

# The Pareto distribution as a disguised Gauss distribution

*Vladimir Pokrovskii*<sup>1</sup>

## Abstract

A simple heuristic model, including the multiple exchanges between economic agents, is used to explain the mechanism of emerging and maintenance of social inequality in the market economy. The model allows calculating a density function of the population distribution over income. The function can be considered as a strongly deformed Gauss distribution function, whereas, at large incomes, it coincides with the Pareto distribution. The external, in relation to the model under consideration, force is necessary to maintain the strong non-equilibrium in a stationary state, and this force is the non-equivalence of elementary exchanges: the agent who already receives the highest income has the advantage: it provokes the rich to be getting more rich and the poor to be getting pauper.

*Key words:* Pareto index, market model, inequality, income distribution, Pareto distribution.

# 1 Introduction

At the end of the nineteenth century, sociologist and economist Wilfredo Pareto studied the distribution of the population of various countries over income and the amount of wealth (Pareto, 1897, pages 299-345) and found that the distribution density function of the individuals  $p(x)$  over income  $x$  in the region of the large values is described by a power function

$$p(x) = Ax^{-(1+\alpha)}. \quad (1)$$

The expression  $p(x)\Delta x$  represents the fraction of people who have the income between  $x$  and  $x + \Delta x$ . The power law (1) has been verified over and over again since then for different countries and at different times; the reliable estimates of the empirical values of index  $\alpha$  in the power distribution (1), according to Ribeiro (2020, p.84), range from 1.2 to 3.2.

The distribution (1), called the Pareto distribution, is not valid, of course, in the region of very small values of income, which are getting the vast majority of people in modern societies, and the problem of finding the shape of the distribution function for those that do not belong to the rich class, according to (Ribeiro, 2020, p. 64), remained basically open. The presented article refers to a simple heuristic model of a market economy, as an assembly of interacting economic agents, in order to calculate the distribution function, including the asymptotic Pareto distribution (1), and thereby to confirm the mechanism of emergence and existence of the wealth inequality. The author relies on a comprehensive review of empirical results and theoretical approaches, which was recently presented by a Brazilian researcher (Ribeiro, 2020).

## 2 Derivation of the distribution function

### 2.1 Heuristic model

Following numerous studies (Ribeiro, 2020), we consider an assembly of agents, each of which is characterized by an income of  $x$ , as a status variable. The market mechanism presupposes free exchange between various economic agents: the efforts of the workers for money, money for products, products for other products, and so on. Under the chaotic interactions, the income of an individual  $x$  can be considered as a random variable, so as a change in the

amount of income  $a$  that is distributed according to the standard Gaussian form, which is assumed to be the same for all individuals

$$w(a, \langle a \rangle, \langle a^2 \rangle) = \left( \frac{1}{2\pi \langle a^2 \rangle} \right)^{\frac{1}{2}} \exp \left[ -\frac{(a - \langle a \rangle)^2}{\langle a^2 \rangle} \right] \quad (2)$$

It is assumed also that the transition probability function can depend on the variable  $x$  through the mean value  $\langle a \rangle$  and standard deviation  $\langle a^2 \rangle$ . The function  $w(a, x)$  is defined as the probability of the agent's transition from the state  $x$  to the state  $x - a$ .

There is a method that allows us to write a kinetic equation for the distribution function, based on the description of elementary transitions from one state to another (see, for example, Lifshitz and Pitaevsky, 1979, chapter 2). In this case, the change in the distribution function can be written as

$$\frac{\partial p(t, x)}{\partial t} = \int_{-\infty}^{+\infty} [w(a, x + a)p(t, x + a) - w(a, x)p(t, x)] da \quad (3)$$

We assume that the change in the income  $a$  is much smaller than its current value,  $a \ll x$ ; based on this, the first term in the integrand (3) can be replaced by the first terms of expansion

$$w(a, x + a)p(t, x + a) \approx w(a, x)p(t, x) + a \left. \frac{\partial(wp)}{\partial x} \right|_{a=0} + a^2 \left. \frac{\partial^2(wp)}{\partial^2 x} \right|_{a=0}.$$

The variables  $a$  and  $x$  are considered independent, and, because of this, the kinetic equation for the distribution function (2) can be written as

$$\frac{\partial p(t, x)}{\partial t} = \frac{\partial}{\partial x} \left[ \left( \langle a \rangle + \frac{\partial \langle a^2 \rangle}{\partial x} \right) p + \langle a^2 \rangle \frac{\partial p}{\partial x} \right]. \quad (4)$$

Under these assumptions, the equation is valid in the region of positive values of  $x$ . If the function  $w(x, a)$  is symmetric with respect to the variable  $a$ ,  $\langle a \rangle = 0$ , and the probability variance does not depend on  $x$ , the first term on the right side of equation (4) disappears, and the kinetic equation reduces to a one-dimensional diffusion equation. To describe more complex situations, it should be assumed that the transition function may be asymmetric with respect to  $a$ , and the average value and variance of the variable may depend on the variable  $x$ . In this case, equation (4) defines a non-equilibrium distribution function.

The square brackets on the right side of the equation (4) contain two terms: the diffusion leveling of the distribution of individuals by income is compensated by the flow of individuals in the direction of large incomes. Even in a stationary situation, equation (4) describes a balanced internal motion.

## 2.2 Steady-state distribution

While observing the results on inequality, Yakovenko and his collaborator noticed, which is described in a short review (Ludwig and Yakovenko, 2021), that the empirical distribution function can be represented as a composition of two functions: for small values of the variable, the distribution is described by the Boltzmann-Gibbs exponential function, while for the large values of the variable, the distribution corresponds to the Pareto power law. This gives them a reason to present the totality of individuals as quasi-independent communities of the poor (Ludwig and Yakovenko estimate it is more than 90

In the steady-state case, the part of expression (4) enclosed in square brackets does not depend on  $x$ , and therefore we can introduce a constant  $C$  and write the equation

$$\frac{dp}{dx} = \frac{1}{\langle a^2 \rangle} \left[ C - \left( \langle a \rangle + \frac{d\langle a^2 \rangle}{dx} \right) p \right]. \quad (5)$$

We are looking for a solution of this equation, which, for large values of  $x$ , corresponds to the Pareto distribution (1). The limit value of the function  $p(\infty)$  is not known, but an expression for the derivative can be set

$$\left( \frac{dp}{dx} \right)_{\infty} = -\hat{p}(1 + \alpha)x^{-(2+\alpha)}, \quad p = p(\infty) + \hat{p}x^{-(1+\alpha)}. \quad (6)$$

The mean value  $\langle a \rangle$  and the variance of  $\langle a^2 \rangle$  in equation (5), depend on income in the region of positive values of  $x$ . It can be expected that these quantities are increasing functions of the values of  $x$  (otherwise, exchanges of agents with high income may be inefficient), which are conveniently represented with power function. To satisfy asymptotic (6), we choose the dependencies

$$\langle a \rangle = \langle a \rangle_0 + rx^{1+\alpha}, \quad \langle a^2 \rangle = \langle a^2 \rangle_0 + kx^{2+\alpha}. \quad (7)$$

With these values of the indices, equation (5) has the desirable asymptotic (6), and value of constant in equation (5) could be found

$$C = \hat{p}[1 + r + (1 + k)(1 + \alpha)], \quad p(\infty) = 0. \quad (8)$$

Equation (5) with relations (7) - (8) can be considered as an ordinary differential equation of the first order with the initial condition  $p(0) = 0$ , which we impose additionally. Without searching for an analytical expression of the solution, we turn to numerical methods that we use for the specific case of the distribution of individuals by income for Russia in 2018.

### 2.3 An example from Russia

Let us consider the income distribution density function for the population of Russia in 2018. In the figure, the empty circles represent the values of the probability density of the distribution estimated according to Rosstat data (Rosstat, 2023). One can notice that the dependence represent typical income distributions (see, for example, Ribeiro, 2020, cc. 93, 98). In the same figure, a dotted line shows the Pareto power law (1) with index  $\alpha = 1.65$ , which reproduces empirical results with an income above  $x > 50$ .

Equation (5) is considered as an ordinary differential equation, which we solve numerically by the standard method. The simple consideration allows us to choose the parameters in relations (7). For individuals with small incomes, the mean values are close to zero, whereas the variance is not zero. Both quantities increase with income, but did not exceed the total amount of income, which determines the values of the parameters

$$\langle a \rangle_0 = 0; \quad r = 0,0000014. \quad (9)$$

The variance of the transition probability function is nonzero for small and large values of income and increases with increasing income according to the law (7) with the parameters

$$\langle a^2 \rangle_0 = 0,02; \quad k = 0,0000005. \quad (10)$$

The value of  $C$  is determined by the relation (8), while the parameter  $\hat{p}$  can take an arbitrary sufficiently large value; calculations are carried out at a value of  $C = 36.6$ .

### Distribution density function

*The empty circles show empirical values of the density of distribution of the Russian population by income in 2018, calculated according to available data (Rosstat, 2019). The dotted curve represents the Pareto distribution (1) at  $\alpha = 1.65$ . The solid curve represents the solution of equation (5) at the values of the parameters (9) and (10). The distribution density function is normalized by 100 units. Income is shown in thousands of rubles.*

---

We are looking for a solution of equations (5)- (8) with values of the parameters (9) and (10). The results of calculating the distribution function are shown in the figure in comparison with the empirical values and the Pareto distribution. The graph of density function of the distribution represents a strongly deformed Gaussian distribution function, and this result convinces us that there is no need to introduce a quasi-equilibrium two-component scheme either on formal or substantive grounds.

### 3 Conclusion

The considered heuristic model represent the simplest model market economy with chaotic exchanges between individuals, and one could wonder what is the force that maintain the non-equilibrium distribution individuals over income. The content of market operations is associated with fixed technological features of the economic system; participants in social production are forced to interact with each other in a certain way and make objectively determined exchanges; this kind of market relations are present in any type of society, both under capitalism and under socialism. One can assume that each agent is free and voluntarily enters into agreements on exchanges; in this situation at every act agents exchange equivalent amounts of their asset, and these operations do not provoke the deformation of Gaussian distribution. However, there are prescription and rules (non-objective factors), different in different types of societies, that affect the exchanges. The rules, which are based on additional considerations, introduce non-equivalence of elementary exchanges: the agent who already has the highest income has the advantage. This is a force, external to the model under consideration, that bring and maintain the non-equilibrium in the system.
