Abstract

We study slow-roll inflation model controlled by the modular flavor symmetry. In the model, the modulus field plays a role of inflaton and the introduction of the stabilizer field coupled to a modular form in the superpotential produces the inflaton potential. In order to generate the flat direction for the slow-roll inflation, we consider the Kähler potential corrected by the modular form. It is noted that the modulus field perpendicular to the inflaton direction is stabilized during the inflation. The model turns out to be consistent with the current observations and behaves similarly to the α -attractor models in some parameter spaces. The inflaton rolls down to the CP-symmetric vacuum at the end of inflation.

1 Introduction

The origin of the flavor structure of quarks and leptons is one of the big mysteries in particle physics. Recently, the flavor symmetry based on the modular group [1] attracts much attention. In these models, the three generations of quarks and leptons transform non-trivially under the modular symmetry, that is, the modular symmetry is in a sense a flavor symmetry. On top of that, Yukawa couplings are assumed to be modular forms, which are holomorphic functions of the modulus τ and non-trivially transform under the action of the modular group. As discussed in Ref. [2], it is remarkable that the (in)homogeneous finite modular group $\Gamma_N^{(\prime)}$ with the level $N \leq 5$ is isomorphic to the well-known (double-covering of) permutation group, such as S_3 , $A_4^{(\prime)}$, $S_4^{(\prime)}$, and $A_5^{(\prime)}$, which have been intensively studied to explain the lepton flavor structure in the literature [1, 3-10]. These non-Abelian finite groups have been studied in flavor models for quarks and leptons [11-21].

The modular symmetry is well-motivated from the higher dimensional theories such as superstring theory. For example, if we consider the torus or its orbifold compactification, the modulus parameter τ is the complex structure modulus, which is a dynamical degree of freedom of the effective field theory determining the shape of the torus. The modular symmetry appears as the geometrical symmetry associated with this compact space. The Yukawa couplings are obtained by the overlap integral of the profile functions of the matter zero-modes and expressed as the function of the modulus which transforms non-trivially under the modular transformation. Hence, the vacuum expectation value of the modulus determines the flavor structure and therefore should be stabilized. The behavior of the zero-mode function under the modular transformation was studied in magnetized D-brane models [22–28], heterotic orbifold models [29–34] and heterotic string theory on Calabi-Yau threefolds [35, 36]. The modular flavor symmetric three-generation models based on the magnetized extra dimension were discussed in Refs. [28, 37]. The modulus stabilization is also discussed in Refs. [38, 39].

The modulus field can be a candidate of the inflaton to realize the inflationary expansion of the early Universe, because modular symmetry acting on it includes a shift symmetry which tends to flatten its scalar potential. In this work, we consider the inflation model controlled by the modular flavor symmetry.¹ The modulus field plays the role of inflaton and its profile is given as the trajectory in the complex plane associated with the complex modulus. Indeed, the inflation driven by modulus field was studied in modular symmetric supergravity model [41]. Also, non-supersymmetric models using modular forms were studied in [42–45].² In this paper, the stabilizer field is introduced in order to generate the scalar potential, which is assumed to be the singlet representation of Γ_N but has the nontrivial weight. We find that the Kähler potential corrected by the modular form makes the scalar potential flatter and realizes slow-roll inflation which is consistent with the current observations.³ Then, the modulus field perpendicular to the inflaton direction is stabilized during the inflation, evading the overshooting problem [54]. Furthermore, the slow-roll α attractor solution [55-61] is realized in some parameter spaces. At the end of the inflation, the modulus turns out to be stabilized at the CP-conserving vacuum. This can be favored in terms of the flavor structure [62] and regarded as a generic consequence in a modular invariant scalar potential [63–66].

The rest part of this paper is organized as follows. In Sec. 2, we give a brief review of the modular flavor symmetry. In Sec. 3, we introduce inflation model based on the modular

¹The hybrid inflation induced by one of right-handed sneutrinos was discussed in the context of modular flavor symmetry [40].

²See also, e.g., [46] for a supersymmetric model.

³The realization of the de Sitter spacetime in string theory is difficult to achieve [47-49], and there is still room for discussion (see also Refs. [50-52] for the reviews.) In the context of the modular symmetry, see Ref. [53].

flavor symmetry. In Sec. 4, we discuss the correction of the modular form in the Kähler potential and the deformation of the potential via this correction. We study the inflationary dynamics of the modulus field and show the parameter space of our model. Sec. 5 is devoted to our conclusions. In App. A, we exhibit modular forms of the finite modular group Γ_N with N = 3, 4, 5. In App. B, the formulae of the multi-field inflation are summarized. In App. C, a model with two modular forms in the superpotential is discussed. In App. D, we show the inflationary dynamics rolling into the vacuum, which is identical to the vacuum discussed in Secs. 3 and 4 via the modular transformation.

2 Modular flavor symmetry

In this section, we give a brief review of the modular flavor symmetry. The homogeneous modular group $\Gamma := SL(2, \mathbb{Z})$ is defined by

$$\Gamma := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \middle| a, b, c, d \in \mathbb{Z}, \quad ad - bc = 1 \right\}.$$
(2.1)

This is generated by

$$S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \qquad R = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{2.2}$$

which satisfy the following relations:

$$S^{2} = R, \quad (ST)^{3} = R^{2} = S^{4} = \mathbb{1}, \quad TR = RT.$$
 (2.3)

Under the $SL(2,\mathbb{Z})$ transformation, the modulus τ transforms as

$$\gamma: \tau \mapsto \gamma \tau = \frac{a\tau + b}{c\tau + d}, \qquad \gamma \in \mathrm{SL}(2, \mathbb{Z}).$$
 (2.4)

In particular, the action of the generators of Γ , S and T, are written as

$$S: \tau \mapsto -\frac{1}{\tau}, \qquad T: \tau \mapsto \tau + 1,$$
 (2.5)

and τ is invariant under R = -1. This transformation is called the modular transformation and $\overline{\Gamma} := \Gamma/\mathbb{Z}_2^R$ is called modular group, where \mathbb{Z}_2^R is generated by R. It is noted that T is similar to a shift symmetry often discussed in axion models [67].

The congruence subgroup of the level N, denoted by $\Gamma(N)$, is defined by

$$\Gamma(N) \coloneqq \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2, \mathbb{Z}), \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mod N \right\}.$$
(2.6)

The quotients $\Gamma_N \coloneqq \overline{\Gamma}/\Gamma(N)$ for N = 2, 3, 4, and 5 are respectively isomorphic to S_3, A_4, S_4 , and A_5 [2]. In addition, the quotients $\Gamma'_N \coloneqq \Gamma/\Gamma(N)$ for N = 3, 4, and 5 are isomorphic

to A'_4 , S'_4 , and A'_5 , which are double covering groups of A_4 , S_4 , and A_5 . In these quotients, T satisfies $T^N = 1$, which generates \mathbb{Z}_N^T symmetry.

Hereafter, we focus on the supergravity (SUGRA) formulation [68,69] for concreteness. Under the modular transformation, a matter (super)field Φ with the modular weight k_{Φ} transforms as

$$\Phi \mapsto (c\tau + d)^{k_{\Phi}} \rho(\gamma) \Phi, \qquad (2.7)$$

where $\rho(\gamma)$ denotes the representation matrix determined by the representation of Φ for $\Gamma(N)$. Here and hereafter, we use the convention that the superfield and its lowest component are denoted by the same letter. A modular form $Y(\tau)$, which depends on τ , similarly transforms under the modular flavor symmetries. The matter Kähler potential is assumed to be given by

$$\mathcal{K}_{\Phi} = \frac{|\Phi|^2}{(-\mathrm{i}\tau + \mathrm{i}\bar{\tau})^{-k_{\Phi}}},\tag{2.8}$$

which is invariant under the transformations (2.4) and (2.7). Later, we will consider the correction which is dependent of the modular form.

The Kähler potential for the modulus field typically has the following form,

$$\mathcal{K}_{\text{moduli}} = -M_P^2 h \log(-i\tau + i\bar{\tau}), \qquad (2.9)$$

and M_P denotes the reduced Planck scale, $M_P \approx 2.4 \times 10^{18}$ GeV. In the following parts, we will set $M_P = 1$ otherwise stated. Here, h is a dimensionless constant, which is related to the choice of the extra dimension in the higher dimensional theory. In the toroidal compactification, for example, it is found that h = 1 for the complex structure or Kähler modulus on \mathbb{T}^2 and h = 3 for the overall complex structure or Kähler modulus on \mathbb{T}^6 .⁴ Then, the kinetic term is given by

$$\boldsymbol{L}_{\text{moduli,kin.}} = -\frac{h}{4\tau_I^2} \partial_\mu \tau \partial_\nu \bar{\tau} g^{\mu\nu} = -\frac{h}{4\tau_I^2} \big[(\partial_\mu \tau_R)^2 + (\partial_\mu \tau_I)^2 \big], \qquad (2.11)$$

where we decompose the modulus as $\tau = \tau_R + i\tau_I$. Under the modular transformation (2.4), this Kähler potential transforms as

$$\mathcal{K}_{\text{moduli}} \mapsto \mathcal{K}_{\text{moduli}} + hf + h\bar{f}, \qquad f = \log(c\tau + d).$$
 (2.12)

$$\mathcal{K}_{\text{moduli}} = -M_P^2 \sum_i h_i \log(-i\tau_i + i\bar{\tau}_i), \qquad (2.10)$$

⁴The modulus field τ in this work is assumed to be general complex modulus which parameterizes the size or the shape of the torus. In heterotic string theory, both complex structure moduli and Kähler moduli play this role. In type II theory, the shape and volume moduli play that in type IIB and IIA, respectively. If there are multiple moduli fields, the Kähler potential is given by the following form:

where i denotes the label of the moduli. In this paper, we focus on the dynamics of the single complex modulus and the Kähler potential is assumed to be given by Eq. (2.9).

The invariance under this Kähler transformation requires that the superpotential W should transform as

$$W \mapsto e^{-hf}W = (c\tau + d)^{-h}W.$$
 (2.13)

We find that the superpotential is the modular form with the weight -h from this equation.

3 Model

3.1 Scalar potential

In this section, we introduce the inflation model controlled by the modular flavor symmetry. As the inflaton field we focus on a complex structure modulus associated with this modular symmetry, since the modular symmetry includes the T transformation $\tau \mapsto \tau + 1$, which tends to flatten the scalar potential and makes it suitable for the slow-roll inflation. The total bosonic action is given by

$$S = \int d^4x \sqrt{-g} \left[\frac{1}{2} \mathcal{R} - \frac{1}{2} K_{ab}(\phi) \partial_\mu \phi^a \partial_\nu \phi^b g^{\mu\nu} - V(\phi) \right], \tag{3.1}$$

where \mathcal{R} is the Ricci scalar. K_{ab} denotes the scalar field metric of this modulus field, and $\phi^a = (\tau_R, \tau_I)^t$. In this work, K_{ab} is derived from Eq. (2.9) and has the following form:

$$K_{ab} = \frac{h}{2\tau_I^2} \begin{pmatrix} 1 & 0\\ 0 & 1 \end{pmatrix}, \qquad K^{ab} = (K_{ab})^{-1} = \frac{2\tau_I^2}{h} \begin{pmatrix} 1 & 0\\ 0 & 1 \end{pmatrix}.$$
 (3.2)

The scalar potential is given by

$$V = e^{\mathcal{K}} \Big[\mathcal{K}^{\alpha \bar{\beta}} D_{\alpha} W \overline{D_{\beta} W} - 3|W|^2 \Big], \qquad (3.3)$$

where $\mathcal{K}_{\alpha\beta}$ is the total Kähler metric. D_I acts on the superpotential as $D_{\alpha}W = \partial_{\alpha}W + W\partial_{\alpha}\mathcal{K}$ with the Kähler potential \mathcal{K} . The indices α, β run all the superfield components, $\alpha, \beta = \tau, X$. In order to generate the scalar potential for the modulus field, we introduce a matter field, so-called a stabilizer field, which is a trivial singlet but has a non-trivial weight under the modular transformation. We consider the following superpotential proportional to the stabilizer field X [70–74],⁵

$$W = \Lambda^2 Y(\tau) X. \tag{3.4}$$

Here, $Y(\tau)$ is a modular form which is a trivial singlet under the modular transformation Γ_N and has a non-zero weight, and Λ is a constant of an energy scale characterizing this interaction. As discussed in the previous section, the modular weights of $Y(\tau)$ and X, denoted by k_Y and k_X , respectively, satisfy $-h = k_Y + k_X$ due to the invariance under the

 $^{^5\}mathrm{See}$ also Refs. [75--78] for the supersymmetry breaking field.

Kähler (modular) transformation. This model is applicable to a general Γ_N flavor symmetry because the dimension of the trivial singlet modular forms is unity up to the weight 10. We summarize the modular forms of level 3 (A_4) , 4 (S_4) , and 5 (A_5) cases as the reference in App. A. You can find that the trivial singlets share the same form and can be given by Eisenstein functions. For the number of the trivial singlets with the higher weight, see Ref. [79]. In the following discussion, we use the singlet with the weight

$$k_Y = 6, \tag{3.5}$$

denoted by $Y_1^{3,6}$ [1] as the concrete modular form. In this case, the modulus field tends to have a minimum around $\tau \sim i$ at $|Y_1^{3,6}| \ll 1$ as explicitly shown in the next section, which can be favored from the flavor structure [62] as well as the moduli stabilization [38]. Furthermore, the stabilizer field X determines the magnitude of supersymmetry (SUSY) breaking as discussed below.

The weight of the stabilizer field is given by $k_X = -h - 6$ for a given h. The scalar potential becomes

$$V \approx \Lambda^4 e^{\mathcal{K}} \mathcal{K}_{X\bar{X}}^{-1} |Y_1^{3,6}(\tau)|^2 = \Lambda^4 (2\tau_I)^{k_Y} |Y_1^{3,6}(\tau)|^2 = \Lambda^4 (2\tau_I)^6 |Y_1^{3,6}(\tau)|^2,$$
(3.6)

where we assumed $X \ll 1$ during the inflation and the Kähler potential is

$$\mathcal{K} = -h\log(-\mathrm{i}\tau + \mathrm{i}\bar{\tau}) + \frac{|X|^2}{(-\mathrm{i}\tau + \mathrm{i}\bar{\tau})^{-k_X}}.$$
(3.7)

We note that the overall modulus dependence in the scalar potential coming from the Kähler potential and Kähler metric are determined by the weight of Y due to the relation $-h = k_Y + k_X$. Unlike the ordinary moduli potential arisen from the dimensional compactification, this potential does not have the runaway structure in $\tau_I \to \infty$ limit.⁶ In this scalar potential, the explicit values of h and k_X are not relevant, but h determines the normalization of the modulus in their kinetic term. Hereafter throughout this paper, we choose

$$h = 2 \qquad \rightarrow \qquad k_X = -8. \tag{3.8}$$

The 3D plot of the potential (3.6) is shown in Fig. 1. It is found that τ_R feels the axion cosine potential. In the τ_I direction, this potential has the exponential dependence in addition to the $(2\tau_I)^{k_Y}$ overall contribution. This behavior can be easily seen from the q expansion of the modular form. The modular form is a function of $q := e^{2\pi i \tau}$. In the $|q| \ll 1$ or $\tau_I \gg 1$ region, we find the following approximate form⁷

$$|Y_1^{3,6}(q)|^2 = |1 - 504q - 16632q^2 + \mathcal{O}(q^3)|^2$$

⁶The no runaway behavior in the modular invariant scalar potential is discussed in Ref. [61]. See also [66] for a recent discussion.

⁷Throughout this paper, we have used q-expansion up to $\mathcal{O}(q^{12})$ in the modular forms and the scalar potential, since we have not find a change in the numerical calculation when comparing such expansions with those of $\mathcal{O}(q^n)$ with n < 12.

Figure 1: The 3D plot of the scalar potential (3.6).

Figure 2: The 3D plot of the scalar potential (3.11) with the correction to the Kähler potential (3.10).

$$= 1 + 504^{2} e^{-4\pi\tau_{I}} + 16632^{2} e^{-8\pi\tau_{I}} + 2(-504 e^{-2\pi\tau_{I}} + 504 \times 16632 e^{-6\pi\tau_{I}}) \cos(2\pi\tau_{R}) + 33264 e^{-4\pi\tau_{I}} \cos(4\pi\tau_{R}) + \cdots$$
(3.9)

The equation of $V \sim |Y_1^{3,6}|^2 \sim |1 - 504q|^2 \sim 0$ shows that the modulus field tends to be stabilized around the $\tau = i$, which is the CP-conserving vacuum.⁸

As discussed in the details in the next section⁹, this simple potential (3.6) does not have a flat direction enough to realize the slow-roll inflation. In order to obtain the slow-roll inflation, let us introduce the following additional term to the Kähler potential in addition

⁸If $Y_1^{3,4}$ is used instead of $Y_1^{3,6}$, the potential minimum will be given by $Y_1^{3,4} \sim 1 + 240q \sim 0$ and the CP-conserving vacuum will be realized around $\tau \sim 1/2 + i$.

⁹See also App. C, in which a model with two kinds of modular forms in the superpotential is discussed in the spirit of multi-natural inflation [80,81]. Then, the slow-roll inflation seems difficult to be realized due to the moduli destabilization during the inflation.

to (3.7)

$$\delta \mathcal{K} = \alpha \frac{|Y_1^{3,6} X|^2}{(-i\tau + i\bar{\tau})^{-k}} = \alpha \frac{|Y_1^{3,6} X|^2}{(-i\tau + i\bar{\tau})^h},\tag{3.10}$$

where k is the modular weight associated with this operator and α is a positive and dimensionless constant characterizing this additional term. The existence of this kind of term is discussed in Refs. [82–85].¹⁰ The modular weight k satisfies $k = k_Y + k_X = -h = -2$, because the superpotential $W \sim Y_1^{3,6}X$ has the modular weight -h = -2. Then, in the presence of $\delta \mathcal{K}_{X\bar{X}}$, the scalar potential (3.6) is deformed as

$$V = \Lambda^4 \frac{(2\tau_I)^6 |Y_1^{3,6}(\tau)|^2}{1 + \alpha (2\tau_I)^6 |Y_1^{3,6}(\tau)|^2}.$$
(3.11)

If we write

$$\tilde{V} = (2\tau_I)^6 |Y_1^{3,6}(\tau)|^2 \ge 0, \qquad (3.12)$$

this potential is written as

$$V = \Lambda^4 \frac{\tilde{V}}{1 + \alpha \tilde{V}}.$$
(3.13)

This shows that the vacuum is determined by the modular form. Note that the vacuum of V is basically the same as that of \tilde{V} , which shares similarity to Refs. [41, 86]. The scalar potential is in general suppressed by $1/(1 + \alpha \tilde{V})$ for $\alpha > 0$ and hence can get flatter enough to realize the slow-roll inflation. In the \tilde{V} dominate region, this potential reduces to the homogeneous constant profile, $V \sim \Lambda^4/\alpha$. The shapes of the potentials are shown in Fig. 2, where $\alpha = 0.1$ in the left panel and $\alpha = 5$ in the right panel. If α becomes large, the potential behaves as the constant one $\sim \Lambda^4/\alpha$ except the minimal points of \tilde{V} . The potential has a pinhole like minimum as α becomes larger. This feature will be similar to the α -attractor models [55–61]. Vacuum in the potential is the CP conserving and hence the modulus tends to be stabilized in the CP-symmetric vacuum for the weight 6 modular form case.¹¹

Comments on axion weak gravity conjecture. Note that there exists τ_R which is shifted by the *T* transformation and hence known to behave like an axion. Let us comment on the constraint from axion weak gravity conjecture [88], which claims that the axion decay constant f_a should satisfy

$$\mathbf{S}_{\text{inst}} \lesssim \mathcal{O}(1) \frac{M_P}{f_a},$$
 (3.14)

¹⁰When α is small such a δK would be supposed to be generated by radiative corrections. The modular form can be regarded as the Yukawa coupling of X to the heavy modes and hence it is natural for Y to appear in the wave function renormalization of X.

¹¹In the top-down approach to stabilize the moduli fields, the CP symmetry is also preserved at the vacua [35, 87].

where S_{inst} denotes an instanton action determining the normalization of the axion potential by $V \sim e^{-S_{\text{inst}}}$. The scalar potential associated with the modular invariance is given by $V \sim q^n + \bar{q}^n$, where $q = \exp(2\pi i \tau)$ and $n \in \mathbb{R}^+$, then the instanton action reads

$$\mathbf{S}_{\text{inst}} \sim -n \log(|q|) = 2\pi n \langle \tau_I \rangle.$$
 (3.15)

The kinetic term of the axion is

$$\boldsymbol{L}_{\rm kin} = -\frac{hM_P^2}{4\left\langle \tau_I \right\rangle^2} (\partial_\mu \tau_R)^2 \eqqcolon -\frac{1}{2} (\partial_\mu a)^2, \qquad (3.16)$$

from Eqs. (2.9) and (3.2), where the canonically normalized axion is defined by $a = \sqrt{\frac{h}{2}} \frac{M_P}{\langle \tau_I \rangle} \tau_R$. From the periodicity of $a \simeq a + 2\pi f_a$, the axion decay constant reads

$$f_a \sim \frac{M_P}{2\pi n \langle \tau_I \rangle} \sqrt{\frac{h}{2}}.$$
(3.17)

Thus, the inequality of axion weak gravity conjecture (3.14) becomes

$$\mathbf{S}_{\text{inst}} \sim 2\pi n \langle \tau_I \rangle \lesssim \frac{M_P}{f_a} \sim 2\pi n \langle \tau_I \rangle \sqrt{\frac{2}{h}},$$
 (3.18)

and we find

$$\sqrt{\frac{h}{2}} \lesssim \mathcal{O}(1), \tag{3.19}$$

which is automatically satisfied for h = 1, 2, 3.

3.2 Toy model

In this subsection, let us make progress of the intuitive understanding of the inflation via the potential (3.11) by using toy models inspired from the q expansion. From the qexpansion result (3.9), the modular form has roughly the structure of $Y \sim 1 - Be^{2\pi i \tau}$, where B is a τ independent constant. Using this and the SUGRA formula, let us show how the flat direction for the slow-roll inflation is produced by the additional contribution by α in the τ_R direction and τ_I direction, respectively. The scalar potential $V \sim \tilde{V}/(1 + \alpha \tilde{V})$ is suppressed by the denominator for $\alpha > 0$ and hence can become flatter for realizing the successful slow-roll inflation.

 τ_R direction inflation. In this case, the scalar potential is given by

$$V = \Lambda^4 \frac{\tilde{V}}{1 + \alpha \tilde{V}}, \qquad \tilde{V} = \cos(2\pi\tau_R) + A, \qquad (3.20)$$

where we use the SUGRA formula to derive $\tilde{V} \sim |Y|^2 \sim \cos(2\pi\tau_R) + A$ and α is a deformation parameter and assumed to be positive as discussed in the previous subsection. This potential

Figure 3: The τ_R potential (3.20). We choose $\alpha = 5$ and A = 1 for the flatter green line, and $\alpha = 0$ and A = 1 for the steeper purple line.

Figure 4: The $\tau_I \sim e^{\chi}$ potential (3.21). We choose $\alpha = 5$ and A = 10 for the flatter green line, and $\alpha = 0$ and A = 10 for the steeper purple line. The right panel shows the enlarged view around the vacuum.

is shown in Fig. 3. The steeper purple line is \tilde{V} and the flatter green line is the deformed potential V. The potential is suppressed by the additional contribution from α , and it is found the flat direction arises between the minima, where the slow-roll inflation can occur. The existence of the minima does not change by this deformation. Note that for a large α the potential can become sufficiently flat for the slow-roll inflation even without the decay constant larger than the Planck scale.

 τ_I direction inflation. In this case, the scalar potential is given by

$$V = \Lambda^4 \frac{\tilde{V}}{1 + \alpha \tilde{V}}, \qquad \tilde{V} = e^{\chi} \left[1 - A \exp(-e^{\chi}) \right]^2.$$
(3.21)

From the SUGRA formula, we calculate \tilde{V} as

$$\tilde{V} \sim \tau_I^n |Y|^2 \sim \tau_I^n (1 - A \mathrm{e}^{-\tau_I})^2$$

$$\sim e^{\chi} \left[1 - A \exp(-e^{\chi}) \right]^2, \tag{3.22}$$

where $\tau_I \sim e^{\chi}$ and $A \gg 1$ is assumed and the size of n is irrelevant to this discussion so long as $n = \mathcal{O}(1)$. This field redefinition is motivated by the non-canonical kinetic term of τ_I , $\mathbf{L}_{\text{kin.}} \sim -(\partial_{\mu}\tau_I/\tau_I)^2$. The potential is shown in Fig. 4. The steeper purple (flatter green) line corresponds to \tilde{V} (V). As shown in these panels, the scalar potential is pushed down by the additional contribution from α and we find the flat direction around the χ vacuum.

4 Modular flavor inflation

We discuss the slow-roll inflationary scenario depending on α in our model. The formulae of multi-field inflation [89–91] are used in order to evaluate the slow-roll parameters, power spectrum, spectral index, and tensor-to-scalar ratio. The slow-roll parameters are given by

$$\epsilon_V = \frac{V_{,a}V^{,a}}{2V^2}, \qquad \eta_{V_b}^a = \frac{V_{,b}^{;a}}{V},$$
(4.1)

where $_{,a}$ and $_{;a}$ denote the derivative and covariant derivative with respect to ϕ^a , respectively. The Levi-Civita connection for this covariant derivative is calculated from the metric K_{ab} , and $\eta_{V_b^a}$ becomes a matrix in a multi-field inflation. The power spectrum $\mathcal{P}_{\mathcal{R}}$, spectral index n_s , and tensor-to-scalar ratio r are expressed as

$$\mathcal{P}_{\mathcal{R}} = \left(\frac{H}{2\pi}\right)^2 N_{,a} N^{,a},\tag{4.2}$$

$$n_s = 1 - 2\epsilon_V - \frac{2}{N_{,a}N^{,a}} + \frac{2\eta_{Vab}N^{,a}N^{,b}}{N_{,c}N^{,c}},$$
(4.3)

$$r = \frac{8}{N_{,a}N^{,a}},\tag{4.4}$$

where H denotes the Hubble parameter during the inflation. Here, $N_{,a}$ is given by¹²

$$N_{,a} = \frac{VV_{,a}}{V_{,b}V^{,b}}.\tag{4.5}$$

The e-folding is defined by $N = \log(a_f/a)$, where a_f is the scale factor at the end of the inflation and a is the one at e-folding N before the end of inflation. For the more details, see App. B.

4.1 Simple model with $\alpha = 0$

First, let us start with the discussion about the simple model with the scalar potential (3.6), which is an undeformed one. Fig. 5 shows the parameter spaces for the slow-roll

¹²As discussed in App. B, in this work we do not include contribution of the isocurvature fluctuation, which is orthogonal to the adiabatic fluctuation on the inflationary trajectories.

Figure 5: The parameter space for the slow-roll inflation with the potential (3.6). The slow-roll inflation does not take place in this model. See the texts for the details of each region.

inflation in (τ_R, τ_I) -plane, where it turns out that the slow-roll inflation does not take place in this simple model. Here, the colored regions indicate the breakdown of the slow-roll condition: the purple region shows $|\eta_{V_b}^a| \ge 1$, whereas the orange one shows $\epsilon_V \ge 1$. The boundary $\epsilon_V = 1$ is set to the field values at the end of the inflation (N = 0) throughout this paper. On the green line, we obtain $n_s = 0.965$ which is the central value of the current observation [92].

4.2 Deformed model with $\alpha \neq 0$

In this subsection, we study the parameter space for the successful slow-roll inflation based on the scalar potential (3.11) with the kinetic term (2.11). The correction to the Kähler potential (3.10) flattens the scalar potential, and hence there indeed exists the parameter space in which the slow-roll inflation can take place. As shown below, for $\alpha \leq 1$, τ_I behaves as the inflaton of the slow-roll inflation, which lasts for a sufficiently long time. Then τ_R can play a role of the waterfall field of the so-called hybrid inflation at the end of the inflation and settles down into the CP-conserving vacuum at last, when τ_R develops a non-zero value during the inflation. For $\alpha \gtrsim 1$, a combination of τ_R and τ_I plays a role of the inflaton, since the scalar potential has the homogeneous constant profile $\sim \Lambda^4/\alpha$ when the slow-roll inflation occurs in apart from the vacuum. It turns out that τ_I can become the inflaton in terms of the pole inflation [93,94] for any $\alpha \gtrsim 10^{-2}$.

Fig. 6 shows the parameter space for the slow-roll inflation in (τ_R, τ_I) -plane in models with $\alpha \neq 0$. The meanings of each colored region and green lines are the same as those in Fig. 5 and hence the blank region in the Fig. 6 implies that there exist successful inflationary

Figure 6: The parameter space for the slow-roll inflation with (3.11) including the correction to the Kähler potential (3.10). We choose $\alpha = 0.01, 0.1, 2, and 5$.

trajectories for the slow-roll inflation which lasts for a long time.¹³ It is noted that the contribution of α changes the parameter space for the successful slow-roll inflation, i.e., a candidate of the inflaton. See also Fig. 7, which shows the vector plots of the potential gradient $-\frac{K^{ab}V_{,b}}{V}$ and examples of the inflationary trajectories starting at N = 60 denoted by bold lines and dashed ones. In the slow-roll regime, where $\epsilon_V < 1$, $|\eta_V_b^a| < 1$, the equations

¹³The blank region shows that all slow-roll parameters are smaller than unity throughout this paper. Then mode orthogonal to the inflaton is also light, however, isocurvature mode is not discussed in this paper.

of motion (EOMs) of τ^{-14} are approximately given by

$$\tau_R' - \frac{2\tau_I^2 V_{,\tau_R}}{hV} = 0, \qquad \tau_I' - \frac{2\tau_I^2 V_{,\tau_I}}{hV} = 0, \tag{4.6}$$

and the inflaton moves along this potential gradient associated with Fig. 7. Prime denotes the derivative with respect to the e-folding N. τ_I^2 in the second term in the both EOMs comes from the inverse scalar field metric K^{ab} (3.2). For $\alpha \leq 1$ (upper panels of Fig. 6), there exists a green line at a larger $\tau_I = \text{const.}$ and wide colored regions around a smaller τ_I where the slow-roll condition is violated. In the left panel of Fig. 7 we find inflationary trajectories, which are actually present within the blank region in the Fig. 6. As arrows shown in the left panel of Fig. 7, the inflation turns out to be mainly driven by τ_I . The inflaton τ_I starts to roll from a larger value to smaller one, and the field value realizing $n_s = 0.965$ at the horizon exit is given by the green line of $\tau_I = \text{const.}$ and the slow-roll inflation ends at the orange contour as shown in Figs. 6 and 7. In the left panel of Fig. 7, the solid line starting from $\tau = 1/2 + i$ to $\tau = i$ along τ_R direction shows the last stage of the inflation, where the slow-roll condition is violated. Then, the inflationary energy along τ_I direction converts to that of τ_R , hence the inflation ends and moduli settles down to the CP-conserving vacuum.¹⁵ This is regarded as a kind of the hybrid inflation and τ_R is then the waterfall field for it. As α becomes larger (in the bottom panels of Fig. 6), a green contour at a larger $\tau_I = \text{const.}$ merges with those around $\tau_I \sim 1$, and there appear green contours around the stationary points in the scalar potential. The scalar potential (3.11)has the pinhole-like shaped vacua due to the deformation by $\delta \mathcal{K}$ as discussed in Sec. 3, and the slow-roll inflation ends at the orange contour around the vacua. (Note that the vacuum at $\tau_R = 0$ is identified with that at $\tau_R = 1$.) Inflationary trajectories are allowed to exist within the wider blank region in the bottom panels of Fig. 6 than that for a smaller α , and green contours show the variety of the field values at the horizon exit. Thus, in general, a combination of τ_R and τ_I is thought to be the inflaton. For instance, either τ_R or τ_I can drive the single-field inflation as seen in the right panel of Fig. 7. Note that for a large α the potential along τ_R direction $V \sim \cos(\tau_R)/[1 + \alpha(\cos(\tau_R) + A)]$ becomes sufficiently flat for the slow-roll inflation even without a larger decay constant than the Planck scale as discussed in the toy model. We note also that τ_I drives the inflation in terms of the pole inflation [93,94] around $\tau_R \sim 0$ for $\alpha \gtrsim 10^{-2}$.

We find that the scalar potential has another CP-conserving vacuum at $\tau = \frac{1+i}{2}$ as shown in the left panel of Fig. 2. Figs. 6 and 7 also indicate the presence of the vacuum. The moduli can be stabilized at this vacuum at the end of the inflation when the inflaton starts to roll in the region where $\tau_I \sim 1/2$. However, $\tau = \frac{1+i}{2}$ is identical to $\tau = i$ under the S and T transformations.

 $^{^{14}\}text{The}$ full EOMs of τ are discussed in App. B.2.

¹⁵The constraint on isocurvature fluctuation could give conditions to our model because the modulus field perpendicular to the inflaton on the inflationary trajectories can be also lighter than the Hubble scale during the inflation in our model. However, in this work, we do not study this constraint further.

Figure 7: The vector plots of the potential gradients $-\frac{K^{ab}V_{,b}}{V}$. The black solid and dashed lines are inflationary trajectories starting at e-folding N = 60 before the end of the inflation. Orange and purple contours show $\epsilon_V = 1$ and $|\eta_V_b^a| = 1$ respectively. As for the black bold line in the left panel, the roll of τ_R at the end of the inflation violates slow-roll condition and τ_R plays the roll of the waterfall field in the hybrid inflation.

In the following part, we will mainly focus on the inflationary trajectories from the field values at the e-folding N = 60 to those around the vacuum $(\tau_R, \tau_I) = (0, 1)$ at N = 0. Fig. 8 shows the time evolution of τ (upper panels) and the magnitude of $\delta \mathcal{K}_{X\bar{X}}$ with k = -h = -2(lower panels) in terms of e-folding N along the black solid lines in Fig. 7. Fig. 9 is similar but shows those on the dashed lines in Fig. 7. In the upper panels of both Figs. 8 and 9, the purple and green lines give the profile of $\tau_R(N)$ and $\tau_I(N)$ respectively. In the upper left panel of Fig. 8, inflaton τ_I rolls from a large value to smaller one, while τ_R stays steady at $\tau_R = 1/2$ during the inflation for $N \gtrsim 1$ and starts to roll at $N \sim 1$ as the waterfall field in the hybrid inflation at the late stage of the inflation. Then τ settles down into the vacuum $\tau = i$. Note that for $\alpha \leq 1$ the adiabatic perturbation of τ_I at the horizon exit (as the coordinate around $\tau \sim 1/2 + 2.6i$ for $\alpha = 0.1$) can realize the spectral index consistent with the current observation. In the upper right panel of Fig. 8, on the other hand, the inflaton τ_R rolls from a large value to smaller ones, while τ_I gets remain at $\tau_I = 1$. Then, the adiabatic perturbation of τ_R at the horizon exit (as the coordinate around $\tau \sim 0.4 + i$ for $\alpha = 5$) can realize the consistent n_s with the current observation. In the lower panels of Fig. 8, $\delta \mathcal{K}_{X\bar{X}}$ is shown to be smaller than the leading field metric of $X, Z_X \coloneqq 1/(2\tau_I)^{-k_X}$ with $k_X = -8$, at the vacuum $\tau = i$, but can be larger than Z_X during the inflation even though $\alpha < 1$ can naively be regarded as a perturbative correction. Thus, $\delta \mathcal{K}$ might not be regarded as the mere perturbative correction to the field metric during the inflation and be originated non-perturbatively from a strong coupling. Therefore, issue of controlling models could arise against modular forms which might exist in our models. However, throughout

Figure 8: The time evolution of the moduli fields along the black solid lines in Fig. 7. α is chosen as 0.1 (left) and 5 (right). N denotes the e-folding before the end of the inflation. The purple and green lines are the profiles for τ_R and τ_I , respectively. In the lower panels, we show the time evolution of $\delta \mathcal{K}_{X\bar{X}}/Z_X = \alpha |Y_1^{3,6}|^2 (2\tau_I)^{k-k_X} = \alpha |Y_1^{3,6}|^2 (2\tau_I)^6$ with k = -h = -2 and $k_X = -8$.

this paper, it is assumed that coefficients of such modular forms in the action are suppressed and dynamics of X is stabilized, and hence we will not discuss this issue further.

As shown in the upper panels of Fig. 9, the inflation is mainly driven by τ_I while τ_R almost gets remain at $\tau_R \sim 0$. The lower panels show the N dependence of $\delta \mathcal{K}_{X\bar{X}}$ by using the these τ profiles. A similar issue concerned with the modular forms in our models could arise as in the previous case. See also Fig. 14 in App. B.2, which shows the time evolution of the moduli after the slow-roll inflation on the black solid lines in Fig. 7. Moduli settle down into the vacuum immediately after the end of the slow-roll inflation, oscillating around the vacuum.

Fig. 10 shows the moduli-dependence of the spectral index n_s at N = 60 (red solid line) and at N = 50 (red dashed line). The upper (lower) panels show τ_{R^-} (τ_I)-dependence of n_s . The results for $\alpha = 0.1$ (5) are shown in the left (right) panels. The orange lines correspond to the current central value, $n_s = 0.965$, observed by the PLANCK collaboration [92]. The

Figure 9: The time evolution of the moduli fields along the black dashed lines in Fig. 7. See the caption of Fig. 8 for the details.

blue bold lines (light blue dashed lines) show the 1σ (2σ) deviation from the central value of the n_s . It is found that the value of n_s tends to increase as N increases. As already mentioned above, for $\alpha = 0.1$ the inflaton is τ_I starting to roll from $\tau_I \sim 2.6$ in terms of the pole inflation with a fixed τ_R . Note also that for $\alpha = 5$ a combination of τ_R and τ_I drives the inflation. For instance, around $\tau \sim 0.4 + i$ ($\tau \sim 1.5i$) the single-field inflation can be driven by τ_R (τ_I) with the fixed $\tau_I \sim 1$ ($\tau_R \sim 0$) and these cases will be well-fitted to the current observation. Similar plots for the tensor-to-scalar ratio r are found in Fig. 11. In our model, r is tiny and therefore the current constraint, r < 0.06, [92] is satisfied.

Fig. 12 shows the predictions of the spectral index n_s and the tensor-to-scalar-ratio r in our models in (n_s, r) -plane. The solid lines with the squares at both ends (the dashed ones with the triangles at both ends) correspond to predictions on the black solid trajectories (the black dashed ones) in Fig. 7. The purple (green) lines are the results for $\alpha = 0.1$ (5). The smaller marks (squares or triangles) represent the result at N = 50 and the bigger ones show the result at N = 60. The larger e-folding N gets, the larger n_s becomes, as shown in Fig. 10. Further, r gets smaller as α increases. This behavior is similar to the α -attractor models [55–61].

Figure 10: Predictions for n_s in our models for $\alpha = 0.1$ and 5.

Figure 11: Predictions for r in our models for $\alpha = 0.1$ and 5.

Figure 12: Predictions of our models for the spectral index n_s and the tensor-to-scalar ratio r in the (n_s, r) -plane. Purple and green lines with marks are results for $\alpha = 0.1$ and 5, respectively. The solid (dashed) lines with the squares (triangles) are predictions corresponding to the solid (dashed) trajectories in Fig. 7. The larger and smaller symbols show the results at N = 60 and N = 50 respectively. The region surrounded by the blue lines and light blue ones are allowed by the PLANCK observation at 1σ and 2σ confidence level, respectively.

Table 1: Values of the spectral index n_s , tensor-to-scalar-ratio r, power spectrum $\mathcal{P}_{\mathcal{R}}$, Λ in the superpotential, and F-component of $X F_X$ for the trajectories in Figs. 8 and 9. n_s and r are evaluated at N = 60.

In the above discussion, we have not considered the normalization Λ of the scalar potential in (3.11) associated with the power spectrum $\mathcal{P}_{\mathcal{R}}$. This overall scale is fixed by the condition of the power spectrum at the pivot scale [92]

$$\mathcal{P}_{\mathcal{R}} = 2.10 \times 10^{-9}.$$
 (4.7)

Taking this into the account against the four inflationary trajectories in Figs. 8 and 9, we have fixed the overall scale Λ and exhibited it in Tab. 1, where n_s and r are also shown. From the Tab. 1, we read $\Lambda \sim 10^{15} \text{ GeV}^{16}$. Note that Λ are almost independent of models

 $^{^{16}\}mathrm{The}$ reduced Planck scale has been shown explicitly in the Tab. 1

since $\mathcal{P}_{\mathcal{R}} \sim \Lambda^4/r$ is fixed and r does not drastically change in models. Let us mention the SUSY breaking scale. Suppose that stabilizer X breaks the SUSY in the vacuum at $\tau = i$. From the above calculation, $F_X \sim \partial_X W = \Lambda^2 Y$ can be estimated at the CP-conserving vacuum and is listed in Tab. 1. Our models tend to have the low SUSY breaking scale of $\mathcal{O}(1)$ TeV due to the suppression by the modular form at the CP-conserving vacuum.

4.3 Non-gaussianity

The non-gaussianity in the multi-field inflation is discussed in Refs. [95–97], where the authors would consider the canonically normalized scalar fields. In the general kinetic term case, this result would be extended to

$$-\frac{3}{5}f_{\rm NL} \approx \frac{\mathcal{N}_{ab}N^{,a}N^{,b}}{2[K^{ab}N_{,a}N_{,b}]^2} \tag{4.8}$$

where we introduce

$$\mathcal{N}_{ab} \coloneqq N_{,b;a},\tag{4.9}$$

so that the covariance of the scalar field space is respected.

From the current observation [98], the absolute value of the non-gaussianity is bounded typically by unity,

$$|f_{\rm NL}| \lesssim 1. \tag{4.10}$$

We show $f_{\rm NL}$ as the function of the moduli at N = 60 (blue solid lines) and N = 50 (dashed ones) in our model in Fig. 13 when $\alpha = 0.1$ and 5. The sharp fins in Fig. 13 correspond to the signature flip of $f_{\rm NL}$. $f_{\rm NL}$ in our model is consistent with the current constraint. In our analysis, we focus on the adiabatic perturbation on the inflationary trajectories which can be reduced to the single-field one effectively, and then a small non-gaussianity given by the slow-roll parameters is consistent with the study in Ref. [99]. Analysis of the isocurvature perturbation orthogonal to the adiabatic one is left for the future work though it can give the additional contributions to observations.

4.4 Inflaton decay

In this subsection, we discuss decay modes of the moduli after the inflation. After the inflation, moduli move to the vacuum at $\tau = i$, start to oscillate around this vacuum and reheat the Universe via the decay finally. We expand the moduli fields as

$$\tau_R = \delta \tau_R, \qquad \tau_I = 1 + \delta \tau_I, \tag{4.11}$$

where $\delta \tau_{R,I}$ denote the fluctuations around this vacuum. The Lagrangian is written as

$$\boldsymbol{L} = -\frac{hM_P^2}{4} \left[(\partial_\mu \delta \tau_R)^2 + (\partial_\mu \delta \tau_I)^2 \right] - V(\delta \tau_R, 1 + \delta \tau_I)$$

Figure 13: The non-gaussianity as the function of the moduli in our model when $\alpha = 0.1$ and 5. The blue solid and dashed lines correspond to $f_{\rm NL}$ at N = 60 and N = 50 respectively.

$$+\frac{hM_P^2}{2}\delta\tau_I \left[(\partial_\mu \delta\tau_R)^2 + (\partial_\mu \delta\tau_I)^2 \right] + \cdots, \qquad (4.12)$$

where the last term comes from $1/\tau_I^2 = 1/(1+\delta\tau_I)^2$ in the non-canonical kinetic term (2.11). In the canonical kinetic term base,

$$\boldsymbol{L} \ni -\frac{1}{2} \left[(\partial_{\mu} \delta \hat{\tau}_R)^2 + (\partial_{\mu} \delta \hat{\tau}_I)^2 \right], \qquad \delta \hat{\tau}_{R,I} \coloneqq \sqrt{\frac{h}{2}} M_P \delta \tau_{R,I}, \tag{4.13}$$

the mass squared matrix of τ is

$$M_{\rm modulus}^2 \approx 5.67 \times 10^3 \left(\frac{2}{h}\right) \left(\frac{\Lambda}{M_P}\right)^4 M_P^2 \begin{pmatrix} 1 & 0\\ 0 & 1 \end{pmatrix}.$$
 (4.14)

Here, the mass matrix is given by the second-order derivative of the scalar potential (3.11) in the vacuum and almost insensitive to values of α . The absence of the mixing between τ_R and τ_I is the consequence of the CP preserving vacuum. These two fields have the same mass in the vacuum. This diagonal terms have a very small difference, but that is able to be ignored in our precision. Λ/M_P is determined by the PLANCK normalization, and we found $\Lambda/M_P \sim 10^{-(3-4)}$ typically as shown in Tab. 1. Using these results, the modulus mass with h = 2 is roughly given by

$$m_{\tau} \sim 1.81 \times 10^{12-14} \text{ GeV}.$$
 (4.15)

Suppose that there exists in the action

$$c \int d^2 \theta \left(\frac{-i\tau}{4\pi}\right) \mathcal{W}^{\alpha} \mathcal{W}_{\alpha} + h.c.,$$
 (4.16)

where θ is the fermionic coordinate in the superspace, \mathcal{W}^{α} is the superfield strength and correction terms in the gauge coupling which might exist in the modular invariant theories are neglected. c is a constant associated with this gauge fields, which is treated as the free parameter here. Such a modulus dependent term would appear in threshold corrections of gauge kinetic functions in the modular symmetric theory and c may be suppressed by a loop factor [100–103]. Then, in our model the main decay channels will be $\tau_R \to AA$ and $\tau_R \to$ $\psi_{3/2}\psi_{3/2}$, where A and $\psi_{3/2}$ denote the MSSM gauge fields and the gravitino respectively¹⁷. The latter decay mode originates from the gravitino mass term $e^{\mathcal{K}/2}W\psi_{3/2}\psi_{3/2}$, where the gravitino mass is given by $m_{3/2} = e^{\mathcal{K}/2}W$ in the vacuum, and it is expected that $m_{\tau} \gg$ $m_{3/2} \sim F_X = \mathcal{O}(1)$ TeV since $V \sim |F_X|^2 - 3m_{3/2}^2 \sim 0$. The interaction terms read

$$\boldsymbol{L}_{\tau F^2} \sim c \delta \tau_R F_{\mu\nu} \tilde{F}^{\mu\nu} + c \delta \tau_I F_{\mu\nu} F^{\mu\nu}, \qquad \boldsymbol{L}_{\tau \psi \psi} \sim \delta \tau F^\tau \psi_{3/2} \psi_{3/2}, \tag{4.18}$$

where the dual field strength is introduced by $\tilde{F}^{\mu\nu} := \frac{1}{2} \epsilon^{\mu\nu\rho\sigma} F_{\rho\sigma}$ and we have expand the gravitino mass around the vacuum to read the interaction as $e^{\mathcal{K}/2}W \ni \delta\tau\partial_{\tau}(e^{\mathcal{K}/2}W) \sim \delta\tau F^{\tau}$. We parameterize F-component of τ as $F^{\tau} \sim d(m_{3/2}^2/m_{\tau})$ [104, 105] because F^{τ} depends on the magnitude of X in the vacuum. Using these interaction terms, the decay widths of τ can be estimated as

$$\Gamma_{\delta\tau\to AA} \sim N_g \frac{c^2}{4\pi} \frac{m_\tau^3}{M_P^2},\tag{4.19}$$

$$\Gamma_{\delta\tau \to \psi_{3/2}\psi_{3/2}} \sim d^2 \frac{m_\tau^3}{96\pi M_P^2} \sqrt{1 - \frac{4m_{3/2}^2}{m_\tau^2}}.$$
(4.20)

$$\boldsymbol{L}_{\delta\tau H \overline{\psi}\psi} \sim -(\partial_{\tau} Y) \delta\tau \overline{\psi}^{\dagger} H \psi, \qquad (4.17)$$

¹⁷The inflaton can directly decay to the SM particles through the Yukawa coupling

but the scaling of the decay width is $\Gamma_{\delta\tau\to H\overline{\psi}\psi} \propto m_{\tau}^3/M_P$ and there is an additional phase suppression factor.

Here $N_g = 12$ for the minimal supersymmetric standard model, and M_P dependence comes from the canonical normalization of the moduli fields. For $d \ll 1$, the reheating temperature is given by

$$T_R \approx \left(\frac{90}{\pi^2 g_*(T_R)}\right)^{1/4} \sqrt{\Gamma_{\delta\tau \to AA} M_P} \approx 8.9 \times 10^7 \text{ GeV}\left(\frac{c}{10^{-2}}\right) \left(\frac{m_\tau}{10^{13} \text{GeV}}\right)^{3/2}.$$
 (4.21)

Here we have used $g_*(T_R) = 915/4$. Because heavy and unstable gravitinos can be produced through the scattering process with particles in the thermal bath at such a high temperature, the condition of $m_{3/2} > \mathcal{O}(1)$ TeV would be required to evade the constraint on the big bang nucleosynthesis destroyed by the abundant gravitino decays [106]. On the other hand, the decay mode into the gravitinos can be dominant for $d \gg 1$. Then the Universe would be dominated by the gravitino and its decay products including neutralino dark matter. The big bang nucleosynthesis would be destroyed by the gravitino decay and the Universe would be overclosed. Hence reheating by the inflaton decay would then fail [104,105]. This problem could be ameliorated and the baryon asymmetry could be produced via leptogenesis if the gravitino abundance is diluted by a late-time entropy production for $m_{3/2} > \mathcal{O}(1)$ TeV [107]. After all $m_{3/2} > \mathcal{O}(1)$ TeV in the vacuum is a solution for the gravitino problem, although $F_X \sim \mathcal{O}(1)$ TeV and therefore $V \sim |F_X|^2 - 3m_{3/2}^2$ may become negative.

To elude this problem, for instance, X can be considered irrelevant to the SUSY breaking in the vacuum. Another source X' is then supposed to exist and to make the gravitino much heavier than $\mathcal{O}(1)$ TeV in the vacuum; the superpotential relevant to the vacuum can be given by $W = \Lambda^2 XY + \mu^2 X'$, where X' is the genuine SUSY breaking field in the vacuum, has the modular weight -h, and μ is a constant. Here, $\mu \ll \Lambda$ but $\mu^2 \gg \Lambda^2 \langle Y \rangle$ in the vacuum; $\mu^2/M_P \sim F_{X'}/M_P \sim m_{3/2} \gg F_X \sim \mathcal{O}(1)$ TeV. X' and μ are considered irrelevant to the inflationary dynamics.

5 Conclusion

In this paper, we study the inflation model controlled by the modular flavor symmetry, where the moduli fields play the role not only in driving the inflaton but also in determining the flavor structure. The extra singlet scalar X, namely stabilizer field, is introduced to generate the modulus potential, which is assumed to have a Kähler potential in (3.7) and a simple superpotential (3.4). This simple model does not realize the slow-roll inflation owing to the steep potential without the modification of the Kähler potential. To make the scalar potential flatter, we introduce the additional Kähler potential (3.10), which corrects the kinetic term of the stabilizer field X and depends on the modular form included in the superpotential. This contribution to the Kähler potential gives the scalar potential in (3.11) and can realize the slow-roll inflation successfully. We show that the parameter space is consistent with the slow-roll inflation and the current observations. In particular, when the contribution from δK becomes larger, the potential becomes much flatter and hence inflaton is given by a combination of not only τ_I but also τ_R , sharing the same behavior of the α -attractor models. τ_I can drive the slow-roll inflation around $\tau_R \sim 0$ in terms of the pole inflation in the wide range of α in Eq. (3.10), whereas τ_R can play the role of the waterfall field at the end of the hybrid inflation driven by τ_I for a small α .

Our analysis in this work focuses on the adiabatic perturbation on the inflationary trajectories, where the isocurvature perturbation is assumed to be small and neglected. However, the modulus which is the orthogonal to the inflaton direction can be also lighter than the Hubble scale during the inflation. This mode can produce the isocurvature perturbation depending on the dynamics of the moduli fields, and would give the additional contribution to the non-gaussianity in our model, which could be tested by future observations. A more precise analysis of our model is left for the future work.

After the inflation, the modulus field rolls down to the CP-symmetric vacuum $\tau =$ i at which the inflaton reheats the Universe through the decay of moduli to the gauge fields and the gravitino. To generate the baryon asymmetry of the Universe, it will be required to break the CP symmetry at the vacuum in the case of spontaneous CP violation, corresponding to a slight deviation of τ from $\tau =$ i. It would be realized by an additional small correction dependent of the moduli to the Kähler potential and superpotential, other uplifting mechanisms to obtain the current cosmological constant or the stabilization of Kähler moduli of the torus from the UV point of view.¹⁸ When the CP symmetry is broken by some mechanism or parameters, one of the realistic mechanisms to generate the baryon asymmetry will be the non-thermal leptogenesis via the inflaton decay to the right-handed neutrino.

On the CP-symmetric vacuum, there also exists the residual discrete symmetry in the moduli space of τ . Since the inflation mechanism is successfully realized by the weight 6 modular form of a finite modular group of Γ_N , the residual symmetry would play an important role of determining the flavor structure of quarks and leptons for several modular flavor models (e.g., Ref. [109]). Furthermore, the *F*-term of stabilizer field *X* can induce the SUSY breaking at the vacuum in addition to the de Sitter expansion. The typical SUSY breaking scale is $\mathcal{O}(1)$ TeV due to the suppression by the modular form at the CP-symmetric vacuum $\tau = i$. The stabilization of *X* will be realized by another higher-order term in the Kähler potential $\mathcal{K} \sim -|X|^4$. It is interesting to explore the SUSY phenomenology which will be left for future work.

In this paper, matter couplings to moduli stabilize them via q-dependent corrections with $q = \exp(2\pi i \tau)$. The matter contribution might be the interesting source to stabilize the moduli and realize the de Sitter vacua in string theory.

 $^{^{18}}$ Such a mechanism was discussed in the context of modular flavor models [108].

A Modular forms

In this section, we summarize the modular form of the finite modular group Γ_N with N = 3, 4, 5. In particular, we focus on the singlet modular forms and their q expansions. In the manuscript, we deal with the weight 6 modular form of level 3 as the concrete modular form, but it is applicable to other modular groups as shown below.

A.1 A_4

The level 3 and weight 2 triplet modular form is $Y_{\mathbf{3}}^{3,2} = (Y_1(\tau), Y_2(\tau), Y_3(\tau))^{\mathrm{t}}$ [1], and the components are given by

$$Y_1(\tau) = \frac{i}{2\pi} \left(\frac{\eta'(\tau/3)}{\eta(\tau/3)} + \frac{\eta'((\tau+1)/3)}{\eta((\tau+1)/3)} + \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} - 27\frac{\eta'(3\tau)}{\eta(3\tau)} \right),$$
(A.1)

$$Y_2(\tau) = \frac{-i}{\pi} \left(\frac{\eta'(\tau/3)}{\eta(\tau/3)} + \omega^2 \frac{\eta'((\tau+1)/3)}{\eta((\tau+1)/3)} + \omega \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} \right),$$
(A.2)

$$Y_3(\tau) = \frac{-i}{\pi} \left(\frac{\eta'(\tau/3)}{\eta(\tau/3)} + \omega \frac{\eta'((\tau+1)/3)}{\eta((\eta+1)/3)} + \omega^2 \frac{\eta'((\tau+2)/3)}{\eta((\tau+2)/3)} \right),$$
(A.3)

where $\omega = e^{2\pi i/3}$. They satisfy the following constraint:

$$Y_2^2 + 2Y_1Y_3 = 0. (A.4)$$

The Dedekind's η function is defined by

$$\eta(\tau) = q^{1/24} \prod_{m=1}^{\infty} (1 - q^m), \qquad q \coloneqq e^{2\pi i \tau}.$$
 (A.5)

Using this definition, η'/η is written as the following form:

$$\frac{\eta'(\tau)}{\eta(\tau)} = 2\pi i \left[\frac{1}{24} + \sum_{m \ge 1} \frac{m}{1 - q^{-m}} \right],\tag{A.6}$$

and, for example, $\eta'((\tau + a)/3)/\eta((\tau + a)/3)$ is explicitly written as

$$\frac{\eta'((\tau+a)/3)}{\eta((\tau+a)/3)} = 2\pi i \left[\frac{1}{24} + \sum_{m\geq 1} \frac{m}{1 - q^{-m/3} e^{-2\pi i a m/3}} \right].$$
 (A.7)

The modular forms with the higher weights are constructed as the products of $Y_i(\tau)$ introduced in the previous subsection. Here, we will summarize the modular forms with weight 4, 6, and 8.

Weight 4:

$$Y_1^{3,4} = Y_1^2 + 2Y_2Y_3, \tag{A.8}$$

$$Y_{1'}^{3,4} = Y_3^2 + 2Y_1Y_2, \tag{A.9}$$

$$Y_{\mathbf{3}}^{3,4} = \begin{pmatrix} Y_1^2 - Y_2 Y_3 \\ Y_3^2 - Y_1 Y_2 \\ Y_2^2 - Y_3 Y_1 \end{pmatrix}.$$
 (A.10)

Weight 6:

$$Y_1^{3,6} = Y_1^3 + Y_2^3 + Y_3^3 - 3Y_1Y_2Y_3, \tag{A.11}$$

$$Y_{\mathbf{3}}^{3,6} = Y_{\mathbf{3}}^{3,2} Y_{\mathbf{1}}^{3,4} = (Y_1^2 + 2Y_2 Y_3) \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix},$$
(A.12)

$$Y_{\mathbf{3}'}^{3,6} = Y_{\mathbf{3}}^{3,2} Y_{\mathbf{1}'}^{3,4} = (Y_3^2 + 2Y_1 Y_2) \begin{pmatrix} Y_3 \\ Y_1 \\ Y_2 \end{pmatrix}.$$
 (A.13)

Weight 8:

$$Y_1^{3,8} = (Y_1^{3,4})^2 = (Y_1^2 + 2Y_2Y_3)^2,$$
(A.14)

$$Y_{1'}^{3,8} = Y_1^{3,4} Y_{1'}^{3,4} = (Y_1^2 + 2Y_2 Y_3)(Y_3^2 + 2Y_1 Y_2),$$
(A.15)

$$Y_{1''}^{3,8} = (Y_{1'}^{3,4})^2 = (Y_3^2 + 2Y_1Y_2)^2, \tag{A.16}$$

$$Y_{\mathbf{3}}^{3,8} = (Y_1^2 + 2Y_2Y_3) \begin{pmatrix} Y_1^2 - Y_2Y_3 \\ Y_3^2 - Y_1Y_2 \\ Y_2^2 - Y_1Y_3 \end{pmatrix},$$
(A.17)

$$Y_{\mathbf{3'}}^{3,8} = (Y_3^2 + 2Y_1Y_2) \begin{pmatrix} Y_2^2 - Y_1Y_3 \\ Y_1^2 - Y_2Y_3 \\ Y_3^2 - Y_1Y_2 \end{pmatrix}.$$
 (A.18)

If $e^{-2\pi\tau_I} \ll 1$, we can consider the expansion of q. The components of $Y_{\mathbf{3}}^{3,2}$ are written as

$$Y_1 = 1 + 12q + 36q^2 + 12q^3 + 84q^4 + \mathcal{O}(q^{13/3}), \tag{A.19}$$

$$Y_2 = -6q^{1/3}(1 + 7q + 8q^2 + 18q^3) + \mathcal{O}(q^{13/3}), \tag{A.20}$$

$$Y_3 = -18q^{3/2}(1 + 2q + 5q^2 + 4q^3) + \mathcal{O}(q^{13/3}).$$
(A.21)

In the same manner, the singlets are expressed as

$$Y_1^{3,4} = 1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \mathcal{O}(q^{13/3}), \tag{A.22}$$

$$Y_{\mathbf{1}}^{3,6} = 1 - 504q - 16632q^2 - 122976q^3 - 532728q^4 + \mathcal{O}(q^{13/3}).$$
(A.23)

Note that the above singlets are also described by Eisenstein series E_4 and E_6 , respectively.

A.2 S_4

The weight 2 modular form of $\Gamma_4 \simeq S_4$ was constructed in Ref. [4]. We first define

$$\begin{split} Y_1^4(\tau) &= Y(1, 1, \omega, \omega^2, \omega, \omega^2, \tau), \\ Y_2^4(\tau) &= Y(1, 1, \omega^2, \omega, \omega^2, \omega, \tau), \\ Y_3^4(\tau) &= Y(1, -1, -1, -1, 1, 1, \tau), \\ Y_4^4(\tau) &= Y(1, -1, -\omega^2, -\omega, \omega^2, \omega, \tau), \\ Y_5^4(\tau) &= Y(1, -1, -\omega, -\omega^2, \omega, \omega^2, \tau), \end{split}$$
(A.24)

with

$$Y(a_1, a_2, a_3, a_4, a_5, a_6, \tau) = a_1 \frac{\eta'(\tau + 1/2)}{\eta(\tau + 1/2)} + 4a_2 \frac{\eta'(4\tau)}{\eta(4\tau)} + \frac{1}{4} \sum_{m=0}^3 a_{m+3} \frac{\eta'((\tau + m)/4)}{\eta((\tau + m)/4)}.$$
 (A.25)

The weight 2 modular forms of the level 4 is of the form:

$$Y_{\mathbf{2}}^{4,2} = \begin{pmatrix} Y_1^4(\tau) \\ Y_2^4(\tau) \end{pmatrix}, \quad Y_{\mathbf{3}'}^{4,2} = \begin{pmatrix} Y_3^4(\tau) \\ Y_4^4(\tau) \\ Y_5^4(\tau) \end{pmatrix}.$$
 (A.26)

The modular form with the higher weights are constructed by the tensor product of the weight 2 modular forms. In the following, we will summarize the modular forms with weight 4, 6, and 8 [110].

Weight 4:

$$Y_{\mathbf{1}}^{4,4} = Y_{1}^{4}Y_{2}^{4}, \quad Y_{\mathbf{2}}^{4,4} = \begin{pmatrix} (Y_{2}^{4})^{2} \\ (Y_{1}^{4})^{2} \end{pmatrix},$$

$$Y_{\mathbf{3}}^{4,4} = \begin{pmatrix} Y_{1}^{4}Y_{4}^{4} - Y_{2}^{4}Y_{5}^{4} \\ Y_{1}^{4}Y_{5}^{4} - Y_{2}^{4}Y_{3}^{4} \\ Y_{1}^{4}Y_{3}^{4} - Y_{2}^{4}Y_{4}^{4} \end{pmatrix}, \quad Y_{\mathbf{3}'}^{4,4} = \begin{pmatrix} Y_{1}^{4}Y_{4}^{4} + Y_{2}^{4}Y_{5}^{4} \\ Y_{1}^{4}Y_{5}^{4} + Y_{2}^{4}Y_{5}^{4} \\ Y_{1}^{4}Y_{3}^{4} + Y_{2}^{4}Y_{4}^{4} \end{pmatrix}.$$
(A.27)

Weight 6:

$$\begin{split} Y_{\mathbf{1}}^{4,6} &= (Y_{1}^{4})^{3} + (Y_{2}^{4})^{3}, \quad Y_{\mathbf{1}'}^{4,6} &= (Y_{1}^{4})^{3} - (Y_{2}^{4})^{3}, \\ Y_{\mathbf{2}}^{4,6} &= Y_{1}^{4}Y_{2}^{4} \begin{pmatrix} Y_{1}^{4} \\ Y_{2}^{4} \end{pmatrix}, \quad Y_{\mathbf{3}}^{4,6} &= \begin{pmatrix} (Y_{2}^{4})^{2}Y_{4}^{4} - (Y_{1}^{4})^{2}Y_{5}^{4} \\ (Y_{2}^{4})^{2}Y_{5}^{4} - (Y_{1}^{4})^{2}Y_{3}^{4} \\ (Y_{2}^{4})^{2}Y_{3}^{4} - (Y_{1}^{4})^{2}Y_{4}^{4} \end{pmatrix}, \\ Y_{\mathbf{3}',I}^{4,6} &= Y_{1}^{4}Y_{2}^{4} \begin{pmatrix} Y_{3}^{4} \\ Y_{4}^{4} \\ Y_{5}^{4} \end{pmatrix}, \quad Y_{\mathbf{3}',II}^{4,6} &= \begin{pmatrix} (Y_{2}^{4})^{2}Y_{4}^{4} + (Y_{1}^{4})^{2}Y_{5}^{4} \\ (Y_{2}^{4})^{2}Y_{5}^{4} + (Y_{1}^{4})^{2}Y_{3}^{4} \\ (Y_{2}^{4})^{2}Y_{3}^{4} + (Y_{1}^{4})^{2}Y_{4}^{4} \end{pmatrix}. \end{split}$$
(A.28)

Weight 8:

$$\begin{split} Y_{1}^{4,8} &= (Y_{1}^{4})^{2} (Y_{2}^{4})^{2}, \quad Y_{2,I}^{4,8} = Y_{1}^{4} Y_{2}^{4} \begin{pmatrix} (Y_{2}^{4})^{2} \\ (Y_{1}^{4})^{2} \end{pmatrix}, \quad Y_{2,II}^{4,8} &= ((Y_{1}^{4})^{3} - (Y_{2}^{4})^{3}) \begin{pmatrix} Y_{1}^{4} \\ -Y_{2}^{4} \end{pmatrix}, \\ Y_{3,II}^{4,8} &= ((Y_{1}^{4})^{3} - (Y_{2}^{4})^{3}) \begin{pmatrix} Y_{3}^{4} \\ Y_{4}^{4} \\ Y_{5}^{4} \end{pmatrix}, \quad Y_{3,II}^{4,8} = Y_{1}^{4} Y_{2}^{4} \begin{pmatrix} Y_{1}^{4} Y_{4}^{4} - Y_{2}^{4} Y_{5}^{4} \\ Y_{1}^{4} Y_{5}^{4} - Y_{2}^{4} Y_{3}^{4} \\ Y_{1}^{4} Y_{3}^{4} - Y_{2}^{4} Y_{4}^{4} \end{pmatrix}, \quad (A.29) \\ Y_{3',II}^{4,8} &= ((Y_{1}^{4})^{3} + (Y_{2}^{4})^{3}) \begin{pmatrix} Y_{3}^{4} \\ Y_{4}^{4} \\ Y_{5}^{4} \end{pmatrix}, \quad Y_{3',II}^{4,8} = Y_{1}^{4} Y_{2}^{4} \begin{pmatrix} Y_{1}^{4} Y_{4}^{4} - Y_{2}^{4} Y_{5}^{4} \\ Y_{1}^{4} Y_{3}^{4} - Y_{2}^{4} Y_{4}^{4} \\ Y_{1}^{4} Y_{3}^{4} - Y_{2}^{4} Y_{4}^{4} \end{pmatrix}. \end{split}$$

Let us consider the q expansion $e^{-2\pi\tau_I} \ll 1$. Since Y_1^4 and Y_2^4 are expanded as

$$Y_1^4 = \frac{3\pi i}{8} \left(1 - 8i\sqrt{3q} + 24q - 32i\sqrt{3}q^{3/2} + 24q^2 - \frac{64i}{\sqrt{3}}q^{5/2} + 64q^3 + \mathcal{O}(q^{7/2}) \right), \quad (A.30)$$

$$Y_2^4 = \frac{3\pi i}{8} \left(1 + 8i\sqrt{3q} + 24q + 32i\sqrt{3}q^{3/2} + 24q^2 + \frac{64i}{\sqrt{3}}q^{5/2} + 64q^3 + \mathcal{O}(q^{7/2}) \right), \quad (A.31)$$

the trivial singlets are expressed as

$$Y_{\mathbf{1}}^{4,4} = -\frac{9\pi^2}{64} \left(1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \mathcal{O}(q^5) \right), \tag{A.32}$$

$$Y_{\mathbf{1}}^{4,6} = -\frac{27\pi^{3}i}{256} \left(1 - 504q - 16632q^{2} - 122976q^{3} - 532728q^{4} + \mathcal{O}(q^{5})\right), \qquad (A.33)$$

$$Y_{\mathbf{1}}^{4,8} = \frac{81\pi^4}{4096} \left(1 + 480q + 61920q^2 + 1050240q^3 + 7926240q^4 + \mathcal{O}(q^5) \right).$$
(A.34)

Thus, these modular forms of level 4 are the same expansion as those of level 3 up to the overall factor. Note that the singlet $Y_1^{4,8}$ is also described by the Eisenstein series E_8 in the same manner as the other singlets.

A.3 A_5

The dimension of weight 2 modular forms of $\Gamma_5 \simeq A_5$ is 11. Following the notation of Ref. [5], we define the weight 2 modular forms of level 5:

$$\begin{split} Y_1^5(\tau) &= -\frac{1}{\sqrt{6}} Y^{(5)}(-5,1,1,1,1,1;-5,1,1,1,1,1,1|\tau), \\ Y_2^5(\tau) &= Y^{(5)}(0,1,\zeta^4,\zeta^3,\zeta^2,\zeta;0,1,\zeta^4,\zeta^3,\zeta^2,\zeta|\tau), \\ Y_3^5(\tau) &= Y^{(5)}(0,1,\zeta^3,\zeta,\zeta^4,\zeta^2;0,1,\zeta^3,\zeta,\zeta^4,\zeta^2|\tau), \\ Y_4^5(\tau) &= Y^{(5)}(0,1,\zeta^2,\zeta^4,\zeta,\zeta^3;0,1,\zeta^2,\zeta^4,\zeta,\zeta^3|\tau), \\ Y_5^5(\tau) &= Y^{(5)}(0,1,\zeta,\zeta^2,\zeta^3,\zeta^4;0,1,\zeta,\zeta^2,\zeta^3,\zeta^4|\tau), \\ Y_6^5(\tau) &= \frac{1}{\sqrt{2}} Y^{(6)}(-\sqrt{5},-1,-1,-1,-1,-1;\sqrt{5},1,1,1,1,1|\tau), \end{split}$$

$$\begin{split} Y_7^5(\tau) &= Y^{(5)}(0, 1, \zeta^4, \zeta^3, \zeta^2, \zeta; 0, -1, -\zeta^4, -\zeta^3, -\zeta^2, -\zeta | \tau), \\ Y_8^5(\tau) &= Y^{(5)}(0, 1, \zeta, \zeta^2, \zeta^3, \zeta^4; 0, -1, -\zeta, -\zeta^2, -\zeta^3, -\zeta^4 | \tau), \\ Y_9^5(\tau) &= \frac{1}{\sqrt{2}} Y^{(5)}(\sqrt{5}, -1, -1, -1, -1, -1; -\sqrt{5}, 1, 1, 1, 1, 1 | \tau), \\ Y_{10}^5(\tau) &= Y^{(5)}(0, 1, \zeta^3, \zeta, \zeta^4, \zeta^2; 0, -1, -\zeta^3, -\zeta, -\zeta^4, -\zeta^2 | \tau), \\ Y_{11}^5(\tau) &= Y^{(5)}(0, 1, \zeta^2, \zeta^4, \zeta, \zeta^3; 0, -1, -\zeta^2, -\zeta^4, -\zeta, -\zeta^3 | \tau), \end{split}$$
(A.35)

where the function $Y^{(5)}$ is defined as

$$Y^{(5)}(c_{1,-1}, c_{1,0}, ..., c_{1,4}; c_{2,-1}, c_{2,0}, ..., c_{2,4} | \tau) := \sum_{i,j} c_{i,j} \frac{\mathrm{d}}{\mathrm{d}\tau} \log \alpha_{i,j}(\tau)$$
(A.36)

with $\sum_{i,j} c_{i,j} = 0$ and

$$\begin{aligned} \alpha_{1,-1}(\tau) &= \theta_3 \left(\frac{\tau+1}{2}, 5\tau \right), \qquad \alpha_{2,-1}(\tau) = e^{2\pi i \tau/5} \theta_3 \left(\frac{3\tau+1}{2}, 5\tau \right), \\ \alpha_{1,0}(\tau) &= \theta_3 \left(\frac{\tau+9}{10}, \frac{\tau}{5} \right), \qquad \alpha_{2,0}(\tau) = \theta_3 \left(\frac{\tau+7}{10}, \frac{\tau}{5} \right), \\ \alpha_{1,1}(\tau) &= \theta_3 \left(\frac{\tau}{10}, \frac{\tau+1}{5} \right), \qquad \alpha_{2,1}(\tau) = \theta_3 \left(\frac{\tau+8}{10}, \frac{\tau+1}{5} \right), \\ \alpha_{1,2}(\tau) &= \theta_3 \left(\frac{\tau+1}{10}, \frac{\tau+2}{5} \right), \qquad \alpha_{2,2}(\tau) = \theta_3 \left(\frac{\tau+9}{10}, \frac{\tau+2}{5} \right), \\ \alpha_{1,3}(\tau) &= \theta_3 \left(\frac{\tau+2}{10}, \frac{\tau+3}{5} \right), \qquad \alpha_{2,3}(\tau) = \theta_3 \left(\frac{\tau}{10}, \frac{\tau+3}{5} \right), \\ \alpha_{1,4}(\tau) &= \theta_3 \left(\frac{\tau+3}{10}, \frac{\tau+4}{5} \right), \qquad \alpha_{2,4}(\tau) = \theta_3 \left(\frac{\tau+1}{10}, \frac{\tau+4}{5} \right). \end{aligned}$$
(A.37)

Here, $\theta_3(z(\tau), t(\tau))$ is the Jacobi theta function. The 11-dimensional space of weight 2 modular forms of level 5 is divided into

$$Y_{\mathbf{5}}^{2,5} = \begin{pmatrix} Y_{1}^{5}(\tau) \\ Y_{2}^{5}(\tau) \\ Y_{3}^{5}(\tau) \\ Y_{4}^{5}(\tau) \\ Y_{5}^{5}(\tau) \end{pmatrix}, \quad Y_{\mathbf{3}}^{2,5} = \begin{pmatrix} Y_{6}^{5}(\tau) \\ Y_{7}^{5}(\tau) \\ Y_{8}^{5}(\tau) \end{pmatrix}, \quad Y_{\mathbf{3}'}^{2,5} = \begin{pmatrix} Y_{9}^{5}(\tau) \\ Y_{10}^{5}(\tau) \\ Y_{11}^{5}(\tau) \end{pmatrix}.$$
(A.38)

The higher weight modular forms can be constructed by the tensor product of the above modular forms. In the following, we show only the trivial singlet modular forms with weight k of level 5, i.e., $Y_1^{k,5}$ with k = 4, 6, 8:

$$Y_{1}^{4,5} = (Y_{1}^{5})^{2} + 2Y_{3}^{5}Y_{4}^{5} + 2Y_{2}^{5}Y_{5}^{5},$$

$$Y_{1}^{6,5} = 3\sqrt{3} \left(Y_{2}^{5}(Y_{3}^{5})^{2} + Y_{5}^{5}(Y_{4}^{5})^{2}\right) + \sqrt{2}Y_{1}^{5} \left((Y_{1}^{5})^{2} + 3Y_{3}^{5}Y_{4}^{5} - 6Y_{2}^{5}Y_{5}^{5}\right),$$

$$Y_{1}^{8,5} = \left((Y_{1}^{5})^{2} + 2Y_{3}^{5}Y_{4}^{5} + 2Y_{2}^{5}Y_{5}^{5}\right) (Y_{6}^{5})^{2} + 2\left((Y_{1}^{5})^{2} + 2Y_{3}^{5}Y_{4}^{5} + 2Y_{2}^{5}Y_{5}^{5}\right) Y_{7}^{5}Y_{8}^{5}.$$
(A.39)

Let us consider the q expansion $e^{-2\pi\tau_I} \ll 1$. Since $Y_{1,2,3,4,5}^4$ is expanded as

$$\begin{split} Y_1^5 &= \pi i \sqrt{\frac{2}{3}} \left(1 + 6q + 18q^2 + 24q^3 + 42q^4 + 6q^5 + \mathcal{O}(q^6) \right), \\ Y_2^5 &= -2\pi i \left(q^{1/5} + 12q^{6/5} + 12q^{11/5} + 31q^{16/5} + 32q^{21/5} + \mathcal{O}(q^{26/5}) \right), \\ Y_3^5 &= -2\pi i \left(3q^{2/5} + 8q^{7/5} + 28q^{12/5} + 18q^{17/5} + 36q^{22/5} + \mathcal{O}(q^{27/5}) \right), \\ Y_4^5 &= -2\pi i \left(4q^{3/5} + 15q^{8/5} + 14q^{13/5} + 39q^{18/5} + 24q^{23/5} + \mathcal{O}(q^{28/5}) \right), \\ Y_5^5 &= -2\pi i \left(7q^{4/5} + 13q^{9/5} + 24q^{14/5} + 20q^{19/5} + 60q^{24/5} + \mathcal{O}(q^{29/5}) \right), \\ Y_6^5 &= -\pi i \sqrt{\frac{2}{5}} \left(-1 + 30q + 20q^2 + 40q^3 + 90q^4 + 130q^5 + \mathcal{O}(q^6) \right), \\ Y_7^5 &= 2\sqrt{5}\pi i \left(q^{1/5} + 2q^{6/5} + 12q^{11/5} + 11q^{16/5} + 12q^{21/5} + \mathcal{O}(q^{26/5}) \right), \\ Y_8^5 &= 2\sqrt{5}\pi i \left(3q^{4/5} + 7q^{9/5} + 6q^{14/5} + 20q^{19/5} + 10q^{24/5} + \mathcal{O}(q^{29/5}) \right), \end{split}$$

the trivial singlets are expressed as

$$Y_{\mathbf{1}}^{4,5} = -\frac{2\pi^2}{3} \left(1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \mathcal{O}(q^5) \right), \tag{A.41}$$

$$Y_{\mathbf{1}}^{6,5} = -\frac{4\pi^3 i}{3\sqrt{3}} \left(1 - 504q - 16632q^2 - 122976q^3 - 532728q^4 + \mathcal{O}(q^5) \right), \tag{A.42}$$

$$Y_{\mathbf{1}}^{8,5} = \frac{4\pi^4}{15} \left(1 + 480q + 61920q^2 + 1050240q^3 + 7926240q^4 + \mathcal{O}(q^5) \right).$$
(A.43)

Thus, these modular forms of level 5 are the same expansion as those of level 3 and 4.

B Multi-field inflation

In this section, we summarize the results of the multi-field inflation according to Refs. [89–91]. The action we consider is

$$S = \int d^4x \sqrt{-g} \left[\frac{M_P^2}{2} \mathcal{R} - \frac{1}{2} K_{ab}(\phi) \partial_\mu \phi^a \partial_\nu \phi^b g^{\mu\nu} - V(\phi) \right], \tag{B.1}$$

where $K_{ab}(\phi)$ is the metric of the scalar field space and $V(\phi)$ is the scalar potential. \mathcal{R} is the Ricci scalar. In order to discuss the inflationary expansion, we consider the following configurations:

$$ds^{2} = -dt^{2} + a(t)^{2}d\vec{x}^{2}, \qquad \phi^{a}(t,\vec{x}) = \phi^{a}(t),$$
(B.2)

and the Hubble parameter is defined by $H \coloneqq \dot{a}/a$. Dot denotes the time derivative. The Klein-Gordon equation and Friedmann equations are given by

$$\ddot{\phi}^{a} + 3H\dot{\phi}^{a} + \gamma^{a}_{bc}\dot{\phi}^{b}\dot{\phi}^{c} + K^{ab}V_{,b} = 0, \qquad H^{2} = \frac{1}{3M_{P}^{2}} \left(\frac{1}{2}K_{ab}\dot{\phi}^{a}\dot{\phi}^{b} + V(\phi)\right), \tag{B.3}$$

where $V_{,a} := \partial_a V$. γ_{bc}^a is the connection in the scalar field space, and we introduce the covariant derivative on the scalar field space \mathcal{D}_a by using this connection:

$$\mathfrak{X}^{b}_{c;a} \coloneqq \mathcal{D}_{a}\mathfrak{X}^{b}_{c} = \partial_{a}\mathfrak{X}^{b}_{c} + \gamma^{b}_{ad}\mathfrak{X}^{d}_{c} - \gamma^{d}_{ac}\mathfrak{X}^{b}_{d}.$$
 (B.4)

For the metric (3.2), we find that the non-vanishing components of this connection are

$$\gamma_{RI}^{R} = \gamma_{IR}^{R} = -\frac{1}{\tau_{I}}, \qquad \gamma_{RR}^{I} = \frac{1}{\tau_{I}}, \qquad \gamma_{II}^{I} = -\frac{1}{\tau_{I}}.$$
 (B.5)

Here, we use the indices $a, b, \ldots = R, I$ for the τ_R and τ_I components. The indices are raised and lowered by the metric K_{ab} and K^{ab} . In addition, the time derivative of the Hubble parameter is the scalar field kinetic energy

$$\dot{H} = -\frac{1}{2M_P^2} K_{ab} \dot{\phi}^a \dot{\phi}^b. \tag{B.6}$$

In the slow-roll regime, where $\epsilon_V < 1$, $|\eta_V_b^a| < 1$, these equations reduce to

$$\dot{\phi}^a \approx -\frac{V^{,a}}{3H}, \qquad H^2 \approx \frac{V}{3M_P^2},$$
(B.7)

where $V^{,a} = K^{ab}V_{,b}$. With the Friedmann equation, the time derivative of the scalar field is given in terms of the scalar fields as

$$\dot{\phi}^a \approx -\frac{M_P V^{,a}}{\sqrt{3V}}.$$
 (B.8)

B.1 Slow-roll parameters, e-folding, and observables

The slow-roll parameters are extended by taking the multi-field contributions into the account as

$$\epsilon_V \coloneqq \frac{M_P^2}{2} \frac{V_{,a} V^{,a}}{V^2},\tag{B.9}$$

$$\eta_{V_b^a} \coloneqq \frac{M_P^2 V_{;b}^{;a}}{V}.$$
(B.10)

The end of the inflation is characterized by $\epsilon_V = 1$, and the slow-roll regime is given by $\epsilon_V < 1$ and $|\eta_V_b^a| < 1$.

The e-folding before the end of the inflation is defined by $N = \log(a_f/a)$, where a_f denotes the scale factor at the end of the inflation. a in the denominator gives the t dependence of N. This is written by the integration of the Hubble parameter as

$$N = \int_{t(\phi)}^{t_f} \mathrm{d}t' H(t'), \tag{B.11}$$

and the derivative of N with respect of t satisfies

$$\frac{\mathrm{d}N}{\mathrm{d}t} = -H.\tag{B.12}$$

From this equation, the following useful relation is obtained

$$H = -N_{,a}\dot{\phi}^a \approx N_{,a}\frac{V^{,a}}{3H},\tag{B.13}$$

where the slow-roll EOM (B.7) is used in the second equality. This equation can be formally solved, and $N_{,a}$ is written as

$$N_{,a} = \frac{1}{M_P^2} \frac{VV_{,a}}{V_{,b}V^{,b}} + \perp_a, \tag{B.14}$$

where \perp_a denotes a term orthogonal to $V_{,a}$. In this work, we focus on the first term. In the canonically normalized single-field case, this equation reduces to the well-known form

$$N_{\phi} = \frac{1}{M_P^2} \frac{V}{\partial_{\phi} V},\tag{B.15}$$

because the $\partial_{\phi} V$ in the numerator and denominator are cancelled.

The power spectrum $\mathcal{P}_{\mathcal{R}}$, spectral index n_s , and tensor-to-scalar ratio r are given by $N_{,a}$ and slow-roll parameters as

$$\mathcal{P}_{\mathcal{R}} = \left(\frac{H}{2\pi}\right)^2 N_{,a} N^{,a},\tag{B.16}$$

$$n_s = 1 - 2\epsilon_V - \frac{2}{M_P^2 N_{,a} N^{,a}} + \frac{2\eta_{Vab} N^{,a} N^{,o}}{N_{,c} N^{,c}},$$
(B.17)

$$r \coloneqq \frac{\mathcal{P}_t}{\mathcal{P}_{\mathcal{R}}} = \frac{8}{M_P^2 N_{,a} N^{,a}}.$$
(B.18)

B.2 Field equations

In this section, let us rewrite the Klein-Gordon equation in (B.3). It is useful to use the e-folding N instead of the physical time. Using (B.12), Eq. (B.3) becomes

$$\phi^{a\prime\prime} - 3\left(1 - \frac{1}{6M_P^2} K_{bc} \phi^{b\prime} \phi^{c\prime}\right) \left(\phi^{a\prime} - \frac{M_P^2 K^{ab} V_{,b}}{V}\right) + \gamma^a_{bc} \phi^{b\prime} \phi^{c\prime} = 0.$$
(B.19)

The prime denotes the derivative with respect to N. When we derive this equation, we use the Friedmann equation, which is written in this case as

$$H^{2} = \frac{\frac{V}{3M_{P}^{2}}}{1 - \frac{1}{6M_{P}^{2}}K_{ab}\phi^{a\prime}\phi^{b\prime}}.$$
 (B.20)

In the slow-roll region, ϕ'' and $(\phi')^2$ are dropped and Eq. (B.19) becomes

$$\phi^{a\prime} = \frac{M_P^2 V^{,a}}{V},\tag{B.21}$$

which is consistent with Eq. (B.8).

Figure 14: The time evolution with N after the slow-roll inflation for $\alpha = 0.1$ (left) and 5 (right). Moduli fields settle down into the vacuum immediately, oscillating around the vacuum. Note that N formally becomes negative for $|\eta_{V_b}^a| > 1$.

Comments on EOMs after slow-roll. In our model introduced in Sec. 3, the EOMs of modulus field (B.19) is given by

$$\tau_R'' - 3\left(1 - h\frac{\tau_R'^2 + \tau_I'^2}{12\tau_I^2}\right) \left(\tau_R' - \frac{2\tau_I^2 V_{,\tau_R}}{hV}\right) - \frac{2\tau_R' \tau_I'}{\tau_I} = 0,$$
(B.22)

$$\tau_I'' - 3\left(1 - h\frac{\tau_R'^2 + \tau_I'^2}{12\tau_I^2}\right) \left(\tau_I' - \frac{2\tau_I^2 V_{,\tau_I}}{hV}\right) + \frac{\tau_R'^2 - \tau_I'^2}{\tau_I} = 0.$$
 (B.23)

When moduli cease slow-roll, we have to use these equations to study the scalar field dynamics after the slow-roll inflation. The time evolution of the moduli fields after the slow-roll inflation is shown in Fig. 14. These time evolutions correspond to the black solid lines at the end of the inflation in Fig. 7. We set N = 0 at $|\eta_{V_b}^a| = 1$ and hence note that N formally becomes negative for $|\eta_{V_b}^a| > 1$ after the slow-roll inflation. Moduli settle down into the vacuum immediately after the end of the slow-roll inflation, oscillating around the vacuum. From these observations, we use the slow-roll approximation of Eq. (B.21) to study the slow-roll inflaton.

C Inflation via balance between two matter contributions

In this appendix, we discuss the other direction of the modification with the superpotential correction. Instead of the introduction of the additional term in the Kähler potential (3.10), let us consider the following additional matter contribution

$$W = \Lambda^2 \left[Y_1^{3,6} X + \beta Y_1^{3,4} X' \right], \tag{C.1}$$

$$K = -h\log(-i\tau + i\bar{\tau}) + \frac{|X|^2}{(-i\tau + i\bar{\tau})^{-k_X}} + \frac{|X'|^2}{(-i\tau + i\bar{\tau})^{-k_{X'}}},$$
(C.2)

Figure 15: The scalar potential with the suprepotential (C.1) and the Kähler potential (C.2). We choose $\beta^2 = 6.2972$.

where $k_{X'}$ denotes the modular weight of X', and β is a parameter associated with the additional contribution in the superpotential. The scalar potential is given by

$$V = (2\tau_I)^6 |Y_1^{3,6}|^2 + \beta^2 (2\tau_I)^4 |Y_1^{3,4}|^2,$$
(C.3)

where we have assumed $X \ll 1$ and $X' \ll 1$. As discussed in Sec. 3, the τ_I dependence in the scalar potential is determined by the modular weights of modular forms. The profile of $(2\tau_I)^6 |Y_1^{3,6}|^2$ and $(2\tau_I)^4 |Y_1^{3,6}|^2$ in $\tau_I = 1$ section is shown in the left panel of Fig. 15. With a tuning of β , it seems possible to realize an apparent flat potential in τ_R direction [80,81] at the first sight, because there is the relative phase shift of π between two modular forms in the superpotential. This can be seen from the q expansion (A.22) and (A.23),

$$Y_1^{3,4} \sim 1 + 240q, \qquad Y_1^{3,6} \sim 1 - 504q,$$
 (C.4)

where $q = e^{2\pi i \tau}$. The scalar potential with $\beta^2 = 6.2972$ is shown in the right panel of Fig. 15 and there seems to exist a flat hilltop in the τ_R direction of the scalar potential (C.3). However, τ_I in this potential is not stabilized around the hilltop and hence that direction still steep for realizing the successful slow-roll inflation as shown in Fig. 16, where colored region shows the slow-roll parameters are bigger than unity. This is one of motivations to introduce δK into the Kähler potential.

D Inflation rolling into other vacuum

In this section, we discuss the inflationary trajectories rolling into the vacuum at $\tau = \frac{1+i}{2}$, which is identical to $\tau = i$ under the *S* and *T* modular transformations. The slow-roll inflation turns out to be similarly feasible around this vacuum as shown below. As arrows seen in Fig. 7, if the initial value of the modulus is $\tau_I \leq 1$, the moduli fields settle down into this vacuum after the inflation. Fig. 17 shows such two trajectories starting at N = 60 for

Figure 16: The parameter spaces of the scalar potential (C.3) with $\beta^2 = 6.2972$. The scalar potential turns out to be steep.

Figure 17: The vector plots of the potential gradients $-\frac{K^{ab}V_{,b}}{V}$ and inflationary trajectories going into the vacuum at $\tau = \frac{1+i}{2}$. For the details, see the caption of Fig. 7.

 $\alpha = 0.1$ (left panel) and 5 (right panel). Black solid lines show the inflationary trajectories where a combination of moduli including τ_R plays the inflaton, whereas black dashed ones show the similar trajectories where τ_I drives the inflation in terms of pole inflation. Figs. 18 and 19 show the time evolution of the moduli fields along the solid lines and dashed ones in Fig. 17, respectively. On the trajectories, the inflation can be realized but the perturbativity of δK during the inflation is not obvious because the small τ_I makes δK large.

We have summarized in Tab. 2 the spectral index n_s , tensor-to-scalar ratio r, power spectrum $\mathcal{P}_{\mathcal{R}}$, the overall scale Λ , and $|F_X|$ in the vacuum for each inflationary trajectory in Figs. 18 and 19. It is found that the inflaton driven by τ_I for $\alpha = 0.1$ produces too small n_s , which is inconsistent with the current observation.

Figure 18: The time evolution of the moduli fields on the black solid lines in Fig. 17. α is chosen as 0.1 (left) and 5 (right).

trajectory	n_s	r	$\mathcal{P}_{\mathcal{R}}/(\Lambda/M_P)^4$	Λ/M_P	$ F_X/M_P^2 $
(a) in Fig. 18	0.966	6.33×10^{-5}	1.07×10^4	6.66×10^{-4}	2.23×10^{-10}
(a') in Fig. 19	0.744	7.69×10^{-11}	8.41×10^{9}	2.24×10^{-5}	2.52×10^{-13}
(b) in Fig. 18	0.993	4.12×10^{-5}	3.28×10^2	1.60×10^{-3}	1.27×10^{-9}
(b') in Fig. 19	0.965	1.40×10^{-5}	9.67×10^2	1.21×10^{-3}	7.42×10^{-10}

Table 2: Values of n_s , r, $\mathcal{P}_{\mathcal{R}}$, Λ in the superpotential, and F_X for each trajectory in Figs. 18 and 19. n_s and r are evaluated at N = 60.
