**Abstract.** A host of elastic systems consisting of active components exhibit pathdependent elastic behaviors not found in classical elasticity, which is known as odd elasticity. Odd elasticity is characterized by antisymmetric (odd) elastic modulus tensor. Here, from the perspective of geometry, we construct the Hamiltonian formalism to show the origin of the antisymmetry of the elastic modulus that is intrinsically anisotropic. Furthermore, both non-conservative stress and the associated nonlinear constitutive relation naturally arise. This work also opens the promising possibility of exploring the physics of odd elasticity in dynamical regime by Hamiltonian formalism.

Keywords: odd elasticity, anisotropic mass, Hamiltonian formalism

## 1. Introduction

In classical elasticity, the input work to deform the elastic body depends only on its initial and final states. Such path-independence is characterized by the elastic potential that yields conservative stress [1, 2]. Recently, it has been reported that the work involved in deformations is dependent on the path in a class of elastic systems consisting of active components, such as in robotic metamaterials [3, 4]. A common feature in these active systems is that nonzero work could be extracted in a cycle of deformation. The dependence of the work on the deformation path could be attributed to an additional antisymmetric (odd) part in the elastic modulus tensor, which is known as odd elasticity [5, 6, 7]. The broken major symmetry of odd-elastic modulus leads to the non-conservative nature of the stress and a series of phenomena not found in classical elasticity, such as the modification of defect strains, interactions and motility [6, 8, 9], and the emergence of non-Hermitian skin effect [3] and chiral edge waves [10].

In the continuum description of odd elasticity, the odd-elastic modulus can be obtained by the coarse-graining procedure of the non-conservative forces between constituents in the elastic body [6, 8, 11]. Experimental realizations of nonconservative interparticle forces include fluid-mediated spinning particle [12, 13], gyroscopic lattices [14, 15], vortices in superfluids [16, 17] and skyrmions [18, 19]. In previous studies, the phenomenon of odd elasticity is attributed the active components of the system. Theoretically, an antisymmetric modulus is introduced to successfully describe the odd-elasticity behaviors at the continuum level. Specifically, a common approach to investigating odd elasticity begins with the dynamic equation and the constitutive relation [5, 6, 7], where an antisymmetric odd-elastic modulus is introduced as a parameter. However, the origin of the antisymmetry of the odd-elastic modulus in general has not yet been fully understood. Exploring this fundamental scientific question yields deeper insights into the nature of odd elasticity, and it also has strong connection to the design of odd elastic systems. One challenge is that due to the nonzero curl, the non-conservative stress involved in odd elasticity is not derivable from a scalar potential like in classical elasticity.

In this work, a field theory in Hamiltonian formalism is constructed to produce the antisymmetric elastic modulus tensor that is essential for a host of odd elastic behaviors. Specifically, a *d*-dimensional continuum elastic body is modeled as a Riemannian manifold embedded in the (d + 1)-dimensional Euclidean space, and the Hamiltonian for the elastic body of finite strain is constructed. The key is introducing an anisotropic tensorial effective mass in the kinetic energy term, as inspired by the work on Hamiltonian curl forces [20, 21, 22]. The resulting antisymmetric elastic modulus tensor also simultaneously inherits the anisotropic nature of the mass tensor. Note that the inherent anisotropy is distinct from the odd elastic modulus generated through other mechanisms [6, 7]. The constitutive relation associated with the non-conservative stress is nonlinear in general, and the nonlinearity originates from the intrinsic geometry of the deformed elastic body. This work provides insights into the origin of the antisymmetry of the elastic modulus tensor in odd elasticity, and opens the promising possibility of exploring the dynamics of odd elasticity in the Hamiltonian framework.

## 2. Model and Method

## 2.1. Geometric viewpoint of elastic deformation

An elastic body in continuum limit is modeled as a *d*-dimensional Riemannian manifold  $(\mathcal{B}, g_{ab})$  embedded in Euclidean space  $\mathcal{E}$  in the study of its interior elastic deformation. The strain state is characterized by the metric tensor  $g_{ab}$  defined on  $\mathcal{B}$ . For example, the strain-free elastic body prior to any deformation is described by a Riemannian manifold isometrically embedded in Euclidean space; the value of  $g_{ab}$  is specified by the pullback of the Euclidean metric [23, 24]. Note that in this work we employ the abstract index notation in Latin letters to represent a tensor; the tensor components are labeled by Greek letters.

In general, the deformation of the body leads to the variation of the element of length, and thus the metric of the manifold [25, 26]. Therefore, the elastic deformation of the body could be characterized by a diffeomorphism  $\phi$  from some reference configuration

to the deformed one:  $(\mathcal{B}, g_{ab}) \to (\mathcal{B}, \tilde{g}_{ab})$ . Note that subscripts 'ab' are to indicate that  $g_{ab}$  is a covariant tensor field of order 2. The topology of  $\mathcal{B}$  is preserved in elastic deformation. To illustrate the  $\phi$  mapping, we present some examples in figure 1. Under the deformations as described by the mappings  $\phi_i$  (i = 1, 2, 3), any given point in the reference configuration, say A, is mapped to  $\phi_i(A)$ . The original 2D elastic body of square shape is deformed to a rectangle (by  $\phi_1$  mapping), to the patches on the sphere (by  $\phi_2$  mapping) and on the cylinder (by  $\phi_3$  mapping), respectively. In these three kinds of deformations,  $\tilde{g}_{ab}$  refers to the Euclidean metric, the spherical metric and the cylindrical metric, respectively.

Figure 1: Illustration of the  $\phi_i$  mappings that connect the undeformed elastic body (represented by the central square as the reference configuration) to the various deformed configurations (represented by the surrounding figures). On the undeformed elastic body as the reference configuration, the length of the line element connecting points A and B is determined by the metric  $g_{ab}$ . Taking the case of  $\phi_2$  mapping (the left lower figure) for example, the reference line in solid blue is deformed to the dashed red line on the sphere, whose length is determined by the new metric  $\tilde{g}_{ab}$ . The corresponding metric  $\bar{g}_{ab}$  on the reference configuration is connected to the deformed length via the pullback of  $\tilde{g}_{ab}$ :  $\bar{g}_{ab} \equiv \phi^* \tilde{g}_{ab}$ .

From the geometric perspective, the deformation is characterized by the variation of the metric from  $g_{ab}$  to  $\phi^* \tilde{g}_{ab}$ , both of which are defined on the same manifold  $\mathcal{B}$ . Specifically, the information of the strain in the deformation is encoded in the difference between  $\phi^* \tilde{g}_{ab}$  and  $g_{ab}$ . To illustrate this point, let us consider a curve  $\gamma(t) \in (\mathcal{B}, g_{ab})$ , where  $t \in [0, 1]$ . The length of the line element on  $\gamma$  is measured by  $g_{ab}$ . After the deformation, the curve is mapped to  $\phi(\gamma(t)) \in (\mathcal{B}, \tilde{g}_{ab})$ . The length of a line element on  $\phi(\gamma)$  measured by  $\tilde{g}_{ab}$  is equal to the length of the corresponding line element on  $\gamma$ measured by  $\phi^* \tilde{g}_{ab}$ . Therefore, the change of the curve length could be measured by  $\phi^* \tilde{g}_{ab} - g_{ab}$ . As such, it is natural to define the strain tensor on  $\mathcal{B}$  as [27, 2, 28]

$$u_{ab} = \frac{1}{2} \left( \bar{g}_{ab} - g_{ab} \right), \tag{1}$$

where  $\bar{g}_{ab} \equiv \phi^* \tilde{g}_{ab}$ . The definition of strain in (1) is also applicable to large deformation [2].

In the following discussion, the Riemannian manifold  $(\mathcal{B}, \bar{q}_{ab})$  is denoted as  $\Sigma$ , representing the deformed configuration of the elastic body. The elastic body is initially free of stress, and is thus isometrically embedded in the (d+1)-dimensional Euclidean space  $\mathcal{E}$ . The metric  $\bar{g}_{ab}$  on the manifold  $\Sigma$  is induced from the metric  $\delta_{ab}$  on  $\mathcal{E}$  [24, 29, 30], i.e.,  $\bar{g}_{ab} = \delta_{ab} - N_a N_b$ , where  $N_a$  is the unit normal covector on  $\Sigma$  in  $\mathcal{E}$ . For example, consider a 2D surface isometrically embedded in  $\mathcal{E}$ . One may construct the Cartesian coordinates  $\{X^1, X^2, X^3\}$  centered at any point P on the surface;  $X^3$ -axis is perpendicular to the tangent plane at point P. The first fundamental form (or the line element) is given explicitly by the metric:  $\bar{g}_{\alpha\beta}(\mathrm{d}X^{\alpha})_{a}(\mathrm{d}X^{\beta})_{b} =$  $\bar{g}_{\mu\nu}(\mathrm{d}s^{\mu})_{a}(\mathrm{d}s^{\nu})_{b} + (\mathrm{d}X^{3})_{a}(\mathrm{d}X^{3})_{b} - (\mathrm{d}X^{3})_{a}(\mathrm{d}X^{3})_{b} = \bar{g}_{\mu\nu}(\mathrm{d}s^{\mu})_{a}(\mathrm{d}s^{\nu})_{b}, \text{ where } \{s^{1}, s^{2}\}$  are local coordinates near the point P. Note that the Greek letters in the indices represent the components of the tensor, and they take the values from 1 to d + 1. Here, the convention of Einstein summation is applied. For spherical surface,  $s^1 = \theta$  and  $s^2 = \phi$ , where the polar angle  $\theta \in [0, \pi]$  and the azimuthal angle  $\phi \in [0, 2\pi)$ . Note that due to the isometric embedding of  $\Sigma$  in  $\mathcal{E}$ , all of the tensors in this work are regarded as being defined on the tangent space of  $\mathcal{E}$ , and the lowering (or raising) of the indices of a tensor is uniformly implemented by  $\delta_{ab}$  (or  $\delta^{ab}$ ).

Now, we characterize the displacement field associated with the deformation in terms of the geometric language introduced in the preceding paragraph. We first establish the Cartesian coordinates system of  $\mathcal{E}$  by  $\{X^1, \ldots, X^{d+1}\}$ . The manifolds  $(\mathcal{B}, g_{ab})$  and  $\Sigma$  are thus represented by the  $\mathbb{R}^{d+1}$ -valued functions  $X_0^{\mu}(p)$  and  $X^{\mu}(\phi(p))$  $(\forall p \in \mathcal{B})$ , respectively.  $\bar{X}^{\mu}(p) \equiv X^{\mu}(\phi(p))$ . The displacement field on  $\mathcal{B}$  is

$$U^{a} = U^{\mu} \left(\frac{\partial}{\partial X^{\mu}}\right)^{a},\tag{2}$$

where the  $\mu$ -component of the displacement field  $U^{\mu}(p) = \bar{X}^{\mu}(p) - X_0^{\mu}(p), \forall p \in \mathcal{B}.$ 

#### 2.2. Construct Hamiltonian of the elastic body

The displacement fields  $U^a$  constitute an infinite dimensional manifold called the configuration space. The Hamiltonian of the elastic body is a scalar on the cotangent bundle of the configuration space, and it can be written formally as [30]:

$$H = T + W = \int_{\Sigma} \rho \left( \mathscr{T} + \mathscr{W} \right) \varepsilon, \tag{3}$$

where  $\mathscr{T}$  and  $\mathscr{W}$  are the kinetic energy and elastic potential per unit mass, respectively.  $\varepsilon$  is the Riemannian volume form compatible with  $\bar{g}_{ab}$ .  $\rho$  is the mass density of the deformed configuration. In this work,  $\mathscr{W}$  is a quadratic local function of  $u_{ab}$ . The gradient of  $\mathscr{W}$  is recognized as the Kirchhoff stress tensor:

$$\tau^{ab} = \frac{\partial \mathscr{W}}{\partial u_{ab}}.\tag{4}$$

 $\tau^{ab}$  is a symmetric tensor field on  $\Sigma$ . It measures the stress experienced by the unit mass of the deformed configuration. Note that the Cauchy stress tensor  $\sigma^{ab}$  is related to the Kirchhoff stress tensor by  $\sigma^{ab} = \rho \tau^{ab}$ , and it measures the stress on the unit volume of the deformed configuration [30]. In (3),  $\mathscr{T}$  could be written as a quadratic function of the generalized momentum density field  $P_a$  that is conjugated to  $U^a$ :

$$\mathscr{T} = \frac{1}{2} \mathscr{M}^{ab} P_a P_b. \tag{5}$$

It is important to point out that here we introduce the effective mass tensor  $\mathscr{M}^{ab}$ .  $\mathcal{M}^{ab}$  is anisotropic and symmetric, and it is invariant in the deformation of the elastic body. In connection to possible experimental realizations, the anisotropy of  $\mathcal{M}^{ab}$  may be introduced by designing a local resonance cavity structure composed of an internal mass that is connected to the wall by two perpendicular Hookean springs; such anisotropic mechanical microstructures have been used to regulate the propagation of acoustic waves in metamaterials [31, 32]. An explanatory example based on the modified mass-inmass model is presented in section 3.4 to show the realization of anisotropic effective mass units. The idea of introducing the anisotropy in the construction of the kinetic energy is inspired by the work on Hamiltonian curl forces [20, 21, 22]. The concept of inducing Hamiltonian curl forces through anisotropic mass was initially introduced in systems with finite degrees of freedom by Berry and Shukla [20, 21, 22]. Specifically, it has been proved that a class of non-conservative (i.e., whose curl is not zero) position depending forces can be generated by the element of anisotropy in the kinetic energy term in Hamiltonian. Here, we extend this idea to the continuum elastic system by incorporating the non-conservative nature into  $\mathcal{M}^{ab}$ . Consequently, (3) admits a nonconservative force density, which is crucial for understanding odd elasticity.

## 3. RESULTS AND DISCUSSION

#### 3.1. Hamilton's Equations

The Hamilton's equations based on (3) are

$$\frac{\partial U^a}{\partial t} = \frac{\delta H}{\delta P_a} = \rho \sqrt{\bar{g}} \mathscr{M}^{ab} P_b, \tag{6a}$$

$$\frac{\partial P_a}{\partial t} = -\frac{\delta H}{\delta U^a} = \sqrt{\bar{g}} f_a,\tag{6b}$$

where  $f_a = \bar{g}_b{}^c \partial_c (\bar{g}_{ad} \sigma^{db})$ . Note that the repeated indices in pairs represents tensor contraction.  $\bar{g}$  is the determinant of  $\bar{g}_{ab}$ ;  $\partial_c$  is the Cartesian derivative operator on  $\mathcal{E}$ acting on the embedding coordinates  $\{\bar{X}^{\mu}\}$  of  $\Sigma$ . The detailed information is presented in Appendix A and Appendix B. Note that the generalized coordinates  $U^a$  in the Hamiltonian formalism is closely related to the strain of an elastic body.

By combining (6a) and (6b), we obtain the dynamic equation of the manifold  $\Sigma$  as

$$\frac{\partial V^a}{\partial t} = M^{ab} f_b \equiv F^a,\tag{7}$$

where the displacement velocity field  $V^a \equiv \partial U^a / \partial t$  and the symmetric tensor field  $M^{ab} \equiv \rho \bar{g} \mathscr{M}^{ab}$ . According to (7),  $F^a$  regulates the acceleration of unit mass in the elastic body, and it is recognized as the Newtonian force per unit mass. (7) suggests that the dynamics of a continuum elastic body with anisotropic mass  $\mathscr{M}^{ab}$  under  $f^a$  is equivalent to the dynamics of a unit scalar mass under  $F^a$ ; the velocity  $V^a$  as associated to the displacement field is the common dynamics variable.

#### 3.2. Hamiltonian curl forces and odd elasticity

Without any loss of generality,  $M^{ab}$  is decomposed as

$$M^{ab} = M\delta^{ab} + \Omega^{ab},\tag{8}$$

where  $M = \delta_{ab} M^{ab}/(d+1)$ , and  $\Omega^{ab}$  is a traceless symmetric tensor field. Here, we shall emphasize that the anisotropic effect in the kinetic energy is captured by  $\Omega^{ab}$ . By (8), the kinetic energy density  $\mathscr{T}$  is divided into the isotropic and the anisotropic parts:

$$\mathscr{T} = \frac{1}{2\rho^2 \bar{g}} P_a P^a + \frac{1}{2\rho \bar{g}} \Omega^{ab} P_a P_b.$$
<sup>(9)</sup>

We also cast  $F^a$  in the following form

$$F^a = M f^a + \Omega^{ab} f_b. \tag{10}$$

Now, let us focus on (10). The first term in (10) is recognized as the force per unit mass as a derivative of the elastic potential for  $M = 1/\rho$  [28, 33, 34, 35]. According to (6*a*) and (6*b*), the power of  $Mf^a$  is expressed as:

$$Mf_a V^a = \mathscr{M}^{ab} \frac{\partial P_a}{\partial t} P_b = \frac{\mathrm{d}\mathscr{T}}{\mathrm{d}t} = -\frac{\mathrm{d}\mathscr{W}}{\mathrm{d}t}.$$
(11)

In the last equality, the conservation of the total energy is applied, i.e., dH/dt = 0. According to (11), the power of  $Mf^a$  is equal to the reduction rate of  $\mathcal{W}$ . Due to the conservation of the total energy, it indicates that the work done by  $Mf^a$  is equal to the energy transfer from the potential energy to the kinetic energy per unit mass in the deformation of the elastic body. Note that for a single-valued  $\mathcal{W}$  function, the integration of (11) over any closed orbits in  $\mathcal{E}$  is zero, implying that  $Mf^a$  is a conservative force. As such, the first term of  $F^a$  in (10) does not alter the value of either  $\mathcal{W}$  or  $\mathcal{T}$  in a cyclic deformation of the elastic body.

We proceed to examine the second term  $\Omega^{ab} f_b$  in (10). The power of  $\Omega^{ab} f_b$  is:

$$\Omega^{ab} f_b V_a = \rho \Omega^{ab} \frac{\partial P_b}{\partial t} \mathcal{M}_a{}^c P_c$$
  
=  $\frac{1}{\rho \bar{g}} \Omega^{ab} \left( \delta_a{}^c + \rho \Omega_a{}^c \right) P_c \frac{\partial P_b}{\partial t}.$  (12)

Under the assumption that the anisotropic tensor  $\rho \Omega^{ab}$  is small compared with  $\delta^{ab}$ , (12) becomes

$$\Omega^{ab} f_b V_a = \frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{1}{2\rho \bar{g}} \Omega^{ab} P_a P_b \right). \tag{13}$$

Here, it is important to point out that the R.H.S. of (13) is identified as the rate of the increase of the anisotropic part of  $\mathscr{T}$ . In other words, the work done by  $\Omega^{ab} f_b$  causes the increase in the anisotropic part of the kinetic energy per unit mass.

In the following, we will show that the second term  $\Omega^{ab} f_b$  in (10) is a nonconservative force. To this end, we first substitute the expression of  $f_a$  in (10), and obtain the expression for the Newtonian force per unit volume as

$$\rho F^{a} = \bar{g}_{b}{}^{c}\partial_{c}\sigma^{ab} + \rho\Omega^{ad}\bar{g}_{b}{}^{c}\partial_{c}\left(\bar{g}_{de}\sigma^{eb}\right) 
= \bar{g}_{b}{}^{c}\partial_{c}\left(\sigma^{ab} + \hat{\sigma}^{ab}\right) - \bar{g}_{bd}\sigma^{dc}\partial_{c}\left(\rho\Omega^{ab}\right),$$
(14)

where  $\hat{\sigma}^{ab} \equiv \rho \Omega^{ac} \bar{g}_{cd} \sigma^{db}$ . Note that  $\hat{\sigma}^{ab}$  is not symmetric. Furthermore,  $\hat{\sigma}^{ab}$  does not live in the tangent space of  $\Sigma$  because of the acting of  $\Omega^{ac} \bar{g}_{cd}$ . For spatially-slowly-varying  $\rho \Omega^{ab}$ , its gradient could be regarded as a small quantity. Therefore, the last term in (14) is much smaller than the second term; note that  $\bar{g}_b{}^c\partial_c\hat{\sigma}^{ab} = \bar{g}_b{}^c\partial_c(\rho \Omega^{ad} \bar{g}_{de}\sigma^{eb})$ . As such, the last term could be neglected. The anisotropic effect boils down to the modification of  $\hat{\sigma}^{ab}$  in  $\sigma^{ab}$  as shown in the first bracket in (14).

Now, to reveal the non-conservative nature of the second term in (10), we analyze the work done by the total stress per unit mass in a cyclic deformation. In the deformation process, the instantaneous strain state of the elastic body is denoted by  $u_{ab}(t)$ , which is represented by a point in the space of the strain field  $u_{ab}$ . The cycle of deformation is thus described by a loop  $\eta(t)$  in the strain space.  $t \in [0, T]$ .  $\eta(0) = \eta(T)$ . The work done per unit mass in a cycle of deformation is [6, 10]:

$$\Delta \mathscr{A} = \oint_{\eta(t)} \left( \tau^{ab} + \hat{\tau}^{ab} \right) du_{ab}$$
$$= \int_{S} \left( \frac{\partial \tau^{ab}}{\partial u_{cd}} + \frac{\partial \hat{\tau}^{ab}}{\partial u_{cd}} \right) du_{cd} \wedge du_{ab},$$
$$\equiv \int_{S} T^{abcd} du_{cd} \wedge du_{ab}, \tag{15}$$

where  $\hat{\tau}^{ab} = \hat{\sigma}^{ab}/\rho$ , and S is the surface enclosed by  $\eta(t)$ . Stokes's theorem is used in the derivation for (15). Since the exterior product is antisymmetric, the stress is conservative (such that  $\Delta \mathscr{A} = 0$  in the cyclic deformation) if and only if  $T^{abcd}$  possesses the major index symmetry, i.e.,  $T^{abcd} = T^{cdab}$ . Especially, quasi-static cyclic deformation can be realized by applying suitable external force on  $\Sigma$ .  $\Delta \mathscr{A}$  is then equal to the work done by the external force.

We analyze the first term of  $T^{abcd}$  in (15). From the expression for  $\mathscr{W}$ 

$$\mathscr{W} = \frac{1}{2} C^{abcd} u_{ab} u_{cd},\tag{16}$$

where  $C^{abcd}$  is the elastic modulus tensor with major index symmetry (i.e,  $C^{abcd} = C^{cdab}$ ), we obtain the linear constitutive relation

$$\tau^{ab} = C^{abcd} u_{cd}.\tag{17}$$

Due to the major index symmetry of  $C^{abcd}$ , the first term of  $T^{abcd}$  satisfies  $\partial \tau^{ab}/\partial u_{cd} = \partial \tau^{cd}/\partial u_{ab}$ , which indicates the conservative nature of  $\tau^{ab}$ . In other words, the work done by  $\tau^{ab}$  is zero in a cyclic deformation.

For the second term in  $T^{abcd}$ , from the definition of  $\hat{\sigma}^{ab}$  and (17), we have

$$\hat{\tau}^{ab} = \rho \Omega^{ac} \bar{g}_{cd} \tau^{db}$$

$$= \rho \Omega^{ae} \left( g_{ef} + 2u_{ef} \right) C^{fbcd} u_{cd}$$

$$= \hat{C}^{abcd} u_{cd} + \hat{D}^{abcdef} u_{cd} u_{ef},$$
(18)

where

$$\hat{C}^{abcd} = \rho \Omega^{ae} g_{ef} C^{fbcd}, \quad \hat{D}^{abcdef} = 2\rho \Omega^{ac} C^{dbef}.$$
(19)

In the nonlinear constitutive relation in (18), the quadratic term naturally arises in the expansion of  $\bar{g}_{cd}$  as the sum of the metric  $g_{cd}$  of the reference configuration and the strain field  $2u_{cd}$ . Furthermore, the anisotropic tensor  $\Omega^{ab}$  leads to the anisotropic nature of the elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$ . Here, we shall point out that in the Hamiltonian formalism based on anisotropic mass tensor, the resulting odd elastic modulus are naturally anisotropic. The anisotropy of  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  is inherent in our formalism. A detailed discussion about the symmetry of  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  is in Appendix D. In general, the odd elastic modulus are not necessarily anisotropic in 2D [6]. By (18), the second term of  $T^{abcd}$  is obtained

$$\frac{\partial \hat{\tau}^{ab}}{\partial u_{cd}} = \hat{C}^{abcd} + \left(\hat{D}^{abcdef} + \hat{D}^{abef(cd)}\right) u_{ef}.$$
(20)

The bracket in the superscript of  $\hat{D}$  indicates the symmetric part of the tensor. Here, it is important to point out that in (19), the involvement of the  $\Omega^{ab}$ -tensor breaks the major index symmetry of  $\hat{C}^{abcd}$ , as well as that of the second and the third terms in the right hand side of (20). Consequently,  $\hat{\tau}^{ab}$  is non-conservative according to (20).

Note that both  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  in (19) are invariant in the deformation of  $\Sigma$ . The reason is as follows. In the expressions for  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$ , both the elastic modulus tensor  $C^{abcd}$  and the metric  $g_{ab}$  are independent of the deformation of  $\Sigma$ . Regarding the factor  $\rho\Omega^{ab}$ , according to (8) and the definition for  $M^{ab}$ ,  $\rho\Omega^{ab} = \rho^2 \bar{g}\mathcal{M}^{ab} - \delta^{ab} = \rho_0^2 g\mathcal{M}^{ab} - \delta^{ab}$ , where  $\rho_0$  is the mass density of the reference configuration.  $\rho\Omega^{ab}$  is therefore invariant in the deformation of  $\Sigma$ .

In the regime of small deformation, where the quadratic term in (18) can be neglected, the constitutive relation of  $\hat{\tau}^{ab}$  becomes linear:

$$\hat{\tau}^{ab} = \hat{C}^{abcd} u_{cd}.$$
(21)

The broken major index symmetry of  $\hat{C}^{abcd}$  indicates the presence of the antisymmetric (odd) part in the elastic modulus tensor, which is responsible for the non-conservativity of the stress and the extra work occurring in cyclic deformations. As such,  $\hat{C}^{abcd}$  is called

the odd elastic modulus in literature [6]. Microscopic mechanism for odd elasticity has been attributed to various non-conservative interparticle forces. Here, the odd elasticity as characterized by the  $\hat{C}^{abcd}$ -tensor in (21) is derived from the anisotropic effective mass in the Hamiltonian formalism in the continuum level.

We shall point out that in the model of odd elasticity based on the Hamiltonian formalism, the total energy is conserved. The work extracted by  $\hat{\tau}^{ab}$  during cyclic deformations is from the conversion of the kinetic energy pre-stored in the internal degree of freedom of the system, rather than from the external energy inputs (see section 3.4 for detailed discussions). The anisotropy of the effective mass  $\mathscr{M}^{ab}$  arises from the coarse-grained internal degrees of freedom. In a cyclic process, according to (13), the non-conservative curl force transfers the kinetic energy between the (coarse-grained) anisotropic parts of  $\mathscr{T}$  and the isotropic parts of  $\mathscr{T}$ . As such, for a cyclic deformation starting and ending at zero velocity, no work can be extracted.

## 3.3. Example of 2D planar deformation

In this section, we illustrate the emergence of odd elasticity for the simple case of planar deformation of a 2D elastic body under small deformation approximation.

The strain tensor  $u_{ab}$  in the deformation can be expanded as  $u_{ab} = u_{\mu} \mathfrak{e}^{\mu}{}_{ab}$ , where  $\mathfrak{e}^{\mu}{}_{ab}$  is a set of orthogonal tensor bases on the reference configuration equipped with a local orthonormal frame fields  $\{e_1{}^a, e_2{}^a\}$  [6]:

$$\mathbf{e}^{1}{}_{ab} = e^{1}{}_{a}e^{1}{}_{b} + e^{2}{}_{a}e^{2}{}_{b}, \tag{22a}$$

$$\mathbf{e}^2{}_{ab} = e^2{}_a e^1{}_b - e^1{}_a e^2{}_b, \tag{22b}$$

$$\mathfrak{e}^{3}{}_{ab} = e^{1}{}_{a}e^{1}{}_{b} - e^{2}{}_{a}e^{2}{}_{b}, \tag{22c}$$

$$\mathbf{e}^{4}{}_{ab} = e^{1}{}_{a}e^{2}{}_{b} + e^{2}{}_{a}e^{1}{}_{b}.$$
(22*d*)

 $u_{\mu}$  characterizes the following local modes of deformation: dilation, rotation, and shearing. The stress tensor can also be expanded as  $\tau^{ab} = \tau^{\mu} \mathfrak{e}_{\mu}{}^{ab}$ , where  $\tau^{\mu}$  are associated with pressure, torque density and shear stress.

The rotationally symmetric elastic modulus tensor field  $C^{abcd}$  could be written as (see Appendix C for details):

$$C^{abcd} = \lambda g^{ab} g^{cd} + 2\mu g^{a(c} g^{d)b}, \tag{23}$$

where  $\lambda$  and  $\mu$  are Lamé coefficients. In the tensor bases of  $\{\mathfrak{e}^{\mu}{}_{ab}\}, g_{ab} = \mathfrak{e}^{1}{}_{ab}$ , and  $C^{abcd} = C^{\mu\nu} \mathfrak{e}_{\mu}{}^{ab} \mathfrak{e}_{\nu}{}^{cd}$ . From (23), we obtain

$$C^{\mu\nu} = \begin{bmatrix} \lambda + \mu & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \mu & 0 \\ 0 & 0 & 0 & \mu \end{bmatrix}.$$
 (24)

Correspondingly, (17) is expressed as  $\tau^{\mu} = C^{\mu\nu}u_{\nu}$ .  $\lambda + \mu$  and  $\mu$  characterize the isotropic stretching rigidity and the isotropic shear rigidity, respectively. Note that the matrix in 24 is invariant under the rotation of  $\{e_1^a, e_2^a\}$ .

We proceed to discuss the components  $\hat{C}^{\mu\nu}$ . By expanding the traceless tensor  $\rho\Omega^{ab}$  in the tensor bases of  $\{e_1^a, e_2^a\}$  as

$$\rho\Omega^{ab} = \kappa e_1{}^a e_1{}^b + \zeta e_1{}^a e_2{}^b + \zeta e_2{}^a e_1{}^b - \kappa e_2{}^a e_2{}^b, \tag{25}$$

where  $\kappa$  and  $\zeta$  are scalars, we finally have

$$\hat{C}^{\mu\nu} = \begin{bmatrix} 0 & 0 & \kappa\mu & \zeta\mu \\ 0 & 0 & \zeta\mu & -\kappa\mu \\ \kappa(\lambda+\mu) & 0 & 0 & 0 \\ \zeta(\lambda+\mu) & 0 & 0 & 0 \end{bmatrix}.$$
(26)

Since  $\hat{C}^{abcd} = \hat{C}^{\mu\nu} \mathbf{e}_{\mu}{}^{ab} \mathbf{e}_{\nu}{}^{cd}$ , the abstract index exchange  $ab \leftrightarrow cd$  in  $\hat{C}^{abcd}$  is identical to the label exchange  $\mu \leftrightarrow \nu$  in  $\hat{C}^{\mu\nu}$ . (26) shows that  $\hat{C}^{\mu\nu} \neq \hat{C}^{\nu\mu}$ , and therefore  $\hat{C}^{abcd} \neq \hat{C}^{cdab}$ . This key feature of the broken major symmetry is exactly the mathematical structure underlying the phenomenon of odd elasticity. The upper right  $2 \times 2$  submatrix in (26) connects shear strain with pressure and torque, and the lower left  $2 \times 2$  submatrix connects dilation with shear stress. The existence of these two non-zero submatrices is an indicator for the anisotropy of  $\hat{C}^{abcd}$  [6].

## 3.4. Example of an anisotropic mass model

In the following, we employ the modified mass-in-mass model as an example to show the emergence of the anisotropic inertial mass and the non-conservative force.

Consider a 2D cavity of mass  $m_1$  that contains an internal mass  $m_2$ , as illustrated in figure 2. The internal mass is connected to the cavity via a spring of resonance frequency  $\omega_{\rm I}$  and a damper of damping constant  $\Omega_{\rm I}$ . The cavity is subject to an external potential W. The dynamic equations for this mass-in-mass model are

$$m_1 \frac{\mathrm{d}^2 X_1}{\mathrm{d}t^2} = -\frac{\partial W}{\partial X_1} - m_2 \omega_\mathrm{I}^2 D - \Omega_\mathrm{I} \frac{\mathrm{d}D}{\mathrm{d}t},\tag{27a}$$

$$m_2 \frac{\mathrm{d}^2 X_2}{\mathrm{d}t^2} = m_2 \omega_\mathrm{I}^2 D + \Omega_\mathrm{I} \frac{\mathrm{d}D}{\mathrm{d}t},\tag{27b}$$

$$m_1 \frac{\mathrm{d}^2 Y_1}{\mathrm{d}t^2} = -\frac{\partial W}{\partial Y_1},\tag{27c}$$

$$m_2 \frac{\mathrm{d}^2 Y_2}{\mathrm{d}t^2} = 0, \tag{27d}$$

where  $(X_1, Y_1)$  and  $(X_2, Y_2)$  represent the Cartesian coordinates of displacements of  $m_1$  and  $m_2$  respectively, and  $D = X_1 - X_2$ .

We focus on the motion along the x-direction. Adding and subtracting (27a) and (27b) lead to:

$$(m_1 + m_2)\frac{\mathrm{d}^2 X_1}{\mathrm{d}\hat{t}^2} - m_2 \frac{\mathrm{d}^2 D}{\mathrm{d}\hat{t}^2} = f_x,$$
(28a)

$$m_1 \frac{\mathrm{d}^2 D}{\mathrm{d}\hat{t}^2} + (m_1 + m_2) \left( \hat{\omega}^2 D + \hat{\Omega} \frac{\mathrm{d}D}{\mathrm{d}\hat{t}} \right) = f_x, \qquad (28b)$$

Figure 2: 2D anisotropic mass model.

where the external force:

$$f_x = -\frac{1}{\omega_{\rm E}^2} \frac{\partial W}{\partial X_1},\tag{29}$$

and the dimensionless quantities are

$$\hat{t} = t\omega_{\rm E}, \quad \hat{\omega} = \frac{\omega_{\rm I}}{\omega_{\rm E}}, \quad \hat{\Omega} = \frac{\Omega_{\rm I}}{m_2\omega_{\rm E}}.$$
(30)

We focus on the regime of  $\hat{\omega} \gg 1$  and  $\hat{\Omega} \gg 1$ , i.e., the dynamics of the internal degree of freedom is much faster than the that of the cavity.

We first analyze (28b) by introducing the following Green's function  $G_{\omega}$ :

$$D(\hat{t}) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} d\omega \int_{-\infty}^{+\infty} d\hat{t}' \exp[-i\omega(\hat{t} - \hat{t}')] G_{\omega} f_x(\hat{t}')$$
$$= \frac{1}{2\pi} \int_{-\infty}^{+\infty} d\omega \int_{-\infty}^{+\infty} d\hat{t}' \exp(-i\omega\hat{t}') G_{\omega} f_x(\hat{t} - \hat{t}'),$$
(31)

where

$$G_{\omega} = \frac{1}{(m_1 + m_2)\left(\hat{\omega}^2 - i\hat{\Omega}\omega\right) - m_1\omega^2}.$$
(32)

We thus have:

$$\frac{\mathrm{d}^2 D}{\mathrm{d}\hat{t}^2} = -\frac{1}{2\pi} \int_{-\infty}^{+\infty} \mathrm{d}\omega \int_{-\infty}^{+\infty} \mathrm{d}\hat{t}' \exp(-\mathrm{i}\omega\hat{t}')\omega^2 G_\omega f_x(\hat{t}-\hat{t}').$$
(33)

The integration over  $\omega$  in (33) is implemented by the residue theorem. Specifically,

$$\int_{-\infty}^{+\infty} d\omega \exp(-i\omega \hat{t}')\omega^2 G_\omega = \int_{-\infty}^{+\infty} d\omega \frac{\exp(-i\omega \hat{t}')\omega^2}{(m_1 + m_2)\left(\hat{\omega}^2 - i\hat{\Omega}\omega\right) - m_1\omega^2}$$
$$= \int_{-\infty}^{+\infty} d\omega \frac{\exp(-i\omega \hat{t}')\left(m_1 + m_2\right)\left(\hat{\omega}^2 - i\hat{\Omega}\omega\right)}{m_1\left(m_1 + m_2\right)\left(\hat{\omega}^2 - i\hat{\Omega}\omega\right) - m_1^2\omega^2} - \frac{1}{m_1}\int_{-\infty}^{+\infty} d\omega \exp(-i\omega \hat{t}')$$
$$= \int_{-\infty}^{+\infty} d\omega \frac{\exp(-i\omega \hat{t}')\left(m_1 + m_2\right)\left(i\hat{\Omega}\omega - \hat{\omega}^2\right)}{m_1^2\left(\omega - \omega_+\right)\left(\omega - \omega_-\right)} - \frac{2\pi}{m_1}\delta(\hat{t}'). \tag{34}$$

The integrand has two poles in the lower half complex  $\omega$ -plane at:

$$\omega_{\pm} = \frac{-\mathrm{i}(m_1 + m_2)\,\hat{\Omega} \pm \sqrt{(m_1 + m_2)\left[(m_1 + m_2)\,\hat{\Omega}^2 - 4m_1\hat{\omega}^2\right]}}{2m_1},\qquad(35)$$

if  $(m_1 + m_2) \hat{\Omega}^2 > 4m_1 \hat{\omega}^2$ .

By the standard method of constructing a closed contour via introducing an infinitely large semicircle in the lower half-plane, and applying the residue theorem, the first term in (34) becomes

$$-\frac{1}{2\pi i} \int_{-\infty}^{+\infty} d\omega \frac{\exp(-i\omega \hat{t}') (m_1 + m_2) \left(\hat{\omega}^2 - i\hat{\Omega}\omega\right)}{m_1 (m_1 + m_2) \left(\hat{\omega}^2 - i\hat{\Omega}\omega\right) - m_1^2 \omega^2} = \frac{\exp(-i\omega_+ \hat{t}') (m_1 + m_2) \left(i\hat{\Omega}\omega_+ - \hat{\omega}^2\right)}{m_1^2 (\omega_+ - \omega_-)} + \frac{\exp(-i\omega_- \hat{t}') (m_1 + m_2) \left(i\hat{\Omega}\omega_- - \hat{\omega}^2\right)}{m_1^2 (\omega_- - \omega_+)}.$$
(36)

By inserting (34) and (36) into (33), we obtain:

$$\frac{\mathrm{d}^{2}D}{\mathrm{d}\hat{t}^{2}} = \int_{0}^{+\infty} \mathrm{d}\hat{t}' \frac{\mathrm{i}\exp(-\mathrm{i}\omega_{+}\hat{t}')(m_{1}+m_{2})\left(\mathrm{i}\hat{\Omega}\omega_{+}-\hat{\omega}^{2}\right)}{m_{1}^{2}(\omega_{+}-\omega_{-})} f_{x}(\hat{t}-\hat{t}') + \int_{0}^{+\infty} \mathrm{d}\hat{t}' \frac{\mathrm{i}\exp(-\mathrm{i}\omega_{-}\hat{t}')(m_{1}+m_{2})\left(\mathrm{i}\hat{\Omega}\omega_{-}-\hat{\omega}^{2}\right)}{m_{1}^{2}(\omega_{-}-\omega_{+})} f_{x}(\hat{t}-\hat{t}') + \frac{f_{x}(\hat{t})}{m_{1}} = -\frac{f_{x}(\hat{t})}{m_{1}} + \frac{f_{x}(\hat{t})}{m_{1}} = 0.$$
(37)

Note that the initial value theorem of Laplace transform is used in the integration over  $\hat{t}'$ . The theorem states that for large real s,

$$\int_{0}^{+\infty} \mathrm{d}\hat{t}' f(\hat{t}') \exp(-s\hat{t}') = \frac{f(0)}{s}.$$
(38)

Consequently, (28a) is simplified to:

$$(m_1 + m_2) \frac{\mathrm{d}^2 X_1}{\mathrm{d}\hat{t}^2} = -\frac{1}{\omega_{\mathrm{E}}^2} \frac{\partial W}{\partial X_1}.$$
(39)

Along with (27c), the equations of motion for the displacement  $R^a = (X_1, Y_1)$  are finally reduced to:

$$m_{ab}\frac{\mathrm{d}^2 R^a}{\mathrm{d}\hat{t}^2} = -\nabla_a \hat{W},\tag{40}$$

where  $\hat{W} = W/\omega_{\rm E}^2$ . Here, it is important to point out that the effective anisotropic mass arises in the mass-in-mass model. In Cartesian coordinates,

$$m_{\mu\nu} = \begin{bmatrix} m_1 + m_2 & 0\\ 0 & m_1 \end{bmatrix}.$$
 (41)

Therefore, elastic media fabricated by connecting such cavity units with Hookean springs could manifest anisotropic mass density, and thus exhibit odd elasticity.

We proceed to discuss the Hamiltonian non-conservative force acting on the cavity. First of all, we construct the Hamiltonian corresponding to (40) as

$$H = T + \hat{W}.\tag{42}$$

The total kinetic energy T includes the kinetic energies of  $m_1$  and  $m_2$ :

$$T = \frac{1}{2}M^{ab}P_aP_b = \frac{1}{2}m_1\left(u^2 + v^2\right) + \frac{1}{2}m_2u^2,$$
(43)

where  $M^{ab} = (m^{-1})^{ab}$ ,  $u = dX_1/d\hat{t}$ ,  $v = dY_1/d\hat{t}$ . The Hamilton's equations are:

$$\frac{\mathrm{d}R^a}{\mathrm{d}\hat{t}} = M^{ab}P_b,\tag{44a}$$

$$\frac{\mathrm{d}P_a}{\mathrm{d}\hat{t}} = -\nabla_a \hat{W}.\tag{44b}$$

Combining (44a) and (44b), the dynamics equation becomes:

$$m\frac{\mathrm{d}^2 R^a}{\mathrm{d}\hat{t}^2} = -mM^{ab}\nabla_b \hat{W} \equiv F^a,\tag{45}$$

where the effective scalar mass  $m = 2/M_a^a$ . Note that (45) could also be derived by multiplying  $mM^{ab}$  at both side of (40). (45) shows the dynamics of an anisotropic mass  $m_{ab}$  under the potential  $\hat{W}$ , which is equivalent to the dynamics of an isotropic mass m subject to a non-conservative force  $F^a$ .

By decomposing  $M^{ab}$  as

$$M^{ab} = \frac{1}{m} \delta^{ab} + \Omega^{ab}, \tag{46}$$

the total force  $F^a$  is divided into the conservative part  $f^a$  and the non-conservative part  $\bar{f}^a$ :

$$F^{a} = f^{a} + \bar{f}^{a}$$
  
=  $-\nabla^{a}\hat{W} - m\Omega^{ab}\nabla_{b}\hat{W}.$  (47)

One may check that in general the curl of  $F^a$  is nonzero:

$$(\mathrm{d}F)_{\mu\nu} = \partial_{\mu}\bar{f}_{\nu} - \partial_{\nu}\bar{f}_{\mu}$$
$$= -\frac{2m_2}{2m_1 + m_2}\frac{\partial^2\hat{W}}{\partial X_1\partial Y_1}.$$
(48)

Now, we analysis the work done by  $F^a$ . Following the discussion in the main text, the total kinetic energy could be separated into the isotropic part  $T_{\rm I}$  and the anisotropic part  $T_{\rm A}$  as:

$$T = T_{\rm I} - T_{\rm A}$$
  
=  $\frac{1}{2}m(u^2 + v^2) - \frac{1}{2}[(m - m_1 - m_2)u^2 + (m - m_1)v^2].$  (49)

In a cyclic motion of  $R^a$  along a closed orbit, the work done by the conservative force  $f^a$  is equal to the change in the total kinetic energy, denoted as  $\Delta T$ . Due to the energy conservation,  $\Delta T = -\Delta \hat{W} = 0$ . Therefore,  $\Delta T_A$  is equal to  $\Delta T_I$ . According to (49), we obtain the following relations:

$$\Delta T_{\rm I} = \frac{1}{2} m \Delta \left( u^2 + v^2 \right), \quad \Delta T_{\rm A} = \frac{m - m_1}{m} \Delta T_{\rm I} - \frac{1}{2} m_2 \Delta (u^2). \tag{50}$$

Consequently,

$$\frac{m_1}{m}\Delta T_{\rm I} = -\frac{1}{2}m_2\Delta(u^2). \tag{51}$$

(51) reveals that in the cyclic motion of  $R^a$ , the net work extracted by the nonconservative force  $F^a$ , which is  $\Delta T_{\rm I}$ , is originated from the reduction of the kinetic energy of  $m_2$  only.

## 4. Conclusions

In summary, from the perspective of geometry, we model a d-dimensional continuum elastic body as a Riemannian manifold embedded in the (d + 1)-dimensional Euclidean space, and construct a Hamiltonian framework for the elastic body of finite strain. It is shown that the antisymmetry of the elastic modulus tensor is originated from the anisotropic mass tensor in the kinetic term. The resulting odd elastic modulus exhibits inherent anisotropy. We also derive the non-conservative stress and the associated nonlinear constitutive relation, where the nonlinearity is caused by the intrinsic geometry of the deformed elastic body. The Hamiltonian formalism constructed in this work for characterizing odd elasticity also allows one to explore the physics of odd elasticity in dynamical regime. We shall finally point out that our findings also raise some questions to be explored: Can the two features of antisymmetry and anisotropy of the elastic modulus be separated? Are there any other mechanisms to generate the characteristic antisymmetry of the odd-elastic modulus in the frame of Hamiltonian formalism?

## Appendix A. Expressions for the induced metric and strain

In this section, we derive the expressions for the induced metric and strain. Note that we employ the abstract index notation in Latin letters to represent a tensor; the tensor components are labeled by Greek letters. Abstract indices indicate the type of a tensor, with repeated indices in pairs denoting tensor contraction. The convention of Einstein summation is applied to repeated Greek indices.

First of all, for any local coordinates system  $\{s^1, \ldots, s^d\}$  on  $\mathcal{B}$ , the associated coordinates base vector on its embedding

$$\left(\frac{\partial}{\partial s^{\mu}}\right)^{a} = \frac{\partial \bar{X}^{\nu}}{\partial s^{\mu}} \left(\frac{\partial}{\partial \bar{X}^{\nu}}\right)^{a},\tag{A.1}$$

where  $\bar{X}^{\nu}$  is the Cartesian coordinates of the embedding of deformed configuration  $\Sigma$  in the Euclidean space  $\mathcal{E}$ .

The isometric embedding of  $\Sigma$  in the Euclidean space  $\mathcal{E}$  indicates that

$$\bar{g}_{ab} = \delta_{ab} - N_a N_b, \tag{A.2}$$

where  $N_a$  is the unit normal covector on  $\Sigma$ . Therefore, the component of the metric tensor  $\bar{g}_{ab}$  is

$$\bar{g}_{\mu\nu} = \bar{g}_{ab} \left(\frac{\partial}{\partial s^{\mu}}\right)^{a} \left(\frac{\partial}{\partial s^{\nu}}\right)^{b} \\
= \left(\delta_{ab} - N_{a}N_{b}\right) \left(\frac{\partial}{\partial s^{\mu}}\right)^{a} \left(\frac{\partial}{\partial s^{\nu}}\right)^{b} \\
= \delta_{ab} \left(\frac{\partial}{\partial s^{\mu}}\right)^{a} \left(\frac{\partial}{\partial s^{\nu}}\right)^{b} \\
= \delta_{\tau\rho} \frac{\partial \bar{X}^{\tau}}{\partial s^{\mu}} \frac{\partial \bar{X}^{\rho}}{\partial s^{\nu}} \\
= \frac{\partial \bar{X}_{\rho}}{\partial s^{\mu}} \frac{\partial \bar{X}^{\rho}}{\partial s^{\nu}}.$$
(A.3)

Here  $\delta_{ab}$  is the Euclid metric of  $\mathcal{E}$ , and  $\delta_{\tau\rho}$  is Kronecker delta which is the components of  $\delta_{ab}$  in Cartesian coordinates. In the derivation of (A.3), we use the fact that  $(\partial/\partial s^{\mu})^{a} N_{a} = 0$ . One has the similar result for  $g_{\mu\nu}$  as

$$g_{\mu\nu} = \frac{\partial X_{0\rho}}{\partial s^{\mu}} \frac{\partial X_{0}^{\rho}}{\partial s^{\nu}},\tag{A.4}$$

where  $X_0^{\rho}$  is the Cartesian coordinates of the embedding of reference configuration.

By substituting (A.3) and (A.4) into the following expression of  $u_{ab}$ 

$$u_{ab} = \frac{1}{2} \left( \bar{g}_{ab} - g_{ab} \right), \tag{A.5}$$

we obtain

1

$$u_{ab} = \frac{1}{2} \left( \frac{\partial \bar{X}_{\rho}}{\partial s^{\mu}} \frac{\partial \bar{X}^{\rho}}{\partial s^{\nu}} - \frac{\partial X_{0\rho}}{\partial s^{\mu}} \frac{\partial X_{0}^{\rho}}{\partial s^{\nu}} \right) (\mathrm{d}s^{\mu})_{a} (\mathrm{d}s^{\nu})_{b}$$
$$= \frac{1}{2} \left( \nabla_{a} \bar{X}_{\rho} \nabla_{b} \bar{X}^{\rho} - \nabla_{a} X_{0\rho} \nabla_{b} X_{0}^{\rho} \right), \qquad (A.6)$$

where  $\nabla_b$  is the covariant derivative operator on  $\Sigma$ .  $\nabla_b$  is metric compatible, i.e.,  $\nabla_b \bar{g}_{ac} = 0$ . (A.6) shows that  $u_{ab}$  could be regarded as a local function of  $\nabla_a \bar{X}^{\rho}$ .

## Appendix B. Variational derivatives of the Hamiltonian

In this section, we present the variational derivatives of the Hamiltonian defined on the manifold  $\mathcal{B}$ , which is recorded here

$$H = T + W$$
  
=  $\frac{1}{2} \int d^d s \rho_0 \sqrt{g} \mathscr{M}^{ab} P_a P_b + \int d^d s \rho_0 \sqrt{g} \mathscr{W}.$  (B.1)

The variational derivative of the Hamiltonian with respect to the generalized momentum density field  $P_a$  is

$$\frac{\delta H}{\delta P_a} = \frac{\delta T}{\delta P_a} = \rho_0 \sqrt{g} \mathcal{M}^{ab} P_b. \tag{B.2}$$

To obtain the variational derivative of the Hamiltonian with respect to  $U^a$ , we first calculate

$$\begin{split} \delta W &= \int \mathrm{d}^{d} s \rho_{0} \sqrt{g} \delta \mathscr{W} \\ &= \int \mathrm{d}^{d} s \rho \sqrt{\bar{g}} \frac{\partial \mathscr{W}}{\partial u_{ab}} \delta u_{ab} \\ &= \int \mathrm{d}^{d} s \sqrt{\bar{g}} \sigma^{ab} \nabla_{a} \bar{X}_{\rho} \nabla_{b} \delta \bar{X}^{\rho} \\ &= \int \mathrm{d}^{d} s \sqrt{\bar{g}} \nabla_{b} \left( \sigma^{ab} \nabla_{a} \bar{X}_{\rho} \delta \bar{X}^{\rho} \right) - \int \mathrm{d}^{d} s \sqrt{\bar{g}} \nabla_{b} \left( \sigma^{ab} \nabla_{a} \bar{X}_{\rho} \right) \delta \bar{X}^{\rho} \\ &= -\int \mathrm{d}^{d} s \sqrt{\bar{g}} \nabla_{b} \left( \sigma^{ab} \nabla_{a} \bar{X}_{\rho} \right) \delta \bar{X}^{\rho}, \end{split}$$
(B.3)

Note that from the first line to the second line in (B.3), the domain of integration is changed from the reference configuration to  $\Sigma$ . In the last equality, we drop the divergence term to the boundary term by utilizing Gauss's theorem; only the energy variation in the interior of the body is considered.

Now, we calculate the variational derivative of the Hamiltonian with respect to the displacement field  $U^a$ :

$$\frac{\delta H}{\delta U^{a}} = \frac{\delta W}{\delta U^{a}}$$

$$= \frac{\delta W}{\delta \bar{X}^{\mu}} \left( d\bar{X}^{\mu} \right)_{a} \nabla_{c} \left( \sigma^{bc} \nabla_{b} \bar{X}_{\mu} \right)$$

$$= -\sqrt{\bar{g}} \left( d\bar{X}^{\mu} \right)_{a} \bar{g}_{c}^{\ d} \partial_{d} \left[ \sigma^{bc} \bar{g}_{b}^{\ e} \left( d\bar{X}_{\mu} \right)_{e} \right]$$

$$= -\sqrt{\bar{g}} \bar{g}_{c}^{\ d} \partial_{d} \left[ \sigma^{bc} \bar{g}_{b}^{\ e} \left( d\bar{X}_{\mu} \right)_{e} \right]$$

$$= -\sqrt{\bar{g}} \bar{g}_{c}^{\ d} \partial_{d} \left( \sigma^{bc} \bar{g}_{b}^{\ e} \delta_{ae} \right)$$

$$= -\sqrt{\bar{g}} \bar{g}_{c}^{\ d} \partial_{d} \left( \bar{g}_{ab} \sigma^{bc} \right)$$

$$\equiv -\sqrt{\bar{g}} f_{a}.$$
(B.4)

 $\partial_a$  is the derivative operator in the Cartesian coordinates on  $\mathcal{E}$ ;  $\partial_a \left( d\bar{X}_{\mu} \right)_b = 0$ .  $(d)_a$  is the exterior derivative operator on  $\mathcal{E}$ .  $\bar{g}_a{}^b$  is a projection operator:  $\bar{g}_a{}^b = \bar{g}_{ac}\delta^{cb} = \delta_a{}^b - N_a N^b$ .

Here, it is of interest to point out that in general  $f_a$  is not tangent to  $\Sigma$ , which is

shown below

$$f_{a} = \bar{g}_{c}{}^{d}\partial_{d} \left(\bar{g}_{ab}\sigma^{bc}\right)$$

$$= \bar{g}_{c}{}^{d}\partial_{d} \left(\sigma^{bc}\bar{g}_{b}{}^{e}\delta_{ae}\right)$$

$$= \delta_{ae}\bar{g}_{c}{}^{d}\partial_{d} \left(\sigma^{bc}\bar{g}_{b}{}^{e}\right)$$

$$= \delta_{ae} \left(\bar{g}_{b}{}^{e}\bar{g}_{c}{}^{d}\partial_{d}\sigma^{bc} + \sigma^{bc}\bar{g}_{c}{}^{d}\partial_{d}\bar{g}_{b}{}^{e}\right)$$

$$= \delta_{ae} \left(\nabla_{c}\sigma^{ec} - \sigma^{bd}N^{e}\partial_{d}N_{b}\right)$$

$$= \bar{g}_{ab}\nabla_{c}\sigma^{bc} - N_{a}\sigma^{bc}K_{bc}, \qquad (B.5)$$

where  $K_{bc}$  is the extrinsic curvature of  $\Sigma$ . In the derivation, we use the definition of extrinsic curvature  $K_{bc} = \bar{g}_b{}^d \bar{g}_c{}^e \partial_d N_e$  and the fact that  $\sigma^{ab} N_b = 0$ . The first and second terms in (B.5) are the tangent and normal components of  $f_a$  [33, 34, 35]. For example, in the case of  $\phi_2$  in figure 1 of the main text, the normal force supporting  $\Sigma$  on the sphere is  $(e_r)^a \sigma^b_b / R$ , where R is the radius of the sphere and  $(e_r)^a$  is the unit normal vector perpendicular to the spherical surface.

Figure B1: Illustrations of 2D torus and Möbius strip. The tangent vectors of the lines constitute the Killing vector field on these two surface.

## Appendix C. The isometric symmetry of elastic modulus tensor

In the main text, we present the following expression for the rotationally symmetric elastic modulus tensor in an axisymmetric continuum elastic body:

$$C^{abcd} = \lambda g^{ab} g^{cd} + 2\mu g^{a(c} g^{d)b}, \tag{C.1}$$

where  $\lambda$  and  $\mu$  are Lamé coefficients. In this section, we present the derivation for (C.1).

Consider an axisymmetric continuum elastic body. Its rotation as a whole belongs to a special isometric mapping that could be generated by a Killing vector field  $v^a$ . By the definition of the Killing vector field, the displacement of the points from  $s^{\mu}$  to  $s^{\mu} + v^{\mu}\epsilon$  leaves the distance relationships unchanged. In other words, the displacement of  $v^{\mu}\epsilon$  defines an isometric mapping. In figure B1(a), we present a 2D torus as an example of the axisymmetric elastic body. The tangent vectors of the toroidal lines constitute the Killing vector field on the torus. The elastic modulus tensor as associated with infinitesimal volume element possesses the rotational symmetry in the sense that it is invariant along the toroidal lines.

The rotational symmetry of the elastic modulus tensor  $C^{abcd}$  is expressed by the zero Lie derivative of  $C^{abcd}$  along the direction as specified by the Killing vector on the reference configuration [36]:

$$\mathcal{L}_{v}C^{abcd} \equiv v^{e}\nabla_{e}C^{abcd} - C^{ebcd}\nabla_{e}v^{a} - C^{aecd}\nabla_{e}v^{b} - C^{abcd}\nabla_{e}v^{c} - C^{abce}\nabla_{e}v^{d} = 0, \qquad (C.2)$$

where  $v^a$  is a Killing vector field satisfying  $\nabla_{(a}v_{b)} = 0$ , and  $\nabla_a$  is the covariant derivative operator on the reference configuration.  $C^{abcd}$  as constructed by the tensor product of  $g^{ab}$ -tensors satisfies (C.2); note that  $\mathscr{L}_v g^{ab} = 0$ . Specifically, there are three kinds of index permutations of the tensor product:

$$C^{abcd} = \lambda g^{ab} g^{cd} + \mu_1 g^{ac} g^{bd} + \mu_2 g^{ad} g^{bc},$$
(C.3)

where  $\lambda$ ,  $\mu_1$  and  $\mu_2$  are constant scalars on  $\mathcal{B}$ .

Due to the extra requirements for the conservation of angular momentum and the conservative nature of stress [6],

$$C^{abcd} = C^{cdab} = C^{bacd} . (C.4)$$

The first equality is automatically satisfied for (C.3). The second equality is satisfied if  $\mu_1 = \mu_2 = \mu$ . The final expression for  $C^{abcd}$  that satisfies both (C.3) and (C.4) is

$$C^{abcd} = \lambda g^{ab} g^{cd} + 2\mu g^{a(c} g^{d)b}. \tag{C.5}$$

For Euclidean reference configuration, the components of  $C^{abcd}$  in Cartesian coordinates system are

$$C^{\mu\nu\eta\gamma} = \lambda \delta^{\mu\nu} \delta^{\eta\gamma} + 2\mu \delta^{\mu(\eta} \delta^{\gamma)\nu}.$$
 (C.6)

By making use of the linear constitutive relation, the elastic potential can be expressed as

$$W = \int d^d s \rho_0 \left[ \lambda \left( u_{\eta\eta} \right)^2 + 2\mu \left( u_{\eta\gamma} \right)^2 \right], \qquad (C.7)$$

where  $d^d s$  is the volume element of Cartesian coordinates on the reference configuration. In comparison with the linear elasticity theory, the parameters  $\lambda$  and  $\mu$  are recognized as the Lamé coefficients [2].

Note that (C.2) could be used to describe the general case that the elastic modulus tensor is invariant along the lines of the Killing vectors, i.e., the isometric symmetry of the elastic modulus tensor. For example, on the Möbius strip in figure (B1b), the tangent vectors of the lines constitute the Killing vector field; the isometric mapping

of the Möbius strip is generated by this Killing vector field.  $C^{abcd}$  that satisfies (C.2) is invariant along these lines. This is the generalization of the rotational symmetry of the elastic modulus tensor of axisymmetric continuum elastic body as discussed in this section.

## Appendix D. The symmetry of $\hat{C}^{abcd}$ and $\hat{D}^{abcdef}$

In the main text, we assert that the odd elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  possess inherent anisotropy, which is different from traditional odd elastic modulus. Following the discussion in Appendix C about the symmetry of elastic modulus tensor, we can now further supplement the symmetry of  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  in details.

According to the definition in Appendix C, the sufficient and necessary condition for odd elastic modulus to be isometric is satisfied if  $\mathscr{L}_v \hat{C}^{abcd} = 0$  and  $\mathscr{L}_v \hat{D}^{abcdef} = 0$ . Specifically, this requires  $C^{abcd}$  to satisfy the following equation:

$$\rho \Omega^{ae} g_{ef} \mathscr{L}_v C^{fbcd} + g_{ef} C^{fbcd} \mathscr{L}_v (\rho \Omega^{ae}) = 0, \qquad (D.1)$$

where the isometric symmetry of  $\hat{C}^{abcd}$  is satisfied; and:

$$\rho \Omega^{ac} \mathscr{L}_v C^{dbef} + C^{dbef} \mathscr{L}_v (\rho \Omega^{ac}) = 0, \qquad (D.2)$$

where the isometric symmetry of  $\hat{D}^{abcdef}$  is satisfied. Substituting (D.2) into (D.1) and eliminating the Lie derivative of  $\rho \Omega^{ab}$ , we obtain an identity. Therefore, (D.1) and (D.2) are equivalent, meaning the symmetries of  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  are consistent. In the following, we perform a detailed calculation of the symmetry of  $\hat{C}^{abcd}$ . The final result shows that, due to the coupling with  $\rho \Omega^{ab}$ ,  $\hat{C}^{abcd}$  is necessarily anisotropic.

Generally, solving for Killing vector fields on a manifold is challenging. However, for simple cases, the corresponding Killing vector fields can be directly written using known properties of manifold symmetries, and the isometric condition for odd elastic modulus can be derived using (C.2) or (D.1).

First, let's consider the case where the reference configuration is a 2D Euclidean plane  $(d = 2, g_{ab} = \delta_{ab})$ .

The 2D Euclidean plane has 3 independent symmetries: translations along the xand y axes, and rotation about the origin. The corresponding 3 Killing vector fields are:  $e_1^a \equiv (\partial/\partial x)^a, e_2^a \equiv (\partial/\partial y)^a, (\partial/\partial \varphi)^a \equiv -y(\partial/\partial x)^a + x(\partial/\partial y)^a$ , where  $\varphi$  is the polar angle. Below, we denote the Lie derivative operators along these three Killing vector fields as  $\mathscr{L}_x, \mathscr{L}_y, \mathscr{L}_{\varphi}$ . In this context, the translational and rotational symmetry of the 2D Euclidean plane correspond to the homogeneous and isotropy of the elastic modulus, respectively.

The analysis is divided into two steps: first, to determine the general form of the odd elastic modulus  $\hat{C}^{abcd}$  that satisfies the homogeneous isotropic condition, and then to find the  $C^{abcd}$  that makes  $\hat{C}^{abcd}$  satisfy this condition.

We begin with (C.2) to give the homogeneous isotropic condition for  $\hat{C}^{abcd}$ , that is,  $\mathscr{L}_v \hat{C}^{abcd} = 0$ . In Cartesian coordinates,  $\hat{C}^{abcd}$  can be expanded as:

$$\hat{C}^{abcd} = \hat{C}^{\mu\nu\eta\gamma} e_{\mu}{}^{a} e_{\nu}{}^{b} e_{\eta}{}^{c} e_{\gamma}{}^{d}.$$
(D.3)

If and only if  $\hat{C}^{\mu\nu\eta\gamma}$  are position-independent constant components, the following equations hold:

$$\mathscr{L}_x \hat{C}^{abcd} = \frac{\partial \hat{C}^{\mu\nu\eta\gamma}}{\partial x} e_\mu{}^a e_\nu{}^b e_\eta{}^c e_\gamma{}^d = 0, \qquad (D.4)$$

$$\mathscr{L}_{y}\hat{C}^{abcd} = \frac{\partial \hat{C}^{\mu\nu\eta\gamma}}{\partial y} e_{\mu}{}^{a} e_{\nu}{}^{b} e_{\eta}{}^{c} e_{\gamma}{}^{d} = 0.$$
(D.5)

In this case,  $\hat{C}^{abcd}$  automatically satisfies the translational symmetry (homogeneous), and only the rotational symmetry (isotropy) condition  $\mathscr{L}_{\varphi}\hat{C}^{abcd} = 0$  needs to be considered. This condition is equivalent to the polar coordinate components of  $\hat{C}^{abcd}$ being independent of  $\varphi$ .

In the following, we derive for the rotational symmetry condition of  $\hat{C}^{abcd}$  in 2D. The polar coordinate components  $\hat{C}_{\varphi}^{\mu\nu\eta\gamma}$  of  $\hat{C}^{abcd}$  are obtained as follows:

$$\hat{C}_{\varphi}{}^{\mu\nu\eta\gamma} = J_{\varphi}{}^{\mu}{}_{\alpha}J_{\varphi}{}^{\nu}{}_{\beta}J_{\varphi}{}^{\eta}{}_{\rho}J_{\varphi}{}^{\gamma}{}_{\sigma}\hat{C}{}^{\alpha\beta\rho\sigma}$$
$$= J_{\varphi}{}^{\mu}{}_{\alpha}J_{\varphi}{}^{\nu}{}_{\beta}J_{\varphi}{}^{\eta}{}_{\rho}J_{\varphi}{}^{\gamma}{}_{\sigma}e{}^{\alpha}{}_{a}e{}^{\beta}{}_{b}e{}^{\rho}{}_{c}e{}^{\sigma}{}_{d}\mathfrak{e}{}_{\tau}{}^{ab}\mathfrak{e}{}_{\theta}{}^{cd}\hat{C}{}^{\tau\theta}, \tag{D.6}$$

where the Jacobian matrix  $J_{\varphi}{}^{\mu}{}_{\nu} \equiv \partial(\varphi, r) / \partial(x, y)$  transforms Euclidean coordinates to polar coordinates. The sufficient and necessary condition for  $\hat{C}^{abcd}$  to have rotational symmetry is:

$$\frac{\partial \hat{C}_{\varphi}{}^{\mu\nu\eta\gamma}}{\partial\varphi} = e^{\alpha}{}_{a}e^{\beta}{}_{b}e^{\rho}{}_{c}e^{\sigma}{}_{d}\mathbf{\mathfrak{e}}_{\tau}{}^{ab}\mathbf{\mathfrak{e}}_{\theta}{}^{cd}\hat{C}^{\tau\theta}\frac{\partial}{\partial\varphi}\left(J_{\varphi}{}^{\mu}{}_{\alpha}J_{\varphi}{}^{\nu}{}_{\beta}J_{\varphi}{}^{\eta}{}_{\rho}J_{\varphi}{}^{\gamma}{}_{\sigma}\right) = 0 \qquad (D.7)$$

In deriving the above equation, we use the condition that  $\hat{C}^{\mu\nu\eta\gamma}$ , and thus  $\hat{C}^{\tau\theta}$ , is a constant matrix. Solving this matrix equation for  $\hat{C}^{\tau\theta}$ , we get:

$$\hat{C}^{11} = \hat{C}^{11}, \quad \hat{C}^{12} = \hat{C}^{12}, \quad \hat{C}^{21} = \hat{C}^{21}, \quad \hat{C}^{22} = \hat{C}^{22}, \quad \hat{C}^{43} = -\hat{C}^{34}, \quad \hat{C}^{33} = \hat{C}^{44}, \quad (D.8)$$

with all other components being zero. When expressed in matrix form, it becomes:

$$\hat{C}^{\tau\theta} = \begin{bmatrix} \hat{C}^{11} & \hat{C}^{12} & 0 & 0\\ \hat{C}^{21} & \hat{C}^{22} & 0 & 0\\ 0 & 0 & \hat{C}^{33} & \hat{C}^{34}\\ 0 & 0 & -\hat{C}^{34} & \hat{C}^{33} \end{bmatrix},$$
(D.9)

(D.9) represents the isotropic condition for  $\hat{C}^{abcd}$ , with 6 independent stiffness coefficients, consistent with the results in the literature [6].

Next, we construct  $C^{abcd}$  that makes  $\hat{C}^{\mu\nu}$  satisfying (D.9).

Since  $\hat{C}^{abcd} = \rho \Omega^{ae} \delta_{ef} C^{fbcd}$ , we have:

$$\hat{C}^{\mu\nu} = \rho \Omega^{ae} \delta_{ef} C^{fbcd} \mathfrak{e}^{\mu}{}_{ab} \mathfrak{e}^{\nu}{}_{cd}. \tag{D.10}$$

Let  $C^{abcd}$  be expanded in the frame  $\{\mathfrak{e}^{\mu}{}_{ab}\}$  as:

$$C^{abcd} = C^{\mu\nu} \boldsymbol{\epsilon}_{\mu}{}^{ab} \boldsymbol{\epsilon}_{\nu}{}^{cd}, \tag{D.11}$$

where  $C^{\mu\nu}$  has the index symmetry, i.e.,  $C^{\mu\nu} = C^{\nu\mu}$ . Substituting (22*d*), (25) and (D.11) into (D.10), we obtain the following matrix equation for  $C^{\mu\nu}$ :

$$\hat{C}^{\mu\nu} = C^{\eta\gamma} \left( \kappa \mathfrak{e}_3{}^{ae} + \zeta \mathfrak{e}_4{}^{ae} \right) \mathfrak{e}^1{}_{ef} \mathfrak{e}_{\eta}{}^{fb} \mathfrak{e}_{\gamma}{}^{cd} \mathfrak{e}^{\mu}{}_{ab} \mathfrak{e}^{\nu}{}_{cd}.$$
(D.12)

The condition for the solution of (D.12) is that  $\rho \Omega^{ab}$  is non-degenerate, and the upperleft submatrix of matrix  $\hat{C}^{\tau\theta}$  is equal to the lower-right submatrix, namely:

$$\hat{C}^{\tau\theta} = \begin{bmatrix} \hat{C}^{33} & \hat{C}^{34} & 0 & 0\\ -\hat{C}^{34} & \hat{C}^{33} & 0 & 0\\ 0 & 0 & \hat{C}^{33} & \hat{C}^{34}\\ 0 & 0 & -\hat{C}^{34} & \hat{C}^{33} \end{bmatrix}.$$
 (D.13)

This represents a specific odd elastic modulus with only 2 independent stiffness coefficients. The solution to (D.12) is then:

$$C^{\mu\nu} = \frac{1}{4\left(\zeta^2 + \kappa^2\right)} \begin{bmatrix} 0 & 0 & \kappa\hat{C}^{33} - \zeta\hat{C}^{34} & \zeta\hat{C}^{33} + \kappa\hat{C}^{34} \\ 0 & 0 & \zeta\hat{C}^{33} + \kappa\hat{C}^{34} & \zeta\hat{C}^{34} - \kappa\hat{C}^{33} \\ \kappa\hat{C}^{33} - \zeta\hat{C}^{34} & \zeta\hat{C}^{33} + \kappa\hat{C}^{34} & 0 & 0 \\ \zeta\hat{C}^{33} + \kappa\hat{C}^{34} & \zeta\hat{C}^{34} - \kappa\hat{C}^{33} & 0 & 0 \end{bmatrix}. \quad (D.14)$$

Thus, by constructing a  $C^{abcd}$  on the elastic body that satisfies (D.14) (which is evidently an anisotropic elastic modulus), one can obtain the homogeneous isotropic odd elastic modulus given by (D.13).

According to our assumption, the rotation of the elastic body does not change its intrinsic geometry, and thus does not induce stress. Therefore,  $C^{abcd}$  will also satisfy  $C^{abcd} = C^{abdc}$ , or  $C^{\mu 2} = 0$ . At this point, (D.12) only has the trivial solution  $C^{\mu\nu} = \hat{C}^{\mu\nu} = 0$ . This implies that for a reference configuration of a 2D Euclidean plane, the odd elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  must be anisotropic due to the coupling with  $\rho\Omega^{ab}$ . It is known that any sufficiently small neighborhood of a point on a Riemannian manifold can be considered as a Euclidean space of the same dimension. Therefore, for any case of a 2D elastic body reference configuration, the odd elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  are anisotropic tensor fields.

Finally, some additional remarks on the assumption of  $C^{\mu 2} = 0$  are warranted. This assumption is known as the "objectivity" of the elastic body [2, 6], predicated on the premise that the interaction forces between the microscopic units of the elastic body depend only on their relative distance and not on the orientation. When a substrate exists, this condition may no longer hold [8, 37]. Thus, a more accurate statement is that, for any 2D elastic body possessing objectivity, the odd elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  are anisotropic tensor fields.

Next, we apply the above discussion to the case where the reference configuration is a 3D Euclidean space  $(d = 3, g_{ab} = \delta_{ab})$ .

A 3D Euclidean space has 6 independent Killing vector fields, corresponding to translational symmetry along the x, y, and z axes:  $e_1{}^a \equiv (\partial/\partial x){}^a, e_2{}^a \equiv (\partial/\partial y){}^a,$  $e_3{}^a \equiv (\partial/\partial z){}^a$ ; and rotational symmetry around the z, x, and y axes:  $(\partial/\partial y){}^a \equiv -y(\partial/\partial x){}^a + x(\partial/\partial y){}^a, (\partial/\partial \varrho){}^a \equiv -z(\partial/\partial y){}^a + y(\partial/\partial z){}^a, (\partial/\partial \zeta){}^a \equiv -x(\partial/\partial z){}^a + z(\partial/\partial x){}^a$ . Assuming that the Cartesian components  $\hat{C}^{\mu\nu\eta\gamma}$  of  $\hat{C}^{abcd}$  are still constant matrices, the homogeneous is automatically satisfied, and only its isotropic properties, i.e., rotational symmetry, need to be considered. We will next calculate the Lie derivatives  $\mathscr{L}_{\vartheta}$ ,  $\mathscr{L}_{\varrho}$ , and  $\mathscr{L}_{\varsigma}$  corresponding to the rotational symmetry around the z, x, and y axes for  $\hat{C}^{abcd}$ .

To facilitate the consideration of rotational symmetry around the z, x, and y axes, three sets of cylindrical coordinates are introduced as follows:

$$\begin{cases} x = r\cos\vartheta, \quad y = r\sin\vartheta, \quad z = z; \\ x = x, \quad y = r\cos\varrho, \quad z = r\sin\varrho; \\ x = r\sin\varsigma, \quad y = y, \quad z = r\cos\varsigma. \end{cases}$$
(D.15)

The components of  $\hat{C}^{abcd}$  in the three sets of cylindrical coordinates,  $\hat{C}_{\lambda}^{\mu\nu\eta\gamma}$  ( $\lambda = \vartheta, \varrho, \varsigma$ ), can be obtained as follows:

$$\hat{C}_{\lambda}{}^{\mu\nu\eta\gamma} = J_{\lambda}{}^{\mu}{}_{\alpha}J_{\lambda}{}^{\nu}{}_{\beta}J_{\lambda}{}^{\eta}{}_{\rho}J_{\lambda}{}^{\gamma}{}_{\sigma}\hat{C}{}^{\alpha\beta\rho\sigma},\tag{D.16}$$

where the Jacobian matrix  $J_{\lambda}{}^{\nu}{}_{\beta}$  transforms Euclidean coordinates to cylindrical coordinates. The necessary and sufficient condition for  $\hat{C}^{abcd}$  to be isotropic, i.e.,  $\mathscr{L}_{\lambda}\hat{C}^{abcd} = 0$ , is:

$$\frac{\partial \hat{C}_{\lambda}{}^{\mu\nu\eta\gamma}}{\partial\lambda} = \hat{C}^{\alpha\beta\rho\sigma} \frac{\partial}{\partial\lambda} \left( J_{\lambda}{}^{\mu}{}_{\alpha} J_{\lambda}{}^{\nu}{}_{\beta} J_{\lambda}{}^{\eta}{}_{\rho} J_{\lambda}{}^{\gamma}{}_{\sigma} \right) = 0.$$
(D.17)

By solving this matrix equation for the constant matrix  $\hat{C}^{\alpha\beta\rho\sigma}$ , we get:

$$\hat{C}^{1111} = \hat{C}^{3333}, \quad \hat{C}^{1133} = \hat{C}^{1122} = \hat{C}^{3322}, \hat{C}^{1212} = \hat{C}^{3232}, \quad \hat{C}^{1221} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \hat{C}^{1313} = \hat{C}^{3232}, \quad \hat{C}^{1331} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \hat{C}^{2112} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \quad \hat{C}^{2121} = \hat{C}^{3232} \hat{C}^{2211} = \hat{C}^{2233} = \hat{C}^{3322}, \quad \hat{C}^{2222} = \hat{C}^{3333} \hat{C}^{2323} = \hat{C}^{3232}, \quad \hat{C}^{2332} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322} \hat{C}^{3113} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \quad \hat{C}^{3131} = \hat{C}^{3232}, \hat{C}^{3223} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \quad \hat{C}^{3311} = \hat{C}^{3232}, \hat{C}^{3223} = \hat{C}^{3333} - \hat{C}^{3232} - \hat{C}^{3322}, \quad \hat{C}^{3311} = \hat{C}^{3322},$$

with all other coefficients being zero. It can be seen that in 3D, the isotropic odd elastic modulus has 3 degrees of freedom, fewer than the 6 in 2D. This is understandable as the isotropic odd elastic modulus in higher dimensions have higher symmetry, leading to more constraints. In fact, such high symmetry automatically imposes principal axis index symmetry on  $\hat{C}^{abcd}$ : from (D.18), it is evident that  $\hat{C}^{\mu\nu\eta\gamma} = \hat{C}^{\eta\gamma\mu\nu}$ . Therefore, 3D odd elastic modulus must be anisotropic. This is a consequence of fundamental symmetry, independent of the specific physical origin of the elastic modulus. This result is consistent with the conclusions drawn using group representation theory in the literature [6].

Similar to the 2D case, since any sufficiently small neighborhood of a point on a 3D manifold can be considered as a 3D Euclidean space, for any 3D elastic body reference configuration, the odd elastic modulus  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  are anisotropic tensor fields. Furthermore, from a physical standpoint, elastic bodies in dimensions higher than 3 are generally not of interest. Therefore, we assert in the main text that due to the

contribution of the anisotropic mass  $\rho \Omega^{ab}$ ,  $\hat{C}^{abcd}$  and  $\hat{D}^{abcdef}$  naturally exhibit anisotropy.
