Enhanced Superconducting Diode Effect due to coexisting Phases

Sayan Banerjee¹ and Mathias S. Scheurer¹

¹Institute for Theoretical Physics, University of Innsbruck, Innsbruck A-6020, Austria

The superconducting diode effect refers to an asymmetry in the critical supercurrent $J_c(\hat{n})$ along opposite directions, $J_c(\hat{n}) \neq J_c(-\hat{n})$. While the basic symmetry requirements for this effect are known, it is, for junction-free systems, difficult to capture within current theoretical models the large current asymmetries $J_c(\hat{n})/J_c(-\hat{n})$ recently observed in experiment. We here propose and develop a theory for an enhancement mechanism of the diode effect arising from spontaneous symmetry breaking. We show—both within a phenomenological and a microscopic theory—that there is a coupling of the supercurrent and the underlying symmetry-breaking order parameter. This coupling can enhance the current asymmetry significantly. Our work might not only provide a possible explanation for recent experiments on trilayer graphene but also pave the way for future realizations of the superconducting diode effect with large current asymmetries.

Diodes, which are characterized by a highly asymmetric relation between resistance R and current J, $R(\mathbf{J}) \neq R(-\mathbf{J})$, are an integral part of modern-day electronics. A superconductor where the critical current J_c is different along opposite directions, $J_c(\hat{n}) > J_c(-\hat{n})$, can realize a superconducting analogue of a diode in the sense that $R(-J\hat{n}) \neq R(J\hat{n}) = 0$, if $J_c(-\hat{n}) < J < J_c(\hat{n})$. While asymmetries in superconducting current-voltage relations in low-symmetry superconductors had been observed before, see, e.g., [1-3], the potential technological applications of and fundamental scientific questions associated with this superconducting diode effect (SDE) have attracted significant experimental [4-28] and theoretical [29–58] attention in recent years; this led to a variety of different realizations both in tunnel-junction setups [10-24] and in single junction-free superconducting phases [4–9, 25–28]. Importantly, critical current asymmetries in superconductors require broken timereversal symmetry (TRS), which can not only be achieved by applying a magnetic field [4–17], a current [21, 22], or magnetic proximity [23, 24, 27, 28], but also result from spontaneous TRS-breaking in a junction [18-20]or homogeneous superconductor [25, 26]; aside from the fundamental interest in the competition of magnetism and superconductivity in a single electron liquid, this might also be useful for integrated designs where external fields are not practical. Another crucial aspect for applications is the degree of current asymmetry, conveniently measured by the dimensionless diode efficiency $\eta(\hat{n}) = |J_c(\hat{n}) - J_c(-\hat{n})| / (J_c(\hat{n}) + J_c(-\hat{n})).$ A large efficiency, as close to 1 as possible, is desirable for the system to operate as a superconducting diode without having to fine-tune the current magnitude.

In this work, we propose and demonstrate theoretically an enhancement mechanism for the SDE efficiency η , specifically for systems with spontaneously broken TRS. While it is clear by symmetry that the condensation of a time-reversal-odd order parameter can affect the critical supercurrent and induce a SDE, we here demonstrate that the supercurrent also couples back to the underlying symmetry-breaking order parameter. If superconductivity and the TRS-breaking order have similar energy scales, this "back action" can be quite large and, as we demonstrate, can enhance η significantly. Although this mechanism is more generally valid and should apply to different models and forms of the time-reversal-odd order parameter, we use a model inspired by graphene moiré systems; this is motivated by Ref. 25 where a junctionfree sample of twisted trilayer graphene was studied and a zero-field SDE with a particularly large η was observed. Our work, thus, both provides a possible route to explaining the large η of Ref. 25 and paves the way for the design of zero-field superconducting diodes with large current asymmetries.

Model for SDE.—As motivated above, we study an electronic Hamiltonian of the form

$$\mathcal{H}_{c} = \sum_{\boldsymbol{k},\eta} \xi_{\boldsymbol{k},\eta} c_{\boldsymbol{k},\eta}^{\dagger} c_{\boldsymbol{k},\eta} + \Phi_{V} \sum_{\boldsymbol{k},\eta} \eta c_{\boldsymbol{k},\eta}^{\dagger} c_{\boldsymbol{k},\eta} + \sum_{\boldsymbol{k},\boldsymbol{q}} \left[\Delta_{\boldsymbol{q}} c_{\boldsymbol{k}+\boldsymbol{q}/2,+}^{\dagger} c_{-\boldsymbol{k}+\boldsymbol{q}/2,-}^{\dagger} + \text{H.c.} \right],$$
(1)

where $c_{\mathbf{k},\eta}^{\dagger}$ creates an electron in valley $\eta = \pm$ and at momentum \mathbf{k} . The three terms in \mathcal{H}_c capture the noninteracting bandstructure of the nearly flat bands at the chemical potential, which obey $\xi_{\mathbf{k},\eta} = \xi_{-\mathbf{k},-\eta} \equiv \xi_{\mathbf{k}\cdot\eta}$ due to TRS, the coupling of the TRS-breaking normal state order (in our case, valley imbalance Φ_V) and of the superconducting order parameter to the electrons, respectively. For notational simplicity, we suppress the spin index in Eq. (1) and in the following, but emphasize that our results apply both for spin polarized bands [59, 60] as well as in the spinful case, with singlet or triplet pairing.

To stabilize superconductivity, we take an attractive $(g_c > 0)$ interaction $\mathcal{H}_{g_c} = -\frac{g_c}{2} \sum_{\boldsymbol{q},\eta,\eta'} C^{\dagger}_{\boldsymbol{q};\eta,\eta'} C_{\boldsymbol{q};\eta,\eta'} C_{\boldsymbol{q$

more susceptible to impurities and, hence, likely less relevant experimentally. The resulting mean-field Hamiltonian for superconductivity for given valley polarization Φ_V then reads as $\mathcal{H}_{\rm S} = \mathcal{H}_c + \sum_{\boldsymbol{q}} |\Delta_{\boldsymbol{q}}|^2 / g_c$. While we will compute the supercurrent systematically below, we start for illustration purposes with a semi-phenomenological approach based on a Ginzburg-Landau expansion. Integrating out the electrons in $\mathcal{H}_{\rm S}$ and expanding up to second order in $\Delta_{\boldsymbol{q}}$, the change $\delta \mathcal{F}_{\rm S} := \mathcal{F}[\Delta_{\boldsymbol{q}}, \Phi_V] - \mathcal{F}[0, \Phi_V]$ of the free-energy with superconductivity reads as

$$\delta \mathcal{F}_{\rm S} \sim \sum_{\boldsymbol{q}} a_{\boldsymbol{q}}^{\rm S} |\Delta_{\boldsymbol{q}}|^2 + b^{\rm S} \sum_{\boldsymbol{q}_i} \Delta_{\boldsymbol{q}_1}^* \Delta_{\boldsymbol{q}_2}^* \Delta_{\boldsymbol{q}_3} \Delta_{\boldsymbol{q}_4} \delta_{\boldsymbol{q}_1 + \boldsymbol{q}_2, \boldsymbol{q}_3 + \boldsymbol{q}_4},$$

where we neglected the momentum dependence of the quartic term. It holds $a_{\boldsymbol{q}}^{\mathrm{S}} = 1/g_c - \Gamma_{\boldsymbol{q}}$ with [34]

$$\Gamma_{\boldsymbol{q}} = \frac{1}{2N} \sum_{\boldsymbol{k}} \frac{\tanh \frac{E_{\boldsymbol{k},\boldsymbol{q},+}}{2T} + \tanh \frac{E_{\boldsymbol{k},\boldsymbol{q},-}}{2T}}{E_{\boldsymbol{k},\boldsymbol{q},+} + E_{\boldsymbol{k},\boldsymbol{q},-}}, \qquad (2)$$

where N is the number of unit cells and $E_{\mathbf{k},\mathbf{q},\eta} = \xi_{\mathbf{k}+\eta\mathbf{q}/2} + \eta \Phi_V$ encodes the normal-state dispersion, associated with the first line of Eq. (1).

The equilibrium superconducting state at given Φ_V is found by minimizing $\delta \mathcal{F}_S$. Restricting the analysis to single- \boldsymbol{q} states, $\Delta_{\boldsymbol{q}} \propto \delta_{\boldsymbol{q},\boldsymbol{q}_0}$, the value of \boldsymbol{q}_0 is determined by the minimum of $a_{\boldsymbol{q}}^S$ (the maximum of $\Gamma_{\boldsymbol{q}}$). As expected, the current [30, 31, 34]

$$\boldsymbol{J}(\boldsymbol{q}) = 2e\Delta_{\boldsymbol{q}}\boldsymbol{v}_{\boldsymbol{q}}, \quad \boldsymbol{v}_{\boldsymbol{q}} = \boldsymbol{\nabla}_{\boldsymbol{q}}a_{\boldsymbol{q}}^{\mathrm{S}}, \quad (3)$$

vanishes in equilibrium, $J(q_0) = 0$; a supercurrentcarrying state, therefore, corresponds to pairing with $q \neq q_0$. We define the critical current $J_c(\hat{n})$ along \hat{n} as the maximal magnitude of J(q) oriented along \hat{n} .

For $\Phi_V = 0$, it holds $E_{\mathbf{k},\mathbf{q},\eta} = E_{\mathbf{k},-\mathbf{q},-\eta}$ and thus $\Gamma_{\mathbf{q}} = \Gamma_{-\mathbf{q}}$ in Eq. (2). This, in turn, immediately implies $\mathbf{J}(\mathbf{q}) = -\mathbf{J}(-\mathbf{q})$ and $J_c(\hat{n}) = J_c(-\hat{n})$, i.e., there is no SDE. This was expected as a consequence of TRS or two-fold rotational symmetry, C_{2z} , for that matter—both have to be broken to get $J_c(\hat{n}) \neq J_c(-\hat{n})$. This is achieved by $\Phi_V \neq 0$ [34], leading to a finite SDE efficiency,

$$\eta = \max_{\hat{n}} \frac{|J_c(\hat{n}) - J_c(-\hat{n})|}{J_c(\hat{n}) + J_c(-\hat{n})} \in [0, 1].$$
(4)

Although generically non-zero by symmetry, it does not guarantee that η can reach high values corresponding to large current asymmetries, $J_c(\hat{n}) \gg J_c(-\hat{n})$ —as mentioned above, a property desirable for applications of the SDE and relevant fundamentally to understand recent experiments [25].

Phenomenological coupling.—The main result of this work is that the diode-effect efficiency η can be significantly enhanced by taking into account that the strength

of the valley polarization is affected by the supercurrent or, put differently, Φ_V entering $E_{k,q,\eta}$ in Eq. (2) also depends on the center of mass momentum \boldsymbol{q} of the Cooper pairs, $\Phi_V \to \Phi_V(\boldsymbol{q})$. Postponing a systematic microscopic computation that treats $\Delta_{\boldsymbol{q}}$ and $\Phi_V(\boldsymbol{q})$ on equal footing, we start with a simpler phenomenological analysis. In this simplified description, we determine $\Phi_V(\boldsymbol{q})$ by minimizing the free energy

$$\mathcal{F}_{\mathrm{V}} \sim a_{\Phi} \Phi_{V}^{2} + b_{\Phi} \Phi_{V}^{4} + \Phi_{V} \sum_{\boldsymbol{q}} |\Delta_{\boldsymbol{q}}|^{2} \left[F(\boldsymbol{q}) + \alpha'' \Phi_{V} \right]$$
(5)

with respect to Φ_V , where terms involving fifth and higher powers of the order parameters Φ_V , Δ_q are neglected. The first two terms in \mathcal{F}_V determine the value of Φ_V in the absence of superconductivity. Meanwhile, the remaining terms in Eq. (5) capture the key coupling between the momentum of the Cooper pairs and valley polarization. The last term, $\propto \alpha''$, simply describes the fact that increasing (decreasing) the superconducting order parameter magnitude suppresses (enhances) valley polarization. The other term with F(q) = -F(-q) describes the fact that superconductivity at finite q breaks TRS and C_{2z} and can, hence, couple to the first (and in general an odd) power of Φ_V . Motivated by twisted graphene systems, which exhibit C_{3z} rotational symmetry, we write

$$F(\boldsymbol{q}) = \alpha \, \hat{\boldsymbol{e}}_{\epsilon} \cdot \boldsymbol{X}(\boldsymbol{q}) + \alpha' \, \chi(\boldsymbol{q}), \tag{6}$$

where X(q) and $\chi(q)$ are real-valued, periodic on the Brillouin zone, odd in q, and transform as a vector and scalar under C_{3z} , respectively; in the limit of small q, it holds $\boldsymbol{X} \sim (q_x, q_y)^T$ and $\chi(\boldsymbol{q}) \sim q_x(q_x^2 - 3q_y^2)$, using a convention where one of the primitive translation vectors, a_i , of the underlying triangular Bravais lattice points along the x direction. For the following calculations, we extend these functions to the Brillouin zone using the leading lattice harmonics (see Appendix A). Importantly, the first term in Eq. (6), requires finite strain or nematic order which break C_{3z} symmetry explicitly. These phenomena, which seem to be ubiquitous in graphene moiré systems [61–67], define a preferred in-plane direction, captured by the unit vector $\hat{\boldsymbol{e}}_{\epsilon}$. For instance, in the case of strain, $\hat{\boldsymbol{e}}_{\epsilon} \propto (\epsilon_{xx} - \epsilon_{yy}, \epsilon_{xy} + \epsilon_{yz})^T$, where ϵ_{ij} are the straintensor elements. We note that the coupling would also be present when Φ_V is replaced by another order parameter that itself already breaks both TRS and C_{3z} simultaneously [67, 68]. The second term in Eq. (6), albeit subleading for small q, is finite regardless of whether C_{3z} is broken.

To study the SDE, we self-consistently minimize $\mathcal{F}_V[\Phi_V, \Delta_{\boldsymbol{q}}]$ and $\delta \mathcal{F}_S[\Phi_V, \Delta_{\boldsymbol{q}}]$ with respect to Φ_V and $\Delta_{\boldsymbol{q}}$, respectively, for given \boldsymbol{q} , and compute the current according to Eq. (3). For concreteness, we use a nearest-neighbor dispersion with finite flux ϕ on the triangular lattice, $\xi_{\boldsymbol{k}} = -\sum_{j=1}^3 t_j \cos(\boldsymbol{a}_j \cdot \boldsymbol{k} - \phi/3)$ where \boldsymbol{a}_j are

FIG. 1: Phenomenological theory with leading nematic coupling, $\alpha \neq 0$, $\alpha' = \alpha'' = 0$ in Eq. (5). $\Phi_v(\boldsymbol{q})$ and $\Gamma(\boldsymbol{q})$ for (a) $\alpha = -0.5$ and (b) $\alpha = -3.0$ are shown in upper and lower panels, respectively. (c) Angular (\hat{n}) dependence of J_c for different α , taking $|\Phi(\boldsymbol{q}=0)| = 0.32$. (d) SDE efficiency η for different α as a function of valley polarization at $\boldsymbol{q} = 0$. We use $g_c^{-1} = 0.8\Gamma_{\boldsymbol{q}=0}[\Phi_V(\boldsymbol{q}=0)], \ \mu = -0.68, \ \phi = -0.7\pi, T = 0.2, \ \hat{\boldsymbol{e}}_{\epsilon} = (\cos \pi/3, \sin \pi/3).$

three C_{3z} -related primitive vectors. We choose $t_1 = t$, $t_2 = t_3 = t(1 + \beta)$ to parameterize the impact of strain $(\propto \beta)$ on the dispersion and, for notational simplicity, measure all energies in units of t in the following.

Back action and SDE.—We start with the first term in Eq. (6), i.e., set $\alpha' = \alpha'' = 0$ in \mathcal{F}_V . As can be seen in Fig. 1(a), finite α now induces a \boldsymbol{q} dependence in Φ_V , which breaks C_{3z} symmetry as a result of the preferred direction associated with $\hat{\boldsymbol{e}}_{\epsilon}$. As we set $\beta = 0$ for now, $\Gamma_{\boldsymbol{q}}$ looks virtually C_{3z} symmetric, while larger α will lead to a noticeable asymmetry in Γ_q as well, see Fig. 1(b). This results from a "back action mechanism", where a finite supercurrent, which is associated with detuning the center of mass momentum $q_0 \rightarrow q + \delta q_0$ of the Cooper pairs away from their equilibrium value q_0 , changes the strength of Φ_V ; as increasing (decreasing) Φ_V will weaken (strengthen) superconductivity, this, in turn, influences Γ_q . This can be thought of as the supercurrent analogue of the coupling between the dissipative current and valley polarization observed in graphene moiré systems [69–71]. We note in passing that a sufficiently strong supercurrent can also flip the sign Φ_V in our theory.

This back action also affects the \boldsymbol{q} dependence of the supercurrent, which allows to enhance the SDE as can be seen in Fig. 1(c). We further present in Fig. 1(d) the diode efficiency η as a function of $\Phi_V(\boldsymbol{q}=0)$ for different strengths of the back action. Without back action $(\alpha = 0, \text{ red dashed line}), \eta$ does not exceed 30%, corresponding to $J_c(\hat{n}) \simeq 1.86J_c(-\hat{n})$. In contrast, increasing α and, thus, boosting the back action mechanism can significantly enhance the SDE, even reaching efficiencies as high as 75% (solid black line), i.e., $J_c(\hat{n}) \simeq 7J_c(-\hat{n})$.

FIG. 2: Phenomenological theory with C_{3z} -symmetric coupling, $\alpha' \neq 0$, $\alpha = 0$, $\alpha'' = 1.0$ in Eq. (5). $\Phi_v(\boldsymbol{q})$ and $\Gamma(\boldsymbol{q})$ in (a) and (b) are shown for $\alpha' = 0.8$ and (c) displays the angular (\hat{n}) dependence of J_c for different α' . We use $g_c^{-1} = 0.7\Gamma_{\boldsymbol{q}=0}[\Phi_V = 0.32], \ \mu = -0.68, \ \phi = -0.7\pi, \ T = 0.2.$

This enhancement mechanism of the SDE is also possible in the presence of C_{3z} , where $\alpha = 0$, if we take into account finite α' in Eq. (6), see Fig. 2. We can clearly see the induced q (and thus supercurrent) dependence of Φ_V in Fig. 2(a). However, the back action onto Γ_q is less clearly seen in Fig. 2(b) at a single α' , since it is C_{3z} symmetric with and without it. Most importantly, though, Fig. 2(c) reveals that also the subleading back action ($\alpha = 0$) enhances the current asymmetry.

Self-consistent theory.—Having established a phenomenological understanding of the enhancement of the SDE from the back action mechanism, we next turn our attention to a systematic self-consistent formalism. We switch to an action formalism and redefine $c_{\mathbf{k},\eta}$ in Eq. (1) as Grassmann variables depending on imaginary time τ . We start from the effective action

$$S = \int \mathrm{d}\tau \left[\sum_{\boldsymbol{k},\eta} c^{\dagger}_{\boldsymbol{k},\eta} \partial_{\tau} c_{\boldsymbol{k},\eta} + \mathcal{H}_{c} + S_{\Delta} + S_{\Phi} \right], \quad (7)$$

that captures the desired phenomenology in a minimal setting. In Eq. (7), $S_{\Delta} = \sum_{\boldsymbol{q}} (\frac{1}{g_c} |\Delta_{\boldsymbol{q}}|^2 + u_{\Delta} |\Delta_{\boldsymbol{q}}|^4)$ and $S_{\Phi} = \frac{1}{g_v} \Phi_V^2 + v_{\Phi_V} \Phi_V^4$ are the bare actions of the Hubbard-Stratonovich fields associated with superconductivity and valley polarization, respectively. We include terms up to quartic order (which, e.g., arise after having integrated out electronic degrees of freedom at higher energies) to stabilize coexistence of these two orders, as is seen in experiment [25, 34, 72].

The saddle-point equations for Φ_V and Δ_q read as

$$\frac{\Phi_V}{g_v} + 2v_{\Phi}\Phi_V^3 = \frac{1}{4}\sum_{\boldsymbol{k}, p=\pm} p \tanh\frac{\mathcal{E}_{\boldsymbol{k}, \boldsymbol{q}, p}}{2T}, \qquad (8a)$$

$$\frac{1}{g_c} + 2u_{\Delta} |\Delta_{\mathbf{q}}|^2 = \sum_{\mathbf{k}} \frac{\left(\tanh \frac{\mathcal{E}_{\mathbf{k},\mathbf{q},+}}{2T} + \tanh \frac{\mathcal{E}_{\mathbf{k},\mathbf{q},-}}{2T}\right)}{2(\mathcal{E}_{\mathbf{k},\mathbf{q},+} + \mathcal{E}_{\mathbf{k},\mathbf{q},-})}, \quad (8b)$$

or $\Delta_{\boldsymbol{q}} = 0$, where $\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},p} = \sqrt{\zeta_{\boldsymbol{k},\boldsymbol{q},+}^2 + |\Delta_{\boldsymbol{q}}|^2} + p \zeta_{\boldsymbol{k},\boldsymbol{q},-}$ with $\zeta_{\boldsymbol{k},\boldsymbol{q},\pm} = (E_{\boldsymbol{k},\boldsymbol{q},+} \pm E_{\boldsymbol{k},\boldsymbol{q},-})/2$. As required, Eq. (8b)

FIG. 3: Coupling of supercurrent to valley polarization within microscopic theory. $\Phi_V(\mathbf{q})$ and $\Delta(\mathbf{q})$ along one-dimensional momentum cut with angle $\pi/6$ relative to the q_x axis (a) without form factors ($f_k = 1$) and (b) with form factors, $f_k = \sum_{j=1}^3 \sin a_j \cdot \mathbf{k}$. The red (blue) hexagon denotes the maximum (minimum) of $\Delta(\mathbf{q})$ and $\Phi_V(\mathbf{q})$, respectively. We use $\beta = 0.6$, $\mu = -1.36$, $g_c = 5.6$, $g_v = 11$, $u_{\Delta} = 0.25$, $v_{\Phi} = 0.125$, T = 0.4.

becomes equivalent to $a_{\boldsymbol{q}}^{\mathrm{S}} = 0$ when expanded to leading order in $\Delta_{\boldsymbol{q}}$.

We solve Eq. (8) self-consistently for both $\Delta_{\boldsymbol{q}}$ and Φ_V for given q. This captures the mutual influence of these two orders, as $\Delta_{\boldsymbol{q}}$ and Φ_{V} enter each other's saddle-point equation, Eqs. (8a) and (8b), respectively, via the dispersion \mathcal{E} . Broken C_{3z} symmetry is entirely encoded in the parameter β entering the bare normal-state dispersion ξ_k . Generically, the two coupled saddle-point equations are expected to capture any symmetry-allowed coupling term between $\Delta_{\boldsymbol{q}}$ and Φ_V in an effective free-energy expansion, including those in Eq. (5) but also terms involving higher powers of the order parameters. It turns out, though, that for the simple coupling in \mathcal{H}_c , where valley polarization only enters as an imbalance of the chemical potential in the two valleys, we find $\alpha = 0$ in Eq. (6) for any β . This is readily shown by expanding Eq. (8a) in terms of $\delta \Phi_V(\boldsymbol{q}) = \Phi_V(\boldsymbol{q}) - \Phi_V(0)$ at fixed $\Delta(\boldsymbol{q})$, see Appendix C. This is why the back action is dominated by the term $\alpha'' |\Delta_q|^2 \Phi_V^2$ in Eq. (6) for small q as can be seen in Fig. 3(a), where $\delta \Phi_V(q) \propto \delta \Delta(q) \sim q^2$ for small q. We have checked that generalizing the coupling to $\Phi_V \sum_{\boldsymbol{k},\eta} \eta f_{\boldsymbol{k}\cdot\eta} c_{\boldsymbol{k},\eta}^{\dagger} c_{\boldsymbol{k},\eta}$, with C_{3z} -invariant form factors f_k , leads to finite α ; this is clearly visible in Fig. 3(b), where $\Phi_V(\boldsymbol{q})$ is found to have a finite slope at the maximum (red hexagon) of $\Delta(\boldsymbol{q})$.

SDE in self-consistent theory.—To demonstrate that the enhancement mechanism for the SDE based on the back action is a robust phenomenon, we here discuss it for the original from of the order parameter Φ_V without form factors, $f_{\mathbf{k}} = 1$, where the leading coupling ($\propto \alpha$) in the phenomenological theory in Eq. (5) is absent. In Fig. 4(a), we plot $\Phi_V(\mathbf{q})$ and $\Delta(\mathbf{q})$, obtained by solving Eq. (8). We can clearly see the supercurrent-induced change of valley polarization, which is manifestly not C_{3z} invariant, due to $\beta \neq 0$, and exhibits the strongest asymmetry under $\mathbf{q} \to -\mathbf{q}$ for \mathbf{q} along q_x . Due to the ad-

FIG. 4: SDE within self-consistent theory, Eq. (7). (a) shows $\Phi_V(\mathbf{q})$ and $\Delta(\mathbf{q})$ in the upper and lower panel, for $|\Phi_V(\mathbf{q}=0)| = 0.48$ and $\beta = 0.6$. Resulting angular dependence of J_c is shown without strain in (b) and with strain ($\beta = 0.6$) in (c). (d) Efficiency η as a function of $\Phi_V(\mathbf{q}=0)$ in presence of strain with back action (black solid line) and without back action (red dotted line). The parameters for g_c , T, μ , v_{Φ} , u_{Δ} are the same as in Fig. 3; only g_v is varied to change $\Phi_V(\mathbf{q}=0)$.

ditional coupling terms beyond those in Eq. (5), $\Phi_V(q)$ looks different at large q from that shown in Fig. 2(a). However, the for our purpose more important $\Delta(q)$ looks very similar to Γ_q in Fig. 2(b). Evaluating the thermal expectation value of the current operator within the full theory (see Appendix D) as a function of q, we compute the directional dependence of the critical current, shown in Fig. 4(b) and (c) for $\beta = 0$ and $\beta \neq 0$, respectively. Exactly as in the phenonemological theory, we find that broken C_{3z} symmetry can enhance the SDE and that the current asymmetry first increases with small Φ_V (as significant TRS breaking is needed to generate a large current asymmetry) but then eventually decreases with large Φ_V (as it destabilizes superconductivity and also weakens the back action). This is also visible in Fig. 4(d), where we plot the SDE efficiency η of the full self-consistent theory (black line) as a function of valley polarization at q = 0 and compare it with the situation without back action (red dashed line); for the latter, we just fix Φ_V at the indicated value $\Phi_V(\boldsymbol{q}=0)$, independent of q and solve for superconductivity via Eq. (2). We observe that the back action not only enhances, as before, the maximum value of η that can be achieved, but also increases the efficiency significantly at smaller values of valley polarization. The reason for this amplification is the aforementioned dominance of the α'' -like couplings in the self-consistent theory, which enhance $\Phi_V(q)$ when suppressing $\Delta_{\boldsymbol{q}}$ with finite \boldsymbol{q} , see also Fig. 3(a). So even if we have very small $\Phi_V(\boldsymbol{q}=0)$, valley polarization can reach sizable values at non-zero q due to the coupling to the supercurrent, which in turn enhances the diode effect. This is why η reaches finite values in the limit $\Phi_V(\boldsymbol{q}=0) \to 0^+$ with back action, while it has to vanish linearly with $\Phi_V(\boldsymbol{q}=0)$ without it in Fig. 4(d). It shows that the proposed back action mechanism also enhances the *typical* η which can reach large values without the need of fine-tuning $\Phi_V(\boldsymbol{q}=0)$ to its optimal strength.

Conclusion.—We have shown, both using a simple freeenergy expansion and a self-consistent theory, that the supercurrent can couple to and, hence, affect the valley polarization, Φ_V , which in turn can enhance the SDE efficiency significantly, see Fig. 1(d) and Fig. 4(d). Motivated by Ref. 25, this was formulated for a theory applicable to graphene-based systems; however, we expect that the basic mechanism based on coupling of the su-

Appendix A: Details of models

We here state the explicit form of the basis functions used to parameterize the phenomenological coupling in Eq. (6) of the main text. Applying the convention, where one of the primitive lattice vectors of the underlying triangular

lattice is given by $\boldsymbol{a}_1 = (1, 0)^T$, these functions read as

$$\boldsymbol{X}(\boldsymbol{q}) = \left(\frac{2}{3}\left(2\cos\frac{q_x}{2} + \cos\frac{\sqrt{3}q_y}{2}\right)\sin\frac{q_x}{2}, \frac{2}{\sqrt{3}}\cos\frac{q_x}{2}\sin\frac{\sqrt{3}q_y}{2}\right),\tag{A1}$$

$$\chi(\boldsymbol{q}) = 16\left(-\cos\frac{q_x}{2} + \cos\frac{\sqrt{3}q_y}{2}\right)\sin\frac{q_x}{2}.$$
(A2)

These are the leading (in the sense of having the fewest number of nodes/nodal lines) functions which obey the required symmetry constraints while being periodic on the Brillouin zone. They are illustrated in Fig. 5.

FIG. 5: Momentum dependence of the two components of the function (a) X(q) and of (b) $\chi(q)$ as defined by Eq. (A2). The black dashed lines indicate the lines across which the function changes sign.

Appendix B: Derivation of the saddle-point equations

To derive saddle point equations, we generalize Eq. (7) to include non-trivial form factors, $f_k \neq \text{const.}$, for the coupling of valley polarization to the electrons. The associated action in Matsubara-frequency notation becomes

$$S[\Delta_{q}, \Phi_{V}] = \frac{1}{g_{v}} \Phi_{V}^{2} + \frac{1}{g_{c}} |\Delta_{q}|^{2} + v_{\Phi_{V}} \Phi_{V}^{4} + u_{\Delta} |\Delta_{q}|^{4} + \sum_{k} \Psi_{k,q}^{\dagger} \mathcal{G}_{k,q}^{-1} \Psi_{k,q},$$
(B1)

where the sum is done over $k = (\mathbf{k}, \omega_n)$, comprising momentum \mathbf{k} and Matsubara frequencies ω_n . $\mathcal{G}_{k,q}$ and $\Psi_{k,q}$ are given by

$$\mathcal{G}_{k,\boldsymbol{q}}^{-1} = \begin{bmatrix} -i\omega_n + \xi_{\boldsymbol{k}+\frac{\boldsymbol{q}}{2},+} + f_{\boldsymbol{k}+\frac{\boldsymbol{q}}{2},+} \Phi_V & \Delta_{\boldsymbol{q}} \\ \Delta_{\boldsymbol{q}}^{\dagger} & -i\omega_n - \xi_{-\boldsymbol{k}+\frac{\boldsymbol{q}}{2},-} + f_{-\boldsymbol{k}+\frac{\boldsymbol{q}}{2},-} \Phi_V \end{bmatrix}, \quad \Psi_{k,\boldsymbol{q}} = \begin{pmatrix} c_{\boldsymbol{k}+\frac{\boldsymbol{q}}{2},+} \\ c_{-\boldsymbol{k}+\frac{\boldsymbol{q}}{2},-}^{\dagger} \end{pmatrix}.$$
(B2)

Integrating out the fermions, we obtain the effective action as,

$$\mathcal{S}_{\text{eff}} = \frac{\beta}{g_v} \Phi_V^2 + \frac{\beta}{g_c} |\Delta_{\boldsymbol{q}}|^2 + \beta v_{\Phi_V} \Phi_V^4 + \beta u_\Delta |\Delta_{\boldsymbol{q}}|^4 - \sum_k \operatorname{tr} \ln \mathcal{G}_{\boldsymbol{k},\boldsymbol{q}}^{-1}.$$
(B3)

Now, we calculate the saddle point equation for $\Delta_{\boldsymbol{q}}$ we set $\delta S_{\text{eff}}/\delta \Delta_{\boldsymbol{q}} \stackrel{!}{=} 0$

$$\beta \frac{\Delta_{\boldsymbol{q}}^{\dagger}}{g_c} + 2\beta u_{\Delta} |\Delta_{\boldsymbol{q}}|^2 \Delta_{\boldsymbol{q}}^{\dagger} - \sum_k \operatorname{tr} \left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} \frac{\delta}{\delta \Delta_{\boldsymbol{q}}} \begin{pmatrix} -i\omega_n + E_{\boldsymbol{k},\boldsymbol{q},+} & \Delta_{\boldsymbol{q}} \\ \Delta_{\boldsymbol{q}}^{\dagger} & -i\omega_n - E_{\boldsymbol{k},\boldsymbol{q},-} \end{pmatrix} \right] = 0$$
(B4)

$$\beta \frac{\Delta_{\boldsymbol{q}}^{\dagger}}{g_c} + 2\beta u_{\Delta} |\Delta_{\boldsymbol{q}}|^2 \Delta_{\boldsymbol{q}}^{\dagger} - \sum_k \operatorname{tr} \left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} \begin{pmatrix} 0 & 1\\ 0 & 0 \end{pmatrix} \right] = 0 \tag{B5}$$

Now,

$$\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} = \frac{-1}{(-i\omega_n + E_{\boldsymbol{k},\boldsymbol{q},+})(-i\omega_n - E_{\boldsymbol{k},\boldsymbol{q},-}) - \Delta_{\boldsymbol{q}}^2} \begin{bmatrix} i\omega_n + E_{\boldsymbol{k},\boldsymbol{q},-} & \Delta_{\boldsymbol{q}} \\ \Delta_{\boldsymbol{q}}^{\dagger} & i\omega_n - E_{\boldsymbol{k},\boldsymbol{q},+} \end{bmatrix}$$
(B6)

where we have redefined our energies as,

$$E_{k,q,+} = \xi_{k+\frac{q}{2},+} + f_{k+\frac{q}{2},+} \Phi_V, \quad E_{k,q,-} = \xi_{-k+\frac{q}{2},-} - f_{-k+\frac{q}{2},-} \Phi_V, \tag{B7}$$

which is the generalization of the energies defined below Eq. (2) of the main text to include form factors. Therefore, the trace term reduces to

$$\sum_{k} \operatorname{tr} \left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \right] = \sum_{\boldsymbol{k},n} \frac{\Delta_{\boldsymbol{q}}^{\dagger}}{\Delta_{\boldsymbol{q}}^{2} + \zeta_{\boldsymbol{k},\boldsymbol{q},+}^{2} + (\omega_{n} + i\zeta_{\boldsymbol{k},\boldsymbol{q},-})^{2}}, \quad \text{with} \quad \zeta_{\boldsymbol{k},\boldsymbol{q},\pm} = (E_{\boldsymbol{k},\boldsymbol{q},+} \pm E_{\boldsymbol{k},\boldsymbol{q},-})/2.$$
(B8)

Performing the sum over Matsubara frequencies, we get

$$\operatorname{tr}\left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}}\begin{pmatrix}0&1\\0&0\end{pmatrix}\right] = \sum_{\boldsymbol{k}} \frac{\Delta_{\boldsymbol{q}}^{\dagger}(\tanh\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},+}}{2T} + \tanh\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},-}}{2T})}{2T(\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},+} + \mathcal{E}_{\boldsymbol{k},\boldsymbol{q},-})} \tag{B9}$$

where $\mathcal{E}_{k,q,p} = \sqrt{\zeta_{k,q,+}^2 + |\Delta_q|^2} + p \zeta_{k,q,-}$. Consequentially, this leads us to our saddle point equation for Δ_q ,

$$\frac{\Delta_{\boldsymbol{q}}^{\dagger}}{g_c} + 2u_{\Delta}|\Delta_{\boldsymbol{q}}|^2 \Delta_{\boldsymbol{q}}^{\dagger} = \sum_{\boldsymbol{k}} \frac{\Delta_{\boldsymbol{q}}^{\dagger}(\tanh\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},+}}{2T} + \tanh\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},-}}{2T})}{2(\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},+} + \mathcal{E}_{\boldsymbol{k},\boldsymbol{q},-})} \tag{B10}$$

as stated in Eq. (8b) of the main text. Moving onto the saddle point equation for valley polarization, we start similarly by setting $\delta S_{\text{eff}}/\delta \Phi_V \stackrel{!}{=} 0$

$$\frac{2\beta\Phi_V}{g_v} + 4v_\Phi\beta\Phi_V^3 - \sum_k \operatorname{tr} \left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} \frac{\delta}{\delta\Phi_V} \begin{pmatrix} -i\omega_n + E_{\boldsymbol{k},\boldsymbol{q},+} & \Delta_{\boldsymbol{q}} \\ \Delta_{\boldsymbol{q}}^{\dagger} & -i\omega_n - E_{\boldsymbol{k},\boldsymbol{q},-} \end{pmatrix} \right] = 0$$
(B11)

$$\frac{2\beta\Phi_V}{g_v} + 4v_{\Phi}\Phi_V^3 - \sum_k \operatorname{tr} \left[\mathcal{G}_{\boldsymbol{k},\boldsymbol{q}} \begin{pmatrix} \mathcal{F}_{\boldsymbol{k},\boldsymbol{q},+} & 0\\ 0 & \mathcal{F}_{\boldsymbol{k},\boldsymbol{q},-} \end{pmatrix} \right] = 0$$
(B12)

where $\mathcal{F}_{k,q,+} = f_{k+\frac{q}{2},+}$ and $\mathcal{F}_{k,q,-} = f_{-k+\frac{q}{2},-}$. Evaluating the trace, we get

$$\sum_{k} \operatorname{tr} \left[\mathcal{G}_{k,q} \begin{pmatrix} \mathcal{F}_{k,q,+} & 0\\ 0 & \mathcal{F}_{k,q,-} \end{pmatrix} \right] = \sum_{k,n} \frac{(i\omega_n + E_{k,q,-})\mathcal{F}_{k,q,+} + (i\omega_n - E_{k,q,+})\mathcal{F}_{k,q,-}}{\Delta_q^2 + \zeta_{k,q,+}^2 + (\omega_n + i\zeta_{k,q,-})^2}$$
(B13)

If we now evaluate the Matsubara sums, we arrive at

$$\sum_{k} \operatorname{tr} \left[\mathcal{G}_{k,q} \begin{pmatrix} \mathcal{F}_{k,q,+} & 0\\ 0 & \mathcal{F}_{k,q,-} \end{pmatrix} \right] = \frac{1}{2} \sum_{k} \left(F_{k,q,+} \tanh \frac{\mathcal{E}_{k,q,+}}{2T} - F_{k,q,-} \tanh \frac{\mathcal{E}_{k,q,-}}{2T} \right)$$
(B14)

where the coefficients are given by

$$F_{\boldsymbol{k},\boldsymbol{q},+} = \mathcal{F}_{\boldsymbol{k},\boldsymbol{q}+} l_{\boldsymbol{k},\boldsymbol{q}} + \mathcal{F}_{\boldsymbol{k},\boldsymbol{q}-} m_{\boldsymbol{k},\boldsymbol{q}}, \quad F_{\boldsymbol{k},\boldsymbol{q},-} = \mathcal{F}_{\boldsymbol{k},\boldsymbol{q}-} l_{\boldsymbol{k},\boldsymbol{q}} + \mathcal{F}_{\boldsymbol{k},\boldsymbol{q}+} m_{\boldsymbol{k},\boldsymbol{q}}$$
(B15)

$$l_{\boldsymbol{k},\boldsymbol{q}} = \frac{1}{2} \left(1 + \frac{\zeta_{\boldsymbol{k},\boldsymbol{q},+}}{\sqrt{\zeta_{\boldsymbol{k},\boldsymbol{q},+}^2 + \Delta_{\boldsymbol{q}}^2}} \right), \quad m_{\boldsymbol{k},\boldsymbol{q}} = \frac{1}{2} \left(1 - \frac{\zeta_{\boldsymbol{k},\boldsymbol{q},+}}{\sqrt{\zeta_{\boldsymbol{k},\boldsymbol{q},+}^2 + \Delta_{\boldsymbol{q}}^2}} \right)$$
(B16)

Therefore, we obtain our saddle point equation for valley polarization as,

$$\frac{\Phi_V}{g_v} + 2v_\Phi \Phi_V^3 = \frac{1}{4} \sum_{\boldsymbol{k}} \left(F_{\boldsymbol{k},\boldsymbol{q},+} \tanh \frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},+}}{2T} - F_{\boldsymbol{k},\boldsymbol{q},-} \tanh \frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q},-}}{2T} \right)$$
(B17)

which reduces to Eq. (8a) when the form factors are trivial $[f_{k,\pm} = 1 \text{ in Eq. (B2)}]$.

Appendix C: Coupling of supercurrent and valley polarization within full self-consistent theory

In this part of the appendix, we elucidate the impact of finite \boldsymbol{q} on superconductivity and valley polarization within the coupled non-linear self-consistency equations in Eq. (8) of the main text. We choose a gauge where $\Delta(\boldsymbol{q}) \in \mathbb{R}$, for notational simplicity, and begin with Eq. (8a) which we expand to linear order in \boldsymbol{q} , $\delta \Phi_V(\boldsymbol{q}) := \Phi_V(\boldsymbol{q}) - \Phi_V(\boldsymbol{q} = 0)$, and $\delta \Delta(\boldsymbol{q}) := \Delta(\boldsymbol{q}) - \Delta(\boldsymbol{q} = 0)$. This leads to

$$C_{\Phi\Phi}\delta\Phi_V(\boldsymbol{q}) + C_{\Phi\Delta}\delta\Delta(\boldsymbol{q}) = \boldsymbol{n}_{\Phi} \cdot \boldsymbol{q} + \mathcal{O}(\boldsymbol{q}^2, \delta\Phi_V^2, \delta\Delta^2), \tag{C1}$$

where

$$C_{\Phi\Phi} = \frac{1}{g_v} + 6v_{\Phi}\Phi_V^2(\boldsymbol{q}=0) - \frac{1}{8T}\sum_{\boldsymbol{k},p} \frac{1}{\cosh^2(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T})},\tag{C2}$$

$$C_{\Phi\Delta} = -\frac{\Delta(\boldsymbol{q}=0)}{8T} \sum_{\boldsymbol{k},p} \frac{1}{\sqrt{\xi_{\boldsymbol{k}}^2 + \Delta^2(\boldsymbol{q}=0)}} \frac{p}{\cosh^2(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T})},\tag{C3}$$

$$\boldsymbol{n}_{\Phi} = \frac{1}{16T} \sum_{\boldsymbol{k},\boldsymbol{p}} \frac{\boldsymbol{\nabla}_{\boldsymbol{k}} \boldsymbol{\xi}_{\boldsymbol{k}}}{\cosh^2(\frac{\boldsymbol{\mathcal{E}}_{\boldsymbol{k},\boldsymbol{q}=0,\boldsymbol{p}}}{2T})}.$$
(C4)

In our case, $\mathcal{E}_{\mathbf{k},\mathbf{q}=0,p} = \sqrt{\xi_{\mathbf{k}}^2 + \Delta^2(\mathbf{q}=0)} + p\Phi_V(\mathbf{q}=0)$ only depends on \mathbf{k} through $\xi_{\mathbf{k}}$, leading to $\mathbf{n}_{\Phi} = 0$. Note this would generically be different if the order parameter of superconductivity or valley polarization $[f_{\mathbf{k}} \neq \text{const. in} \text{ Eq. (B2)}]$ depended on momentum. We thus conclude that $\delta\Phi_V(\mathbf{q}) \propto \delta\Delta(\mathbf{q}) + \mathcal{O}(\mathbf{q}^2)$. This is consistent with Fig. 3(a) and $\alpha = 0$ in Eq. (6) of the main text.

We can learn more by expanding Eq. (8b) in the same way,

$$C_{\Delta\Delta}\delta\Delta(\boldsymbol{q}) + C_{\Delta\Phi}\delta\Phi(\boldsymbol{q}) = \boldsymbol{n}_{\Delta} \cdot \boldsymbol{q} + \mathcal{O}(\boldsymbol{q}^2, \delta\Phi_V^2, \delta\Delta^2), \tag{C5}$$

where the coefficients are given by

$$C_{\Delta\Delta} = 4u_{\Delta}\Delta(\boldsymbol{q}=0) + \frac{1}{2}\sum_{\boldsymbol{k},p} \tanh\left(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T}\right) \frac{\Delta(\boldsymbol{q}=0)}{(\xi_{\boldsymbol{k}}^2 + \Delta^2(\boldsymbol{q}=0))^{\frac{3}{2}}} - \frac{1}{4T}\sum_{\boldsymbol{k},p}\frac{\Delta(\boldsymbol{q}=0)}{\xi_{\boldsymbol{k}}^2 + \Delta^2(\boldsymbol{q}=0)}\frac{1}{\cosh^2(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T})}, \quad (C6)$$

$$C_{\Delta\Phi} = -\frac{1}{2T} \sum_{\boldsymbol{k},p} \frac{1}{\sqrt{\xi_{\boldsymbol{k}}^2 + \Delta^2(\boldsymbol{q}=0)}} \frac{p}{\cosh^2(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T})},\tag{C7}$$

$$\boldsymbol{n}_{\Delta} = \frac{1}{8T} \sum_{\boldsymbol{k},p} \frac{1}{\sqrt{\xi_{\boldsymbol{k}}^2 + \Delta^2(\boldsymbol{q}=0)}} \frac{p \boldsymbol{\nabla}_{\boldsymbol{k}} \xi_{\boldsymbol{k}}}{\cosh^2(\frac{\mathcal{E}_{\boldsymbol{k},\boldsymbol{q}=0,p}}{2T})}.$$
(C8)

The same comments as those above for \mathbf{n}_{Φ} also apply for \mathbf{n}_{Δ} , which thus vanishes, $\mathbf{n}_{\Delta} = 0$. Without fine-tuning, we expect $C_{\Phi\Phi}C_{\Delta\Delta} \neq C_{\Phi\Delta}C_{\Delta\Phi}$ and Eqs. (C1) and (C5) therefore imply $\delta\Delta(\mathbf{q}), \delta\Phi_V(\mathbf{q}) = \mathcal{O}(\mathbf{q}^2)$ exactly as we find numerically, see Fig. 3(a). This is the reason why the maximum of $\Delta(\mathbf{q})$ [minimum of $\Phi_V(\mathbf{q})$] can be pinned to $\mathbf{q} = 0$ even when C_{3z} is broken. As $\mathbf{n}_{\Phi}, \mathbf{n}_{\Delta}$ become non-zero when form factors are introduced, the maximum of $\Delta(\mathbf{q})$ [minimum of $\Phi_V(\mathbf{q})$] move to finite values when C_{3z} is broken as is observed in Fig. 3(b).

Appendix D: Microscopic calculation of current

We can write a BdG Hamiltonian for our system as,

$$H_{\rm BdG} = \begin{bmatrix} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} & \Delta_{\mathbf{q}} \\ \Delta_{\mathbf{q}}^{*} & -E_{-\mathbf{k}+\mathbf{q}/2,-} \end{bmatrix}, \quad \Psi = \begin{pmatrix} c_{\mathbf{k}+\frac{\mathbf{q}}{2},+} \\ c_{-\mathbf{k}+\frac{\mathbf{q}}{2},-}^{\dagger} \end{pmatrix}, \quad \Psi^{\dagger} = \begin{pmatrix} c_{\mathbf{k}+\frac{\mathbf{q}}{2},+}^{\dagger} & c_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} \end{pmatrix}$$
(D1)

and

$$\begin{pmatrix} c_{\mathbf{k}+\frac{\mathbf{q}}{2},+} \\ c^{\dagger}_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} \end{pmatrix} = \begin{pmatrix} u_{\mathbf{k},\mathbf{q}} & v_{\mathbf{k},\mathbf{q}} \\ -v^{*}_{\mathbf{k},\mathbf{q}} & u^{*}_{\mathbf{k},\mathbf{q}} \end{pmatrix} \begin{pmatrix} \gamma_{\mathbf{k},\mathbf{q},+} \\ \gamma^{\dagger}_{-\mathbf{k},\mathbf{q},-} \end{pmatrix}.$$
(D2)

The BdG Hamiltonian in diagonal basis can be now written as,

$$H_{\rm BdG} = U H_{\rm diag} U^{\dagger}, \quad U = \begin{pmatrix} u_{\mathbf{k},\mathbf{q}} & v_{\mathbf{k},\mathbf{q}} \\ -v_{\mathbf{k},\mathbf{q}}^* & u_{\mathbf{k},\mathbf{q}}^* \end{pmatrix}, \quad U^{\dagger} = \begin{pmatrix} u_{\mathbf{k},\mathbf{q}}^* & -v_{\mathbf{k},\mathbf{q}} \\ v_{\mathbf{k},\mathbf{q}}^* & u_{\mathbf{k},\mathbf{q}}^* \end{pmatrix}$$
(D3)

The expression for the current (see, e.g., [30]) reads as

$$J = \sum_{\mathbf{k}} \operatorname{tr} \left[\partial_{\mathbf{q}} H_{\mathrm{N}} n_{F} (H_{\mathrm{BdG}}) \right] \tag{D4}$$

$$=\sum_{\mathbf{k}} \operatorname{tr} \left[\begin{pmatrix} \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} & 0\\ 0 & -\partial_{\mathbf{q}} E_{-\mathbf{k}+\mathbf{q}/2,-} \end{pmatrix} n_{F}(H_{\mathrm{BdG}}) \right], \tag{D5}$$

where $n_F(\epsilon) = (1 + e^{\beta\epsilon})^{-1}$ is the Fermi distribution function and

$$H_{\rm N} = \begin{pmatrix} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} & 0\\ 0 & -E_{-\mathbf{k}+\mathbf{q}/2,-} \end{pmatrix}.$$
 (D6)

Therefore we have,

$$n(H_{\rm BdG}) = U n_F (H_{\rm diag}) U^{\dagger} \tag{D7}$$

$$= U \begin{pmatrix} \frac{1}{1+e^{\beta E_{1,\mathbf{k},\mathbf{q}}}} & 0\\ 0 & \frac{1}{1+e^{-\beta E_{2,\mathbf{k},\mathbf{q}}}} \end{pmatrix} U^{\dagger}$$
(D8)

Plugging this into the expression for current we get:

$$J = \sum_{\mathbf{k}} \operatorname{tr} \left[U^{\dagger} \begin{pmatrix} \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} & 0\\ 0 & -\partial_{\mathbf{q}} E_{-\mathbf{k}+\mathbf{q}/2,-} \end{pmatrix} U n_{F}(H_{\operatorname{diag}}) \right]$$
(D9)

$$=\sum_{\mathbf{k}} \operatorname{tr} \left[\begin{pmatrix} u_{\mathbf{k},\mathbf{q}}^{*} & -v_{\mathbf{k},\mathbf{q}} \\ v_{\mathbf{k},\mathbf{q}}^{*} & u_{\mathbf{k},\mathbf{q}} \end{pmatrix} \begin{pmatrix} u_{\mathbf{k},\mathbf{q}}\partial_{\mathbf{q}}E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} & v_{\mathbf{k},\mathbf{q}}\partial_{\mathbf{q}}E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} \\ v_{\mathbf{k},\mathbf{q}}^{*}\partial_{\mathbf{q}}E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} & -u_{\mathbf{k},\mathbf{q}}^{*}\partial_{\mathbf{q}}E_{-\mathbf{k}+\mathbf{q}/2,-} \end{pmatrix} n_{F}(H_{\mathrm{diag}}) \right]$$
(D10)

$$=\sum_{\mathbf{k}} \operatorname{tr} \left[\begin{pmatrix} |u_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} - |v_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} & u_{\mathbf{k},\mathbf{q}}^* v_{\mathbf{k},\mathbf{q}} \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} + u_{\mathbf{k},\mathbf{q}}^* v_{\mathbf{k},\mathbf{q}}^* \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} \\ v_{\mathbf{k},\mathbf{q}}^* u_{\mathbf{k},\mathbf{q}} \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} + u_{\mathbf{k},\mathbf{q}} v_{\mathbf{k},\mathbf{q}}^* \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} & |v_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} - |u_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-} \end{pmatrix} n_F(H_{\mathrm{diag}}) \right]$$

$$(D11)$$

$$J = \sum_{\mathbf{k}} (|u_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} - |v_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-}) n_F(E_{1,\mathbf{k},\mathbf{q}}) + \sum_{\mathbf{k}} (|v_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{\mathbf{k}+\frac{\mathbf{q}}{2},+} - |u_{\mathbf{k},\mathbf{q}}|^2 \partial_{\mathbf{q}} E_{-\mathbf{k}+\frac{\mathbf{q}}{2},-}) n_F(-E_{2,\mathbf{k},\mathbf{q}})$$
(D12)
