty$, provided $f$ has sufficient decay at infinity and sufficient regularity. For a subset $S \subset \Lambda_{L}^{*}$ we set $\int_{S, *} f(p) d p:=\left|\Lambda_{L}\right|^{-1} \sum_{p \in S} f(p)$. Furthermore, we introduce the notation for the canonical norm in the $\ell^{q}$-spaces. For $f \in \ell^{q}\left(\Lambda_{L}^{*}\right)$ with $q \in[1, \infty]$, we write

$$
\|f\|_{*, q}=\left(\int_{\Lambda_{L}^{*}}|f(k)| d k\right)^{1 / q}(1 \leq q<\infty), \quad\|f\|_{*, \infty}=\sup _{k \in \Lambda_{L}^{*}}|f(k)|
$$

For compactness of notation we shall denote $\|\cdot\|_{*, 2}$ simply by $\|\cdot\|_{*}$.
For any $f \in L^{1}\left(\Lambda_{L}\right)$ we define the Fourier series

$$
\hat{f}(p)=\int_{\Lambda_{L}} e^{-2 \pi i p \cdot x} f(x) d x \text { for } p \in \Lambda_{L}^{*}
$$

Further, for $g \in \ell^{1}\left(\Lambda_{L}^{*}\right)$ we define the inverse

$$
\check{g}(x)=\int_{\Lambda_{L}^{*}} e^{2 \pi i p \cdot x} g(p) d p=\frac{1}{\left|\Lambda_{L}\right|} \sum_{p \in \Lambda_{L}^{*}} e^{2 \pi i p \cdot x} g(p) \text { for } x \in \Lambda_{L} .
$$

Note that $(\cdot)$ extends uniquely to a continuous linear map from $\ell^{2}\left(\Lambda_{L}^{*}\right)$ to $L^{2}\left(\Lambda_{L}\right)$. We shall denote this extension again by the same symbol. This extension maps $\ell^{2}\left(\Lambda_{L}^{*}\right)$ unitarily to $L^{2}\left(\Lambda_{L}\right)$ and it is the inverse of $\left(\left.\hat{(\cdot)}\right|_{L^{2}\left(\Lambda_{L}\right)}\right.$, see for example [Fol13, Theorem 8.20]. In physics literature, one might be familiar with the notation where $L^{2}\left(\Lambda_{L}\right)$ represents the position space, while $\ell^{2}\left(\Lambda_{L}^{*}\right)$ would be called momentum space, or Fourier space. For $p \in \Lambda_{L}^{*}$ and $x \in \Lambda_{L}$, we define

$$
\begin{equation*}
\varphi_{p}(x)=\left|\Lambda_{L}\right|^{-1 / 2} e^{i 2 \pi p \cdot x} . \tag{2.2}
\end{equation*}
$$

Observe that $\left\{\varphi_{p}: p \in \Lambda_{L}^{*}\right\}$ is an orthonormal Basis (ONB) of $L^{2}\left(\Lambda_{L}\right)$ Fol13, Theorem 8.20] and that $\hat{f}(p)=\left|\Lambda_{L}\right|^{1 / 2}\left\langle\varphi_{p}, f\right\rangle_{L^{2}\left(\Lambda_{L}\right)}$.

When restricting the Laplacian to a finite box, we choose periodic boundary conditions, which will be technically convenient when working in momentum space. Therefore, we are going to introduce the Laplacian with periodic boundary conditions on $L^{2}\left(\Lambda_{L}\right)$ by means of Fourier series. In this paper, we shall adapt the standard convention that for a vector $a=\left(a_{1}, \ldots, a_{d}\right)$ we use the notation $a^{2}:=|a|^{2}$ where $|a|:=\sqrt{\sum_{j=1}^{d}\left|a_{j}\right|^{2}}$. In that sense, we define the energy function

$$
\begin{equation*}
\nu: \mathbb{R}^{d} \rightarrow \mathbb{R}_{+}, \quad p \mapsto \nu(p):=\frac{1}{2} p^{2} \tag{2.3}
\end{equation*}
$$

which we can now use to define $-\Delta_{L}$ as the linear operator with domain

$$
D\left(-\Delta_{L}\right)=\left\{f \in L^{2}\left(\Lambda_{L}\right): \nu \hat{f} \in \ell^{2}\left(\Lambda_{L}^{*}\right)\right\},
$$

and the mapping rule

$$
\begin{equation*}
-\Delta_{L}: D\left(-\Delta_{L}\right) \rightarrow L^{2}\left(\Lambda_{L}\right), \quad f \mapsto-\Delta_{L} f=(2 \pi)^{2}(\nu \hat{f})^{\vee} \tag{2.4}
\end{equation*}
$$

Observe that $-\Delta_{L}$ is self-adjoint, since it is unitary equivalent to a multiplication operator by a real valued function, and that we have the identity

$$
\begin{equation*}
\left[-\frac{1}{2(2 \pi)^{2}} \Delta_{L} f\right]^{\wedge}(p)=\nu(p) \hat{f}(p) . \tag{2.5}
\end{equation*}
$$

By

$$
\begin{equation*}
H_{L}:=H_{\lambda, L}:=-\frac{\hbar^{2}}{2 m} \Delta_{L}+\lambda V_{L} \tag{2.6}
\end{equation*}
$$

we denote a random Schrödinger operator acting on $L^{2}\left(\Lambda_{L}\right)$ with a random potential $V_{L}=V_{L, \omega}(x)$, defined below, and a coupling constant $\lambda \geq 0$. As in [ESY08] we choose units for the mass $m$ and Planck's constant so that $\frac{\hbar^{2}}{2 m}=\left[2(2 \pi)^{2}\right]^{-1}$. For a function
$h: \mathbb{R}^{d} \rightarrow \mathbb{C}$ we denote by $h_{\#}$ the $L$-periodic extension of $\left.h\right|_{\Lambda_{L}}$ to $\mathbb{R}^{d}$. The potential is given by

$$
\begin{equation*}
V_{L, \omega}(x):=\int_{\Lambda_{L}} B_{\#}(x-y) d \mu_{L, \omega}(y) \tag{2.7}
\end{equation*}
$$

where $B$, having the physical interpretation as a single site potential profile, is assumed to be a real valued Schwartz function on $\mathbb{R}^{d}$. Moreover, we assume that either $B$ has compact support or that $B$ is symmetric with respect to the reflections of the coordinate axis, i.e. for $j=1, \ldots, d$,

$$
\begin{align*}
\mathfrak{S}_{j}:\left(x_{1}, \ldots, x_{j}, \ldots, x_{d}\right) & \mapsto\left(x_{1}, \ldots,-x_{j}, \ldots, x_{d}\right)  \tag{2.8}\\
B \circ \mathfrak{S}_{j} & =B .
\end{align*}
$$

Remark 2.1. Each of the two conditions is mathematically convenient in the sense that they ensure sufficiently fast decay of the Fourier transform. Further the reflection symmetry condition is satisfied by rationally invariant potentials, which occur naturally.

Furthermore, let $\mu_{L, \omega}$ be a Poisson point measure on $\Lambda_{L}$ with homogeneous unit density and with independent indentically distributed (i.i.d.) random masses. More precisely, for almost all events $\omega$, it consists of $M$ points $\left\{y_{L, \gamma}(\omega) \in \Lambda_{L}: \gamma=1,2, \ldots, M\right\}$, where $M=M(\omega)$ is a Poisson variable with expectation $\left|\Lambda_{L}\right|$, and $\left\{y_{L, \gamma}(\omega)\right\}$ are i.i.d. random variables uniformly distributed on $\Lambda_{L}$. Both are independent of the random i.i.d. weights $\left\{v_{\gamma}: \gamma=1,2, \ldots\right\}$ and the random measure is given by

$$
\mu_{L, \omega}=\sum_{\gamma=1}^{M(\omega)} v_{\gamma}(\omega) \delta_{y_{L, \gamma}(\omega)},
$$

where $\delta_{y}$ denotes the Dirac mass at the point $y$. Note that the case where $M(\omega)=0$ corresponds to a vanishing potential. Note that for convenience the notation will not reflect the dependence on the specific choice of the common distribution of the weights $\left\{v_{\gamma}\right\}$. We assume that the moments

$$
\begin{equation*}
m_{k}:=\mathbf{E} v_{\gamma}^{k} \tag{2.9}
\end{equation*}
$$

satisfy

$$
\begin{equation*}
m_{k}<\infty, \quad \text { for all } k \in \mathbb{N} . \tag{2.10}
\end{equation*}
$$

For some of the results we will use that the first moment $m_{1}=\mathbf{E} v_{\gamma}$ vanishes. Observe that we can write (2.7) as

$$
\begin{equation*}
V_{L, \omega}(x)=\sum_{\gamma=1}^{M} V_{L, \gamma}(x) \quad \text { with } \quad V_{L, \gamma}(x):=v_{\gamma} B_{\#}\left(x-y_{L, \gamma}\right) . \tag{2.11}
\end{equation*}
$$

The expectation with respect to the joint measure of $\left\{M, y_{L, \gamma}, v_{\gamma}\right\}$ is denoted by $\mathbf{E}_{L}$. Sometimes we will use the notation

$$
\begin{equation*}
\mathbf{E}_{L}=\mathbf{E}_{M} \mathbf{E}_{y_{L}}^{\otimes M} \mathbf{E}_{v}^{\otimes M} \tag{2.12}
\end{equation*}
$$

referring to the expectation of $M,\left\{y_{L, \gamma}\right\}$ and $\left\{v_{\gamma}\right\}$ separately. In particular, $\mathbf{E}_{y}^{\otimes M}$ stands for the normalized integral

$$
\begin{equation*}
\frac{1}{\left|\Lambda_{L}\right|^{M}} \int_{\left(\Lambda_{L}\right)^{M}} d y_{1} \cdots d y_{M} \tag{2.13}
\end{equation*}
$$

Since the potential is almost surely bounded it follows by standard perturbation theorems, e.g. the Kato-Rellich theorem [RS75], that the operator (2.6) is almost surely self-adjoint for all $\lambda \geq 0$.

The main object of our interest is the expectation of matrix values of the resolvent

$$
\begin{equation*}
\mathbf{E}_{L}\left\langle\psi_{1},\left(H_{L}-z\right)^{-1} \psi_{2}\right\rangle \quad \text { for } \psi_{1}, \psi_{2} \in L^{2}\left(\Lambda_{L}\right) \tag{2.14}
\end{equation*}
$$

as the spectral parameter approaches the real axis. Note that (2.14) is the expectation of the interacting resolvent, which is difficult to study. To analyze (2.14) we will use a Neumann expansion to express the interacting resolvent as the sum of products of powers of the potential and the resolvent of the periodic Laplacian, $\Delta_{L}$. For notational compactness we shall denote the resolvent of $-\Delta_{L}$ by

$$
R_{L}(z):=\left(-\frac{\hbar^{2}}{2 m} \Delta_{L}-z\right)^{-1}
$$

where $z \in \mathbb{C} \backslash[0, \infty)$. Note that we use a notation for the resolvent of the free Laplacian, which one might expect for the interacting one.

For $z \in \mathbb{C} \backslash[0, \infty)$ and $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{d}\right)$ we define

$$
\begin{equation*}
T_{n, L}\left[z ; \psi_{1}, \psi_{2}\right]:=\mathbf{E}_{L}\left\langle\psi_{1, \#}, R_{L}(z)\left[V_{L} R_{L}(z)\right]^{n} \psi_{2, \#}\right\rangle \tag{2.15}
\end{equation*}
$$

By definition the potential is almost surely bounded. Thus (2.15) is well defined almost surely. To state the results we will define the infinite volume Fourier transform and inverse Fourier transform for $f \in L^{1}\left(\mathbb{R}^{d}\right)$

$$
\hat{f}(k)=\int_{\mathbb{R}^{d}} f(x) e^{-2 \pi i k \cdot x} d x, \quad k \in \mathbb{R}^{d}
$$

and

$$
\check{f}(x)=\int_{\mathbb{R}^{d}} f(k) e^{2 \pi i k \cdot x} d k, \quad x \in \mathbb{R}^{d}
$$

respectively.
Next we state a result that shows that the matrix elements of the resolvent of the Hamiltonian can be calculated to arbitrary precision in terms of the expansion coefficients $T_{n, L}$ defined in (2.15). The error estimate which we obtain is uniform in the volume $\Lambda_{L}$. To obtain the result we use a Du Hamel expansion and a combinatorical estimate. To formulate the main theorems we introduce the following hypothesis and the subsequent definition.

Hypothesis A. The random potential v satisfies that there exists a constant $C$ such that

$$
m_{n}:=\mathbf{E}\left(|v|^{n}\right) \leq C
$$

for all $n \in \mathbb{N}$.
In addition we will work with a regularization function, whose properties are as follows.
Definition 2.2. Let $\chi: \mathbb{R} \rightarrow[0,1]$ is a $C_{c}^{\infty}(\mathbb{R})$ be a function such $\chi=1$ on $[-1,1]$ and $\chi(t)=0$ for $|t| \geq 2$. Let $\chi_{a}(t):=\chi($ at $)$ for all $a, t \in \mathbb{R}$.

A proof of the existence of such a regularization function can be found in Hör15, Theorem 1.4.1] for example. We can now state the first main result of this paper.

Theorem 2.3. Suppose Hypothesis $\mathbf{A}$ holds. Let $\eta>0, \varepsilon>0$, and $\lambda_{0}>0$. Then there exists an $N=N\left(\varepsilon, \eta, \lambda_{0}\right) \in \mathbb{N}$ such that for all $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{3}\right), E \in \mathbb{R}, \lambda \in\left[-\lambda_{0}, \lambda_{0}\right]$, and $L \geq 1$

$$
\begin{equation*}
\left|\mathbf{E}_{L}\left\langle\psi_{1, \#},\left(H_{\lambda}-(E+i \eta)\right)^{-1} \psi_{2, \#}\right\rangle-\sum_{n=0}^{N} \lambda^{n} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]\right| \leq \varepsilon\left\|\psi_{1, \#}\right\|_{*}\left\|\psi_{2, \#}\right\|_{*}, \tag{2.16}
\end{equation*}
$$

where we defined

$$
\begin{equation*}
S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]:=(-1)^{n} \int_{\mathbb{R}} \widehat{\chi}_{a(\eta, \varepsilon)}(\alpha) T_{n, L}\left[E+i \eta+2 \pi \alpha ; \psi_{1}, \psi_{2}\right] d \alpha \tag{2.17}
\end{equation*}
$$

and

$$
\begin{equation*}
a:=a(\eta, \varepsilon):=\frac{\eta}{\left|\ln \left(\frac{\eta \varepsilon}{2}\right)\right|+1} . \tag{2.18}
\end{equation*}
$$

The proof of 2.3 will be given in Section 3 ,

Remark 2.4. We note that the typical form of the so called Wegner estimate gives an upper bound of the order $|\lambda|^{-1}$. The trivial estimate A.5 gives a bound $\eta^{-1}$. Thus by interpolation we find that the resolvent in the above expression is bounded by $\lambda^{-1+c} \eta^{-c}$ for any $c \in[0,1]$. Theorem 2.3 allows to choose $\varepsilon$ arbitrary small, e.g., much smaller than $\lambda^{-1+c} \eta^{-c}$. Thus Theorem 2.3 allows to determine the resolvent to arbitrary good precision.

As a corollary of Theroem [2.3 we can approximate the density of states up to arbitrary precision. To formulate the corollary we introduce the notation

$$
\begin{equation*}
f_{E, \eta}(x)=\frac{\eta}{(x-E)^{2}+\eta^{2}} \tag{2.19}
\end{equation*}
$$

For this we assume $d \leq 3$, which is necessary to describe the density of states in terms of the real part of the resolvent, by means of (2.19), and to ensure at the same time that the trace in (2.20) is well defined. Let $\operatorname{Tr}_{L}$ denote the trace with respect to $L^{2}\left(\Lambda_{L}\right)$.

Corollary 2.5. Let $d \leq 3$. Suppose Hypothesis $\mathbf{A}$ holds. Assume that the support of the distribution of $v_{\alpha}$ is contained in $(0, \infty)$. Let $\eta>0, \varepsilon>0, E>0$, and $\lambda_{0}>0$. Then there exists $N=N\left(\varepsilon, \eta, \lambda_{0}\right) \in \mathbb{N}$ and a number $\kappa=\kappa\left(\varepsilon, \eta, \lambda_{0}\right)>0$ such that for all $\lambda \in\left[0, \lambda_{0}\right]$, $E \in \mathbb{R}$, and $L \geq 1$

$$
\begin{equation*}
\left|\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \operatorname{Tr}_{L} f_{E, \eta}\left(H_{\lambda}\right)-\sum_{n=0}^{N} \int_{|q| \leq \kappa, *} \lambda^{n} \operatorname{Im} S_{n, L}\left[E+i \eta ; \chi ; \varphi_{q}, \varphi_{q} ; \varepsilon\right] d q\right| \leq \varepsilon \tag{2.20}
\end{equation*}
$$

with coefficients defined in (2.17) and (2.18).
The proof of Corollary 2.5 will be given in Section 3 .
Remark 2.6. Although the estimate of Corollary 2.5allows us to approximate the density of states to arbitrary precision in terms of expectations of products of the free resolvent, we do not have a priori control on the large $N$ behavior of the expression

$$
\begin{equation*}
\sum_{n=0}^{N} \int_{|q| \leq \kappa, *} \lambda^{n} \operatorname{Im} S_{n, L}\left[E+i \eta ; \chi ; \varphi_{q}, \varphi_{q} ; \varepsilon\right] d q \tag{2.21}
\end{equation*}
$$

uniformly in $\eta \in\left(0, \eta_{0}\right]$ for some $\eta_{0}>0$. It would be interesting to establish control of the growth of (2.21) directly or its infinite volume limit, cf. ESY07a; ESY07b; ESY08] for an analysis in this direction. Nevertheless, the estimate (2.20) shows that the expansion (2.21) converges. In fact, a Wegner estimate which is optimal in volume as well as interval length for the Poisson distributed random Potential, as considered in this paper, would imply the convergence of the infinite volume limit of (2.21), by means of (2.20).

Finally, we analyze the expansion coefficients (2.17) more closely using results from [HK22]. First, we will show that their infinite volume limit exists and, second, we show that the infinite volume limit is in fact finite as the spectral parameter approaches the real axis. Before we address this, we need to make sure that the limit $L \rightarrow \infty$ indeed exists. To this end we use results from [HK22]. The next theorem shows that for each expansion coefficient the infinite volume limit exists and gives an upper bound dependent on the spectral parameter for each expansion coefficient.

Theorem $2.7(\lfloor\mathrm{HK} 22])$. Let $n \in \mathbb{N}$. For all $z \in \mathbb{C} \backslash[0, \infty)$, and $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{d}\right)$ the limit $\lim _{L \rightarrow \infty} T_{n, L}\left[z ; \psi_{1}, \psi_{2}\right]$ exists in $\mathbb{C}$. There exists a constant $K_{n}$ such that the inequality

$$
\begin{equation*}
\left|T_{n, L}\left[z ; \psi_{1}, \psi_{2}\right]\right| \leq \frac{K_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\|}{\operatorname{dist}(z,[0, \infty))^{n+1}} \tag{2.22}
\end{equation*}
$$

holds for all $L \geq 1, z \in \mathbb{C} \backslash[0, \infty)$, and $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{d}\right)$.
Due to Theorem 2.7, we can define the infinite volume limit of the expansion coefficients

$$
\begin{equation*}
T_{n, \infty}\left[z ; \psi_{1}, \psi_{2}\right]:=\lim _{L \rightarrow \infty} T_{n, L}\left[z ; \psi_{1}, \psi_{2}\right], \tag{2.23}
\end{equation*}
$$

for any $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{d}\right)$ and $z \in \mathbb{C} \backslash[0, \infty)$. Theorem 2.7 can also be used to calculate the $L \rightarrow \infty$ limit of $S_{n, L}$.

Proposition 2.8. Suppose Hypothesis $\mathbf{A}$ holds. Let $E>0$ and $\eta>0$. Then for (2.17) with (2.18) we find

$$
\begin{equation*}
\lim _{L \rightarrow \infty} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]=\int_{\mathbb{R}} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \tag{2.24}
\end{equation*}
$$

Proof. Using the estimate in (2.22) of Theorem [2.7 we obtain an $L^{1}$-bound for the integrand on the LHS found in (2.17). Now the statement follows from the dominated convergence theorem.

To state the next result about the expansion coefficients of the resolvent (2.23), we need some regularity assumptions for the profile function and the wave functions with respect to which we calculate the matrix element of the resolvent. These regularity assumptions are formulated in terms of so called analytic dilations, cf. [CT73; RS78]. Let us first introduce the group of dilations.

Definition 2.9. The group of unitary operators $u(\theta)$ on $L^{2}\left(\mathbb{R}^{d}\right)$ given by

$$
\begin{equation*}
(u(\theta) \psi)(x)=e^{\frac{d \theta}{2}} \psi\left(e^{\theta} x\right) \quad \text { for } \theta \in \mathbb{R} \tag{2.25}
\end{equation*}
$$

is called the group of dilation operators on $\mathbb{R}^{d}$.

It is straightforward to verify that $\mathbb{R} \mapsto \mathcal{B}\left(L^{2}\left(\mathbb{R}^{d}\right)\right), \theta \mapsto u(\theta)$ is indeed a strongly continuous one parameter group of unitary operators, cf. [RS72, Page 265]. Observe that from the definition of the Fourier transform and the dilation operator it is easy to see that for any $\psi \in L^{2}\left(\mathbb{R}^{d}\right)$ and all $\theta \in \mathbb{R}$

$$
\begin{equation*}
(u(\theta) \psi)^{\wedge}=u(-\theta) \hat{\psi} \tag{2.26}
\end{equation*}
$$

Analogously to [HK22] we assume the following hypotheses. First we state a hypothesis about the profile function needed for Theorem 2.10, below.

Hypothesis B. There exists $\vartheta_{B}>0$ such that the Fourier transform, $\hat{B}$, of the Schwartz function $B$ satisfies that for $p=1$ and $p=\infty$ the function $\mathbb{R} \rightarrow L^{p}\left(\mathbb{R}^{d}\right), \theta \mapsto \widehat{B}_{\theta}:=$ $(u(\theta) B)^{\wedge}$ has an extension to an analytic function $D_{\vartheta_{B}}:=\left\{z \in \mathbb{C}:|z|<\vartheta_{B}\right\} \rightarrow L^{p}\left(\mathbb{R}^{d}\right)$.

Let us now state the hypothesis about the wave function with respect to which we shall calculate matrix elements of the resolvent in Theorem 2.10 below.

Hypothesis C. For the vector $\psi \in L^{2}\left(\mathbb{R}^{d}\right)$ and there exists $\vartheta_{\psi}>0$ such that the transform $\hat{\psi}$ satisfies that the function $\mathbb{R} \rightarrow L^{p}\left(\mathbb{R}^{d}\right), \theta \mapsto \widehat{\psi}_{\theta}:=\widehat{\psi}\left(e^{\theta} \cdot\right)$ has an extension to an analytic function $D_{\vartheta_{\psi}}:=\left\{z \in \mathbb{C}:|z|<\vartheta_{\psi}\right\} \rightarrow L^{2}\left(\mathbb{R}^{d}\right)$.

In [HK22] we give examples of functions satisfying Hypothesis C.
We can now state the result from [HK22], which established the existence of the boundary value of the expansion coefficients.
Theorem 2.10 ([HK22]). Suppose Hypothesis $B$ holds and suppose $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{d}\right)$ satisfy Hypothesis C. Then for any $E>0$ the following limit exists as a finite complex number

$$
T_{n, \infty}\left[E \pm i 0^{+} ; \psi_{1}, \psi_{2}\right]:=\lim _{\eta \downarrow 0} T_{n, \infty}\left[E \pm i \eta ; \psi_{1}, \psi_{2}\right] .
$$

Moreover, $z \mapsto T_{n, \infty}\left[z ; \psi_{1}, \psi_{2}\right]$ as a function on $\mathbb{C}_{+}:=\{z \in \mathbb{C}: \Im(z)>0\}$ has a continuous extension to a function on $\mathbb{C}_{+} \cup\{z \in \mathbb{C}: \Re(z)>0$ and $\Im(z)=0\}$.

Now using Theorem 2.10 to control the boundary value of the expansion coefficients (2.17), we obtain the following result.

Theorem 2.11. Suppose Hypotheses $\mathbf{A}$ and $\mathbf{B}$ hold. Let $E>0$ and $\varepsilon>0$. Then for all $\psi_{1}, \psi_{2} \in L^{2}\left(\mathbb{R}^{3}\right)$ satisfying Hypothesis $\mathbf{C}$ the limit

$$
\lim _{\eta \downarrow 0} \lim _{L \rightarrow \infty} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]=T_{n}\left[E+i 0^{+} ; \psi_{1}, \psi_{2}\right]
$$

exists, where $S_{n, L}$ is defined in (2.17).
The proof of Theorem 2.11 will be given in Section 3.

## 3 Proof of the Main Results

In this section, we give proofs of Theorem 2.3, Corollary 2.5 and Theorem 2.8, We will start by outlining the basic idea of the proof of Theorem 2.3. First we observe that, by the spectral theorem for $\eta>0$ we have

$$
\begin{equation*}
\left\langle\psi_{1},\left(H_{0}+\lambda V-E-i \eta\right)^{-1} \psi_{2}\right\rangle=i \int_{0}^{\infty}\left\langle\psi_{1}, e^{-i t\left(H_{0}+\lambda V-E-i \eta\right)} \psi_{2}\right\rangle d t \tag{3.1}
\end{equation*}
$$

Using a so called Du Hamel expansion we will determine the time evolution appearing on the RHS of (3.1). To control the Du Hamel expansion for large $t$, we will use the following lemma.

Lemma 3.1. Let $A$ be a self-adjoint operator in a Hilbert space $\mathcal{H}$ and let $\psi_{1}$ and $\psi_{2}$ be normalized vectors in $\mathcal{H}$. Let $\varepsilon>0$. Then, for all $\eta>0$ and $\tau>0$ with

$$
\begin{equation*}
\tau^{-1} \geq \eta^{-1}(-\ln (\eta \varepsilon)) \tag{3.2}
\end{equation*}
$$

we have

$$
\begin{equation*}
\left|i \int_{0}^{\infty} \chi_{\tau}(t)\left\langle\psi_{1}, e^{-i t(A-E-i \eta)} \psi_{2}\right\rangle d t-\left\langle\psi_{1},(A-E-i \eta)^{-1} \psi_{2}\right\rangle\right| \leq \varepsilon \tag{3.3}
\end{equation*}
$$

Proof. Using (3.1) we estimate

$$
\begin{aligned}
& \left|i \int_{0}^{\infty} \chi_{\tau}(t)\left\langle\psi_{1}, e^{-i t(A-E-i \eta)} \psi_{2}\right\rangle d t-\left\langle\psi_{1},(A-E-i \eta)^{-1} \psi_{2}\right\rangle\right| \\
& \leq\left|\int_{0}^{\infty}\left(\chi_{\tau}(t)-1\right)\left\langle\psi_{1}, e^{-i t(A-E-i \eta)} \psi_{2}\right\rangle d t\right| \\
& \leq|\int_{0}^{\infty}\left(\chi_{\tau}(t)-1\right) \underbrace{\left\|\psi_{1}\right\|}_{\leq 1} \underbrace{\left\|e^{-i t(A-E)}\right\|}_{\leq 1}\left\|e^{-t \eta}\right\| \underbrace{\left\|\psi_{2}\right\|}_{\leq 1} d t| \\
& \leq\left|\int_{0}^{\infty}\left(\chi_{\tau}(t)-1\right) e^{-\eta t} d t\right| \\
& \leq \int_{\tau^{-1}}^{\infty} e^{-\eta t} d t=\frac{1}{\eta} e^{-\frac{\eta}{\tau}} \leq \varepsilon
\end{aligned}
$$

using (3.2) in the final step.
The following lemma contains the expansion which we will be used for the proof of Theorem [2.3, which is known as Du Hamel expansion. To formulate the next lemma we recall the inductive definition of the finite product of the first $n$ operators of a sequence of bounded operators $\left(A_{j}\right)_{j \in \mathbb{N}}$

$$
\prod_{j=1}^{1} A_{j}:=A_{1}, \quad \prod_{j=1}^{n+1} A_{j}:=\left(\prod_{j=1}^{n} A_{j}\right) A_{n+1}
$$

Lemma 3.2. Let $\lambda \in \mathbb{R}$, and let $D$ and $W$ be self-adjoint operators on a Hilbert space with $W$ bounded. Then for $t \geq 0$

$$
e^{-i t(D+\lambda W)}=\sum_{n=0}^{N-1}(-i \lambda)^{n} E_{n}(t)+(-i \lambda)^{N} F_{N}(t)
$$

where we defined $E_{0}(t)=e^{-i t D}$ and for $n \geq 1$

$$
\begin{align*}
& E_{n}(t):=\int_{[0, t]^{n}} 1_{\sum_{j=1}^{n} s_{j} \leq t} e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right) D} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d\left(s_{1}, \ldots, s_{n}\right)  \tag{3.4}\\
&=\int_{\mathbb{R}_{+}^{n}} \int_{\mathbb{R}_{+}} \delta\left(\sum_{j=0}^{n} s_{j}-t\right) e^{-i s_{0} D} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d s_{0} d\left(s_{1}, \ldots, s_{n}\right),  \tag{3.5}\\
& F_{n}(t):=\int_{[0, t]^{n}} 1 \sum_{j=1}^{n} s_{j} \leq t  \tag{3.6}\\
& e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right)(D+\lambda W)} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d\left(s_{1}, \ldots, s_{n}\right) .
\end{align*}
$$

where $\delta(s-a) d s:=d \delta_{a}(s)$ denotes the Dirac measure at the point $a$ and the integrals in (3.4), (3.5), and (3.6) are understood as Riemann-integrals with respect to the strong operator topology.

Proof. Let $A=D+\lambda W$. Differentiating $s \mapsto e^{i s H} e^{-i s D}$, integrating from zero to $t$, and multiplying by $e^{-i t A}$ from the right, we find

$$
\begin{equation*}
e^{-i t A}=e^{-i t D}+\int_{0}^{t} e^{-i(t-s) A}(-i \lambda W) e^{-i s D} d s \tag{3.7}
\end{equation*}
$$

This shows the formula for $N=1$. The formula for general $N$ now holds inductively, since inserting (3.7) into the first factor of $F_{n}$ implies that $F_{n}=E_{n}+(-i \lambda) F_{n+1}$, which
can be seen as follows

$$
\begin{aligned}
F_{n}(t)= & \int_{[0, t]^{n}} 1_{\sum_{j=1}^{n} s_{j} \leq t} e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right)(D+\lambda W)} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d\left(s_{1}, \cdots, s_{n}\right) \\
= & \int_{[0, t]^{n}} 1_{\sum_{j=1}^{n} s_{j} \leq t} e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right) D} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d\left(s_{1}, \cdots, s_{n}\right) \\
+ & \int_{[0, t]^{n}} 1_{\sum_{j=1}^{n} s_{j} \leq t} \int_{0}^{t-\sum_{j=1}^{n} s_{j}} \\
& \times e^{-i\left(t-\sum_{j=1}^{n+1} s_{j}\right)(D+\lambda W)}(-i \lambda W) e^{-i s_{n+1} D} \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d s_{n+1} d\left(s_{1}, \cdots, s_{n}\right) \\
= & E_{n}(t)-i \lambda \int_{[0, t]^{n+1}} 1_{\sum_{j=1}^{n+1} s_{j} \leq t} e^{-i\left(t-\sum_{j=1}^{n+1} s_{j}\right)(D+\lambda W)} W e^{-i s_{n+1} D} \\
\times & \prod_{j=1}^{n}\left\{W e^{-i s_{j} D}\right\} d\left(s_{1}, \cdots, s_{n}, s_{n+1}\right) \\
= & E_{n}(t)-i \lambda F_{n+1}(t),
\end{aligned}
$$

where in the last line we used a simple permutation of integration variables. Finally observe that an evaluation of an integral with respect to the Dirac point measure shows that (3.4) and (3.5) are equal.

Remark 3.3. Note that we can estimate the error term of Lemma 3.2 by $\left|F_{N}(t)\right| \leq$ $|\lambda|^{N}\|W\|^{N} \frac{t^{N}}{N!}$. Since the Poisson distributed random potential is not bounded as a measurable function, we need to use a different estimate and work with expectations.

For the proofs of the main results, we shall make use of the representation in momentum space. To this end this we shall expand with respect to the ONB $\varphi_{p}$ defined in (2.2). That is, we shall insert the following identity, which holds in strong operator topology

$$
\begin{equation*}
\psi(x)=\sum_{p \in \Lambda_{L}^{*}}\left\langle\varphi_{p}, \psi\right\rangle \varphi_{p}(x)=\int_{\Lambda_{L}^{*}}\left\langle e^{2 \pi i\langle p,\rangle}, \psi(\cdot)\right\rangle e^{2 \pi i\langle p, x\rangle} d p, \quad x \in \Lambda_{L} \tag{3.8}
\end{equation*}
$$

for all $\psi \in L^{2}\left(\Lambda_{L}\right)$, which provides the representation via the $\operatorname{ONB}\left\{\varphi_{p}: p \in \Lambda_{L}^{*}\right\}$.
To state the next lemma, we are now going to introduce the discrete delta function in momentum space for $u \in \Lambda_{L}^{*}$

$$
\begin{equation*}
\delta_{*}(u)=1_{\{0\}}(u) \tag{3.9}
\end{equation*}
$$

as well as the normalized discrete delta function

$$
\begin{equation*}
\delta_{*, L}(u)=\left|\Lambda_{L}\right| \delta_{*}(u), \tag{3.10}
\end{equation*}
$$

where we used the notation of the characteristic function on a set $A$, i.e. $1_{A}(x)=1$, if $x \in A$, and $1_{A}(x)=0$, if $x \notin A$. Let $\mathcal{A}_{n}$ be the set of partitions of the set $\{1,2, \ldots, n\}$.

Lemma 3.4. For the model introduced in Section 0 we have

$$
\begin{equation*}
\mathbf{E}_{L}\left(\prod_{j=1}^{n} \hat{V}_{L, \omega}\left(p_{j}-p_{j+1}\right)\right)=\sum_{A \in \mathcal{A}_{n}} \prod_{a \in A}\left\{m_{|a|} \delta_{*, L}\left(\sum_{l \in a}\left(p_{l}-p_{l+1}\right)\right) \prod_{l \in a} \hat{B}_{\#}\left(p_{l}-p_{l+1}\right)\right\} . \tag{3.11}
\end{equation*}
$$

For a proof of Lemma 3.4 see [ESY08] or [HK22] respectively.
Proof of Theorem 2.3. Let

$$
\begin{equation*}
a=\frac{\eta}{\left|\ln \left(\frac{\eta \varepsilon}{2}\right)\right|+1} . \tag{3.12}
\end{equation*}
$$

(a) Inserting the Du Hamel expansion as stated in Lemma 3.2 for $D=-\frac{\hbar^{2}}{2 m} \Delta_{L}$ and $W=V_{L}$ into (3.3), we find

$$
\begin{align*}
& \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, e^{-i t\left(D+\lambda V_{L}-E-i \eta\right)} \psi_{2, \#}\right\rangle d t \\
& =\int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, \sum_{n=0}^{N-1}(-i \lambda)^{n} E_{n}(t) e^{i E t-\eta t} \psi_{2, \#}\right\rangle d t  \tag{3.13}\\
& +\int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#},(-i \lambda)^{N} F_{N}(t) e^{i E t-\eta t} \psi_{2, \#}\right\rangle d t \tag{3.14}
\end{align*}
$$

Let us first consider the error term, i.e., the second term in (3.14). Using the definition (3.6), interchanging integrals (which is justified by continuity in $s_{j}$ and the bounded domain of integration for the $s_{j}$ variables), using Cauchy-Schwarz for the inner product
and again for the probability measure $\mathbf{E}_{L}$ we find

$$
\begin{align*}
& \left|\mathbf{E}_{L}\left\langle\psi_{1, \#}, F_{N}(t) e^{i E t-\eta t} \psi_{2, \#}\right\rangle\right| \\
& =\left|\mathbf{E}_{L}\left\langle\psi_{1, \#}, \prod_{j=1}^{N}\left\{\int_{0}^{t} d s_{j}\right\} 1_{\sum_{j=1}^{N} s_{j} \leq t} e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right)\left(D+\lambda V_{L}\right)} \prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} e^{i E t-\eta t} \psi_{2, \#}\right\rangle\right| \\
& =\left|\prod_{j=1}^{N}\left\{\int_{0}^{t} d s_{j}\right\} 1_{\sum_{j=1}^{N} s_{j} \leq t} \mathbf{E}_{L}\left\langle\psi_{1, \#}, e^{-i\left(t-\sum_{j=1}^{n} s_{j}\right)\left(D+\lambda V_{L}\right)} \prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} e^{i E t-\eta t} \psi_{2, \#}\right\rangle\right| \\
& \leq \prod_{j=1}^{N}\left\{\int_{0}^{t} d s_{j}\right\} 1_{\sum_{j=1}^{N} s_{j} \leq t} \mathbf{E}_{L}\left\|\psi_{1, \#}\right\|\left\|\prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} e^{i E t-\eta t} \psi_{2, \#}\right\| \\
& \leq\left\|\psi_{1, \#}\right\| \prod_{j=1}^{N}\left\{\int_{0}^{t} d s_{j}\right\} 1_{\sum_{j=1}^{N} s_{j} \leq t}\left[\mathbf{E}_{L}\left\|\prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} e^{i E t-\eta t} \psi_{2, \#}\right\|^{2}\right]^{1 / 2} \\
& =\left\|\psi_{1, \#}\right\| e^{-\eta t} \prod_{j=1}^{N}\left\{\int_{0}^{t} d s_{j}\right\} 1_{\sum_{j=1}^{N} s_{j} \leq t}\left[\mathbf{E}_{L}\left\|\prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} \psi_{2, \#}\right\|^{2}\right]^{1 / 2} . \tag{3.15}
\end{align*}
$$

To estimate the right hand side, we use (3.8) and (3.11) and Fubini (which can be justified by conditioning over the number $M$ of Poisson points and observing that the conditioned
potentials are bounded and have sufficient decay in Fourier space, cf. Lemma A.2). Hence

$$
\begin{align*}
R & :=\mathbf{E}_{L}\left\|\prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} \psi_{2, \#}\right\|^{2} \\
& =\left|\mathbf{E}_{L}\left\langle\prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} \psi_{2, \#}, \prod_{j=1}^{N}\left\{V_{L} e^{-i s_{j} D}\right\} \psi_{2, \#}\right\rangle\right| \\
& =\mid \mathbf{E}_{L} \int_{\left(\Lambda_{L} *\right)^{2 N+1}} \overline{\hat{\psi}_{2, \#}}\left(p_{1}\right) \prod_{j=1}^{N} e^{i \nu\left(p_{j}\right) s_{N+1-j}} \hat{V}_{L}\left(p_{j}-p_{j+1}\right) \\
& \left.\times \prod_{j=N+1}^{2 N} \hat{V}_{L}\left(p_{j}-p_{j+1}\right) e^{-i \nu\left(p_{j+1}\right) s_{j-N}} \hat{\psi}_{2, \#}\left(p_{2 N+1}\right)\right) d\left(p_{1}, \ldots, p_{2 N+1}\right) \mid \\
& =\mid \int_{\left(\Lambda_{L} *\right)^{2 N+1}} \overline{\hat{\psi}_{2, \#}\left(p_{1}\right)} \hat{\psi}_{2, \#}\left(p_{2 N+1}\right) e^{i \sum_{j=1}^{N} \nu\left(p_{j}\right) s_{N+1-j}} e^{-i \sum_{j=N+1}^{2 N} \nu\left(p_{j+1}\right) s_{j-N}} \\
& \times \sum_{A \in \mathcal{A}_{2 N}} \prod_{a \in A}\left\{m_{|a|} \delta_{*, L}\left(\sum_{l \in a}\left(p_{l}-p_{l+1}\right)\right) \prod_{l \in a} \hat{B}_{\#}\left(p_{l}-p_{l+1}\right)\right\} d\left(p_{1}, \ldots, p_{2 N+1}\right) \mid \\
& \leq \int_{\left(\Lambda_{L} *\right)^{2 N+1}} \sum_{A \in \mathcal{A}_{2 N}} \mid \overline{\hat{\psi}_{2, \#}\left(p_{1}\right)} \hat{\psi}_{2, \#}\left(p_{2 N+1}\right) \\
& \times \prod_{a \in A}\left\{m_{|a|} \delta_{*, L}\left(\sum_{l \in a}\left(p_{l}-p_{l+1}\right)\right) \prod_{l \in a} \hat{B}_{\#}\left(p_{l}-p_{l+1}\right)\right\} \mid d\left(p_{1}, \ldots, p_{2 N+1}\right) . \tag{3.16}
\end{align*}
$$

We introduce a change of variables given by

$$
\begin{equation*}
u_{0}=k_{1}, \quad u_{s}=p_{s+1}-p_{s}, \quad s=1, \ldots, 2 N \tag{3.17}
\end{equation*}
$$

to be able to resolve the discrete delta functions one at a time. Expressing the variables $k$ in terms of the variables $u=\left(u_{0}, \ldots u_{2 N}\right) \in\left(\mathbb{R}^{d}\right)^{2 N+1}$ we find

$$
p_{j}=\sum_{l=0}^{j-1} u_{l}
$$

Applying this change of variables in (3.16) we arrive at

$$
\begin{align*}
R & \leq \int_{\Lambda_{L} *^{2 N+1}} \sum_{A \in \mathcal{A}_{2 N}}\left|\widehat{\widehat{\psi}}_{2, \#}\left(u_{0}\right) \widehat{\psi}_{2, \#}\left(\sum_{l=0}^{2 N} u_{l}\right) \prod_{a \in A}\left\{m_{|a|} \delta_{*, L}\left(\sum_{s \in a} u_{s}\right) \prod_{s \in a} \hat{B}_{\#}\left(-u_{s}\right)\right\}\right| \\
& \times d u_{0} \cdots d u_{2 N} . \tag{3.18}
\end{align*}
$$

At this point, we introduce second change of variables as in [HK22]. For a given partition $A \in \mathcal{A}_{n}$ for $n=2 N$ we define the set of all indices, which are the maximum of a set $a$ by

$$
\begin{equation*}
J_{A}:=\{\max a: a \in A\} \tag{3.19}
\end{equation*}
$$

as well as its complement

$$
\begin{equation*}
I_{A}:=\{1, \ldots, n\} \backslash J_{A} \tag{3.20}
\end{equation*}
$$

Since $A$ is a partition, for any $j \in\{1, \ldots, n\}$ there is a unique set $a \in A$ such that $j \in a$, we denote this set by $a(j)$. We define the map $M_{A}:\left(\mathbb{R}^{d}\right)^{\left|I_{A}\right|} \rightarrow\left(\mathbb{R}^{d}\right)^{n}$ as

$$
\left[M_{A}(v)\right]_{j}:=\left\{\begin{array}{cl}
v_{j} & : j \in I_{A}  \tag{3.21}\\
-\sum_{l \in a(j) \backslash\{j\}} v_{l} & : j \in J_{A},
\end{array}\right.
$$

where $v=\left(v_{1}, \ldots, v_{n}\right)$ with $v_{j} \in \mathbb{R}^{d}$ for all $j \in\{1, \ldots, n\}$. Note that (3.21) contains the case in which $j$ is the only element of $a(j)$ and $\left[M_{A}(v)\right]_{j}=0$ holds. Inserting this change of variables in (3.18) we find

$$
\begin{align*}
R & \leq \sum_{A \in \mathcal{A}_{2 N}} \int_{\Lambda_{L}^{*}} d u_{0} \prod_{l \in I_{A}}\left\{\int_{\Lambda_{L}^{*}} d v_{l}\right\} \mid \widehat{\widehat{\psi}}_{2, \#}\left(u_{0}\right) \widehat{\psi}_{2, \#}\left(u_{0}+\sum_{l=1}^{2 N}\left[M_{A}(v)\right]_{l}\right) \prod_{a \in A}\left\{m_{|a|}\right\}  \tag{3.22}\\
& \times \prod_{j=1}^{2 N} \hat{B}_{\#}\left(-\left[M_{A}(v)\right]_{j}\right) \mid \\
& \leq C^{2 N}\left|\mathcal{A}_{2 N}\right|\left\|\psi_{2, \#}\right\|^{2}\left(\left\|\hat{B}_{\#}\right\|_{*, \infty}+\left\|\hat{B}_{\#}\right\|_{*, 1}\right)^{2 N}, \tag{3.23}
\end{align*}
$$

with $C \geq 1$ such that for all $n \in \mathbb{N}\left|m_{n}\right| \leq C$, which exists by Hypothesis $\mathbf{A}$. In the last step we used the Cauchy-Schwarz inequality for the integration over $u_{0}$ and an $l^{1}$-bound for the integration over the $v_{j}$ variable for $j \in I_{A}$. For compactness of notation we shall write

$$
\begin{equation*}
\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}:=\left\|\hat{B}_{\#}\right\|_{*, \infty}+\left\|\hat{B}_{\#}\right\|_{*, 1} . \tag{3.24}
\end{equation*}
$$

Obeserve that by Lemma A.2, we know that (3.24) is bounded uniformly in $L \geq 1$. Thus, we find from (3.23) that

$$
\begin{equation*}
\sqrt{R} \leq \mathfrak{B}_{2 N}^{1 / 2} C^{N}\left\|\psi_{2, \#}\right\|_{2, *}\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}^{N}, \tag{3.25}
\end{equation*}
$$

where $\mathfrak{B}_{n}$ denotes the Bell number, which counts the number of partitions of a set of $n$ elements. The Bell numbers have the following asymptotic bound [BT10]

$$
\begin{equation*}
\mathfrak{B}_{n}<\left(\frac{0.792 n}{\ln (n+1)}\right)^{n} \tag{3.26}
\end{equation*}
$$

Now inserting (3.25) into (3.15) we find

$$
\begin{align*}
& \left|\mathbf{E}_{L}\left\langle\psi_{1, \#}, F_{N}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle\right| \\
& \leq\left\|\psi_{1, \#}\right\| e^{-\eta t} \int_{[0, t]^{N}} 1_{\sum_{j=1}^{N} s_{j} \leq t} d\left(s_{1}, \ldots, s_{N}\right) \\
& \times \mathfrak{B}_{2 N}^{1 / 2} C^{N}\left\|\psi_{2, \#}\right\|\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}^{N} \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}^{N} C^{N} \mathfrak{B}_{2 N}^{1 / 2} e^{-\eta t} \frac{t^{N}}{N!}, \tag{3.27}
\end{align*}
$$

where we used that the integral in the second line coincides with the volume of the $N$ dimensional standard simplex with side length $t$, which has a volume of $\frac{t^{N}}{N!}$. Using (3.27) to estimate the second term of (3.14) yields

$$
\begin{aligned}
& \left|\int_{0}^{\infty} \mathbf{E}_{L} \chi_{a}(t)\left\langle\psi_{1, \#}, F_{N}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t\right| \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|\left(C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}\right)^{N} \frac{\mathfrak{B}_{2 N}^{1 / 2}}{N!} \int_{0}^{\infty}\left|\chi_{a}(t)\right| t^{N} e^{-\eta t} d t
\end{aligned}
$$

Now using that the support of $\chi_{a}$ is contained in $[-2 / a, 2 / a]$ we can estimate the integral and find

$$
\begin{align*}
& \left|\int_{0}^{\infty} \mathbf{E}_{L} \chi_{a}(t)\left\langle\psi_{1, \#}, F_{N}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t\right| \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|\left(C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}\right)^{N} \frac{\mathfrak{B}_{2 N}^{1 / 2}}{N!} \int_{0}^{2 / a} \underbrace{\left|\chi_{a}(t)\right|}_{\leq 1} t^{N} \underbrace{e^{-\eta t}}_{\leq 1} d t \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|\left(C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}\right)^{N} \frac{\mathfrak{B}_{2 N}^{1 / 2}}{(N+1)!}(2 / a)^{N+1} \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|\left(C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}\right)^{N}\left(\frac{1.584 N}{\ln (2 N+1)}\right)^{N} \frac{1}{(N+1)!}(2 / a)^{N+1} \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\| \frac{2}{a}\left(\frac{3.168 C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}}{a}\right)^{N}\left(\frac{N}{\ln (2 N+1)}\right)^{N} \frac{1}{N!} \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\| \frac{2}{a}\left(\frac{3.168 C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}}{a}\right)^{N}\left(\frac{N}{\ln (2 N+1)}\right)^{N} \frac{e^{N}}{\sqrt{2 \pi N} N^{N}} \\
& \leq\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\| \frac{2}{a}\left(\frac{3.168 e C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}}{a \ln (2 N+1)}\right)^{N} \frac{1}{\sqrt{2 \pi N}} \rightarrow 0, \tag{3.28}
\end{align*}
$$

as $N \rightarrow \infty$, where in the third equality we made use of the asymptotics of the Bell numbers (3.26) and in the second to last equality we applied Sterling's approximation

$$
\begin{equation*}
N!=\sqrt{2 \pi N}\left(\frac{N}{e}\right)^{N}\left(1+\frac{1}{12 N}+o\left(N^{-1}\right)\right) \tag{3.29}
\end{equation*}
$$

Now, we treat the main terms, i.e., the first term in (3.14). A calculation using (3.5) and Fubini shows that

$$
\begin{align*}
& \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, E_{n}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t  \tag{3.30}\\
& =\int_{0}^{\infty} \chi_{a}(t) \int_{\mathbb{R}_{+}^{n+1}} \delta\left(t-\sum_{j=0}^{n} s_{j}\right) \\
& \times\left\langle\psi_{1, \#}, e^{-i s_{0}(D-E-i \eta)} \prod_{j=1}^{n}\left\{V_{L} e^{-i s_{j}(D-E-i \eta)}\right\} \psi_{2, \#}\right\rangle d\left(s_{0}, s_{1} \cdots s_{n}\right) d t \\
& =\int_{\mathbb{R}_{+}^{n+1}} \chi_{a}\left(\sum_{j=0}^{n} s_{j}\right)\left\langle\psi_{1, \#}, e^{-i s_{0}(D-E-i \eta)} \prod_{j=1}^{n}\left\{V_{L} e^{-i s_{j}(D-E-i \eta)}\right\} \psi_{2, \#}\right\rangle d\left(s_{0}, s_{1} \cdots s_{n}\right) \\
& =\int_{\mathbb{R}} \widehat{\chi}_{a}(\alpha) \int_{\mathbb{R}_{+}^{n+1}} e^{2 \pi i \sum_{j=0}^{n} s_{j} \alpha} \\
& \times\left\langle\psi_{1, \#}, e^{-i s_{0}(D-E-i \eta)} \prod_{j=1}^{n}\left\{V_{L} e^{-i s_{j}(D-E-i \eta)}\right\} \psi_{2, \#}\right\rangle d\left(s_{0}, s_{1} \cdots s_{n}\right) d \alpha \\
& =(-i)^{n+1} \int_{\mathbb{R}} \widehat{\chi}_{a}(\alpha) \\
& \times\left\langle\psi_{1, \#},(D-E-2 \pi \alpha-i \eta)^{-1} \prod_{j=1}^{n}\left\{V_{L}(D-E-2 \pi \alpha-i \eta)^{-1}\right\} \psi_{2, \#}\right\rangle d \alpha,
\end{align*}
$$

where in the second to last step we used

$$
\int_{0}^{\infty} e^{-i s x-\eta s} d s=\frac{1}{i x+\eta}=\frac{-i}{x-i \eta}, \quad \eta>0 .
$$

Calculating the expectation of (3.30) using (2.15) we find

$$
\begin{equation*}
\mathbf{E}_{L} \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, E_{n}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t=(-i)^{n+1} \int_{\mathbb{R}} \widehat{\chi}_{a}(\alpha) T_{n, L}\left[E+i \eta+2 \pi \alpha ; \psi_{1}, \psi_{2}\right] . \tag{3.31}
\end{equation*}
$$

Now we collect the previous estimates. Using first the definition of $S_{n, L}$ given in (2.17) together with Eq. (3.31), second Eq. (3.14) and third Lemma 3.1 for $\tau=a$ and (3.28),
we find

$$
\begin{align*}
& \left|\mathbf{E}_{L}\left\langle\psi_{1, \#},\left(H_{\lambda}-E-i \eta\right)^{-1} \psi_{2, \#}\right\rangle-\sum_{n=0}^{N-1} \lambda^{n} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]\right| \\
& =\mid \mathbf{E}_{L}\left\langle\psi_{1, \#},\left(H_{\lambda}-E-i \eta\right)^{-1} \psi_{2, \#}\right\rangle \\
& -i \sum_{n=0}^{N-1}(-i \lambda)^{n} \mathbf{E}_{L} \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, E_{n}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t \mid \\
& \leq\left|\mathbf{E}_{L}\left\langle\psi_{1, \#},\left(H_{\lambda}-E-i \eta\right)^{-1} \psi_{2, \#}\right\rangle-i \mathbf{E}_{L} \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, e^{-i t\left(D+\lambda V_{L}-E-i \eta\right)} \psi_{2, \#}\right\rangle d t\right| \\
& +\left|\lambda^{N} \mathbf{E}_{L} \int_{0}^{\infty} \chi_{a}(t)\left\langle\psi_{1, \#}, F_{N}(t) e^{-i E t-\eta t} \psi_{2, \#}\right\rangle d t\right| \\
& \leq \frac{\varepsilon}{2}\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\|+\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\| \frac{2}{a}\left(\frac{3.168 e C\left\|\hat{B}_{\#}\right\|_{*, 1, \infty}}{a \ln (2 N+1)}\right)^{N} \frac{1}{\sqrt{2 \pi N}}, \tag{3.32}
\end{align*}
$$

as oberved after (3.28) the second term on the right hand side tends to zero for large $N$. This shows (2.16).

We are now going to prove Corollary 2.5,
Proof of Corollary 2.5. Let $\eta>0, E>0$ and $\varepsilon>0$ and $\lambda_{0}>0$. We are going to show below that there exists $\kappa>0$ such that

$$
\begin{align*}
& \left|\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \operatorname{Tr}_{L} f_{E, \eta}\left(H_{\lambda}\right)-\int_{|q| \leq \kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q}, f_{E, \eta}\left(H_{\lambda}\right) \varphi_{q}\right\rangle d q\right| \\
& =\left|\int_{|q|>\kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q}, f_{E, \eta}\left(H_{\lambda}\right) \varphi_{q}\right\rangle d q\right| \leq \frac{\varepsilon}{2} . \tag{3.33}
\end{align*}
$$

With this the statement, i.e., Eq. (2.20), is concluded using Theorem 2.3, as follows: Explicitly, let $M_{\kappa}:=\sup _{L \geq 1} \int_{|q| \leq \kappa, *} 1 d q$. Clearly $M_{\kappa}<\infty$. By Theorem 2.3 for $\varepsilon^{\prime}=\frac{\varepsilon}{2 M_{\kappa}}>$ 0 we can choose an $N=N\left(\varepsilon^{\prime}, \eta, \lambda_{0}\right)$ such that

$$
\begin{align*}
& \left|\mathbf{E}_{L}\left\langle\psi_{1, \#},\left(H_{\lambda}-E-i \eta\right)^{-1} \psi_{2, \#}\right\rangle-\sum_{n=0}^{N} \lambda^{n} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right]\right| \\
& \leq \frac{\varepsilon}{2 M_{\kappa}}\left\|\psi_{1, \#}\right\|\left\|\psi_{2, \#}\right\| . \tag{3.34}
\end{align*}
$$

Now using $f_{E, \eta}\left(H_{\lambda}\right)=\operatorname{Im} \frac{1}{H_{\lambda}-E+i \eta}$ it follows using (3.33), (3.34), and the triangle inequal-
ity that
LHS of (2.20)

$$
\begin{aligned}
& \leq\left|\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \operatorname{Tr}_{L} f_{E, \eta}\left(H_{\lambda}\right)-\int_{|q| \leq \kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q}, f_{E, \eta}\left(H_{\lambda}\right) \varphi_{q}\right\rangle d q\right| \\
& +\left|\int_{|q| \leq \kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q}, f_{E, \eta}\left(H_{\lambda}\right) \varphi_{q}\right\rangle d q-\int_{|q| \leq \kappa, *} \sum_{n=0}^{N} \lambda^{n} \operatorname{Im} S_{n, L}\left[E+i \eta ; \chi ; \varphi_{q}, \varphi_{q} ; \varepsilon\right] d q\right| \\
& \leq \frac{\varepsilon}{2}+\mid \operatorname{Im}\left[\int_{|q| \leq \kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q},\left(H_{\lambda}-E-i \eta\right)^{-1} \varphi_{q}\right\rangle d q\right. \\
& \left.-\int_{|q| \leq \kappa, *} \sum_{n=0}^{N} \lambda^{n} S_{n, L}\left[E+i \eta ; \chi ; \varphi_{q}, \varphi_{q} ; \varepsilon\right] d q\right] \mid \\
& \leq \frac{\varepsilon}{2}+\int_{|q| \leq \kappa, *} 1 d q \frac{\varepsilon}{2 M_{\kappa}}=\varepsilon .
\end{aligned}
$$

Thus, it remains to show (3.33). To this end, let $D_{L}=-\frac{\hbar^{2}}{2 m} \Delta_{L}$. First observe that by the support assumption of $v_{\alpha}$ we have for $\lambda \geq 0$ that with $D_{L}+\lambda V \geq 0$. By the square inequality, we have for all $x \in \mathbb{R}$ and $\eta>0$

$$
\begin{aligned}
(x+1)^{2} & =(x-E)^{2}+2(x-E)(1+E)+(1+E)^{2} \leq 2(x-E)^{2}+2(1+E)^{2} \\
& \leq 2\left((x-E)^{2}+\eta^{2}\right)+2(1+E)^{2} \frac{\eta^{2}}{\eta^{2}}+\frac{2(x-E)^{2}(1+E)^{2}}{\eta^{2}} \\
& =2\left((x-E)^{2}+\eta^{2}\right)\left(1+\frac{(1+E)^{2}}{\eta^{2}}\right) .
\end{aligned}
$$

Hence, by shifting, multiplying by $\eta$ and with $C_{\eta, E}=2\left(\eta+\frac{(1+E)^{2}}{\eta}\right)$, we find

$$
f_{E, \eta}(x)=\frac{\eta}{(x-E)^{2}+\eta^{2}} \leq \frac{C_{\eta, E}}{(x+1)^{2}}
$$

Thus, we find using the spectral theorem

$$
\begin{equation*}
f_{E, \eta}\left(H_{\lambda}\right) \leq \frac{C_{\eta, E}}{\left(D_{L}+\lambda V+1\right)^{2}} \tag{3.35}
\end{equation*}
$$

Next, we estimate the trace of the right hand side of (3.35), when projected onto high momenta. Now (3.35), positivity and writing

$$
\begin{equation*}
\mathcal{I}_{\kappa, L}:=\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{\left(D_{L}+\lambda V+1\right)^{2}} \varphi_{p}\right\rangle \tag{3.36}
\end{equation*}
$$

yield

$$
\begin{equation*}
\left|\int_{|q|>\kappa, *} \mathbf{E}_{L}\left\langle\varphi_{q}, f_{E, \eta}\left(H_{\lambda}\right) \varphi_{q}\right\rangle d q\right| \leq C_{\eta, E} \mathcal{I}_{\kappa, L} \tag{3.37}
\end{equation*}
$$

Applying the second resolvent identity to (3.36), we find

$$
\begin{aligned}
\mathcal{I}_{\kappa, L} & =\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{D_{L}+1} \frac{1}{D_{L}+\lambda V+1} \varphi_{p}\right\rangle \\
& +\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{D_{L}+1} \lambda V \frac{1}{\left(D_{L}+\lambda V+1\right)^{2}} \varphi_{p}\right\rangle \\
& =: \mathcal{E}_{\mathrm{I}}+\mathcal{E}_{\mathrm{II}} .
\end{aligned}
$$

Using the Cauchy Schwarz inequality applied to the trace in the first step and in the second that by the positivity assumption $\left(D_{L}+\lambda V+1\right)^{-1} \leq 1$ holds we find

$$
\begin{aligned}
\left|\mathcal{E}_{\text {II }}\right| & =\left|\frac{1}{\left|\Lambda_{L}\right|} \mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{D_{L}+1} \lambda V \frac{1}{\left(D_{L}+\lambda V+1\right)^{2}} \varphi_{p}\right\rangle\right| \\
& \leq \frac{1}{\left|\Lambda_{L}\right|}\left(\sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{D_{L}+1} \mathbf{E}_{L}(\lambda V)^{2} \frac{1}{D_{L}+1} \varphi_{p}\right\rangle\right)^{1 / 2} \\
& \times\left(\mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{\left(D_{L}+\lambda V+1\right)^{4}} \varphi_{p}\right\rangle\right)^{1 / 2} \\
& \leq \frac{1}{\left|\Lambda_{L}\right|}\left(\sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{D_{L}+1} \mathbf{E}_{L}(\lambda V)^{2} \frac{1}{D_{L}+1} \varphi_{p}\right\rangle\right)^{1 / 2} \\
& \times\left(\mathbf{E}_{L} \sum_{|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{\left(D_{L}+\lambda V+1\right)^{2}} \varphi_{p}\right\rangle\right)^{1 / 2} .
\end{aligned}
$$

To show that $\mathbf{E}_{L}(\lambda V)^{2}$ is uniformly bounded in $L \geq 1$, we have

$$
\begin{align*}
\mathbf{E}_{L} V^{2} & =\mathbf{E}_{L}\left(\sum_{\gamma=1}^{M} v_{\gamma} B_{\#}\left(\cdot-y_{L, \gamma}\right)\right)^{2} \\
& =\mathbf{E}_{L}\left(\sum_{\gamma=1}^{M} \sum_{\beta=1}^{M} v_{\gamma} v_{\beta} B_{\#}\left(\cdot-y_{L, \gamma}\right) B_{\#}\left(\cdot-y_{L, \beta}\right)\right) \\
& =\mathbf{E}_{M}\left(\sum_{\gamma, \beta \in\{1, \ldots, M\}: \gamma \neq \beta} \mathbf{E}_{v}\left(v_{\gamma} v_{\beta}\right) \mathbf{E}_{y} B_{\#}\left(\cdot-y_{L, \gamma}\right) B_{\#}\left(\cdot-y_{L, \beta}\right)\right) \\
& +\mathbf{E}_{M}\left(\sum_{\gamma=1}^{M} \mathbf{E}_{v}\left(v_{\gamma}^{2}\right) \mathbf{E}_{y} B_{\#}\left(\cdot-y_{L, \gamma}\right)^{2} .\right) \tag{3.38}
\end{align*}
$$

To calculate the first term on the right hand side, we use Fubinis theorem and (2.13) with $\gamma \neq \beta$

$$
\begin{align*}
& \mathbf{E}_{y}\left(B_{\#}\left(x-y_{L, \gamma}\right) B_{\#}\left(x-y_{L, \beta}\right)\right) \\
& =\mathbf{E}_{y} \int_{\Lambda_{L}^{*}} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}\left(k^{\prime}\right) e^{2 \pi i k \cdot\left(x-y_{L, \gamma}\right)} e^{2 \pi i k^{\prime} \cdot\left(x-y_{L, \beta}\right)} d k d k^{\prime} \\
& =\frac{1}{\left|\Lambda_{L}\right|^{2}} \int_{\Lambda_{L}^{*}} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}\left(k^{\prime}\right) \int_{\left(\Lambda_{L}\right)^{2}} e^{2 \pi i k \cdot\left(x-y_{1}\right)} e^{2 \pi i k^{\prime} \cdot\left(x-y_{2}\right)} d y_{1} d y_{2} d k d k^{\prime} \\
& =\int_{\Lambda_{L}^{*}} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}\left(k^{\prime}\right) \delta_{k, 0} \delta_{k^{\prime}, 0} d k d k^{\prime} \\
& =\frac{1}{\left|\Lambda_{L}\right|^{2}} \hat{B}_{\#}(0) \hat{B}_{\#}(0) . \tag{3.39}
\end{align*}
$$

and for the second sum

$$
\begin{align*}
& \mathbf{E}_{y}\left(B_{\#}\left(x-y_{L, \gamma}\right) B_{\#}\left(x-y_{L, \gamma}\right)\right) \\
& =\mathbf{E}_{y} \int_{\Lambda_{L}^{*}} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}\left(k^{\prime}\right) e^{2 \pi i k \cdot\left(x-y_{L, \gamma}\right)} e^{2 \pi i k^{\prime} \cdot\left(x-y_{L, \gamma}\right)} d k d k^{\prime} \\
& =\int_{\Lambda_{L}^{*}} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}\left(k^{\prime}\right) e^{2 \pi i k \cdot x} e^{2 \pi i k^{\prime} \cdot x} \delta_{0, k+k^{\prime}} d k d k^{\prime} \\
& =\frac{1}{\left|\Lambda_{L}\right|} \int_{\Lambda_{L}^{*}} \hat{B}_{\#}(k) \hat{B}_{\#}(-k) d k \\
& =\frac{1}{\left|\Lambda_{L}\right|} \int_{\Lambda_{L}}\left|B_{\#}(x)\right|^{2} d x \tag{3.40}
\end{align*}
$$

Now inserting (3.40) and (3.39) into (3.38), for $\beta \neq \gamma$ and using that $\left\{v_{\gamma}\right\}_{\gamma \in \mathbb{N}}$ are i.i.d.
and that by Lemma A.1, $\mathbf{E}_{M} M=\left|\Lambda_{L}\right|$ and $\mathbf{E}_{M}(M(M-1))=\left|\Lambda_{L}\right|^{2}$ hold, we find

$$
\begin{align*}
\mathbf{E}_{L} V^{2} & \leq \mathbf{E}_{M}(M(M-1)) \mathbf{E}_{v}\left(v_{\gamma} v_{\beta}\right)\left|\Lambda_{L}\right|^{-2} \hat{B}_{\#}(0) \hat{B}_{\#}(0) \\
& +\mathbf{E}_{M} M \mathbf{E}_{v}\left(v_{\gamma}^{2}\right)\left|\Lambda_{L}\right|^{-1} \int_{\Lambda_{L}}\left|B_{\#}(x)\right|^{2} d x \\
& \leq\left(\mathbf{E}_{v} v_{\gamma}\right)^{2} \hat{B}_{\#}(0) \hat{B}_{\#}(0)+\mathbf{E}_{v}\left(v_{\gamma}^{2}\right) \int_{\Lambda_{L}}\left|B_{\#}(x)\right|^{2} d x \tag{3.41}
\end{align*}
$$

Thus let

$$
\begin{equation*}
\mathcal{R}_{\kappa, L}:=\frac{1}{\left|\Lambda_{L}\right|} \sum_{p \in \Lambda_{L}^{*}:|p| \geq \kappa}\left\langle\varphi_{p}, \frac{1}{\left(D_{L}+1\right)^{2}} \varphi_{p}\right\rangle=\int_{|p| \geq \kappa, *} \frac{1}{\left(\frac{1}{2} p^{2}+1\right)^{2}} \tag{3.42}
\end{equation*}
$$

Now using the Fourier transfrom an elementary estimate shows that there exists a constant $c$ such that for all $L \geq 1$ and $\kappa \geq 1$ we can estimate RHS of (3.42) in terms of an improper Riemann-integral, cf. Lemma A.3, by

$$
\mathcal{R}_{\kappa, L}=\int_{|p| \geq \kappa, *} \frac{1}{\left(\frac{1}{2} p^{2}+1\right)^{2}} d p \leq \int_{|p| \geq \kappa} \frac{c}{\left(\frac{1}{2} p^{2}+1\right)^{2}} d p
$$

Note that the right hand side is finite for $d \leq 3$. Hence, by dominated convergence

$$
\begin{equation*}
\mathcal{R}_{\kappa, L} \rightarrow 0 \tag{3.43}
\end{equation*}
$$

as $\kappa \rightarrow \infty$ uniformly in $L \geq 1$. Thus we find using Cauchy-Schwarz and the above bounds

$$
\mathcal{I}_{\kappa, L} \leq \mathcal{I}_{\kappa, L}^{1 / 2} \mathcal{R}_{\kappa, L}^{1 / 2}+\left[\mathbf{E}_{L}(\lambda V)^{2}\right]^{1 / 2} \mathcal{I}_{\kappa, L}^{1 / 2} \mathcal{R}_{\kappa, L}^{1 / 2}
$$

Dividing by $\mathcal{I}_{\kappa, L}^{1 / 2}$ and squaring shows that

$$
\begin{equation*}
\mathcal{I}_{\kappa, L} \leq\left(1+\left[\mathbf{E}_{L}(\lambda V)^{2}\right]^{1 / 2}\right)^{2} \mathcal{R}_{\kappa, L} \tag{3.44}
\end{equation*}
$$

Now the right hand side tends to zero uniformly in $L \geq 1$ by (3.43) and (3.41) and therefore

$$
\begin{equation*}
\mathcal{I}_{\kappa, L} \rightarrow 0 \tag{3.45}
\end{equation*}
$$

as $\kappa \rightarrow 0$. Finally (3.33) follows from inserting (3.45) into (3.37).
Next we are ready to give the proof of the regularity of the expansion coefficients.

Proof of Theorem 2.8. From (2.24) we find

$$
\begin{align*}
& \lim _{L \rightarrow \infty} S_{n, L}\left[E+i \eta ; \chi ; \psi_{1}, \psi_{2} ; \varepsilon\right] \\
& =\int_{\mathbb{R}} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \\
& =\int_{\mathbb{R}} 1_{|E+2 \pi \alpha| \leq E / 2} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \\
& +\int_{2 \pi \alpha \leq-\frac{3 E}{2}} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \\
& +\int_{-\frac{E}{2}<2 \pi \alpha} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha, \tag{3.46}
\end{align*}
$$

where the second equality follows from a simple partition of $\mathbb{R}$ into three intervals. The last term in (3.46) has the following limit as $\eta \downarrow 0$ recalling the relation in Eq. (3.12)

$$
\begin{align*}
& \lim _{\eta \downarrow 0} \int_{-\frac{E}{2(2 \pi)}<\alpha} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \\
& =\lim _{\eta \downarrow 0} \int_{\mathbb{R}} \widehat{\chi}(\alpha) 1_{-\frac{E}{2(2 \pi)}<a \alpha} T_{n, \infty}\left[E+2 \pi a \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha \\
& =T_{n, \infty}\left[E+i 0 ; \psi_{1}, \psi_{2}\right] \tag{3.47}
\end{align*}
$$

where the first equality follows by a simple change of variables and for the second equality we used Theorem 2.10, dominated convergence and $\int_{\mathbb{R}} \widehat{\chi}(\alpha) d \alpha=\chi(0)=1$. To estimate the first term of the right hand side of (3.46) we use the bound

$$
\begin{equation*}
\left|T_{n, \infty}\left[\cdot+i \eta ; \psi_{1}, \psi_{2}\right]\right| \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\||\eta|^{-n-1} \tag{3.48}
\end{equation*}
$$

which holds by Theorem 2.10. Since $\chi$ is smooth with compact support its Fourier transform decays faster than any polynomial. More explicitly, for any $m \in \mathbb{N}$ there exists a constant $\tilde{c}_{m}$ such that

$$
\begin{align*}
\left|\hat{\chi}_{a}(s)\right| & =\left|\int_{\mathbb{R}} e^{-2 \pi i s t} \chi(a t) d t\right|=\left|\frac{1}{a} \int_{\mathbb{R}} e^{-2 \pi i(s / a) t} \chi(t) d t\right| \\
& \leq \frac{1}{a} \frac{\tilde{c}_{m}}{1+|s / a|^{m}}=\frac{\tilde{c}_{m} a^{m-1}}{a^{m}+|s|^{n}} \leq \frac{\tilde{c}_{m} a^{m-1}}{|s|^{m}} . \tag{3.49}
\end{align*}
$$

We find using (3.48) and (3.49) with $m=n+3$ and (3.12) that

$$
\begin{align*}
& \left|\int_{\mathbb{R}} 1_{|E+2 \pi \alpha| \leq E / 2} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha\right| \\
& \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\||\eta|^{-n-1} \int_{\mathbb{R}} 1_{|E+2 \pi \alpha| \leq E / 2}\left|\widehat{\chi}_{a}(\alpha)\right| d \alpha \\
& \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\||\eta|^{-n-1} \int_{E /(4 \pi)}^{3 E /(4 \pi)} \frac{\tilde{c}_{m} a^{m-1}}{|\alpha|^{m}} d \alpha \\
& \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\||\eta|^{-n-1} \frac{E}{2 \pi} \frac{\tilde{c}_{m} a^{m-1}}{(E / 4 \pi)^{m}} \\
& \leq \frac{(4 \pi)^{n+3} C_{n} \tilde{c}_{m}}{2 \pi}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\| E^{-n-2} \frac{|\eta|}{(|\ln (\varepsilon \eta / 2)|+1)^{n+3}} \rightarrow 0 \tag{3.50}
\end{align*}
$$

as $\eta \downarrow 0$. To estimate the second term in (3.46) we use for $s>0$ the bound $\left|T_{n, \infty}\left[-s ; \psi_{1}, \psi_{2}\right]\right| \leq$ $C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\| s^{-n}$ from Theorem 2.10. This gives

$$
\begin{align*}
& \left|\int_{2 \pi \alpha \leq-\frac{3 E}{2}} \widehat{\chi}_{a}(\alpha) T_{n, \infty}\left[E+2 \pi \alpha+i \eta ; \psi_{1}, \psi_{2}\right] d \alpha\right| \\
& \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\|(E / 2)^{-n} \int_{2 \pi \alpha \leq-\frac{3 E}{2}}\left|\widehat{\chi}_{a}(\alpha) d \alpha\right| \\
& \leq C_{n}\left\|\psi_{1}\right\|\left\|\psi_{2}\right\|(E / 2)^{-n} \int_{2 \pi \alpha \leq-\frac{3 E}{2 a}}|\widehat{\chi}(\alpha)| d \alpha \rightarrow 0, \tag{3.51}
\end{align*}
$$

where limit as $a \downarrow 0$ (and hence as $\eta \downarrow 0$ ) follows from dominated convergence. Now the claim follows by inserting (3.47), (3.50), (3.51) into (3.46).

## A Appendix

The following lemma is used in the proof of Corollary 2.5.
Lemma A. 1 (HK22]). For a Poisson distributed random variable $N$ with mean $\lambda$ we have for any $k \in \mathbb{N}$

$$
\begin{equation*}
\mathbb{E}\left[\prod_{j=0}^{k-1}(N-j)\right]=\lambda^{k} \tag{A.1}
\end{equation*}
$$

The following Lemma will be used for the proof of Theorem 2.3. For this we introduce the notation

$$
\begin{equation*}
\langle x\rangle=\left(1+x^{2}\right)^{1 / 2} \tag{A.2}
\end{equation*}
$$

Lemma A. 2 ([HK22]). There exists a constant $C_{d}$ (explicitly given in the proof) and a constant $\tilde{C}_{d}$ such that for all $L \geq 1$ and $f \in \mathcal{S}\left(\mathbb{R}^{d}\right)$ which are symmetric with respect to the reflections $\rho_{j}:\left(x_{1}, \ldots, x_{j}, \ldots, x_{d}\right) \mapsto\left(x_{1}, \ldots,-x_{j}, \ldots, x_{d}\right)$ for all $j=1, \ldots, d$ (i.e. $f \circ \rho_{j}=f$ for all $j=1, \ldots, d$ ), we have

$$
\begin{equation*}
\left\langle k_{1}\right\rangle^{2} \cdots\left\langle k_{d}\right\rangle^{2}\left|\widehat{f}_{\#}(k)\right| \leq C_{d} \sum_{\substack{x \in \mathbb{N}_{0}^{d}: \\ \alpha_{j} \leq 2}} \sup _{x \in \mathbb{R}^{d}}\left|\langle x\rangle^{2 d} \partial^{\alpha} f(x)\right| \tag{A.3}
\end{equation*}
$$

for all $k=\left(k_{1}, \ldots, k_{d}\right) \in \mathbb{R}^{d}$. Furthermore $\widehat{f}_{\#} \in \ell_{*}^{1}\left(\Lambda_{L}^{*}\right)$, and

$$
\begin{equation*}
\left\|\widehat{f}_{\#}\right\|_{*, 1} \leq \tilde{C}_{d} \sum_{\substack{\alpha \in \mathbb{N}_{d}^{d}: \\ \alpha_{j} \leq 2}} \sup _{x \in \mathbb{R}^{d}}\left|\langle x\rangle^{2 d} \partial^{\alpha} f(x)\right| . \tag{A.4}
\end{equation*}
$$

We now present two estimates, while the second one is an estimate on a discrete integrals, i.e., infinite sums.

Let us first mention a basic inequality. For any $z \in \mathbb{C}$ we have the elementary bound

$$
\begin{equation*}
\left|z^{-1}\right| \leq|\operatorname{Im} z|^{-1} . \tag{A.5}
\end{equation*}
$$

The following lemma is used in the proof of Corollary 2.5.
Lemma A. 3 (HK22]). Let $I=[-c, c]^{d}$ and $I_{j}, j=1, \ldots, N$, be a partition (up to boundaries) of I into translates of a square $Q$ which is centered at the origin. Let $\xi_{j} \in I_{j}$ and $\Delta x_{j}=\left|I_{j}\right|$. Suppose $g \geq 0$ is a Riemann integrable function on $I$ and we have

$$
\begin{equation*}
\sup _{\xi \in I_{j}} f(\xi) \leq \inf _{\xi \in I_{j}} g(\xi) \tag{A.6}
\end{equation*}
$$

Then

$$
\left|\sum_{i=1}^{N} f\left(\xi_{j}\right) \Delta x_{j}\right| \leq \int_{I} g(x) d x
$$

Proof. The statement follows directly from the theory of Riemann integration.
