# Interior Point Methods with a Gradient Oracle 

Adrian Vladu*

#### Abstract

We provide an interior point method based on quasi-Newton iterations, which only requires first-order access to a strongly self-concordant barrier function. To achieve this, we extend the techniques of Dunagan-Harvey [STOC '07] to maintain a preconditioner, while using only first-order information. We measure the quality of this preconditioner in terms of its relative excentricity to the unknown Hessian matrix, and we generalize these techniques to convex functions with a slowly-changing Hessian. We combine this with an interior point method to show that, given first-order access to an appropriate barrier function for a convex set $K$, we can solve well-conditioned linear optimization problems over $K$ to $\varepsilon$ precision in time $\widetilde{O}\left(\left(\mathcal{T}+n^{2}\right) \sqrt{n \nu} \log (1 / \varepsilon)\right)$, where $\nu$ is the self-concordance parameter of the barrier function, and $\mathcal{T}$ is the time required to make a gradient query.

As a consequence we show that: - Linear optimization over $n$-dimensional convex sets can be solved in time $\widetilde{O}\left(\left(\mathcal{T} n+n^{3}\right) \log (1 / \varepsilon)\right)$. This parallels the running time achieved by state of the art algorithms for cutting plane methods, when replacing separation oracles with first-order oracles for an appropriate barrier function. - We can solve semidefinite programs involving $m \geq n$ matrices in $\mathbb{R}^{n \times n}$ in time $\widetilde{O}\left(m n^{4}+m^{1.25} n^{3.5} \log (1 / \varepsilon)\right)$, improving over the state of the art algorithms, in the case where $m=\Omega\left(n^{\frac{3.5}{\omega-1,25}}\right)$. Along the way we develop a host of tools allowing us to control the evolution of our potential functions, using techniques from matrix analysis and Schur convexity.

[^0]
## 1 Introduction

Gradient methods are the most basic elements of continuous optimization [BTN01, Nes18, Bub15]. While they have been central to many important results in the theory of minimizing convex functions, especially due to their simplicity, they are typically unable to provide high precision solutions unless the functions they are used are extremely well behaved (smooth and stronglyconvex). In addition to this, their behavior can differ wildly when performing a change of basis, so finding the appropriate basis turns out to be a challenging task that may have drastic effects on their convergence [KOSZ13]. However, for many important scenarios a single good basis can simply not exist.

In particular, when considering linear optimization objectives over general convex sets, methods that are able to provide high precision solutions are cutting plane methods (CPM) or interior point methods (IPM). These overcome the limitations of standard gradient methods, as they all implicitly maintain a changing basis, which permit very fast convergence to a near minimizer of the objective. Doing so is, however, very costly. In the case of cutting plane methods, one needs to carefully maintain an appropriate center of the current domain, which needs to be updated fast when adding new constraints, while in the case of interior point methods one needs access to the Hessian matrix of an appropriate barrier function, whose mere evaluation may be extremely costly [NN92, JKL $\left.{ }^{+} 20\right]$.

In the context of interior point methods, several works have tried to bridge the gap between the standard version, which requires access to the Hessian matrix, and that where only gradients are available, by resorting to quasi-Newton methods. These attempt to mimic the classical Newton iterations performed in IPM's (which can be thought of as gradient steps, preconditioned with the Hessian matrix) by maintaining a "fake" Hessian matrix which gets corrected whenever the step obtained using it certifiably points towards a wrong direction [GS19, GS22, Tun01]. A related line of remarkable work has produced efficient quasi-Newton methods [Bro70, Fle70, Gol70, Sha70, BNS94], which aim to match the performance of second order methods only by using a gradient oracle. While extremely promising, it is unclear to what extent these methods yield good convergence bounds when applied to standard tasks, such as those modeled by linear or semidefinite programs. Addressing these questions will yield new and improved algorithms, opening a fresh research direction for efficient optimization. Relatedly, Dunagan and Harvey [DH07] provided a beautiful method for solving linear systems, partially inspired from the conjugate gradient method, which was based on maintaining a dynamic preconditioner. While they explicitly stated the possibility of using their algorithm inside quasi-Newton methods, for strange reasons this direction has not been pursued until now.

As an important benchmark for optimization algorithms, we consider the semidefinite programs (SDPs), which optimize a linear objective over the intersection between an affine space and the cone of positive semidefinite matrices. These have broad applications in multiple scientific fields, including theoretical computer science, operations research, and engineering [VB96].

We formally define semidefinite programming with $n \times n$ variables and $m$ constraints.
Definition 1 (Semidefinite programming). Given symmetric matrices $\boldsymbol{B}, \boldsymbol{A}_{1}, \ldots, \boldsymbol{A}_{m} \in \mathbb{R}^{n \times n}$, and $c_{i} \in \mathbb{R}$ for all $i \in\{1, \ldots, m\}$ we aim to solve the optimization problem:

$$
\begin{equation*}
\max \left\{\langle\boldsymbol{B}, \boldsymbol{X}\rangle: \boldsymbol{X} \succeq 0,\left\langle\boldsymbol{A}_{i}, \boldsymbol{X}\right\rangle=c_{i}, \text { for all } 1 \leq i \leq m\right\}, \tag{1}
\end{equation*}
$$

where $\langle\boldsymbol{A}, \boldsymbol{B}\rangle:=\sum_{i, j} \boldsymbol{A}_{i j} \boldsymbol{B}_{i j}$ is the trace product.

Standard methods for solving SDPs to high precision rely either on cutting plane methods or interior point methods. While the early works, as well as the more recent improvements to the running time of SDP solvers have used cutting planes methods [Kha79, LSW15, JLSW20], a recent trend has been to seek further improvements by using interior point methods instead [JKL $\left.{ }^{+} 20, \mathrm{HJS}^{+} 22\right]$. As stated before, one major bottleneck in obtaining fast algorithms via IPMs for certain optimization problems consists of the unyieldingly large time required to evaluate the Hessian matrix, and this is precisely one of the regimes where this obstacle occurs. While [NN92] use a series of clever tricks to speed up the time to compute the Hessian, [JKL ${ }^{+}$20] develop a series of sophisticated techniques based on rectangular matrix multiplication. It therefore appears that quasiNewton methods, which do not need access to the true Hessian matrix, could possibly represent a valid path towards obtaining faster and more practical algorithms for semidefinite programming.

Hence the question we address in this paper is:
Can we obtain efficient interior point methods that rely only on gradient information?

### 1.1 Our Results

We present a fast interior point method for solving linear optimization problems over convex sets, when only gradient access to a barrier function for these sets is available. In this paper we rely on a slightly stronger notion of barriers functions than the one used in standard interior point literature, namely strongly self-concordant barriers [LLV20]. We provide a more extensive overview of these in Section 2.4. Strong self-concordance is a property implicitly used in many recent works [CLS19], and is shared by standard barrier functions such as the logarithmic barrier [JKL ${ }^{+}$20], the universal barrier [Nes18, Gü196], or the entropic barrier [BE15]. As shown in [LLV20], for the latter two cases, strong self-concordance is a property that follows from recent developments on the KLS conjecture [Che21, JLV22]. The number of iterations of an interior point method depends on the quality of the barrier function, captured by the self-concordance parameter (see Definition 11). The self-concordance parameter of the universal and entropic barriers for a set in $\mathbb{R}^{n}$ is $\widetilde{O}(n)$.

Our main result is the following theorem.
Theorem 2 (informal). Let $K \subseteq \mathbb{R}$ be a convex set. There is an interior point method that solves linear optimization problems over $K$ in time $\widetilde{O}\left(\sqrt{\nu n}\left(n^{2}+\mathcal{T}_{\text {gradient }}\right)\right)$, where $\mathcal{T}_{\text {gradient }}$ is the time required to evaluate the gradient of a $\nu$-strongly self-concordant barrier function for $K$. Given gradient access to the universal or entropic barriers, the running time is $\widetilde{O}\left(n^{3}+n \mathcal{T}_{\text {gradient }}\right)$.

The gradient complexity of interior point methods. Interestingly, our running time parallels the ones achieved by state-of-the-art cutting plane methods, when replacing the gradient oracle with a separation oracle for $K$. While these two oracles are incomparable, our result contributes to an exciting direction towards understanding the query complexity of optimization problems under different access models $\left[\mathrm{BBE}^{+} 22\right]$. Note that naively, one would expect a gradient query complexity of $\widetilde{O}\left(n^{3 / 2}\right)$, as running $\widetilde{O}(\sqrt{n})$ iterations of an interior point method would naively require $O(n)$ gradient queries per iteration, in order to approximate the Hessian matrix of the barrier function. While recent works [CLS19, LSZ19, vdBLSS20, vdB20, JKL ${ }^{+}$20, HJS ${ }^{+}$22] have exhaustively leveraged the stability of the Hessian matrix across iterations to obtain running time improvements for interior-point methods, it is unclear how to use these in our setting, as their amortized analysis crucially uses the structure of the underlying Hessian matrix.

This raises several interesting questions concerning the adaptive query complexity of barrier optimization. Notably, it would be interesting to know whether the parallel query complexity can be reduced below $\widetilde{O}(n)$, and understand the trade-offs between the number of parallel rounds and the total number of queries. In particular, achieving a parallel round complexity of $o(\sqrt{n})$ is likely to have broad consequences, as it would plausibly lead to more efficient interior-point methods, whenever fast solvers for structured linear systems are available.

| Year | References | Method | \#Iters | Cost per iter |

| 2020 | [JLSW20] | CPM | $n$ | $n^{2}+\mathcal{T}_{\text {cutting plane }}$ |
| 2022 | Our Result | IPM | $n$ | $n^{2}+\mathcal{T}_{\text {gradient }}$ |

Table 1: Comparison of linear optimization algorithms over convex sets $K \subseteq \mathbb{R}^{n}$. CPM stands for cutting plane method, and IPM for interior point method. $\mathcal{T}_{\text {cutting plane }}$ is the time required to compute a cutting plane, while $\mathcal{T}_{\text {gradient }}$ represents the time required to evaluate the gradient of an barrier function for $K$.

Semidefinite programming. Using Theorem 2 we obtain the following result on solving general semidefinite programs, which follows from using a standard logarithmic barrier on the SDP cone.

Theorem 3 (informal). There is an interior point method that solves a general SDP with variable size $n \times n$ and $m$ constraints in time $\widetilde{O}\left(m n^{4}+m^{1.25} n^{3.5}\right)$.

Our running time can be interpreted as follows: $n$ is the number of iterations of the method, $m n^{2}$ is the input size, $m n^{2}+n^{\omega}$ is the time to evaluate on gradient of the barrier function, which requires computing a weighted sum of the input matrices, and computing its inverse using fast matrix multiplication. We note that when $m \geq n$, which holds in the case of most standard SDP applications, the running time is $\widetilde{O}\left(m n^{4}+m^{\overline{1.25}} n^{3.5}\right)$, even when using naive matrix inversion in $O\left(n^{3}\right)$. This may be an advantage for applications where matrix multiplication algorithms with faster than $O\left(n^{3}\right)$ theoretical running require extensive tuning and dedicated hardware [Hua18].

Table 2: Summary of key SDP algorithms. CPM stands for cutting plane method, and IPM for interior point method. $n$ is the size of the variable matrix, and $m$ is the number of constraints. Runtimes hide $n^{o(1)}, m^{o(1)}$ and polylog $(1 / \varepsilon)$ factors, where $\varepsilon$ is the accuracy parameter, as well as factors depending on the bit complexity.

### 1.2 Our Techniques

To achieve our results we build on the ideas of Dunagan and Harvey [DH07] to maintain a dynamic preconditioner for the linear systems that show up when running an interior point method. In the case of strongly self-concordant barriers these systems are strongly related to each other, so we can recycle the preconditioner across multiple iterations of the interior point method.

Linear system solving with an adaptive preconditioner. In Section 3 we review the main ideas from [DH07], as we will build on this framework to develop our gradient-based interior point method. The basic idea is as follows: when one attempts to solve a linear system $\boldsymbol{H} \boldsymbol{x}=\boldsymbol{b}$ using the Richardson iteration, a standard measure of progress is the residual norm $\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}\|_{2}$. After running the Richardson iteration for a single step, the change in the norm of the residual faces two possibilities. In the first case, it decreases by a constant factor, which is the ideal scenario, since this allows a very fast convergence towards the optimum. In the second case, the decrease is small. This, however, can only happen because the underlying matrix has some very large or very small eigenvalues, and our attempted descent direction happens to align well with these. Therefore, this situation constitutes a certificate for the existence of very large or very small eigenvalues. We can quantify this, by showing that we can use these directions to build a preconditioner, which will prevent such occurrences in the future.

The main idea developed by Dunagan and Harvey is that this preconditioner can be maintained by performing rank-1 updates involving the direction that certifies the existence of large/small eigenvalues. While they can not directly show that this permanently reduces the impact of the extreme eigenvalues certified by this direction, they make progress in the sense that a certain potential function called excentricity, which measures the quality of our current preconditioner $\widetilde{\boldsymbol{H}}$, gets reduced. Hence, in each step one either manages to reduce the gradient norm or excentricity by a constant factor. This automatically yields an upper bound on the number of iterations which depends on the quality of the preconditioner when the method is initialized.

We formally recover this argument in Section 3, and obtain a simple algorithm entirely based on preconditioned Richardson. For completeness, we recover the convergence guarantees from [DH07] using our simpler algorithm.

We stress the importance of our contribution, since [DH07] uses a slightly different set of updates, for which theoretical guarantees are difficult to prove in the situation where quantities involving the matrix can only be approximated (as we do in Section 4).

Newton steps on convex functions with a slowly moving Hessian. In Section 4 we extend the analysis from Section 3 to the setting where access to the matrix $\boldsymbol{H}$ is restricted. While the analysis from Section 4 only uses matrix-vector products, in the setting we care about we are even more constrained, as this matrix represents the Hessian of a convex function $g$, which can only be accessed through gradient queries. To handle this difficulty, we approximate matrix-vector products using two gradient queries, since intuitively:

$$
\boldsymbol{H}_{y} \boldsymbol{v} \approx \frac{1}{\tau}(\nabla g(\boldsymbol{y}+\tau \boldsymbol{v})-\nabla g(\boldsymbol{y}))
$$

for some appropriate step size $\tau$. To do so it is important to consider the conditioning of $\boldsymbol{H}_{\boldsymbol{y}}$, as obtaining an accurate estimate requires setting $\tau$ sufficiently large. However, we do not want $\tau$ to be extremely large, as its magnitude determines among others the number of bits of precision required
to evaluate this approximation. We therefore need to provide robust versions of the algorithms from Section 3, and show that they satisfy similar guarantees, even though we only access the function $g$ through gradient queries.

While the proof roughly follows the same lines as before, it is significantly more involved, as even picking the right step size for preconditioned Richardson requires estimating quantities that are not directly available. Furthermore, since we aim to be mindful about the size of the bit representation of our numbers, we always control the range of the preconditioner's eigenvalues. These technical difficulties require us to very carefully analyze the produced excentricity certificates. The main result of the section is given in the Robust Step-or-Update Lemma (Lemma 20), and can be thought of as a Newton step with an adaptive preconditioner $\widetilde{\boldsymbol{H}}$, which either performs a step that reduces the "fake" dual local norm $\|\nabla g(\boldsymbol{y})\|_{\widetilde{\boldsymbol{H}}^{-1}}$, or exhibits an excentricity certificate which we use to reduce the excentricity potential.

Interior point method with an adaptive preconditioner. The main contribution of our paper lies in using adaptive preconditioning inside interior point methods. In Section 5 we describe the main path-following method. To do so, we approximately follow the central path constituted by minimizers for the family of functions

$$
g_{\mu}(\boldsymbol{y})=\frac{\langle\boldsymbol{c}, \boldsymbol{y}\rangle}{\mu}+\phi(\boldsymbol{y}),
$$

where $\phi$ is a $\nu$-strongly self-concordant barrier function for $K \subseteq \mathbb{R}^{n}$ (see Section 2.4). In classical interior point methods, path following consists of generating a sequence of iterates $\boldsymbol{y}$ which are close to the central path, which represents the set of unique minimizers of $g_{\mu}$ for all $\mu \in(0, \infty)$. Closeness to central path is measured in terms of the dual local norm of the gradients $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\mu}^{-1}}$. Classically, one generates these iterates by maintaining the invariant that $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\mu}^{-1}} \leq O(1)$, dialing down $\mu$ by some factor, and restoring closeness to the central path by executing one (or a few) Newton steps, corresponding to a sequence of linear system solves. The amount by which $\mu$ gets dialed down is determined by the self-concordance parameter $\nu$. Typically, one moves from $\mu$ to $\mu^{\prime}=\mu /(1+O(1 / \sqrt{\nu}))$, which determines the total number of iterations of the path-following method to be $\widetilde{O}(\sqrt{\nu})$.

In this work, we slow down the interior point method, by performing significantly shorter steps. Specifically we dial down the centrality parameter only by a factor of $1+O(1 / \sqrt{n \nu})$ and we maintain the invariant that $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{H_{\mu}^{-1}} \leq O(1 / \sqrt{n})$. The reason for doing this is that between two subsequent iterates $\boldsymbol{y}$ and $\boldsymbol{y}^{\prime}$ produced by path following methods, the Hessian matrix changes significantly. Unfortunately, too large a change, which is likely to occur when using standard step sizes, makes the preconditioner significantly worse, so the excentricity between the preconditioner $\widetilde{\boldsymbol{H}}$ and the two Hessians $\boldsymbol{H}_{y}$, and $\boldsymbol{H}_{y^{\prime}}$, respectively, can increase by a lot. Using very short steps guarantees that this is not the case, and allows us to match the increases in excentricity that occur when changing the iterate with the decreases in excentricity caused by rank- 1 updates of the preconditioner.

An important feature of the excentricity potential is that while changes caused by rank-1 updates of the preconditioner are easy to control, the changes caused by modifying the preconditioned matrix are generally not. In particular using the notation defined in Section 2 we aim to compare $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right)$ against $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}^{\prime}}\right)$.

We are able to prove upper bounds on the increase in excentricity by leveraging properties of strongly self-concordant barriers. To do so we show, using majorization techniques and Schur convexity, that the change in excentricity depends on the eigenvalues of $\boldsymbol{H}_{y}^{-1} \boldsymbol{H}_{y^{\prime}}$. These can be tightly controlled using strong self-concordance. We prove this in Section 5.2.

We conclude that with each step along the central path excentricity increases by at most a constant factor, while each rank-1 update caused by an excentricity certificate found by our preconditioned Richardson iteration causes decrease in excentricity by at least a constant factor. Therefore, when properly initialized, our interior point method only requires $\widetilde{O}\left(\sqrt{n \nu} \log \frac{1}{\varepsilon}\right)$ rank-1 updates to the preconditioner $\widetilde{\boldsymbol{H}}$. Since all the rank-1 updates on $\widetilde{\boldsymbol{H}}$ and $\widetilde{\boldsymbol{H}}^{-1}$, which we explicitly maintain using the Sherman-Morrison formula, take $O\left(n^{2}\right)$ time, we bound the total running time by

$$
\widetilde{O}\left(\left(n^{2}+\mathcal{T}_{\text {gradient }}\right) \sqrt{n \nu} \log \frac{1}{\varepsilon}\right)
$$

where $\mathcal{T}_{\text {gradient }}$ is the time required to perform a query on the gradient oracle which on input $\boldsymbol{y}$ returns $\nabla \phi(\boldsymbol{y})$.

The formal statement of the theorem is given in Theorem 25.
As a corollary we see that when given access to a gradient oracle for an $\widetilde{O}(n)$-strongly self-concordant barrier for the domain $K$, we can perform linear optimization in time $\widetilde{O}\left(n^{3}+n \mathcal{T}_{\text {gradient }} \log \frac{1}{\varepsilon}\right)$ time. We give the formal statement in Corollary 26.

SDP via interior point methods. For our SDP application, instead of directly solving the objective (1), just like in [JKL+ ${ }^{+}$20], we consider the dual problem

$$
\begin{equation*}
\min \left\{\langle\boldsymbol{c}, \boldsymbol{y}\rangle: \boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i} \succeq 0\right\}, \tag{2}
\end{equation*}
$$

which we optimize by solving the barrier formulation

$$
\begin{equation*}
g_{\mu}(\boldsymbol{y})=\frac{\langle\boldsymbol{c}, \boldsymbol{y}\rangle}{\mu}+\phi(\boldsymbol{y}), \tag{3}
\end{equation*}
$$

where $\phi$ is a strongly self-concordant barrier function for the set $\left\{\boldsymbol{y}: \boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i} \succeq 0\right\}$. Unfortunately, the standard $\log$ det barrier does not satisfy the required strong self-concordance property required by our potential function analysis. We fix this by scaling it by a factor of $\sqrt{m}$, which in exchange further slows down the interior point method. Specifically, in our case we use

$$
\phi(\boldsymbol{y})=-\sqrt{m} \cdot \log \operatorname{det}\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)
$$

for which we can show that it satisfies the required strong self-concordance property with $\nu=n \sqrt{m}$. To evaluate gradients of the barrier it suffices to compute

$$
[\nabla \phi(\boldsymbol{y})]_{i}=\left\langle\boldsymbol{A}_{i},\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)^{-1}\right\rangle
$$

which can be done in time $O\left(m n^{2}+n^{\omega}\right)$. Compared to previous works on fast SDP solving our crucial advantage is that we never need to compute the Hessian of $\phi$, which involves very costly
matrix multiplication, and hence additional running time dependence in $m$. In fact [NN92] use a series of clever tricks to compute the Hessian matrix in time $O\left(m n^{\omega}+m^{2} n^{2}+m^{\omega}\right)$, while [JKL ${ }^{+} 20$ ] develop a series of techniques based on rectangular matrix multiplication to reduce this running time to the time required to multiply an $m \times n^{2}$ matrix by an $n^{2} \times m$ matrix. Fortunately, we can completely avoid these bottlenecks by using our dynamic preconditioner.

Together with our analysis on gradient-based interior point methods we obtain our final running time of $\widetilde{O}\left(m n^{4}+m^{1.25} n^{3.5}\right)$. We provide a formal statement in Theorem 32.

### 1.3 Related Work

The literature on optimization methods is truly extensive. Here we summarize a few relevant results in literature.

Cutting plane methods. A class of optimization techniques known as cutting plane methods repeatedly refine a convex set that contains the sought solution, via queries to a separation oracle. Designing efficient cutting plane algorithms has been a long-running effort since its introduction in the 1950s [Sho77, YN76, Kha80, KTE88, NN89, Vai89, AV95, BV04, LSW15, JLSW20].

Interior point methods. Interior point methods are fundamental optimization techniques for minimizing linear functions over convex sets, provided first and second order access to a barrier function for the set. Extensive early work [Fri55, KMY89, Meg89, FM90] has been beautifully explained by Nesterov and Nemirovski [NN94], who developed the theory of self-concordant barriers, and expanded the area of IPM applications to more general settings, including semidefinite programming and more broadly conic optimization. Recent developments have used IPM theory to provide important progress towards reducing the theoretical running time of linear and semidefinite programming [LS14, CLS19, LSZ19, vdBLSS20, vdB20, JKL+ 20 , HJS ${ }^{+}$22].

Quasi-Newton methods. An important series of developments has focused on quasi-Newton methods, which attempt to obtain convergence guarantees comparable to those of Newton's method using only gradient access. A famous set of results is given by the BFGS and L-BFGS methods [Bro70, Fle70, Gol70, Sha70, BNS94], which are used in practical settings. Also see [GS19, GS22, Tun01] for applications of quasi-Newton methods to interior point solvers. We note that [GS19, GS22] use quasi-Newton steps interspersed with standard Newton steps. Although their results do not rely solely on gradient information, they provide important practical speedups since they reduce the total number of linear system solves. In [Tun01], both zeroth and first order methods for linear programming are provided, but they are only shown to converge in finite time, without an explicit bound on the iteration complexity.

SDP solvers. Early SDP solvers have relied on cutting plane methods. Starting with the works of Nesterov-Nemirovski [NN92] and Anstreicher [Ans00], several SDP solvers based on IPMs have been developed. Recently, new techniques based on inverse matrix maintenance have provided fast algorithms for SDPs [JKL ${ }^{+}$20, $\mathrm{HJS}^{+}$22].

## 2 Preliminaries

### 2.1 Notation

We write matrices and vectors in bold. We use $\langle\cdot, \cdot\rangle$ to denote inner products. Given a symmetric matrix $\boldsymbol{A}$, we use $\|\boldsymbol{A}\|$ to represent the spectral norm of $\boldsymbol{A}$, that is $\|\boldsymbol{A}\|=$ $\max \left\{-\lambda_{\min }(\boldsymbol{A}), \lambda_{\max }(\boldsymbol{A})\right\}$, where $\lambda_{\text {min }}(\boldsymbol{A})$ and $\lambda_{\max }(\boldsymbol{A})$ denote the smallest and largest eigenvalues of $\boldsymbol{A}$, respectively. We use $\|\boldsymbol{A}\|_{F}$ to represent its Frobenius norm, that is the $\ell_{2}$ norm of its eigenvalues. Similarly we use $\|\boldsymbol{A}\|_{1}$ to denote the $\ell_{1}$ norm of its eigenvalues. For an arbitrary symmetric matrix $\boldsymbol{A}$, we use $\boldsymbol{A}_{\geq 1}$ to denote the matrix obtained from $\boldsymbol{A}$ by increasing all of its sub-unitary eigenvalues to 1 , and we define $\boldsymbol{A}_{<1}$ analogously.

Given a function $g: K \rightarrow \mathbb{R}$, where $K \subseteq \mathbb{R}^{n}$ is a convex set, we use $\nabla g(\boldsymbol{y})$ to represent the gradient of $g$ and $\nabla^{2} g(\boldsymbol{y})$ for the Hessian matrix at $\boldsymbol{y}$. To simplify notation, we use $\boldsymbol{H}_{y}:=\nabla^{2} g(\boldsymbol{y})$, whenever the meaning is clear from the context. When solving linear systems, we maintain a preconditioner which typically denote by $\widetilde{\boldsymbol{H}}$.

### 2.2 The Excentricity Potential

One of our main tools for analyzing the method is the excentricity potential function, which has been introduced by Dunagan and Harvey [DH07] in the context of analyzing a certain version of the conjugate gradient method, without resorting to arguments based on the best interpolating polynomial. In broad terms, excentricity measures how good of a preconditioner a matrix $\widetilde{\boldsymbol{H}}$ is for some other matrix $\boldsymbol{H}$. In standard analyses, one crucially aims to bound the spectral norm

$$
\|X-I\|
$$

where

$$
\boldsymbol{X}=\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2} .
$$

Naturally, the closer this is to 0 , the better of a preconditioner $\widetilde{\boldsymbol{H}}$ is for $\boldsymbol{H}$. As this function is not necessarily the easiest one to work with, Dunagan and Harvey introduced the excentricity potential defined as

$$
\mathcal{E}(\boldsymbol{X})=\operatorname{det}\left(\frac{\boldsymbol{X}^{1 / 2}+\boldsymbol{X}^{-1 / 2}}{2}\right)=\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{X}+\boldsymbol{I})}{\sqrt{\operatorname{det}(\boldsymbol{X})}}
$$

for which one can easily verify that it is minimized when $\boldsymbol{X}=\boldsymbol{I}$, in which case $\widetilde{\boldsymbol{H}}$ is a perfect preconditioner. This potential function enjoys several favorable properties, including the fact that its value is easy to track after performing rank-1 updates on either $\widetilde{\boldsymbol{H}}$ or $\boldsymbol{H}$. In the following lemma we see how how excentricity evolves after a rank-1 update (proof in Appendix A.1).

Lemma 4. A rank-1 update

$$
\boldsymbol{X}^{\prime}=\boldsymbol{X}+\boldsymbol{u} u^{\top}
$$

determines the multiplicative change in excentricity:

$$
\frac{\mathcal{E}\left(\boldsymbol{X}^{\prime}\right)}{\mathcal{E}(\boldsymbol{X})}=\frac{1+\boldsymbol{u}^{\top}(\boldsymbol{I}+\boldsymbol{X})^{-1} u}{\sqrt{1+\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} u}} .
$$

We also show that if we have access to a vector $\boldsymbol{u}$ that aligns well with very small/large eigenvectors of $\boldsymbol{X}$, then we can use it to obtain a rank-1 update that significantly reduces excentricity.

Lemma 5. If a unit vector $\boldsymbol{u}$ satisfies

1. $\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u} \geq \gamma$, then $\frac{\mathcal{E}\left(\boldsymbol{X}+\boldsymbol{u} \boldsymbol{u}^{\top}\right)}{\mathcal{E}(\boldsymbol{X})} \leq \frac{2}{\sqrt{1+\gamma}}$,
2. $\boldsymbol{u}^{\top} \boldsymbol{X} u \geq \gamma$, then $\frac{\mathcal{E}\left(X-\frac{X^{4} u^{\top} X}{1+u^{\top} \boldsymbol{X u}}\right)}{\mathcal{E}(\boldsymbol{X})} \leq \frac{2}{\sqrt{1+\gamma}}$.

We show this in Appendix A.2. Crucially, both the proofs and our algorithm relies on the Sherman-Morrison formula for the inverse of a matrix after performing a rank-1 update.
Lemma 6 (Sherman-Morrison). Suppose $\boldsymbol{A} \in \mathbb{R}^{n \times n}$ is an invertible matrix, and $\boldsymbol{u}, \boldsymbol{v} \in \mathbb{R}^{n}$ are column vectors. Then $\boldsymbol{A}+\boldsymbol{u} \boldsymbol{v}^{\top}$ is invertible iff $1+\boldsymbol{v}^{\top} \boldsymbol{A}^{-1} \boldsymbol{u} \neq 0$. In this case,

$$
\left(\boldsymbol{A}+\boldsymbol{u} \boldsymbol{v}^{\top}\right)^{-1}=\boldsymbol{A}^{-1}-\frac{\boldsymbol{A}^{-1} \boldsymbol{u} \boldsymbol{v}^{\top} \boldsymbol{A}^{-1}}{1+\boldsymbol{v}^{\top} \boldsymbol{A}^{-1} \boldsymbol{u}}
$$

To simplify our proofs, we also state a useful property of excentricity.
Lemma 7. Excentricity is invariant under similarity transformations. Given invertible $\boldsymbol{X}, \boldsymbol{Y}$, we have

$$
\mathcal{E}(\boldsymbol{X})=\mathcal{E}\left(\boldsymbol{Y} \boldsymbol{X} \boldsymbol{Y}^{-1}\right) .
$$

Additionally

$$
\mathcal{E}\left(\boldsymbol{X}^{-1}\right)=\mathcal{E}(\boldsymbol{X}) .
$$

Finally, we strongly rely on the following Lemma, which relies on an eigenvalue bound that we prove in Section 5 via majorization techniques. It allows us to control the change in excentricity when the involved matrix changes slightly.
Lemma 8. Let $\boldsymbol{A}, \boldsymbol{B}$ be invertible matrices. Then

$$
\mathcal{E}(\boldsymbol{A B}) \leq \mathcal{E}(\boldsymbol{A}) \cdot \sqrt{\frac{\operatorname{det}\left(\boldsymbol{B}_{\geq 1}\right)}{\operatorname{det}\left(\boldsymbol{B}_{<1}\right)}}
$$

Proof. Using Lemma 27, we write:

$$
\mathcal{E}(\boldsymbol{A B})=\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{A B}+\boldsymbol{I})}{\sqrt{\operatorname{det}(\boldsymbol{A B} \boldsymbol{B}}} \leq \frac{1}{2^{n}} \cdot \frac{\operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \cdot \operatorname{det}\left(\boldsymbol{B}_{\geq 1}\right)}{\sqrt{\operatorname{det}(\boldsymbol{A})} \cdot \sqrt{\operatorname{det}(\boldsymbol{B})}}=\mathcal{E}(\boldsymbol{A}) \cdot \sqrt{\frac{\operatorname{det}\left(\boldsymbol{B}_{\geq 1}\right)}{\operatorname{det}\left(\boldsymbol{B}_{<1}\right)}} .
$$

### 2.3 Richardson Iteration

The Richardson iteration is probably the most important iterative method for solving linear systems of equations. Generally, given a linear system $\boldsymbol{H} \boldsymbol{x}=\boldsymbol{b}$, the iteration consists of steps that attempt to improve the current iterate by performing iterations of the form $\boldsymbol{x}^{\prime}=\boldsymbol{x}+\eta(\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x})$, for some appropriate step size $\eta$. Denoting the residual by $\boldsymbol{r}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}$, this iteration updates the solution by moving into it a small fraction of the residual. To improve the convergence rate of this iterative method, one often uses preconditioning. Namely, by using a matrix $\widetilde{\boldsymbol{H}}$ which approximates $\boldsymbol{H}$ for some appropriate notion of approximation, and whose inverse is available, we can instead run the iteration $\boldsymbol{x}^{\prime}=\boldsymbol{x}+\eta \widetilde{\boldsymbol{H}}^{-1}(\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x})$. This is equivalent to running the vanilla Richardson iteration on the original system, after doing a change of basis by letting $\boldsymbol{y}=\widetilde{\boldsymbol{H}}^{1 / 2} \boldsymbol{x}$ and considering the equivalent system

$$
\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2} \cdot \boldsymbol{y}=\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{b}
$$

### 2.4 Strongly Self-Concordant Barriers and Interior Point Methods

We solve general optimization problems of the form

$$
\begin{equation*}
\min _{y \in K}\langle\boldsymbol{c}, \boldsymbol{y}\rangle \tag{4}
\end{equation*}
$$

where $K$ is a convex domain. To do so we resort to a path-following interior-point method which solves a sequence of barrier objectives, which are convex minimization problems of the form

$$
g_{\mu}(\boldsymbol{y})=\frac{\langle\boldsymbol{c}, \boldsymbol{y}\rangle}{\mu}+\phi(\boldsymbol{y}),
$$

where $\phi$ is a barrier function for the domain $K$. Each function $g_{\mu}$ has a unique minimizer. The set of minimizers $\boldsymbol{y}^{\star}{ }_{\mu}=\arg \min g_{\mu}(\boldsymbol{y})$, for all $\mu \in(0, \infty)$ represent the central path corresponding to the barrier objective. To solve (4), classical interior point literature (Lemma 21) shows that it suffices to obtain a near minimizer to $g_{\mu}$ for a sufficiently small value of the centrality parameter $\mu$.

To do so we implement a path-following procedure. In each iteration of the procedure, for a sufficiently small scalar $\delta$, we solve the minimization problem form $g_{\mu /(1+\delta)}$ by warm starting it with a (near) optimizer of $g_{\mu}$. The choice of $\delta$ depends on the properties of the barrier function, and hence determine the speed of convergence of the method. The properties of the barrier function are crucial to obtaining an efficient algorithm. While the standard theory of interior point methods uses properties of self-concordant barrier functions [NN94], in this work we use a slightly stronger property, namely the strong self-concordance property [LLV20].

This gives a slightly more powerful condition on the change in the Hessian when moving between iterates than vanilla self-concordance. While not explicitly mentioned in the classical literature, it is, however, enjoyed by many standard barrier functions including the logarithmic, universal, and entropic barriers.

Definition 9 (strongly self-concordant function). Given a convex domain $K$ and $g: K \rightarrow \mathbb{R}$, we say that a convex function $g$ is strongly self-concordant if for any $\boldsymbol{y} \in K$, and $\boldsymbol{h}$ :

$$
\left\|\boldsymbol{H}_{y}^{-1 / 2} \frac{d}{d t} \boldsymbol{H}_{y+t \boldsymbol{h}} \boldsymbol{H}_{y}^{-1 / 2}\right\|_{F} \leq 2\|\boldsymbol{h}\|_{\boldsymbol{H}_{y}} .
$$

We recall that standard self-concordance replaces the bound involving the Frobenius norm with the weaker spectral norm.

Lemma 10. Given any strongly self-concordant function $g: K \rightarrow \mathbb{R}$, for any $\boldsymbol{x}, \boldsymbol{\delta}$, such that $\boldsymbol{x}, \boldsymbol{x}+\boldsymbol{\delta} \in K,\|\boldsymbol{\delta}\|_{H_{y}}<1$,

$$
\left\|\boldsymbol{H}_{y}^{-1 / 2}\left(\boldsymbol{H}_{y+\boldsymbol{\delta}}-\boldsymbol{H}_{y}\right) \boldsymbol{H}_{y}^{-1 / 2}\right\|_{F} \leq \frac{\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}{\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}}
$$

Furthermore, if $g$ is only self-concordant, then

$$
\boldsymbol{H}_{\boldsymbol{y}} \cdot\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2} \preceq \boldsymbol{H}_{\boldsymbol{y}+\boldsymbol{\delta}} \preceq \boldsymbol{H}_{y} \cdot \frac{1}{\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}} .
$$

In addition to these properties, we also use the notion of $\nu$-strongly self-concordant barriers, which is the analog of self-concordant barriers which also satisfy strong self-concordance.

Definition 11 ( $\nu$-strongly self-concordant barrier). Given a convex domain $K$ and a strongly selfconcordant function $g: K \rightarrow \mathbb{R}$, we say that $g$ is a $\nu$-strongly self-concordant barrier if $g(\boldsymbol{y}) \rightarrow \infty$ as $\boldsymbol{y} \rightarrow \partial K$ and

$$
\|\nabla g(\boldsymbol{y})\|_{\boldsymbol{H}_{\bar{y}}^{-1}}^{2} \leq \nu
$$

for all $\boldsymbol{y} \in K$.
The stronger property helps to obtain tighter bounds on the increase in excentricity when only slightly changing the Hessian matrix. We rely on the following important lemma, which we prove in Section 5:

Lemma 12. Let $K \subseteq \mathbb{R}^{n}$ be a convex set. Given any strongly self-concordant function $g: K \rightarrow \mathbb{R}$, for any $\boldsymbol{y}, \boldsymbol{\delta}$, such that $\boldsymbol{y}, \boldsymbol{y}+\boldsymbol{\delta} \in K,\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{\boldsymbol{y}}}<\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}<1$, and any preconditioner $\widetilde{\boldsymbol{H}}$,

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}+\boldsymbol{\delta}}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}}\right) \cdot \exp \left(\frac{1}{2} \sqrt{n} \cdot \frac{\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}{\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}\right) .
$$

In addition, we require some guarantees involving the well-conditionedness of the points on the neighborhood of the central path. This is captured by the following definition.

Definition 13 ( $\kappa(\mu)$-conditioned objective). A a barrier objective (5) is $\kappa(\mu)$-conditioned if letting $\boldsymbol{y}_{\mu^{\prime}}$ be the minimizer of $g_{\mu^{\prime}}$, one has that

$$
\max \left\{\left\|\boldsymbol{H}_{y_{\mu^{\prime}}}\right\|,\left\|\boldsymbol{H}_{y_{\mu^{\prime}}}^{-1}\right\|\right\} \leq \kappa(\mu)
$$

for all $\mu^{\prime} \geq \mu$.
This captures how large or small the eigenvalues of the Hessian corresponding to points on the central path can be, for all centrality parameters above a given threshold $\mu$. While only implicitly used in standard literature, this quantity is relevant in most instantiations of interior point methods, as even in the case where one uses fast matrix multiplication for solving the linear systems involved, the condition number of the barrier objective $\kappa(\mu)$ determines the number of bits of precision required to store the Hessian matrices and their inverses. A standard feature of this upper bound is that it also holds for points in the neighborhood of the central path, which we show in Appendix A. 4 .

Lemma 14. Let $g_{\mu}: K \rightarrow \mathbb{R}$ be a barrier objective with a self-concordant barrier function as in (5), and let $\boldsymbol{y} \in \operatorname{int}(K)$, such that $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}} \leq 1 / 3$. Then

$$
\max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|\right\} \leq 4 \kappa(\mu) .
$$

These facts determine the notion of $\varepsilon$-condition number of a barrier formulation, which we formally define and discuss in Definition 22, which we will use to provide our convergence guarantees.

## 3 Solving Linear Systems with an Adaptive Preconditioner

We first consider the case of solving linear systems of the form $\boldsymbol{H} \boldsymbol{x}=\boldsymbol{b}$, and provide an algorithm based on the techniques used by [DH07]. We stress the importance of our contribution, since [DH07] uses a slightly different set of updates, for which theoretical guarantees are difficult to prove in the situation where quantities involving the matrix can only be approximated, as we do in the following Section 4.

While the analysis in this section assumes access to $\boldsymbol{H}$, which will not be true in the subsequent sections, we note that we only access it through matrix vector products. This will be important, as estimating Hessian vector products can be done by making a constant number of gradient queries.

In this section we show that failure to make a lot of progress within a single step of the Richardson iteration produces a certificate which allows us to improve our current preconditioner. This analysis roughly follows the same ideas as in Dunagan-Harvey, but is slightly simplified from a technical point of view, as it does not attempt to match the conjugate gradient algorithm. Instead, it merely performs the Richardson iteration with a step size chosen such that it minimizes the norm of the residual. We provide the essential lemmas, then we show how they can be used to recover the main result in [DH07]. In the following section we will extend these to the case where the Hessian is non-constant, for which we will leverage additional techniques from matrix analysis.

### 3.1 Minimizing Residual Norm via the Richardson Iteration

We give the lemma which provides the certificate of excentricity in case a single step of (nonpreconditioned) Richardson update fails to reduce gradient norm significantly. In Appendix B. 1 we proceed by providing an analysis for the non-preconditioned case (see Lemma 34). As a corollary, we obtain a general version of the Lemma corresponding to making a preconditioned step.
Lemma 15. Let $\boldsymbol{H}, \widetilde{\boldsymbol{H}} \in \mathbb{R}^{n \times n}$, and vectors $\boldsymbol{b}, \boldsymbol{x} \in \mathbb{R}^{n}$. Let $\boldsymbol{r}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}$, and consider the step

$$
\boldsymbol{x}^{\prime}=\boldsymbol{x}+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{\boldsymbol{H}}^{2}}{\left\|\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} .
$$

Let $\beta \in(0,1)$ be a scalar. Provided that the new residual $\boldsymbol{r}^{\prime}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}^{\prime}$ satisfies

$$
\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \geq(1-\beta)\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2},
$$

we obtain at least one of the following excentricity certificates:

1. $\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H^{-1 / 2} \tilde{H}^{-1 / 2}}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\beta}}$,
2. $\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H^{1 / 2} \tilde{H}^{-1} \boldsymbol{H}^{1 / 2}}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\mathcal{P}}}$.

The proof can be found in Appendix B.2. Finally, based on the certificates provided in Lemma 15 we can design a routine which updates our fake Hessian $\widetilde{\boldsymbol{H}}^{-1}$. Its effect on excentricity is given in the following lemma, which we prove in Appendix B.3.

Lemma 16. Let $\boldsymbol{H}, \widetilde{\boldsymbol{H}} \in \mathbb{R}^{n \times n}$, and suppose that the inverse $\widetilde{\boldsymbol{H}}^{-1}$ is available. Given an excentricity certificate of type 1 or 2 as provided by Lemma 15, there is an algorithm (Algorithm 1) which performs a rank-1 update on $\widetilde{\boldsymbol{H}}$ and on its inverse to obtain a new preconditioner $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime-1} \boldsymbol{H}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}\right) \cdot \frac{2}{\sqrt{1+\frac{1}{\sqrt{\beta}}}} .
$$

This update can be implemented in $O\left(n^{2}\right)$ time. Furthermore, either

1. $1 \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{\varepsilon}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right)}\right)^{2}$, or
2. $1 \leq\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \widetilde{\boldsymbol{H}}^{\prime-1} \widetilde{\boldsymbol{H}}^{1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right)}\right)^{2}$.
```

Ensure: Updates the preconditioner \(\widetilde{H}\) and its inverse in \(O\left(n^{2}\right)\) time, plus a constant number of
    gradient queries.
    procedure UpdatePreconditioner \(\left(\widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}^{-1}, \boldsymbol{r}\right.\), type)
        if type \(=1\) then
            \(\widetilde{\boldsymbol{H}}=\widetilde{\boldsymbol{H}}-\frac{r r^{\top}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}+\|r\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}, \widetilde{\boldsymbol{H}}^{\prime^{-1}}=\widetilde{\boldsymbol{H}}^{-1}+\frac{\widetilde{\boldsymbol{H}}^{-1} r r^{\top} \widetilde{\boldsymbol{H}}^{-1}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}}\)
        else
                                    \(\triangleright\) type \(=2\)
            \(\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}+\frac{H \widetilde{\boldsymbol{H}}^{-1} r r^{\top} \widetilde{\boldsymbol{H}}^{-1} H}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}}, \widetilde{\boldsymbol{H}}^{\prime-1}=\widetilde{\boldsymbol{H}}^{-1}-\frac{\widetilde{\boldsymbol{H}}^{-1} H \widetilde{\boldsymbol{H}}^{-1} r r^{\top} \widetilde{\boldsymbol{H}}^{-1} H \widetilde{\boldsymbol{H}}^{-1}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}+\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}\)
        end if
        return \(\left(\widetilde{\boldsymbol{H}}^{\prime}, \widetilde{\boldsymbol{H}}^{\prime-1}\right)\)
    end procedure
```

### 3.2 Taking Stock

Combining Lemma 15 and Lemma 16 (Algorithm 1) we obtain a procedure (Algorithm 2) which either performs a step that reduces the residual $\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}$ by a constant multiplicative factor, or updates $\widetilde{\boldsymbol{H}}$ and $\widetilde{\boldsymbol{H}}^{-1}$ in $O\left(n^{2}\right)$ time, such that excentricity reduces by a constant factor. This will be the main driver of the path following method described in the next section.

While this procedure suffices for our interior point method, we first provide as a warm-up an analysis for the regime where we indent to solve a single linear system, thus recovering the main result from [DH07]. Its full proof can be found in Appendix B.4.
Lemma 17. Consider the linear system $\boldsymbol{H} \boldsymbol{x}=\boldsymbol{b}$, where $\boldsymbol{H}$ is a symmetric positive definite matrix, let $\boldsymbol{x}_{0}$ be an initial solution, and let $\widetilde{\boldsymbol{H}}_{0}=\boldsymbol{I}$ be an initial preconditioner. Running the iteration

$$
\left(\widetilde{\boldsymbol{H}}_{t+1}, \widetilde{\boldsymbol{H}}_{t+1}^{-1}, \boldsymbol{x}_{t+1}\right)=\operatorname{StEpORUpdate}\left(\boldsymbol{H}, \widetilde{\boldsymbol{H}}_{t}, \widetilde{\boldsymbol{H}}_{t}^{-1}, \boldsymbol{b}, \boldsymbol{x}_{t}\right)
$$

for $T=100\left(\log \mathcal{E}(\boldsymbol{H})+\log \frac{1}{\varepsilon}\right)$ steps, we obtain a vector $\boldsymbol{x}_{T}$ such that

$$
\left\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}_{T}\right\| \leq \varepsilon \cdot\left\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}_{0}\right\| .
$$

Algorithm 2 Pseudocode for the step problem.
Ensure: Returns a new iterate $\boldsymbol{x}^{\prime}$ such that $\left\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq(1-\beta)\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}\|_{\widetilde{\boldsymbol{H}}^{-1}}$, or returns a new preconditioner $\widetilde{\boldsymbol{H}}^{\prime}$ together with its inverse such that $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{1}{\sqrt{\mathcal{B}}}}}$, and either $1 \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right)}\right)^{2}$, or $1 \leq\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \widetilde{\boldsymbol{H}}^{\prime-1} \widetilde{\boldsymbol{H}}^{1 / 2}\right\| \leq$ $\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}^{\prime}} \boldsymbol{H}^{-1}\right)}\right)^{2}$.

$$

$$
\text { if }\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \leq(1-\beta)\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \text { then }
$$

return $\left(\widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}^{-1}, \boldsymbol{x}^{\prime}\right) \quad \triangleright$ return new iterate else
if $\frac{\|r\|_{\tilde{H}^{-1}}^{2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}} \geq \frac{1}{\sqrt{\beta}}$ then $\quad \triangleright$ test for type 1 excentricity certificate $\left(\widetilde{\boldsymbol{H}}^{\prime}, \widetilde{\boldsymbol{H}}^{\prime-1}\right)=\operatorname{UPDATEPRECONDITIONER}\left(\widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}^{-1}, \boldsymbol{r}\right.$, type $\left.=1\right)$
else $\quad \triangleright$ if test fails, then we must have a type 2 excentricity certificate $\left(\widetilde{\boldsymbol{H}^{\prime}}, \widetilde{\boldsymbol{H}}^{\prime}{ }^{-1}\right)=\operatorname{UPDATEPRECONDITIONER}\left(\widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}^{-1}, \boldsymbol{r}\right.$, type $\left.=2\right)$ end if return $\left(\widetilde{\boldsymbol{H}}^{\prime}, \widetilde{\boldsymbol{H}}^{\prime^{-1}}, \boldsymbol{x}\right) \quad \triangleright$ return new preconditioner end if
end procedure

## 4 Estimating Hessian-Vector Products

While the analysis in Section 3 provides a tight bounds on the evolution of the preconditioner's quality, the algorithms described there rely almost entirely on having access to the matrix $\boldsymbol{H}$. In our setting our matrix is a Hessian matrix for a convex function, which we can not directly access. Instead, we note that our entire interaction with $\boldsymbol{H}$ occurs in the form of matrix-vector products. Hence we should expect that rather than having to compute products of the form $\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{v}$ we could instead approximate them

$$
\boldsymbol{H}_{y} \boldsymbol{v} \approx \frac{1}{\tau}(\nabla g(\boldsymbol{y}+\tau \boldsymbol{v})-\nabla g(\boldsymbol{y})),
$$

for some appropriate step size $\tau$. To do so it is important to consider the conditioning of $\boldsymbol{H}_{\boldsymbol{y}}$, as obtaining an accurate estimate requires setting $\tau$ sufficiently large. However, we do not want $\tau$ to be extremely large, as its magnitude determines among others the number of bits of precision required to evaluate this approximation.

In this section we provide robust versions of the algorithms from Section 3, and show that they satisfy similar guarantees, even though we only access the function $g$ through gradient queries. In Appendix C. 2 we provide formal statements concerning the quality of the approximations $p_{y}(\boldsymbol{v}) \approx$ $\boldsymbol{H}_{y}(\boldsymbol{v})$ and $n_{y}(v) \approx\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}}$ that we employ.

At this point we are ready to present the appropriate modifications to the algorithms from Section 3.

Lemma 18. Let $g: K \rightarrow \mathbb{R}$ be a self-concordant function, let $\boldsymbol{y} \in \operatorname{int}(K)$, let $\boldsymbol{H}_{y}=\nabla^{2} g(\boldsymbol{y})$, let $\widetilde{\boldsymbol{H}} \in \mathbb{R}^{n \times n}$, and let vectors $\boldsymbol{b}, \boldsymbol{x} \in \mathbb{R}^{n}$. Furthermore, suppose that $\max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|,\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|,\|\boldsymbol{b}\|_{2}\right\} \leq B$, for some scalar $B \geq 1000$. Let $\boldsymbol{r}=\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})$, and consider the step

$$
\boldsymbol{x}^{\prime}=\boldsymbol{x}+\frac{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}}{\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)
$$

Let $\beta \in\left(\frac{1}{B}, 1\right)$ be a scalar. Let the new residual $\boldsymbol{r}^{\prime}=\boldsymbol{b}-p_{y}\left(\boldsymbol{x}^{\prime}\right)$. Provided that $\min \left\{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}},\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\right\} \geq \frac{1}{B}$, and

$$
\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \geq(1-\beta)\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}
$$

we obtain at least one of the following excentricity certificates:

$$
\begin{aligned}
& \text { 1. } \frac{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}^{1 / 2}}}{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\frac{20}{9} \beta}} \text {, } \\
& \text { 2. } \frac{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}^{1 / 2}}^{2}}{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\frac{20}{9} \beta}} .
\end{aligned}
$$

The proof is laborious but not particularly insightful, so we defer it to Appendix C.3. The approach is based on providing multiplicative error bounds between all the quantities involving

```

$\boldsymbol{H}_{y}$ and their approximations using $p_{y}$ or $n_{y}$. We obtain these by showing that approximations introduce small additive errors, and use the upper bounds on matrix norms to show that these are much smaller than the other quantities involved. To do so we also need to assume that the residuals $\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}},\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}$ are sufficiently large. This, however, is automatically true by the hypothesis. Using this assumption will not hurt us, since we always stop the iterative method once the norm becomes small enough.

Finally, we need to show that the rank-1 updates performed in Algorithm 3, which involve the approximations $p_{y}$ and $n_{y}$ still provide a sufficient decrease in excentricity. To do so we require a robust version of Lemma 16 .

Lemma 19. Let $g: K \rightarrow \mathbb{R}$ be a self-concordant function, let $\boldsymbol{y} \in \operatorname{int}(K)$, let $\boldsymbol{H}_{y}=\nabla^{2} g(\boldsymbol{y})$, let $\widetilde{\boldsymbol{H}} \in \mathbb{R}^{n \times n}$, and suppose that the inverse $\widetilde{\boldsymbol{H}}^{-1}$ is available. Furthermore, suppose that $\max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|,\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} \leq B$, for some scalars $B \geq 1000$. Given an excentricity certificate of type 1 or 2 as provided by Lemma 18, there is an algorithm (Algorithm 3) which performs a rank-1 update on $\widetilde{\boldsymbol{H}}$ and on its inverse to obtain a new preconditioner $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime-1} \boldsymbol{H}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}\right) \cdot \frac{2}{\sqrt{1+\frac{99}{100} \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}}}
$$

This update can be implemented in $O\left(n^{2}\right)$ time, plus the time required to make a constant number of gradient queries for $g$. In addition, $\max \left\{\left\|\widetilde{\boldsymbol{H}}^{\prime}\right\|-\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{\prime-1}\right\|-\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} \leq$ $2 \max \left\{\left\|\boldsymbol{H}_{\boldsymbol{y}}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|\right\}^{2}$.

The proof is based on the one we gave for Lemma 16, and is presented in Appendix C.4. Finally, combining Lemmas 18 and 19 we obtain the main result of this section.

Lemma 20 (Robust Step-or-Update). Let $g: K \rightarrow \mathbb{R}$ be a self-concordant function, let $\boldsymbol{y} \in$ $\operatorname{int}(K)$, let $\boldsymbol{H}_{y}=\nabla^{2} g(\boldsymbol{y})$, let $\widetilde{\boldsymbol{H}} \in \mathbb{R}^{n \times n}$, and let vectors $\boldsymbol{b}, \boldsymbol{x} \in \mathbb{R}^{n}$. Furthermore, suppose that $\max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|,\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|,\|\boldsymbol{b}\|_{2}\right\} \leq B$, for some scalar $B \geq 1000$. Let $\beta \in\left(\frac{1}{B}, 1\right)$ be a scalar. There is an algorithm (Algorithm 4) which has exactly one of the following two outcomes:

1. Returns new iterate $\boldsymbol{x}^{\prime}$ such that $\left\|\boldsymbol{b}-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \leq \max \left\{\frac{2}{B},\left(1-\frac{\beta}{2}\right)\left\|\boldsymbol{b}-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\right\}$,
2. Updates $\widetilde{\boldsymbol{H}}$ and to obtain a new preconditioner $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime-1} \boldsymbol{H}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}\right) \cdot \frac{2}{\sqrt{1+\frac{99}{100} \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}}}
$$

This step can be implemented in $O\left(n^{2}\right)$ time, plus the time required to make a constant number of gradient queries for $g$. In addition, $\max \left\{\left\|\widetilde{\boldsymbol{H}}^{\prime}\right\|-\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{\prime-1}\right\|-\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} \leq$ $2 \max \left\{\left\|\boldsymbol{H}_{\boldsymbol{y}}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|\right\}^{2}$.

Proof. In addition to invoking Lemmas 18 and 19 we perform two checks. First we verify if the $\widetilde{\boldsymbol{H}}^{-1}$ norm original residual $\boldsymbol{r}=\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})$ is too small, in which case we return the iterate unchanged. Then, after computing the new iterate and the corresponding residual, we again verify whether $r^{\prime}$ is too small, in which case we again return it. Following these checks we verify whether the norm $\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq(1-\beta)\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}$. If this check fails, then we call Algorithm 3 to update the preconditioner. The total time required to run this routine is again dominated by the gradient queries used in the estimation procedures, and the time to perform a rank-1 update which is $O\left(n^{2}\right)$.

Finally, we need to convert the guarantees involving the residual $\boldsymbol{r}^{\prime}=\boldsymbol{b}-p_{\boldsymbol{y}}\left(\boldsymbol{x}^{\prime}\right)$ to guarantees involving the linear function $\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}^{\prime}$.

Note that in the former, using the same approximations we proved in Lemma 18 (equation (15)), we have that the bound $\left\|\boldsymbol{b}-p_{\boldsymbol{y}}\left(\boldsymbol{x}^{\prime}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \leq \frac{1}{B}$ implies

$$
\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq\left(\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}+\frac{1}{400 \cdot B^{16}}\right) \frac{1}{1-\frac{1}{400 \cdot B^{18}}} \leq \frac{2}{B} .
$$

In the other case using (16) we have

$$
\begin{aligned}
& \left\|\boldsymbol{b}-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1-\frac{1}{200 \cdot B^{15}}\right) \leq\left\|\boldsymbol{b}-p_{\boldsymbol{y}}\left(\boldsymbol{x}^{\prime}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \\
& \leq(1-\beta)\left\|\boldsymbol{b}-p_{y}(\boldsymbol{x})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \leq(1-\beta)\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{200 \cdot B^{15}}\right),
\end{aligned}
$$

and so

$$
\begin{aligned}
&\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq(1-\beta)\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{200 \cdot B^{15}}\right) \frac{1}{1-\frac{1}{200 \cdot B^{15}}} \\
& \leq(1-\beta / 2)\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}
\end{aligned}
$$

which concludes the proof.

Handling matrices with a null space. While we have previously assumed that the underlying matrix $\boldsymbol{H}_{y}$ is full-rank, our analysis carries over to the case where it has a non-trivial null space $\mathcal{S}$, if the right hand side vector $\boldsymbol{b} \in \mathcal{S}^{\perp}$, i.e. it is orthogonal to $\mathcal{S}$. To show this, we note that the analysis of Algorithm 4 can be restricted to $\mathcal{S}^{\perp}$. Note that by self-concordance the Hessian of the underlying function $g$ always has $\mathcal{S}$ as null space. If this were not true, by slightly perturbing the argument we could move to a new point where the new Hessian fails to approximate the original one because one entire direction in the span gets zeroed out, so the two Hessians fail to approximate each other, which contradicts self-concordance. This shows that $p_{y}(\boldsymbol{v})$ always outputs a vector orthogonal to $\mathcal{S}$, and therefore the estimated residuals $r$ are always orthogonal to $\mathcal{S}$. Similarly, $n_{y}(\boldsymbol{v})$ zeroes out the components of $\boldsymbol{v}$ parallel to $\mathcal{S}$, so everything it evaluates occurs in $\mathcal{S}^{\perp}$. While we do not explicitly impose restrictions on the preconditioner $\widetilde{\boldsymbol{H}}$, we can replace it in the analysis with the projection $\boldsymbol{\Pi}_{\mathcal{S}^{\perp}} \widetilde{\boldsymbol{H}} \boldsymbol{\Pi}_{\mathcal{S} \perp}$ without affecting the provided guarantees, since this does not affect the excentricity certificates.

Numerical precision aspects. The exposition of the analysis so far is under the assumption of exact arithmetic. Our algorithms do in fact tolerate finite fixed-point precision on the scale of
the natural parameters of the problem $(n, \varepsilon, B)$. Assuming we represent numbers using a number of bits that is polylogarithmic in these parameters, we can ensure that all the round-off errors are bounded by $1 /$ poly $(n, \varepsilon, B)$. These add only a polynomially small additive errors to our evaluations of the residual norm, which are already captured by the analysis. Crucially, we need to ensure that these errors do not affect the excentricity potential. First, polynomially small additive error does not affect the excentricity certificates - they still certify the existence of a poorly conditioned direction, potentially suffering a polynomially small multiplicative decrease in the quality of the bound provided by Lemma 18. Second, and more importantly, we need to argue that the rank-1 updates to the fake preconditioner and its inverse still decrease excentricity as needed, even though round-off errors are introduced. This is because we can view the round-off errors as an adversarial perturbation $\boldsymbol{\Delta}$ done on the preconditioned matrix $\boldsymbol{X}=\boldsymbol{H}_{\boldsymbol{y}}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}_{y}^{-1 / 2}$ such that all entries of $\boldsymbol{\Delta}$ are polynomially small. We show that such perturbations do not significantly increase excentricity. Indeed, since the determinant is multiplicatively stable under small perturbations,

$$
\begin{aligned}
& \operatorname{det}(\boldsymbol{A}+\boldsymbol{\Delta})=\operatorname{det}(\boldsymbol{A}) \operatorname{det}\left(\boldsymbol{I}+\boldsymbol{A}^{-1 / 2} \boldsymbol{\Delta} \boldsymbol{A}^{-1 / 2}\right) \leq \operatorname{det}(\boldsymbol{A}) \cdot\left(1+\frac{\|\boldsymbol{\Delta}\|}{\left\|\boldsymbol{A}^{-1}\right\|}\right)^{n} \\
& \leq \operatorname{det}(\boldsymbol{A}) \cdot\left(1+\frac{n \max _{i, j}\left|\boldsymbol{\Delta}_{i j}\right|}{\left\|\boldsymbol{A}^{-1}\right\|}\right)^{n}
\end{aligned}
$$

we can make increases in excentricity caused by the noise in $\boldsymbol{\Delta}$ only affect by a $1+\frac{1}{\text { poly }(n, \varepsilon, B)}$ multiplicative factor. Thus polynomially small error is sufficient, requiring only logarithmically many bits.

## 5 Path Following with a Fake Hessian

The robust version of Lemmas 15 and 16 (Lemmas and 18 and 19) give us a method for maintaining a preconditioner for the Hessian of a self-concordant function $g$ at a fixed point $\boldsymbol{y}$. To use them within a path following method, we need to be able to control the quality of the preconditioner $\widetilde{\boldsymbol{H}}$ as we move to a new point on the central path. Fortunately, strong self-concordance turns out to be exactly the property required to ensure that the excentricity $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right)$ does not drastically increase as we move to a new point $\boldsymbol{y}^{\prime}$.

Here we crucially rely on Lemma 12, whose proof we provide at the end of the section. To prove Lemma 12 we use a determinant inequality (Lemma 27) which we prove by using a majorization bound for the eigenvalues of the sum of two matrices, together with some properties related to the Schur convexity of elementary symmetric polynomials.

### 5.1 Setup

We consider the barrier formulation

$$
\begin{equation*}
g_{\mu}(\boldsymbol{y})=\frac{\langle\boldsymbol{c}, \boldsymbol{y}\rangle}{\mu}+\phi(\boldsymbol{y}), \tag{5}
\end{equation*}
$$

where $\phi: K \rightarrow \mathbb{R}$ is a $\nu$-strongly self-concordant barrier for a convex set $K$. Our goal is to obtain a near-minimizer for $g_{\mu}$, for a sufficiently small $\mu$. This is quantitatively given by the following lemma, which is standard in interior point methods.

Lemma 21 (Approximate optimality [Ren01]). Suppose that $\varepsilon_{N} \leq 1 / 10$, a feasible solution $\boldsymbol{y} \in \mathbb{R}^{m}$ and the parameter $\mu \leq 1$ satisfy the following bound on the Newton step size

$$
\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\bar{y}}^{-1}} \leq \varepsilon_{N} .
$$

Let $\boldsymbol{y}^{\star}$ be an optimal solution to the objective original objective $\min \{\langle\boldsymbol{c}, \boldsymbol{y}\rangle: \boldsymbol{y} \in K\}$. Then $\langle\boldsymbol{c}, \boldsymbol{y}\rangle \leq$ $\left\langle\boldsymbol{c}, \boldsymbol{y}^{\star}\right\rangle+\mu \nu\left(1+2 \varepsilon_{N}\right)$.

Having established via Lemma 21 that to solve the problem to precision $\varepsilon$ we require finding the minimizer of $g_{\mu}$ for $\mu \lesssim \frac{\varepsilon}{2 \nu}$, we know that throughout the entire execution of a standard interior point method the matrices in the neighborhood of the central path will have eigenvalues (and their inverses) that are bounded by the $\varepsilon$-condition number of the barrier formulation
Definition 22 ( $\varepsilon$-condition number). Given a barrier formulation (5), where $\phi$ is a $\nu$-strongly self-concordant barrier, we define the $\varepsilon$-condition number of the formulation as

$$
\begin{equation*}
\kappa_{\star}:=4 \kappa\left(\frac{\varepsilon}{2 \nu}\right) . \tag{6}
\end{equation*}
$$

This parameter determines the precision to which we have to estimate Hessian-vector products, as well as the number of iterations of the entire algorithm. The latter is true because, being unable to measure the true dual local norm of our gradients, we generally do not know whether we have managed to be close enough to the central path, that we can advance by dialing down $\mu$. The promise on the Hessian eigenvalues, together with upper bounds we maintain on the eigenvalues of the preconditioner and its inverse, enable us to approximate $\|\nabla g(\boldsymbol{y})\|_{\boldsymbol{H}_{\boldsymbol{y}}^{-1}}$.

Throughout the entire execution of the algorithm we will maintain the following invariant on the preconditioner and the Hessian matrices in the neighborhood of the central path.

Invariant 1. For $B_{H}=4 \kappa_{\star}$ and $B_{\widetilde{H}}=10^{9} \cdot \kappa_{\star}^{2} \cdot\left(n \log \kappa_{\star}+\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)$, we always have $\max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|\right\} \leq B_{\boldsymbol{H}}$ and $\max \left\{\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} \leq B_{\widetilde{\boldsymbol{H}}}$.

While the upper bound on $B_{H}$ automatically holds if we always stay close to the central path, per Lemma 14 provided that we stop the interior point method at $\mu=\frac{\varepsilon}{2 \nu}$, we also need to show that the preconditioner $\widetilde{\boldsymbol{H}}$ never becomes too poorly conditioned. This will show that this holds by tracking its evolution throughout the execution of the interior point method.
Lemma 23. Let $\boldsymbol{y}$ such that $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\boldsymbol{y}}^{-1}} \leq \frac{1}{20 \sqrt{n}}$. Then Algorithm 5 returns a new iterate $\boldsymbol{y}^{\prime}$ such that $\left\|\nabla g_{\mu /\left(1+\frac{1}{20 \sqrt{\nu n}}\right)}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}} \leq \frac{1}{20 \sqrt{n}}$.
Proof. The algorithm essentially corresponds to performing a single Newton step to restore centrality, followed by adjusting the centrality parameter $\mu$. Over the course of its execution, it may call the RobustSteporUpdate routine several times, as it may need to adjust its preconditioner. When calling it we use the parameters $B=B \frac{10}{\boldsymbol{H}}$, and $\beta=1 / 100$. First we show that indeed, at the end of the execution, the returned iterate still has a small dual local norm.

After a successful call when the preconditioner does not change, per the guarantees of Lemma 20, we have that

$$
\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{y} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq \max \left\{\frac{2}{B_{\widetilde{\boldsymbol{H}}}^{10}},\left(1-\frac{\beta}{2}\right)\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\right\}
$$

and the counter $t$ gets increased. Since the counter stops after $T=\frac{100}{\beta} \log \left(B_{H} B_{\widetilde{H}}\right)$ successful iterations, at the end of the execution the returned variable $\boldsymbol{x}$ satisfies

$$
\begin{aligned}
\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} & \leq \max \left\{\frac{2}{B_{\widetilde{\boldsymbol{H}}}^{10}},\left(1-\frac{\beta}{2}\right)^{T}\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\right\} \\
& \leq \max \left\{\frac{2}{B_{\widetilde{\boldsymbol{H}}}^{10}},\left(1-\frac{\beta}{2}\right)^{T}\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}^{2} \cdot\left\|\boldsymbol{H}_{y}\right\|\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} \leq \frac{2}{B_{\widetilde{\boldsymbol{H}}}^{10}} .
\end{aligned}
$$

Therefore

$$
\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}} \leq\left\|\boldsymbol{H}_{y}^{-1}\right\|\|\widetilde{\boldsymbol{H}}\| \frac{2}{B_{\widetilde{\boldsymbol{H}}}^{10}} \leq \frac{2}{B_{\widetilde{\boldsymbol{H}}}^{8}} .
$$

From a standard argument shown in Lemma 38 we obtain that

$$
\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}} \leq \frac{4}{B_{\widetilde{\boldsymbol{H}}}^{8}}+7 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\boldsymbol{y}}^{-1}}^{2}
$$

Thus moving from centrality $\mu$ to $\mu /\left(1+\frac{1}{200 \sqrt{\nu n}}\right)$ we obtain via Lemma 39 that

$$
\begin{aligned}
\left\|\nabla g_{\mu /\left(1+\frac{1}{200 \sqrt{\nu n}}\right)}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}} & =\left\|\left(1+\frac{1}{200 \sqrt{\nu n}}\right) \nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)-\frac{1}{200 \sqrt{\nu n}} \nabla \phi\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}} \\
& \leq\left(1+\frac{1}{200 \sqrt{\nu n}}\right)\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}}+\frac{1}{200 \sqrt{\nu n}}\left\|\nabla \phi\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1}}{ }^{-1} \\
& \leq\left(1+\frac{1}{200 \sqrt{\nu n}}\right)\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{H}^{\prime}}^{-1}}+\frac{1}{200 \sqrt{n}} \\
& \leq\left(1+\frac{1}{200 \sqrt{\nu n}}\right)\left(\frac{4}{B_{\widetilde{H}}^{8}}+7 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{-1}}^{2}}^{2}\right)+\frac{1}{200 \sqrt{n}} \\
& \leq\left(1+\frac{1}{200 \sqrt{\nu n}}\right)\left(\frac{4}{B_{\widetilde{\boldsymbol{H}}}^{8}}+7 \cdot\left(\frac{1}{20 \sqrt{n}}\right)^{2}\right)+\frac{1}{200 \sqrt{n}} \\
& \leq \frac{1}{20 \sqrt{n}} .
\end{aligned}
$$

Next we prove an upper bound on the total number of calls to the preconditioner update routine.

Lemma 24. Let $\boldsymbol{y}_{0}$ such that $\left\|\nabla g_{\mu}\left(\boldsymbol{y}_{0}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}_{0}}^{-1}} \leq \frac{1}{20 \sqrt{n}}$, for $\mu=n^{O(1)}$, and let $\widetilde{\boldsymbol{H}}_{0}=\boldsymbol{I}$ be the preconditioner at initialization. In $\widetilde{O}\left(\sqrt{\nu n} \log \left(\frac{n \nu}{\varepsilon}\right)\right)$ calls to Algorithm 5 we obtain a new point $\boldsymbol{y}^{\prime}$ such that $\left\langle\boldsymbol{c}, \boldsymbol{y}^{\prime}\right\rangle-\left\langle\boldsymbol{c}, \boldsymbol{y}^{\star}\right\rangle \leq \varepsilon$. Over the entire course of the execution, the algorithm, makes at most $O\left(\log \mathcal{E}\left(\boldsymbol{H}_{y_{0}}\right)+\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)$ preconditioner updates.

Proof. First, by Lemma 23, in a single call to Algorithm 5, the centrality parameter $\mu$ gets reduced by a factor of $1+\frac{1}{20 \sqrt{\nu n}}$ while maintaining an upper bound of $1 /(20 \sqrt{n})$ on the dual local norm. By Lemma 21, stopping once $\mu \leq \frac{\varepsilon}{\nu\left(1+2 \cdot \frac{1}{20}\right)}$ ensures that error in the objective is at most $\varepsilon$, so we are done. Therefore in $O\left(\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)$ calls, the algorithm can return a solution with $\varepsilon$ additive
error. We bound the number of preconditioner updates by analyzing the evolution of excentricity. In each call to Algorithm 5, excentricity can increase exactly once, whenever we move from $\boldsymbol{y}$ to $\boldsymbol{y}^{\prime}$ and hence we replace $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right)$ with $\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}^{\prime}}\right)$.

When doing so, from Lemma 38, we have that the change in iterate $\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{\boldsymbol{y}}}=\left\|\boldsymbol{y}-\boldsymbol{y}^{\prime}\right\|_{\boldsymbol{H}_{y}} \leq$ $\frac{2}{B_{\bar{H}}^{10}}+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}} \leq \frac{1}{10 \sqrt{n}}$. Thus by Lemma 12,
$\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}^{\prime}}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \exp \left(\frac{1}{2} \sqrt{n} \cdot \frac{\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}{\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \exp \left(\frac{1}{10}\right)$.
In addition all the other changes in excentricity are only due to preconditioner updates. And we know by Lemma 20 that these decrease excentricity in the sense that

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime-1} \boldsymbol{H}_{y}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \frac{2}{\sqrt{1+\frac{99}{100} \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}}} \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \frac{3}{4}
$$

As over the entire course of the algorithm excentricity can increase by at most $\exp \left(O\left(\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)\right)$, and each other preconditioner update decreases it by at least a factor of $3 / 4$, the total number of preconditioner updates can not be too large (as excentricity is always at least 1 ). Hence we bound the total number of preconditioner updates to

$$
O\left(\log \mathcal{E}\left(\widetilde{\boldsymbol{H}}_{0}^{-1} \boldsymbol{H}_{y_{0}}\right)+\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)=O\left(\log \mathcal{E}\left(\boldsymbol{H}_{y_{0}}\right)+\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)
$$

which concludes the proof.
Finally we need to argue that over the entire execution Invariant 1 is preserved. To do this we need to bound $\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|$. This is easy to see, as from Lemma 20 each step increases both of these norms by at most $2 \max \left\{\left\|\boldsymbol{H}_{y}\right\|,\left\|\boldsymbol{H}_{y}^{-1}\right\|\right\}^{2} \leq 2 \kappa_{\star}^{2}$, so by the end we have

$$
\begin{aligned}
\max \left\{\|\widetilde{\boldsymbol{H}}\|,\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|\right\} & \leq 2 \kappa_{\star}^{2} \cdot\left(\log \mathcal{E}\left(\boldsymbol{H}_{y_{0}}\right)+O\left(\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)\right) \\
& \leq 2 \kappa_{\star}^{2} \cdot\left(n \log \kappa_{\star}+O\left(\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right)\right),
\end{aligned}
$$

which shows that invariants hold throughout the entire execution.
Putting everything together, together with classical techniques involving initializing interior point methods [Nes98] the main theorem of this section follows.
Theorem 25. Given a convex set $K \subseteq \mathbb{R}^{n}$, with a $\nu$-strongly self-concordant barrier $\phi: K \rightarrow$ $\mathbb{R}$, which we can access through a gradient oracle, and given an initial point $\boldsymbol{y}_{0} \in \operatorname{int}(K)$, $\left\|\nabla \phi\left(\boldsymbol{y}_{0}\right)\right\|_{\boldsymbol{H}_{y_{0}}^{-1}} \leq \frac{1}{20 \sqrt{n}}$, in time

$$
O\left(\left(\log \mathcal{E}\left(\boldsymbol{H}_{y_{0}}\right)+\sqrt{\nu n} \log \frac{n \nu}{\varepsilon}\right) \cdot\left(n^{2}+\mathcal{T}_{\text {gradient }}\right)\right)
$$

we can obtain an iterate $\boldsymbol{y}^{\prime}$ such that $\langle\boldsymbol{c}, \boldsymbol{y}\rangle \leq\left\langle\boldsymbol{c}, \boldsymbol{y}^{\star}\right\rangle+\varepsilon$, where $\boldsymbol{y}^{\star}$ is the minimizer of the original objective $\min \{\langle\boldsymbol{c}, \boldsymbol{y}\rangle: \boldsymbol{y} \in K\}$. Furthermore, all the matrices we encounter, together their inverses have eigenvalues bounded by $\left(\kappa_{\star} n \nu \log \frac{1}{\varepsilon}\right)^{O(1)}$, where $\kappa_{\star}$ is the $\varepsilon$-condition number of the barrier formulation (Definition 22).

Note that the condition on the dual local norm on the barrier gradient corresponds to being close to the central path. This is usually handled through appropriately modifying the optimization problem such that the guarantee is enforced.

It is important to note that for as long as $\kappa_{\star}$ is quasi-polynomially bounded, all the involved quantities are quasi-polynomial, hence we can implement the interior point method using only poly-logarithmically many bits of precision for each number.

Additionally this implies the following important corollary for optimizing linear functions over convex domains. This follows from the $\widetilde{O}(n)$-strong self-concordance of the universal and entropic barriers [LLV20], which in turn results from recent progress on the KLS conjecture [Che21, JLV22]. While [LLV20] prove that the universal and entropic barriers satisfy an approximate version of Definition 9, with a polylogarithmic constant in front of the right-hand side, they can be brought to satisfy it exactly by slightly scaling them down. In exchange they suffer a small polylogarithmic increase in the self-concordance parameter, but this does not affect our bounds.

Corollary 26. Given a convex set $K \subseteq \mathbb{R}^{n}$, with query access to a gradient oracle for the universal or entropic barrier $\phi: K \rightarrow \mathbb{R}$, and given an initial point $\boldsymbol{y}_{0} \in \operatorname{int}(K),\left\|\nabla \phi\left(\boldsymbol{y}_{0}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}_{0}}} \leq \frac{1}{20 \sqrt{n}}$, in time

$$
O\left(\log \left(\frac{n \kappa_{\star}}{\varepsilon}\right) \cdot\left(n^{3}+n \mathcal{T}_{\text {gradient }}\right)\right)
$$

we can obtain an iterate $\boldsymbol{y}^{\prime}$ such that $\langle\boldsymbol{c}, \boldsymbol{y}\rangle \leq\left\langle\boldsymbol{c}, \boldsymbol{y}^{\star}\right\rangle+\varepsilon$, where $\boldsymbol{y}^{\star}$ is the minimizer of the original objective $\min \{\langle\boldsymbol{c}, \boldsymbol{y}\rangle: \boldsymbol{y} \in K\}$. Furthermore, all the matrices we encounter, together their inverses have eigenvalues bounded by $\left(\kappa_{\star} n \nu \log \frac{1}{\varepsilon}\right)^{O(1)}$, where $\kappa_{\star}$ is the $\varepsilon$-condition number of the barrier formulation (Definition 22).

```
Algorithm 5 Path Following.

        end while
        return \(\left(\boldsymbol{y}-\boldsymbol{x}, \widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}^{-1}, \mu /\left(1+\frac{1}{200 \sqrt{n \nu}}\right)\right)\)
    end procedure
```

### 5.2 Excentricity Proofs

First we provide the proof of Lemma 12.

Proof of Lemma 12. Using Lemma 8 we write

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}+\boldsymbol{\delta}}\right)=\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{\boldsymbol{y}} \cdot \boldsymbol{H}_{y}^{-1} \boldsymbol{H}_{y+\boldsymbol{\delta}}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \sqrt{\frac{\operatorname{det}\left(\left(\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{y+\delta} \boldsymbol{H}_{y}^{-1 / 2}\right)_{\geq 1}\right)}{\operatorname{det}\left(\left(\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{y+\delta} \boldsymbol{H}_{y}^{-1 / 2}\right)_{<1}\right)}} .
$$

Let $\lambda_{1}, \ldots, \lambda_{n}$ be the eigenvalues of $\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{y+\delta} \boldsymbol{H}_{y}^{-1 / 2}$. Since $g$ is strongly self-concordant, we also have by Lemma 10, for $\alpha=\frac{\|\boldsymbol{\delta}\|_{H_{y}}}{\left(1-\|\delta\|_{H_{y}}\right)^{2}}$, that

$$
\sqrt{\sum_{i=1}^{n}\left(\lambda_{i}-1\right)^{2}} \leq \alpha
$$

Therefore, using $\frac{1}{1-x} \leq 1+\beta x$ whenever $0 \leq x \leq 1-\frac{1}{\beta}$, we have

$$
\left|\lambda_{i}-1\right| \leq \alpha=1-\frac{1}{(1-\alpha)^{-1}}
$$

so that

$$
\frac{1}{1-\left|\lambda_{i}-1\right|} \leq 1+\frac{1}{1-\alpha}\left|\lambda_{i}-1\right| .
$$

Thus,

$$
\begin{align*}
\prod_{i=1}^{n} \max \left\{\lambda_{i}, \frac{1}{\lambda_{i}}\right\} & =\prod_{i=1}^{n} \max \left\{1+\left(\lambda_{i}-1\right), \frac{1}{1+\left(\lambda_{i}-1\right)}\right\} \leq \prod_{i=1}^{n} \max \left\{1+\left|\lambda_{i}-1\right|, \frac{1}{1-\left|\lambda_{i}-1\right|}\right\} \\
& \leq \prod_{i=1}^{n} \max \left\{1+\left|\lambda_{i}-1\right|, 1+\frac{1}{1-\alpha}\left|\lambda_{i}-1\right|\right\} \\
& \leq \prod_{i=1}^{n}\left(1+\frac{1}{1-\alpha}\left|\lambda_{i}-1\right|\right) \\
& \leq\left(1+\frac{1}{n} \sum_{i=1}^{n} \frac{1}{1-\alpha}\left|\lambda_{i}-1\right|\right)^{n}  \tag{AM-GM}\\
& \leq\left(1+\frac{1}{1-\alpha} \sqrt{\frac{1}{n}} \sum_{i=1}^{n}\left|\lambda_{i}-1\right|^{2}\right)^{n}  \tag{QM-AM}\\
& \leq\left(1+\frac{\alpha}{1-\alpha} \sqrt{\frac{1}{n}}\right)^{n} \\
& \leq \exp \left(\sqrt{n} \cdot \frac{\alpha}{1-\alpha}\right)
\end{align*}
$$

Plugging this back into the bound on the new excentricity we obtain

$$
\begin{aligned}
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y+\boldsymbol{\delta}}\right) & \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \exp \left(\frac{1}{2} \sqrt{n} \cdot \frac{\alpha}{1-\alpha}\right) \\
& =\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}_{y}\right) \cdot \exp \left(\frac{1}{2} \sqrt{n} \cdot \frac{\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}{\left(1-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}\right)^{2}-\|\boldsymbol{\delta}\|_{\boldsymbol{H}_{y}}}\right)
\end{aligned}
$$

which concludes the proof.
To prove Lemma 12 we rely on the following important inequality.
Lemma 27. Let $\boldsymbol{A}$ and $\boldsymbol{D}$ be symmetric positive definite matrices. Let $\boldsymbol{D}_{\geq 1}$ denote the matrix obtained from $\boldsymbol{D}$ by increasing all the sub-unitary eigenvalues to 1 , and let $\boldsymbol{D}_{<1}$ be defined analogously. Then

$$
\operatorname{det}(\boldsymbol{A D}+\boldsymbol{I}) \leq \operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \operatorname{det}\left(\boldsymbol{D}_{\geq 1}\right)
$$

The proof follows from majorization bounds on the eigenvalues of a sum of two PSD matrices.
Definition 28 (majorization). Given $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^{d}$ we say that $\boldsymbol{y}$ majorizes $\boldsymbol{x}$ (denoted by $\left.\boldsymbol{x} \prec \boldsymbol{y}\right)$ iff

$$
\sum_{i=1}^{k} \boldsymbol{x}_{i} \leq \sum_{i=1}^{k} \boldsymbol{y}_{i}, \text { for all } 1 \leq k \leq d
$$

and

$$
\sum_{i=1}^{d} \boldsymbol{x}_{i}=\sum_{i=1}^{d} \boldsymbol{y}_{i}
$$

Given two symmetric positive definite matrices, one can show a majorization relation involving their eigenvalues. The following lemma follows from [And94].

Lemma 29 ([And94]). Given a symmetric PSD matrix $\boldsymbol{M}$, let $\lambda^{\uparrow}(\boldsymbol{M})$ and $\lambda^{\downarrow}(\boldsymbol{M})$ denote the eigenvalues of $\boldsymbol{M}$ in ascending and descending order, respectively. Then

$$
\lambda^{\downarrow}(\boldsymbol{A})+\lambda^{\uparrow}\left(\boldsymbol{D}^{-1}\right) \prec \lambda^{\downarrow}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right)
$$

Such bounds are helpful, since the theory of Schur convexity allows to prove inequalities involving functions applied to vectors related by a majorization relation.

Definition 30 (Schur-convexity). A function $f: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is called Schur-convex if for any $\boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^{d}$ such that $\boldsymbol{x} \prec \boldsymbol{y}$, one has $f(\boldsymbol{x}) \leq f(\boldsymbol{y})$. A function $f$ is called Schur-concave if the reverse inequality holds, i.e. $\boldsymbol{x} \prec \boldsymbol{y}$ implies $f(\boldsymbol{x}) \geq f(\boldsymbol{y})$.

There is extensive theory on Schur-convex/Schur-concave functions [VR73]. Here we are only concerned with a particular function which is the elementary symmetric polynomial.

Lemma 31. The function $f: \mathbb{R}_{>0}^{d} \rightarrow \mathbb{R}$ defined by $f(\boldsymbol{x})=\prod_{i=1}^{d} \boldsymbol{x}_{i}$ is Schur-concave.
Using Lemma 31, together with 29 we are ready to prove Lemma 27.

Proof of Lemma27. Let $\lambda^{\uparrow}(\boldsymbol{M})$ and $\lambda^{\downarrow}(\boldsymbol{M})$ denote the eigenvalues of $\boldsymbol{M}$ in ascending and descending order, respectively. By Lemma 29, the eigenvalues satisfy the majorization relation:

$$
\lambda^{\downarrow}(\boldsymbol{A})+\lambda^{\uparrow}\left(\boldsymbol{D}^{-1}\right) \prec \lambda^{\downarrow}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right) .
$$

Using 31 we know that the map $\left(x_{1}, \ldots, x_{n}\right) \rightarrow \prod_{i=1}^{n} x_{i}$ is an elementary symmetric function, it is Schur concave whenever all $x_{i}>0$. Applying it to $\lambda^{\downarrow}(\boldsymbol{A})+\lambda^{\uparrow}\left(\boldsymbol{D}^{-1}\right)$ and $\lambda^{\downarrow}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right)$, respectively, we obtain:

$$
\begin{aligned}
\operatorname{det}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right) & =\prod_{j} \lambda_{j}^{\downarrow}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right) \leq \prod_{j}\left(\lambda_{j}^{\downarrow}(\boldsymbol{A})+\lambda_{j}^{\uparrow}\left(\boldsymbol{D}^{-1}\right)\right) \\
& \leq \prod_{j} \begin{cases}\left(\lambda_{j}^{\downarrow}(\boldsymbol{A})+1\right) \lambda_{j}^{\uparrow}\left(\boldsymbol{D}^{-1}\right) & \lambda_{j}^{\uparrow}\left(\boldsymbol{D}^{-1}\right) \geq 1 \\
\lambda_{j}^{\downarrow}(\boldsymbol{A})+1 & \lambda_{j}^{\uparrow}\left(\boldsymbol{D}^{-1}\right) \leq 1\end{cases} \\
& =\prod_{j}\left(\lambda_{j}^{\downarrow}(\boldsymbol{A})+1\right) \cdot \prod_{j} \max \left\{1, \lambda_{j}^{\uparrow}\left(\boldsymbol{D}^{-1}\right)\right\} \\
& =\operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \cdot \prod_{j} \frac{1}{\min \left\{1, \lambda_{j}^{\uparrow}(\boldsymbol{D})\right\}} \\
& =\operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \frac{1}{\operatorname{det}\left(\boldsymbol{D}_{<1}\right)} .
\end{aligned}
$$

Therefore

$$
\begin{array}{r}
\operatorname{det}(\boldsymbol{A} \boldsymbol{D}+\boldsymbol{I})=\operatorname{det}(\boldsymbol{D}) \operatorname{det}\left(\boldsymbol{A}+\boldsymbol{D}^{-1}\right) \leq \operatorname{det}(\boldsymbol{D}) \operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \frac{1}{\operatorname{det}\left(\boldsymbol{D}_{<1}\right)} \\
=\operatorname{det}(\boldsymbol{A}+\boldsymbol{I}) \operatorname{det}\left(\boldsymbol{D}_{\geq 1}\right),
\end{array}
$$

which concludes the proof.

## 6 Solving SDPs

Here we provide the main theorem on solving semidefinite programs. We provide a statement that matches the form of the one in $\left[\mathrm{JKL}^{+} 20\right]$.

Theorem 32. Consider a semidefinite program with variable size $n \times n$ and $m \geq n$ constraints of the form

$$
\max \left\{\langle\boldsymbol{B}, \boldsymbol{X}\rangle: \boldsymbol{X} \succeq 0,\left\langle\boldsymbol{A}_{i}, \boldsymbol{X}\right\rangle=\boldsymbol{c}_{i}, \text { for all } 1 \leq i \leq m\right\}
$$

Assume that any feasible solution $\boldsymbol{X} \succeq 0$ satisfies $\|\boldsymbol{X}\| \leq R$. Then for any error parameter $0<\varepsilon<$ 0.01, there is an algorithm that outputs in time

$$
\widetilde{O}\left(m n^{4}+m^{1.25} n^{3.5} \log \frac{1}{\varepsilon}\right)
$$

a matrix $\boldsymbol{X} \succeq 0$ such that

$$
\langle\boldsymbol{B}, \boldsymbol{X}\rangle \geq\left\langle\boldsymbol{B}, \boldsymbol{X}^{\star}\right\rangle-\varepsilon\|\boldsymbol{B}\| R
$$

and

$$
\sum_{i=1}^{m}\left|\left\langle\boldsymbol{A}_{i}, \boldsymbol{X}\right\rangle-\boldsymbol{c}_{i}\right| \leq 4 n \varepsilon\left(R \sum_{i=1}^{m}\left\|\boldsymbol{A}_{i}\right\|_{1}+\|\boldsymbol{c}\|_{1}\right) .
$$

Furthermore, provided that the barrier objective (3)) has a quasi-polynomial $\varepsilon$-condition number (Definition 22), all the matrices we encounter, together with their inverses, have quasi-polynomially bounded eigenvalues.

To prove this statement we require mapping back the solution obtained from the solution to the barrier objective to a solution to the primal objective. We point the reader to Theorem 5.1 of [JKL $\left.{ }^{+} 20\right]$ for a careful treatment of this matter. Similarly for initializing the interior point method, please consult Section 9 from [JKL $\left.{ }^{+} 20\right]$. With these technicalities settled, it suffices to understand how fast one can solve the corresponding barrier objective.

To apply Theorem 25 we need to find an appropriate strongly self-concordant barrier for the feasible set. Unfortunately, in the case of SDPs we can not prove that the standard logarithmic barrier is strongly self-concordant. In fact, this does not even appear to be true. Instead, we show that after scaling it up by a factor of $\sqrt{m}$ it becomes strongly self-concordant. The corresponding self-concordance parameter of this scaled barrier becomes $\nu=n \sqrt{m}$. We prove this in Lemma 33 .

Note that the gradients of the scaled barrier

$$
\phi(\boldsymbol{y})=-\sqrt{m} \cdot \log \operatorname{det}\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)
$$

defined by

$$
[\nabla \phi(\boldsymbol{y})]_{i}=\sqrt{m} \cdot\left\langle\boldsymbol{A}_{i},\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)^{-1}\right\rangle
$$

can be evaluated in time $\mathcal{T}_{\text {gradient }}=O\left(m n^{2}+n^{\omega}\right)$. To do so we first evaluate the slack matrix $\boldsymbol{S}_{y}=\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}$ in time $O\left(m n^{2}\right)$, we invert it in time $O\left(n^{\omega}\right)$, then we evaluate all the inner products $\left\langle\boldsymbol{A}_{i}, \boldsymbol{S}_{y}^{-1}\right\rangle$ in time $O\left(m n^{2}\right)$.

Next we use Theorem 25. Here, although the fake Hessian we maintain has dimension $m \times m$, we note that its rank is always at most $n^{2}$. This is because

$$
\nabla^{2} \phi(\boldsymbol{y})=\sqrt{m} \cdot \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right) \mathcal{A}
$$

where $\mathcal{A} \in \mathbb{R}^{n^{2} \times m}$ is the matrix whose $i^{t h}$ column is obtained by flattening $\boldsymbol{A}_{i}$ into a vector vec $\left(\boldsymbol{A}_{i}\right)$ of length $n^{2}$. Therefore, per our discussion from Section 4 we can run the entire analysis in a subspace of ambient dimension $\min \left\{m, n^{2}\right\}$. By Theorem 25, after bounding $\log \mathcal{E}\left(\boldsymbol{H}_{y_{0}}\right)=$ $\widetilde{O}\left(\min \left\{m, n^{2}\right\}\right)$, we require time

$$
\begin{aligned}
& \widetilde{O}\left(\left(\min \left\{m, n^{2}\right\}+\sqrt{n \sqrt{m} \cdot \min \left\{m, n^{2}\right\}} \log \frac{n m}{\varepsilon}\right) \cdot\left(n^{2}+\mathcal{T}_{\text {gradient }}\right)\right) \\
= & \widetilde{O}\left(\left(n^{2}+n^{3 / 2} m^{1 / 4} \log \frac{1}{\varepsilon}\right)\left(m n^{2}+n^{\omega}\right)\right)
\end{aligned}
$$

to solve the dual problem to $\varepsilon$ precision. Assuming that $m \geq n$, this time is

$$
\widetilde{O}\left(m n^{4}+m^{1.25} n^{3.5} \log \frac{1}{\varepsilon}\right)
$$

which gives our claimed bound.

Lemma 33. The barrier $\phi(\boldsymbol{y})=-\sqrt{m} \cdot \log \operatorname{det}\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)$ is a strongly self-concordant barrier function with $\nu=n \sqrt{m}$.

Proof. Let $\psi(\boldsymbol{y})=-\log \operatorname{det}\left(\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}\right)$ be the standard logarithmic barrier. Let $\boldsymbol{H}_{y}=$ $\nabla^{2} \psi(\boldsymbol{y})$. We will show that for any $\boldsymbol{h}$ it satisfies

$$
\left\|\boldsymbol{H}_{y}^{-1 / 2} \frac{d}{d t} \boldsymbol{H}_{y+t h} \boldsymbol{H}_{y}^{-1 / 2}\right\|_{F} \leq \frac{2}{\sqrt{m}}\|\boldsymbol{h}\|_{\boldsymbol{H}_{\boldsymbol{y}}} .
$$

Hence scaling it up by a factor of $\sqrt{m}$ yields a $n \sqrt{m}$-self-concordant barrier function that matches the requirements from Definition 9. To verify this, we first compute the entries of the Hessian matrix

$$
\left(\boldsymbol{H}_{y}\right)_{i j}=\operatorname{tr}\left(\boldsymbol{S}_{y}^{-1} \boldsymbol{A}_{i} \boldsymbol{S}_{y}^{-1} \boldsymbol{A}_{j}\right),
$$

which allows us to write

$$
\boldsymbol{H}_{y}=\mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right) \mathcal{A}
$$

where $\boldsymbol{S}_{y}=\boldsymbol{B}-\sum_{i=1}^{m} \boldsymbol{y}_{i} \boldsymbol{A}_{i}$ is the slack matrix, $\mathcal{A} \in \mathbb{R}^{n^{2} \times m}$ is the matrix whose $i^{\text {th }}$ column is obtained by flattening $\boldsymbol{A}_{i}$ into a vector of length $n^{2}$, and $\otimes$ denotes the Kronecker product. For any $\boldsymbol{h} \in \mathbb{R}^{m}$, let $\Delta \boldsymbol{S}(\boldsymbol{h})=\boldsymbol{S}_{y+h}-\boldsymbol{S}_{y}=-\sum_{i} \boldsymbol{h}_{i} \boldsymbol{A}_{i}$. Therefore, using the expansion $(\boldsymbol{X}+t \boldsymbol{Y})^{-1}=$ $\boldsymbol{X}^{-1}-t \boldsymbol{X}^{-1} \boldsymbol{Y} \boldsymbol{X}^{-1}+O_{\boldsymbol{X}, \boldsymbol{Y}}\left(t^{2}\right) \boldsymbol{I}$, we calculate :

$$
\begin{aligned}
\frac{d}{d t} \boldsymbol{H}_{y+t h} & =\lim _{t \rightarrow 0} \frac{1}{t} \cdot \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}-\boldsymbol{S}_{y+t \delta}^{-1} \otimes \boldsymbol{S}_{y+t \boldsymbol{\delta}}^{-1}\right) \mathcal{A} \\
& =\lim _{t \rightarrow 0} \frac{1}{t} \cdot \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}-\left(\boldsymbol{S}_{y}+\Delta \boldsymbol{S}(t \boldsymbol{\delta})\right)^{-1} \otimes\left(\boldsymbol{S}_{y}+\Delta \boldsymbol{S}(t \boldsymbol{\delta})\right)^{-1}\right) \mathcal{A} \\
& =\lim _{t \rightarrow 0} \frac{1}{t} \cdot \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}-\left(\boldsymbol{S}_{y}^{-1}-t \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right) \otimes\left(\boldsymbol{S}_{y}^{-1}-t \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right)\right) \mathcal{A} \\
& =\lim _{t \rightarrow 0} \frac{1}{t} \cdot \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}-\left(\boldsymbol{S}_{y}^{-1}-t \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right) \otimes\left(\boldsymbol{S}_{y}^{-1}-t \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right)\right) \mathcal{A} \\
& =\mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}+\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right) \mathcal{A}
\end{aligned}
$$

Using the inequality

$$
\left\|\left(\boldsymbol{M}^{\top} \boldsymbol{X} \boldsymbol{M}\right)^{-1 / 2}\left(\boldsymbol{M}^{\top} \boldsymbol{Y} \boldsymbol{M}\right)\left(\boldsymbol{M}^{\top} \boldsymbol{X} \boldsymbol{M}\right)^{-1 / 2}\right\|_{F} \leq\left\|\boldsymbol{X}^{-1 / 2} \boldsymbol{Y} \boldsymbol{X}^{-1 / 2}\right\|_{F}=\left\|\boldsymbol{X}^{-1} \boldsymbol{Y}\right\|_{F}
$$

we can bound the Frobenius norm

$$
\begin{align*}
& \left\|\boldsymbol{H}_{y}^{-1 / 2} \frac{d}{d t} \boldsymbol{H}_{y+t h} \boldsymbol{H}_{y}^{-1 / 2}\right\|_{F} \\
& \leq\left\|\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right)^{-1}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}+\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right)\right\|_{F} \\
& =\left\|\left(\boldsymbol{S}_{y} \otimes \boldsymbol{S}_{y}\right)\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}+\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right)\right\|_{F} \\
& =\left\|\boldsymbol{I}_{m} \otimes \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}+\Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{I}_{m}\right\|_{F} \\
& \leq 2\left\|\boldsymbol{I}_{m} \otimes \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right\|_{F} \\
& =2\left\|\boldsymbol{I}_{m}\right\|_{F}\left\|\Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right\|_{F} \\
& =2 \sqrt{m}\left\|\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta})\right\|_{F} \tag{7}
\end{align*}
$$

Give a matrix $\boldsymbol{X}$ let vec $(\boldsymbol{X})$ be its flattening into a vector. Using the identity $\left(\boldsymbol{B}^{\top} \otimes \boldsymbol{A}\right) \operatorname{vec}(\boldsymbol{X})=$ $\operatorname{vec}(\boldsymbol{A X} \boldsymbol{B})$ we obtain:

$$
\begin{align*}
\|\boldsymbol{h}\|_{\boldsymbol{H}_{y}}^{2} & =\boldsymbol{h}^{\top} \mathcal{A}^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right) \mathcal{A} \boldsymbol{h} \\
& =\operatorname{vec}(\Delta \boldsymbol{S}(\boldsymbol{\delta}))^{\top}\left(\boldsymbol{S}_{y}^{-1} \otimes \boldsymbol{S}_{y}^{-1}\right) \operatorname{vec}(\Delta \boldsymbol{S}(\boldsymbol{\delta})) \\
& =\left\langle\operatorname{vec}(\Delta \boldsymbol{S}(\boldsymbol{\delta})), \operatorname{vec}\left(\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right)\right\rangle \\
& =\left\langle\Delta \boldsymbol{S}(\boldsymbol{\delta}), \boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta}) \boldsymbol{S}_{y}^{-1}\right\rangle \\
& =\left\|\boldsymbol{S}_{y}^{-1} \Delta \boldsymbol{S}(\boldsymbol{\delta})\right\|_{F}^{2} . \tag{8}
\end{align*}
$$

Combining (7) and (8) we obtain the desired bound on the relative change in Hessian. Finally, since $\psi(\boldsymbol{y})$ is $n$-self-concordant by standard arguments, scaling it by $\sqrt{m}$ shows that $\nabla \phi(\boldsymbol{y})^{\top}\left(\nabla^{2} \phi(\boldsymbol{y})\right)^{-1} \nabla \phi(\boldsymbol{y})=\sqrt{m} \cdot \nabla \psi(\boldsymbol{y})^{\top}\left(\nabla^{2} \psi(\boldsymbol{y})\right)^{-1} \nabla \psi(\boldsymbol{y}) \leq n \sqrt{m}$. This concludes the proof.

## A Proofs from Section 2

## A. 1 Proof of Lemma 4

Proof. We use the identity

$$
\begin{align*}
\mathcal{E}(\boldsymbol{X}) & =\operatorname{det}\left(\frac{\boldsymbol{X}^{1 / 2}+\boldsymbol{X}^{-1 / 2}}{2}\right)=\frac{1}{2^{n}} \operatorname{det}\left((\boldsymbol{X}+\boldsymbol{I}) \boldsymbol{X}^{-1 / 2}\right)  \tag{9}\\
& =\frac{1}{2^{n}} \operatorname{det}(\boldsymbol{X}+\boldsymbol{I}) \operatorname{det}\left(\boldsymbol{X}^{1 / 2}\right)^{-1}=\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{X}+\boldsymbol{I})}{\sqrt{\operatorname{det}(\boldsymbol{X})}}
\end{align*}
$$

Therefore we have

$$
\begin{aligned}
\mathcal{E}\left(\boldsymbol{X}^{\prime}\right) & =\frac{1}{2^{n}} \frac{\operatorname{det}\left(\boldsymbol{X}^{\prime}+\boldsymbol{I}\right)}{\sqrt{\operatorname{det}\left(\boldsymbol{X}^{\prime}\right)}}=\frac{1}{2^{n}} \frac{\operatorname{det}\left(\boldsymbol{X}+\boldsymbol{I}+\boldsymbol{u} \boldsymbol{u}^{\top}\right)}{\sqrt{\operatorname{det}\left(\boldsymbol{X}+\boldsymbol{u} \boldsymbol{u}^{\top}\right)}}=\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{X}+\boldsymbol{I}) \cdot\left(1+\boldsymbol{u}^{\top}(\boldsymbol{I}+\boldsymbol{X})^{-1} \boldsymbol{u}\right)}{\sqrt{\operatorname{det}(\boldsymbol{X})\left(1+\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u}\right)}} \\
& =\mathcal{E}(\boldsymbol{X}) \cdot \frac{1+\boldsymbol{u}^{\top}(\boldsymbol{I}+\boldsymbol{X})^{-1} \boldsymbol{u}}{\sqrt{1+\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u}}}
\end{aligned}
$$

where we used the identity $\operatorname{det}\left(\boldsymbol{X}+\boldsymbol{v} \boldsymbol{v}^{\top}\right)=\operatorname{det}(\boldsymbol{X})\left(1+\boldsymbol{v}^{\top} \boldsymbol{X}^{-1} \boldsymbol{v}\right)$.

## A. 2 Proof of Lemma 5

Proof. Per Lemma 4 we need to upper bound

$$
\frac{1+\boldsymbol{u}^{\top}(\boldsymbol{I}+\boldsymbol{X})^{-1} \boldsymbol{u}}{\sqrt{1+\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u}}} \leq \frac{1+\boldsymbol{u}^{\top} \boldsymbol{u}}{\sqrt{1+\gamma}}=\frac{2}{\sqrt{1+\gamma}} .
$$

We analyze the second case using the fact that $\mathcal{E}(\boldsymbol{X})=\mathcal{E}\left(\boldsymbol{X}^{-1}\right)$ and hence we can make a rank-1 update on $\boldsymbol{X}^{-1}$. More precisely, via the Sherman-Morrison formula (Lemma 6) we have:

$$
\frac{\mathcal{E}\left(\boldsymbol{X}-\frac{X u u^{\top} \boldsymbol{X}}{1+u^{\top} \boldsymbol{X} u}\right)}{\mathcal{E}(\boldsymbol{X})}=\frac{\mathcal{E}\left(\left(\boldsymbol{X}^{-1}+u u^{\top}\right)^{-1}\right)}{\mathcal{E}(\boldsymbol{X})}=\frac{\mathcal{E}\left(\boldsymbol{X}^{-1}+u u^{\top}\right)}{\mathcal{E}\left(\boldsymbol{X}^{-1}\right)} \leq \frac{2}{\sqrt{1+\gamma}} .
$$

## A. 3 Proof of Lemma 7

Proof. We apply the formula from (9), and using $\operatorname{det}(\boldsymbol{A B})=\operatorname{det}(\boldsymbol{A}) \operatorname{det}(\boldsymbol{B})$ :

$$
\begin{aligned}
\mathcal{E}(\boldsymbol{X}) & =\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{X}+\boldsymbol{I})}{\sqrt{\operatorname{det}(\boldsymbol{X})}}=\frac{1}{2^{n}} \frac{\operatorname{det}(\boldsymbol{Y}) \operatorname{det}(\boldsymbol{X}+\boldsymbol{I}) \operatorname{det}\left(\boldsymbol{Y}^{-1}\right)}{\sqrt{\operatorname{det}(\boldsymbol{Y}) \operatorname{det}(\boldsymbol{X}) \operatorname{det}\left(\boldsymbol{Y}^{-1}\right)}} \\
& =\frac{1}{2^{n}} \frac{\operatorname{det}\left(\boldsymbol{Y} \boldsymbol{X} \boldsymbol{Y}^{-1}+\boldsymbol{I}\right)}{\sqrt{\operatorname{det}\left(\boldsymbol{Y} \boldsymbol{X} \boldsymbol{Y}^{-1}\right)}}=\mathcal{E}\left(\boldsymbol{Y} \boldsymbol{X} \boldsymbol{Y}^{-1}\right) .
\end{aligned}
$$

The second property holds by definition.

## A. 4 Proof of Lemma 14

Proof. From the self-concordance property we have that if $\boldsymbol{y}^{\star}$ is the minimizer of $g_{\mu}$, then from standard arguments [Ren01] it follows that

$$
\left\|\boldsymbol{y}-\boldsymbol{y}^{\star}\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\star}}} \leq \frac{\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}}{1-\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}} \leq \frac{1}{2} .
$$

Therefore

$$
\boldsymbol{H}_{\boldsymbol{y}} \cdot\left(1-\left\|\boldsymbol{y}-\boldsymbol{y}^{\star}\right\|_{\boldsymbol{H}_{y}}\right)^{2} \preceq \boldsymbol{H}_{\boldsymbol{y}^{\star}} \preceq \boldsymbol{H}_{\boldsymbol{y}} \cdot\left(\frac{1}{1-\left\|\boldsymbol{y}-\boldsymbol{y}^{\star}\right\|_{\boldsymbol{H}_{y}}}\right)^{2}
$$

which gives

$$
\boldsymbol{H}_{\boldsymbol{y}^{\star}} \cdot \frac{1}{4} \preceq \boldsymbol{H}_{y} \preceq \boldsymbol{H}_{\boldsymbol{y}^{\star}} \cdot 4 .
$$

Using the bound from the hypothesis we obtain $\max \left\{\left\|\boldsymbol{H}_{y^{\star}}\right\|,\left\|\boldsymbol{H}_{y^{\star}}^{-1}\right\|\right\} \leq \kappa(\mu)$, which yields the claim.

## B Proofs from Section 3

## B. 1 Excentricity Certificates from the Richardson Iteration

Lemma 34. Let $\boldsymbol{H} \in \mathbb{R}^{n \times n}$, and vectors $\boldsymbol{b}, \boldsymbol{x} \in \mathbb{R}^{n}$. Let $\boldsymbol{r}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}$, and consider the step

$$
\boldsymbol{x}^{\prime}=\boldsymbol{x}+\frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle}{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}} \boldsymbol{r} .
$$

Let $\beta \in(0,1)$ be a scalar. Provided that the new residual $\boldsymbol{r}^{\prime}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}^{\prime}$ satisfies

$$
\frac{\|\boldsymbol{r}\|_{2}^{2}-\left\|\boldsymbol{r}^{\prime}\right\|_{2}^{2}}{\|\boldsymbol{r}\|_{2}^{2}} \leq \beta
$$

we obtain at least one of the following excentricity certificates:

1. $\frac{\|\boldsymbol{r}\|_{H}^{2}}{\|r\|_{2}^{2}} \leq \sqrt{\beta} \Longleftrightarrow \frac{\left\|\boldsymbol{H}^{1 / 2} r\right\|_{H-1}^{2}}{\left\|\boldsymbol{H}^{1 / 2} r\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\beta}}$,
2. $\frac{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}}{\|\boldsymbol{r}\|_{H}^{2}} \geq \frac{1}{\sqrt{\beta}} \Longleftrightarrow \frac{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{H}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\beta}}$.

Proof. We note that the step size we consider is the one that minimizes the $\ell_{2}$ norm of the new residual $\boldsymbol{r}^{\prime}$. Using this update, we measure the new norm:

$$
\begin{aligned}
\left\|\boldsymbol{r}^{\prime}\right\|_{2}^{2} & =\left\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}^{\prime}\right\|_{2}^{2}=\left\|\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}-\boldsymbol{H}\left(\boldsymbol{x}^{\prime}-\boldsymbol{x}\right)\right\|_{2}^{2}=\left\|\boldsymbol{r}-\boldsymbol{H}\left(\boldsymbol{x}^{\prime}-\boldsymbol{x}\right)\right\|_{2}^{2} \\
& =\left\|\boldsymbol{r}-\boldsymbol{H} \cdot \frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle}{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}} \boldsymbol{r}\right\|_{2}^{2}=\|\boldsymbol{r}\|_{2}^{2}+\frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle^{2}}{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{4}}\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}-2 \cdot \frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle^{2}}{\|\boldsymbol{H}\|_{2}^{2}} \\
& =\|\boldsymbol{r}\|_{2}^{2}-\frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle^{2}}{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}} .
\end{aligned}
$$

Therefore we can write multiplicative progress as:

$$
\frac{\|\boldsymbol{r}\|_{2}^{2}-\left\|\boldsymbol{r}^{\prime}\right\|_{2}^{2}}{\|\boldsymbol{r}\|_{2}^{2}}=\frac{\langle\boldsymbol{r}, \boldsymbol{H} \boldsymbol{r}\rangle^{2}}{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}\|\boldsymbol{r}\|_{2}^{2}} \leq \beta
$$

Hence failure to make a lot of progress gives us that one of the two following conditions must be true. Either $\|\boldsymbol{r}\|_{2} \geq\|\boldsymbol{H} \boldsymbol{r}\|_{2}$, in which case the upper bound on multiplicative progress implies that

$$
\frac{\|\boldsymbol{r}\|_{\boldsymbol{H}}^{4}}{\|\boldsymbol{r}\|_{2}^{4}} \leq \beta \Longleftrightarrow \frac{\|\boldsymbol{r}\|_{\boldsymbol{H}}^{2}}{\|\boldsymbol{r}\|_{2}^{2}} \leq \sqrt{\beta} \Longleftrightarrow \frac{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{\boldsymbol{H}^{-1}}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\beta}} .
$$

Otherwise we must have $\|\boldsymbol{H} \boldsymbol{r}\|_{2} \geq\|\boldsymbol{r}\|_{2}$, in which case we have

$$
\frac{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{4}}{\|\boldsymbol{r}\|_{H}^{4}} \geq \frac{1}{\beta} \Longleftrightarrow \frac{\|\boldsymbol{H} \boldsymbol{r}\|_{2}^{2}}{\|\boldsymbol{r}\|_{H}^{2}} \geq \frac{1}{\sqrt{\beta}} \Longleftrightarrow \frac{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \boldsymbol{r}\right\|_{2}^{2}} \geq \frac{1}{\sqrt{\beta}} .
$$

This concludes the proof.

## B. 2 Proof of Lemma 15

Proof. We perform the change of variable $\boldsymbol{y}=\widetilde{\boldsymbol{H}}^{1 / 2} \boldsymbol{x}$ and consider the equivalent system $\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2} \cdot \boldsymbol{y}=\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{b}$. Let the non-preconditioned residual $\boldsymbol{r}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}$, and let the preconditioned residual $\widehat{\boldsymbol{r}}=\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{b}-\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{y}\right)=\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r}$. Per Lemma 34, the iteration

$$
\boldsymbol{y}^{\prime}=\boldsymbol{y}+\frac{\left\langle\widehat{\boldsymbol{r}},\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widehat{\boldsymbol{r}}\right\rangle}{\left\|\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widehat{\boldsymbol{r}}\right\|_{2}^{2}} \cdot \widehat{\boldsymbol{r}}
$$

maps back to

$$
\begin{aligned}
\boldsymbol{x}^{\prime} & =\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{y}^{\prime}=\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{y}+\frac{\left\langle\widehat{\boldsymbol{r}},\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widehat{\boldsymbol{r}}\right\rangle}{\left\|\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widehat{\boldsymbol{r}}\right\|_{2}^{2}} \cdot \widehat{\boldsymbol{r}}\right) \\
& =\boldsymbol{x}+\frac{\left\langle\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r},\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r}\right\rangle}{\left\|\left(\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right) \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r}\right\|_{2}^{2}} \cdot \widetilde{\boldsymbol{H}}^{-1 / 2} \cdot \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r} \\
& =\boldsymbol{x}+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}{\left\|\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}^{-1}}^{2}} \cdot \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r},
\end{aligned}
$$

in the original parametrization. The condition on the decrease in $\|\widehat{\boldsymbol{r}}\|$ maps back to

$$
\frac{\|\widehat{\boldsymbol{r}}\|_{2}^{2}-\left\|\widehat{\boldsymbol{r}}^{\prime}\right\|_{2}^{2}}{\|\widehat{\boldsymbol{r}}\|_{2}^{2}}=\frac{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}-\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \leq \beta
$$

Finally, the provided excentricity certificates are either
or

$$
\frac{\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2} \cdot \widehat{\boldsymbol{r}}\right\|_{2}^{2}}{\|\widehat{\boldsymbol{r}}\|_{\widetilde{\boldsymbol{H}}^{-1 / 2}}^{2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}}=\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}^{1 / 2}}^{2} \geq \frac{1}{\sqrt{\beta}}, ~ \text { H } \boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \|_{2}^{2}}{\text {, }}
$$

which concludes the proof.

## B. 3 Proof of Lemma 16

Proof. We analyze each of the two types of certificates.
Type 1. Letting $\boldsymbol{X}=\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}$ and $\boldsymbol{u}=\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}$, we have $\boldsymbol{u}^{\top} \boldsymbol{X} \boldsymbol{u} \geq \frac{1}{\sqrt{\beta}} \boldsymbol{u}^{\top} \boldsymbol{u}$. Using Lemma 5 we obtain that changing the preconditioner to $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\begin{aligned}
\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1 / 2} & =\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}-\frac{\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top} \boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}^{2}+\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}^{-1 / 2}} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}} \\
& =\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}-\frac{\boldsymbol{H}^{-1 / 2} \boldsymbol{r} \boldsymbol{r}^{\top} \boldsymbol{H}^{-1 / 2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}+\|\boldsymbol{r}\|_{\boldsymbol{H}^{-1}}^{2}},
\end{aligned}
$$

and equivalently setting

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}-\frac{r \boldsymbol{r}^{\top}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}+\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}},
$$

we obtain

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{1}{\sqrt{\beta}}}} .
$$

Type 2. Letting $\boldsymbol{X}=\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}$ and $\boldsymbol{u}=\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}$, we have $\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u} \geq \frac{1}{\sqrt{\beta}} \boldsymbol{u}^{\top} \boldsymbol{u}$. Using Lemma 5 we obtain that changing the preconditioner to $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}} \boldsymbol{H}^{-1 / 2}=\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}+\frac{\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}^{2}}
$$

and equivalently setting

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}+\frac{\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{\boldsymbol{H}}^{2}}
$$

we obtain

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{1}{\sqrt{\beta}}}}
$$

We describe the preconditioner updates in Algorithm 1. The updates to the inverse preconditioner $\widetilde{\boldsymbol{H}}^{-1}$ follow from applying the Sherman-Morrison formula (Lemma 6).

Change in preconditioner norm. Now, we verify that the updates do not increase the norms of $\widetilde{\boldsymbol{H}}^{\prime}$ and $\widetilde{\boldsymbol{H}}^{\prime-1}$ by too much compared to those of $\widetilde{\boldsymbol{H}}$ and $\widetilde{\boldsymbol{H}}^{-1}$, respectively. Whenever the preconditioner norm increases, it is because of a type 2 certificate, in which case we have:

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}+\frac{\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} r \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}=\widetilde{\boldsymbol{H}}^{1 / 2}\left(\boldsymbol{I}+\frac{\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}\right) \widetilde{\boldsymbol{H}}^{1 / 2}
$$

and therefore

$$
\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\| \leq 1+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\|}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}=1+\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}^{1 / 2}}^{2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{H}^{1 / 2}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}
$$

At this point we use the fact that the decrease in excentricity is determined by the magnitude of the eigenvalue proved by the certificate. In fact, setting $\beta$ to match exactly the ratio $\beta=$ $\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u} / \boldsymbol{u}^{\top} \boldsymbol{u}$, we have:

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H^{1 / 2} \tilde{\tilde{L}}^{-1} H^{1 / 2}}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}}}},
$$

and combining with the previous inequality we can now upper bound:

$$
\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}^{\prime}} \boldsymbol{H}^{-1}\right)}\right)^{2}
$$

The other case is similar. Whenever the inverse preconditioner norm increases, it is because of a type 1 certificate, in which case we have:

$$
\widetilde{\boldsymbol{H}}^{\prime^{-1}}=\widetilde{\boldsymbol{H}}^{-1}+\frac{\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}=\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{I}+\frac{\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1 / 2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}}\right) \widetilde{\boldsymbol{H}}^{-1 / 2},
$$

so

$$
\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \widetilde{\boldsymbol{H}}^{\prime-1} \widetilde{\boldsymbol{H}}^{1 / 2}\right\| \leq 1+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{r}\right\|_{2}^{2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}}^{2}} .
$$

Again we use the fact that the decrease in excentricity is determined by the magnitude of the eigenvalue proved by the certificate. Setting $\beta$ to match exactly the ratio $\beta=\boldsymbol{u}^{\top} \boldsymbol{X} \boldsymbol{u} / \boldsymbol{u}^{\top} \boldsymbol{u}$, we have:

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{H^{-1 / 2} \tilde{H} H^{-1 / 2}}^{2}}{\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{2}^{2}}}}=\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} r\right\|_{2}^{2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{H}^{2}}}},
$$

and combining with the previous inequality we upper bound:

$$
\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \widetilde{\boldsymbol{H}}^{\prime-1} \widetilde{\boldsymbol{H}}^{1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right)}\right)^{2} .
$$

## B. 4 Proof of Lemma 17

Proof. Let $\boldsymbol{r}_{t}=\boldsymbol{b}-\boldsymbol{H} \boldsymbol{x}_{t}$. We note that for any vector $\boldsymbol{v}$, and any $\widetilde{\boldsymbol{H}}, \widetilde{\boldsymbol{H}}{ }^{\prime}$,

$$
\|\boldsymbol{v}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}=\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{v}\right\|_{2}^{2}=\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}^{1 / 2}} \cdot \widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}^{-1 / 2}} \boldsymbol{v}\right\|_{2}^{2} \leq\left\|\widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}^{1 / 2}} \widetilde{\boldsymbol{H}}^{-1} \widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}^{1 / 2}}\right\| \cdot\|\boldsymbol{v}\|_{\widetilde{\boldsymbol{H}}^{\prime-1}}^{2} .
$$

Using this inequality, we can write:

$$
\begin{aligned}
\left\|\boldsymbol{r}_{T}\right\|^{2} & \leq\left(\prod_{t=0}^{T-1}\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\|\right)\left\|\widetilde{\boldsymbol{H}}_{T}^{-1 / 2} \boldsymbol{r}_{T}\right\|_{2}^{2} \\
& =\left(\prod_{t=0}^{T-1}\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\|\right)\left(\prod_{t=0}^{t-1} \frac{\left\|\widetilde{\boldsymbol{H}}_{t+1}^{-1 / 2} \boldsymbol{r}_{t+1}\right\|^{2}}{\left\|\widetilde{\boldsymbol{H}}_{t}^{-1 / 2} \boldsymbol{r}_{t}\right\|^{2}}\right)\left\|\widetilde{\boldsymbol{H}}_{0}^{-1 / 2} \boldsymbol{r}_{0}\right\|_{2}^{2} \\
& \leq \prod_{t=0}^{T-1}\left(\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\| \cdot \frac{\left\|\boldsymbol{r}_{t+1}\right\|_{\widetilde{\boldsymbol{H}}_{t+1}^{-1}}^{2}}{\| \boldsymbol{r}_{t} \widetilde{\widetilde{\boldsymbol{H}}}_{t}^{-1}}\right) \cdot\left\|\boldsymbol{r}_{0}\right\|_{\widetilde{\boldsymbol{H}}_{0}^{-1}}^{2} \\
& =\Phi_{T} \cdot\left\|\boldsymbol{r}_{0}\right\|_{\widetilde{\boldsymbol{H}}_{0}^{-1}}^{2}
\end{aligned}
$$

where we use the potential function $\Phi$ defined as

$$
\Phi_{t}= \begin{cases}1, & \text { if } t=0 \\ \prod_{t=0}^{t-1}\left(\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\| \cdot \frac{\left\|r_{t+1}\right\|_{\widetilde{\boldsymbol{H}}_{t+1}^{-1}}^{2}}{\left\|\boldsymbol{r}_{t}\right\|_{\widetilde{\boldsymbol{H}}_{t}^{-1}}^{2}}\right), & \text { if } t \geq 1\end{cases}
$$

Now we see how $\Phi_{t}$ evolves. There are two cases. In the former, $\left\|\boldsymbol{r}_{t+1}\right\|_{\widetilde{\boldsymbol{H}}_{t+1}^{-1}}^{2} \leq(1-\beta)\left\|\boldsymbol{r}_{t}\right\|_{\widetilde{\boldsymbol{H}}_{t}^{-1}}^{2}$ and thus the preconditioner stays unchanged, so $\Phi_{t} \leq(1-\beta) \Phi_{t-1}$. In the latter we perform a preconditioner update, but keep the iterate unchanged $\boldsymbol{r}_{t+1}=\boldsymbol{r}_{t}$. Based on Lemma 16, there are two possibilities.

If $1 \leq\left\|\widetilde{\boldsymbol{H}}_{t}^{-1 / 2} \widetilde{\boldsymbol{H}}_{t+1} \widetilde{\boldsymbol{H}}_{t}^{-1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}_{t+1} \boldsymbol{H}^{-1}\right)}\right)^{2}$, then $\left\|\boldsymbol{r}_{t+1}\right\|_{\widetilde{\boldsymbol{H}}_{t+1}^{-1}} \leq\left\|\boldsymbol{r}_{t+1}\right\|_{\widetilde{\boldsymbol{H}}_{t}^{-1}}$, but $\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\|=\left\|\widetilde{\boldsymbol{H}}_{t}^{-1 / 2} \widetilde{\boldsymbol{H}}_{t+1} \widetilde{\boldsymbol{H}}_{t}^{-1 / 2}\right\|$ and therefore

$$
\Phi_{t} \leq \Phi_{t-1} \cdot\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}_{t+1} \boldsymbol{H}^{-1}\right)}\right)^{2}
$$

If $1 \leq\left\|\widetilde{\boldsymbol{H}}_{t}^{1 / 2} \widetilde{\boldsymbol{H}}_{t+1}^{-1} \widetilde{\boldsymbol{H}}_{t}^{1 / 2}\right\| \leq\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} H^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}_{t+1} \boldsymbol{H}^{-1}\right)}\right)^{2}$, then $\left\|\widetilde{\boldsymbol{H}}_{t+1}^{1 / 2} \widetilde{\boldsymbol{H}}_{t}^{-1} \widetilde{\boldsymbol{H}}_{t+1}^{1 / 2}\right\|=\frac{1}{\left\|\widetilde{\boldsymbol{H}}_{t}^{1 / 2} \widetilde{\boldsymbol{H}}_{t+1}^{-1} \widetilde{\boldsymbol{H}}_{t}^{1 / 2}\right\|} \leq 1$, but $\frac{\left\|\boldsymbol{r}_{t+1}\right\|_{\tilde{\boldsymbol{H}}_{t+1}^{-1}}^{2}}{\left\|\boldsymbol{r}_{t}\right\|_{\tilde{\boldsymbol{H}}_{t}^{-1}}^{2}}=\frac{\left\|\widetilde{\boldsymbol{H}}_{t}^{-1 / 2} \boldsymbol{r}_{t}\right\|_{\widetilde{\boldsymbol{H}}_{t}^{1 / 2} \widetilde{\boldsymbol{H}}_{++1}^{-1} \widetilde{\boldsymbol{H}}_{t}^{1 / 2}}^{2}}{\left\|\widetilde{\boldsymbol{H}}_{t}^{-1 / 2} r_{t}\right\|_{2}^{2}} \leq\left\|\widetilde{\boldsymbol{H}}_{t}^{1 / 2} \widetilde{\boldsymbol{H}}_{t+1}^{-1} \widetilde{\boldsymbol{H}}_{t}^{1 / 2}\right\|$, and therefore

$$
\Phi_{t} \leq \Phi_{t-1} \cdot\left(2 \cdot \frac{\mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right)}{\mathcal{E}\left(\widetilde{\boldsymbol{H}}_{t+1} \boldsymbol{H}^{-1}\right)}\right)^{2}
$$

Finally since whenever the preconditioner changes, excentricity gets reduced in the worst case by a factor of $\frac{2}{\sqrt{1+\frac{1}{\sqrt{\beta}}}} \geq \beta^{1 / 4}\left(\right.$ Lemma 34), this can happen at most $T_{\text {prec }}=\frac{4 \log \mathcal{E}\left(X_{0}\right)}{\log (1 / \beta)}$ times, since $\mathcal{E}(\boldsymbol{X}) \geq 1$ at all times. Therefore letting

$$
T=T_{\text {prec }}+\log _{1-\beta} \varepsilon=\frac{4 \log \mathcal{E}\left(\boldsymbol{X}_{0}\right)}{\log \left(\frac{1}{\beta}\right)}+\frac{\log (1 / \varepsilon)}{\log (1 /(1-\beta))}
$$

we are guaranteed that

$$
\Phi_{T} \leq \Phi_{0}(1-\beta)^{T-T_{\text {prec }}}=\Phi_{0} \cdot \varepsilon=\varepsilon,
$$

which yields $\left\|\boldsymbol{r}_{T}\right\|_{2}^{2} \leq \varepsilon\left\|\boldsymbol{r}_{0}\right\|_{2}^{2}$. Finally, setting $\beta=\frac{1}{2}$, we obtain $T=O\left(\log \mathcal{E}\left(\boldsymbol{X}_{0}\right)+\log \frac{1}{\varepsilon}\right)$, which concludes the proof.

## C Proofs from Section 4

## C. 1 Robustness Proofs

Lemma 35. Let a vector $\boldsymbol{u}$ and an over-estimate for its norm $n(\boldsymbol{u})$ such that $\|\boldsymbol{u}\| \leq n(\boldsymbol{u}) \leq\|\boldsymbol{u}\| \cdot \alpha$ for some $\alpha \geq 1$. If $\boldsymbol{u}$ satisfies

1. $\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u} \geq \gamma \cdot \boldsymbol{u}^{\top} \boldsymbol{u}$, then $\frac{\mathcal{E}\left(\boldsymbol{X}+\frac{u u^{\top}}{n(u)^{2}}\right)}{\mathcal{E}(\boldsymbol{X})} \leq \frac{2}{\sqrt{1+\frac{\gamma}{\alpha^{2}}}}$,
2. $\boldsymbol{u}^{\top} \boldsymbol{X} \boldsymbol{u} \geq \gamma \cdot \boldsymbol{u}^{\top} \boldsymbol{u}$, then $\frac{\mathcal{E}\left(X-\frac{X_{u}{ }^{\top} \boldsymbol{X}}{n(\underline{u})^{2}+u^{\top} \boldsymbol{X} u}\right)}{\mathcal{E}(\boldsymbol{X})} \leq \frac{2}{\sqrt{1+\frac{\gamma}{\alpha^{2}}}}$.

Proof. We use a similar proof to the one for Lemma 5. In the first case, using Lemma 4, we obtain

$$
\frac{\mathcal{E}\left(\boldsymbol{X}+\frac{u u^{\top}}{n(u)^{2}}\right)}{\mathcal{E}(\boldsymbol{X})}=\frac{1+\frac{u^{\top}(\boldsymbol{I}+\boldsymbol{X})^{-1} u}{n(\boldsymbol{u})^{2}}}{\sqrt{1+\frac{u^{\top} X^{-1} u}{n(u)^{2}}}} \leq \frac{2}{\sqrt{1+\frac{u^{\top} X^{-1} u}{n(u)^{2}}}} \leq \frac{2}{\sqrt{1+\frac{u^{\top} X^{-1} u}{\alpha^{2}\|u\|^{2}}}} \leq \frac{2}{\sqrt{1+\frac{\gamma}{\alpha^{2}}}} .
$$

For the second case we use the fact that excentricity is invariant under inversion, and hence

$$
\begin{aligned}
\frac{\mathcal{E}\left(\boldsymbol{X}-\frac{X u u^{\top} X}{n(u)^{2}+u^{\top} X u}\right)}{\mathcal{E}(\boldsymbol{X})} & =\frac{\mathcal{E}\left(\boldsymbol{X}-\frac{\left.\frac{X_{u u^{\top} X}^{n(u)^{2}}}{1+\frac{u^{\top} u}{n(u)^{2}}}\right)}{\mathcal{E}(\boldsymbol{X})}\right.}{=}=\frac{\mathcal{E}\left(\left(\boldsymbol{X}^{-1}+\frac{u u^{\top}}{n(u)^{2}}\right)^{-1}\right)}{\mathcal{E}(\boldsymbol{X})}=\frac{\mathcal{E}\left(\boldsymbol{X}^{-1}+\frac{u u^{\top}}{n(u)^{2}}\right)}{\mathcal{E}\left(\boldsymbol{X}^{-1}\right)} \\
& \leq \frac{2}{\sqrt{1+\frac{\gamma}{\alpha^{2}}}} .
\end{aligned}
$$

## C. 2 Lemmas for Estimating Hessian-Vector Products

The following two estimation lemmas use properties of self-concordant functions.
Lemma 36. Let $g: K \rightarrow \mathbb{R}$ be a self-concordant function, let $\boldsymbol{y} \in \operatorname{int}(K)$ and let $\boldsymbol{H}_{y}:=\nabla^{2} g(\boldsymbol{y})$ be the Hessian at $\boldsymbol{y}$, which satisfies $\left\|\boldsymbol{H}_{\boldsymbol{y}}\right\| \leq B$. Then for any vector $\boldsymbol{v} \in \mathbb{R}^{n}$, using two calls to $a$ gradient oracle for $g$ we can obtain an estimate

$$
\begin{aligned}
n_{\boldsymbol{y}}(\boldsymbol{v}) & =\left(\frac{1}{1-\frac{1}{1000}}\right) \cdot \sqrt{\frac{1}{\tau} \cdot\langle\boldsymbol{v}, \nabla g(\boldsymbol{y}+\tau \boldsymbol{v})-\nabla g(\boldsymbol{y})\rangle} \text {, where } \\
\tau & =\frac{1}{1000\|\boldsymbol{v}\| B},
\end{aligned}
$$

such that

$$
\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \leq n_{y}(\boldsymbol{v}) \leq\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \cdot\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} .
$$

Proof. We proceed to analyze the quality of the approximation. Since

$$
\nabla g(\boldsymbol{y}+\tau \boldsymbol{v})-\nabla g(\boldsymbol{y})=\left(\int_{0}^{1} \nabla^{2} g(\boldsymbol{y}+t \cdot \tau \boldsymbol{v}) d t\right) \cdot(\tau \boldsymbol{v}),
$$

we have

$$
\begin{aligned}
n_{\boldsymbol{y}}(\boldsymbol{v}) & =\frac{1}{1-\frac{1}{1000}} \cdot \sqrt{\frac{1}{\tau} \cdot\left\langle\boldsymbol{v},\left(\int_{0}^{1} \nabla^{2} g(\boldsymbol{y}+t \cdot \tau \boldsymbol{v}) d t\right) \tau \boldsymbol{v}\right\rangle} \\
& =\frac{1}{1-\frac{1}{1000}} \cdot\left\langle\boldsymbol{v},\left(\int_{0}^{1} \nabla^{2} g(\boldsymbol{y}+t \cdot \tau \boldsymbol{v}) d t\right) \boldsymbol{v}\right\rangle^{1 / 2} .
\end{aligned}
$$

Using the bound

$$
\|\tau \boldsymbol{v}\|_{\boldsymbol{H}_{y}} \leq \tau \cdot\|\boldsymbol{v}\| \cdot\left\|\boldsymbol{H}_{y}\right\| \leq \tau \cdot\|\boldsymbol{v}\| \cdot B=\frac{1}{1000}
$$

we apply self-concordance to sandwich

$$
\left(1-\|\tau \boldsymbol{v}\|_{\boldsymbol{H}_{y}}\right)^{2} \cdot \boldsymbol{H}_{y} \preceq \nabla^{2} g(\boldsymbol{y}+t \cdot \tau \boldsymbol{v}) \preceq\left(\frac{1}{1-\|\tau \boldsymbol{v}\|_{\boldsymbol{H}_{y}}}\right)^{2} \cdot \boldsymbol{H}_{y}
$$

which also implies that our query point is feasible, since the Hessian stays bounded throughout the entire path between $\boldsymbol{y}$ and $\boldsymbol{y}+\tau \boldsymbol{v}$.

$$
\left(1-\frac{1}{1000}\right)^{2} \cdot \boldsymbol{H}_{y} \preceq \nabla^{2} g(\boldsymbol{y}+t \cdot \tau \boldsymbol{v}) \preceq\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} \cdot \boldsymbol{H}_{\boldsymbol{y}} .
$$

Plugging this back into our identity for $n_{y}(\boldsymbol{v})$ we have that

$$
\frac{1}{1-\frac{1}{1000}} \cdot\left(1-\frac{1}{1000}\right) \cdot\|\boldsymbol{v}\|_{H_{y}} \leq n_{y}(\boldsymbol{v}) \leq\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} \cdot\|\boldsymbol{v}\|_{H_{y}}
$$

which concludes the proof.
Lemma 37. Let $g: \mathbb{R}^{n} \rightarrow \mathbb{R}$ be a self-concordant function, let $\boldsymbol{y} \in \mathbb{R}^{n}$ and let $\boldsymbol{H}_{y}:=\nabla^{2} g(\boldsymbol{y})$ be the Hessian at $\boldsymbol{y}$, which satisfies $\left\|\boldsymbol{H}_{y}\right\| \leq B$, for $B \geq 1$. Then for any vector $\boldsymbol{v} \in \mathbb{R}^{n}$, using two calls to a gradient oracle for $g$ we can obtain an estimate for the Hessian vector product:

$$
\begin{aligned}
p_{y}(\boldsymbol{v}) & =\frac{1}{\tau}(\nabla g(\boldsymbol{y}+\tau \boldsymbol{v})-\nabla g(\boldsymbol{y})), \text { where } \\
\tau & =\frac{1}{1000\|\boldsymbol{v}\| B^{21}},
\end{aligned}
$$

such that

$$
\left\|p_{y}(\boldsymbol{v})-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\boldsymbol{H}_{y}^{-1}} \leq \frac{1}{400 \cdot B^{20}}\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} .
$$

Proof. We proceed to analyze the error. For the same reason as in the proof of Lemma 36, the query point is feasible. Letting $\overline{\boldsymbol{H}}_{\tau}=\int_{0}^{1} \boldsymbol{H}_{y+t \tau v} d t$, we can write $p_{\boldsymbol{y}}(\boldsymbol{v})=\frac{1}{\tau} \overline{\boldsymbol{H}}_{\tau} \cdot(\tau \boldsymbol{v})=\overline{\boldsymbol{H}}_{\tau} \boldsymbol{v}$. Therefore using self-concordance we bound:

$$
\begin{aligned}
\left\|p_{\boldsymbol{y}}(\boldsymbol{v})-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\boldsymbol{H}_{y}^{-1}} & =\left\|\boldsymbol{H}_{y}^{-1 / 2}\left(\overline{\boldsymbol{H}}_{\tau}-\boldsymbol{H}_{y}\right) \boldsymbol{H}_{y}^{-1 / 2} \cdot \boldsymbol{H}_{y}^{1 / 2} \boldsymbol{v}\right\|_{2} \leq\left\|\boldsymbol{H}_{y}^{-1 / 2}\left(\overline{\boldsymbol{H}}_{\tau}-\boldsymbol{H}_{y}\right) \boldsymbol{H}_{y}^{-1 / 2}\right\|\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \\
& \leq\left(\left(\frac{1}{1-\tau\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}}}\right)^{2}-1\right)\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \leq\left(\left(\frac{1}{1-\tau \cdot\left\|\boldsymbol{H}_{y}\right\|\|\boldsymbol{v}\|}\right)^{2}-1\right)\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \\
& \leq\left(\left(\frac{1}{1-\frac{1}{1000 \cdot B^{20}}}\right)^{2}-1\right)\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \leq \frac{1}{400 \cdot B^{20}}\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} .
\end{aligned}
$$

## C. 3 Proof of Lemma 18

Proof. We perform the appropriate error analysis by comparing the residual obtained using the estimators $p_{y}$ and $n_{y}$ to the one we would have obtained had we used exact access to the matrix $\boldsymbol{H}_{\boldsymbol{y}}$ instead. First we use the fact that

$$
\left\|\widetilde{\boldsymbol{H}}^{-1} r\right\|_{\boldsymbol{H}_{y}} \leq n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right) \leq\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}} \cdot\left(\frac{1}{1-\frac{1}{1000}}\right)^{2}
$$

and

$$
\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}=\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}+\left(\boldsymbol{H}_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)-p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}
$$

We bound

$$
\begin{align*}
& \left\|\boldsymbol{H}_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}  \tag{10}\\
& =\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2} \cdot \boldsymbol{H}_{y}^{-1 / 2}\left(\boldsymbol{H}_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right)\right\|_{2} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\|\left\|\boldsymbol{H}_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\left\|\boldsymbol{H}_{y}^{-1 / 2} \widetilde{\boldsymbol{H}}^{1 / 2}\right\|\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2} \cdot \boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2} \\
& =\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\|\left\|\boldsymbol{H}_{y}^{-1 / 2} \widetilde{\boldsymbol{H}}^{1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \\
& \leq \frac{1}{400 \cdot B^{18}} \cdot\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}, \tag{11}
\end{align*}
$$

which gives us that

$$
\begin{equation*}
\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \cdot\left(1-\frac{1}{400 B^{18}}\right) \leq\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \cdot\left(1+\frac{1}{400 B^{18}}\right) . \tag{12}
\end{equation*}
$$

Thus we can sandwich

$$
\begin{equation*}
\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}}{\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}} \cdot \frac{1}{\left(1+\frac{1}{400 B^{18}}\right)} \leq \frac{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)}{\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}} \leq \frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}}{\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}} \cdot \frac{\left(\frac{1}{1-\frac{1}{1000}}\right)^{2}}{\left(1-\frac{1}{400 B^{18}}\right)} . \tag{13}
\end{equation*}
$$

Additionally, we can measure the residual error. Given an arbitrary vector $\boldsymbol{v}$, we have

$$
\left\|\boldsymbol{b}-p_{y}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}=\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}+\boldsymbol{H}_{y} \boldsymbol{v}-p_{y}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}
$$

and we bound

$$
\begin{align*}
\left\|\boldsymbol{H}_{y} \boldsymbol{v}-p_{y}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}} & =\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2} \cdot \boldsymbol{H}_{y}^{-1 / 2}\left(\boldsymbol{H}_{y} \boldsymbol{v}-p_{\boldsymbol{y}}(\boldsymbol{v})\right)\right\|_{2} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\| \cdot\left\|\boldsymbol{H}_{y} \boldsymbol{v}-p_{y}(\boldsymbol{v})\right\|_{\boldsymbol{H}_{y}-1} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\|\boldsymbol{v}\|_{\boldsymbol{H}_{y}} \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \boldsymbol{H}_{y}^{-1 / 2}\right\|\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2} \cdot \boldsymbol{H}_{y}^{1 / 2} \boldsymbol{v}\right\|_{2} \\
& =\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y}^{1 / 2}\right\|\left\|\widetilde{\boldsymbol{H}}^{1 / 2} \boldsymbol{H}_{y}^{-1 / 2}\right\| \cdot \frac{1}{400 \cdot B^{20}} \cdot\left\|\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \\
& \leq \frac{1}{400 \cdot B^{18}} \cdot\left\|\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \\
& \leq \frac{1}{400 \cdot B^{18}} \cdot\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}+\frac{1}{400 \cdot B^{18}}\|\boldsymbol{b}\|_{\widetilde{\boldsymbol{H}}^{-1}} \\
& \leq \frac{1}{400 \cdot B^{18}} \cdot\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}+\frac{1}{400 \cdot B^{16}} \cdot \tag{14}
\end{align*}
$$

from where we conclude that

$$
\begin{align*}
\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} & \left(1-\frac{1}{400 \cdot B^{18}}\right)-\frac{1}{400 \cdot B^{16}} \leq\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}  \tag{15}\\
& \leq\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{400 \cdot B^{18}}\right)+\frac{1}{400 \cdot B^{16}} .
\end{align*}
$$

Hence provided that

$$
\frac{1}{B} \leq\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}
$$

as guaranteed in the statement, we additionally have $\frac{1}{400 \cdot B^{16}} \leq \frac{1}{400 \cdot B^{15}} \cdot\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}$, and thus

$$
\begin{aligned}
& \left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1-\frac{1}{400 \cdot B^{18}}\right)\left(1+\frac{1}{400 \cdot B^{15}}\right)^{-1} \\
& \leq\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{400 \cdot B^{18}}\right)\left(1+\frac{1}{400 \cdot B^{15}}\right),
\end{aligned}
$$

which implies the simpler condition that

$$
\begin{equation*}
\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1-\frac{1}{200 \cdot B^{15}}\right) \leq\left\|\boldsymbol{b}-p_{y}(\boldsymbol{v})\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{200 \cdot B^{15}}\right) . \tag{16}
\end{equation*}
$$

Performing a similar analysis we can show that

$$
\begin{align*}
& \left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1-\frac{1}{200 \cdot B^{9}}\right) \\
& \leq\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{v})\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \leq\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(1+\frac{1}{200 \cdot B^{9}}\right),  \tag{17}\\
& \left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{v}\right)\right\|_{\boldsymbol{H}_{y}}\left(1-\frac{1}{200 \cdot B^{9}}\right) \\
& \leq\left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{y}(\boldsymbol{v})\right)\right\|_{\boldsymbol{H}_{y}} \leq\left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{v}\right)\right\|_{\boldsymbol{H}_{y}}\left(1+\frac{1}{200 \cdot B^{9}}\right) \tag{18}
\end{align*}
$$

Now we consider the new residual $\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{H}^{-1}}^{2}$. Provided that $\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{H}^{-1}}^{2} \geq \frac{1}{B}$, as specified in the hypothesis, we can bound it as

$$
\begin{aligned}
& \left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}=\left\|\boldsymbol{b}-p_{y}\left(\boldsymbol{x}^{\prime}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1} \leq\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2}}^{=\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}-\boldsymbol{H}_{y}\left(\frac{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}}{\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{y}(\boldsymbol{x})\right)\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2}} \\
& =\left(\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}+\frac{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{4}}{\left\|p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{4}} \cdot\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\right. \\
& \left.-2 \cdot \frac{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}}{\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}\left\langle\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right), \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\rangle\right) \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2} .
\end{aligned}
$$

We lower bound, using $\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \geq 1 / B$,

$$
\begin{align*}
& \left\langle\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right), \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\rangle \\
= & \left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\|_{\boldsymbol{H}_{y}}^{2}-\left\langle\widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right), \widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1 / 2} \cdot \widetilde{\boldsymbol{H}}^{-1 / 2}\left(\boldsymbol{H}_{y} \boldsymbol{x}-p_{y}(\boldsymbol{x})\right)\right\rangle \\
\geq & \left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\|_{\boldsymbol{H}_{y}}^{2}-\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\|\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left\|p_{\boldsymbol{y}}(\boldsymbol{x})-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}} \\
\geq & \left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\|_{\boldsymbol{H}_{y}}^{2} \\
& -\left\|\widetilde{\boldsymbol{H}}^{-1 / 2} \boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1 / 2}\right\|_{\left\|\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right\|_{\widetilde{\boldsymbol{H}}^{-1}}\left(\frac{1}{400 \cdot B^{18}} \cdot\left\|\boldsymbol{b}-\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}+\frac{1}{400 \cdot B^{16}}\right)}^{\geq} \begin{array}{l} 
\\
\\
-\frac{1}{400 \cdot \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\left\|_{\boldsymbol{H}_{y}}^{2}-\frac{1}{400 \cdot B^{16}}\right\| \boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\left\|_{\widetilde{\boldsymbol{H}}^{-1}}\right\| \boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\left\|_{\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{x}}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}} \\
\geq \\
\geq \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\left\|_{\boldsymbol{H}_{y}}^{2}-\frac{1}{200 \cdot B^{15}}\right\| \boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\left\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}-\frac{1}{400 \cdot B^{14}}\right\| \boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x}) \|_{\widetilde{\boldsymbol{H}}^{-1}} \\
\geq \\
\geq \\
\geq \widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right) \|_{\boldsymbol{H}_{y}}^{2}\left(1-\frac{1}{200 \cdot B^{15}}-\frac{1}{400 \cdot B^{14}}\right) \\
\geq
\end{array}\left\|\widetilde{\boldsymbol{H}}^{-1}\left(\boldsymbol{b}-p_{\boldsymbol{y}}(\boldsymbol{x})\right)\right\|_{\boldsymbol{H}_{y}}^{2}\left(1-\frac{1}{200 \cdot B^{14}}\right) .
\end{align*}
$$

Returning to our inequality on the new residual, using $(16),(13),(19)$ we obtain:

$$
\begin{aligned}
& \left\|r^{\prime}\right\|_{\widetilde{H}^{-1}}^{2} \\
& \leq\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{4} \\
& +\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{4}}\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \cdot \frac{\left(\frac{1}{1-\frac{1}{1000}}\right)^{8}}{\left(1-\frac{1}{400 B^{18}}\right)^{4}} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2} \\
& -2 \cdot \frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{2}}{\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{2}\left(1-\frac{1}{200 \cdot B^{14}}\right)^{2} \cdot \frac{1}{\left(1+\frac{1}{400 B^{18}}\right)}\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2} \\
& \leq\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{4} \\
& -\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \\
& \left(2\left(1-\frac{1}{200 \cdot B^{14}}\right)^{2} \cdot \frac{1}{\left(1+\frac{1}{400 B^{18}}\right)}\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2}-\frac{\left(\frac{1}{1-\frac{1}{1000}}\right)^{8}}{\left(1-\frac{1}{400 B^{18}}\right)^{4}} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{2}\right) \\
& \leq\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2} \cdot\left(1+\frac{1}{200 \cdot B^{15}}\right)^{4}-\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \cdot \frac{9}{10} .
\end{aligned}
$$

Therefore, the failure condition

$$
\frac{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}-\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \leq \beta
$$

implies that

$$
1-\left(1+\frac{1}{200 \cdot B^{15}}\right)^{4}+\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \cdot \frac{9}{10} \leq 1-\frac{\left\|\boldsymbol{r}^{\prime}\right\|_{\widetilde{\boldsymbol{H}}^{2}}^{2}}{\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \leq \beta
$$

and so

$$
\begin{gathered}
\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \leq \frac{10}{9}\left(\beta+\left(1+\frac{1}{200 \cdot B^{15}}\right)^{4}-1\right) \\
\frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{4}}{\left\|\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}} \leq \frac{20}{9} \beta
\end{gathered}
$$

which just like in Lemma 15 shows that $\boldsymbol{r}$ is an excentricity certificate, and concludes the proof.

## C. 4 Proof of Lemma 19

Proof. It suffices to show that the rank-1 updates performed in Algorithm 3 still suffice to decrease excentricity. To do so, we analyze each of the two types of certificates.

Type 1. Letting $\boldsymbol{X}=\boldsymbol{H}_{y}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}_{y}^{-1 / 2}$ and $\boldsymbol{u}=\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}$, we have $\boldsymbol{u}^{\top} \boldsymbol{X} \boldsymbol{u} \geq \frac{1}{\sqrt{\frac{20}{9} \beta}} \boldsymbol{u}^{\top} \boldsymbol{u}$. As the updated mandated by this certificate would require us, in order to apply Lemma 5, exact access to the norm $\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}$ which we do not have available, we instead use a robust version (Lemma 35 in Appendix C.1). Since $\|\boldsymbol{u}\|_{2}=\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{\boldsymbol{y}}}$, we have that per Lemma 36, $\|\boldsymbol{u}\|_{2} \leq n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right) \leq$ $\|\boldsymbol{u}\|_{2} \cdot\left(\frac{1}{1-\frac{1}{1000}}\right)^{2}$, and thus using Lemma 35, we obtain that changing the preconditioner to $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\begin{aligned}
& \boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\boldsymbol{\prime}} \boldsymbol{H}^{-1 / 2} \\
& =\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}-\frac{\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\left(\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top} \boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}}{n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}+\left\|\boldsymbol{H}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}^{-1 / 2}}^{2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}} \\
& =\boldsymbol{H}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1 / 2}-\frac{\boldsymbol{H}^{-1 / 2} \boldsymbol{r} \boldsymbol{r}^{\top} \boldsymbol{H}^{-1 / 2}}{n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}+\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}},
\end{aligned}
$$

and equivalently setting

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}-\frac{\boldsymbol{r} \boldsymbol{r}^{\top}}{n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}+\|\boldsymbol{r}\|_{\widetilde{\boldsymbol{H}}^{-1}}^{2}}
$$

we obtain

$$
\mathcal{E}\left(\widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}^{-1}\right) \leq \mathcal{E}\left(\widetilde{\boldsymbol{H}} \boldsymbol{H}^{-1}\right) \cdot \frac{2}{\sqrt{1+\frac{1}{\left(\frac{1}{1-\frac{1}{1000}}\right)^{4} \sqrt{\frac{20}{9} \beta}}}} \leq \frac{2}{\sqrt{1+\frac{99}{100} \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}}} .
$$

Type 2. Letting $\boldsymbol{X}=\boldsymbol{H}_{y}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}_{\boldsymbol{y}}^{-1 / 2}$ and $\boldsymbol{u}=\boldsymbol{H}_{\boldsymbol{y}}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}$, we have $\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u} \geq \frac{1}{\sqrt{\frac{20}{9} \beta}} \boldsymbol{u}^{\top} \boldsymbol{u}$. As the update mandated by this certificate would require us, in order to apply Lemma 5, exact access to the norm $\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}$ and the vector $\boldsymbol{H} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}$, which we do not have available. Using Lemma using 37 , we obtain an approximation $p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)$ satisfying:

$$
\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{-1}}} \leq \frac{1}{400 \cdot B^{20}}\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}=\frac{1}{400 \cdot B^{20}}\|\boldsymbol{u}\|_{2} .
$$

Therefore letting $\boldsymbol{u}^{\prime}=\boldsymbol{H}_{\boldsymbol{y}}^{-1 / 2} p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)$, we have that $\boldsymbol{u}^{\prime \top} \boldsymbol{X}^{-1} \boldsymbol{u}^{\prime} \geq\left(\frac{1-\frac{1}{100}}{1+\frac{1}{100}}\right)^{2} \cdot \boldsymbol{u}^{\prime \top} \boldsymbol{u}^{\prime}$. This is because

$$
\begin{aligned}
\frac{\boldsymbol{u}^{\top} \boldsymbol{X}^{-1} \boldsymbol{u}^{\prime}}{\boldsymbol{u}^{\prime \top} \boldsymbol{u}^{\prime}} & =\frac{\left\|\boldsymbol{u}^{\prime}\right\|_{\boldsymbol{X}^{-1}}^{2}}{\left\|\boldsymbol{u}^{\prime}\right\|_{2}^{2}}=\frac{\left\|\boldsymbol{u}^{\prime}-\boldsymbol{u}+\boldsymbol{u}\right\|_{\boldsymbol{X}}^{2-1}}{\left\|\boldsymbol{u}^{\prime}-\boldsymbol{u}+\boldsymbol{u}\right\|_{2}^{2}} \geq \frac{\left(\|\boldsymbol{u}\|_{\boldsymbol{X}^{-1}}-\left\|\boldsymbol{u}^{\prime}-\boldsymbol{u}\right\|_{\boldsymbol{X}^{-1}}\right)^{2}}{\left(\|\boldsymbol{u}\|_{2}+\left\|\boldsymbol{u}^{\prime}-\boldsymbol{u}\right\|_{2}\right)^{2}} \\
& =\frac{\left(\|\boldsymbol{u}\|_{X^{-1}}-\left\|\boldsymbol{H}_{y}^{-1 / 2} p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{X}^{-1}}\right)^{2}}{\left(\|\boldsymbol{u}\|_{2}+\left\|\boldsymbol{H}_{y}^{-1 / 2} p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}\right)^{2}} \\
& \geq \frac{\left(\|\boldsymbol{u}\|_{\boldsymbol{X}^{-1}}-\left\|\boldsymbol{X}^{-1}\right\|\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} r\right\|_{\boldsymbol{H}_{y}^{-1}}\right)^{2}}{\left(\|\boldsymbol{u}\|_{2}+\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \nabla g(\boldsymbol{y})\right)-\boldsymbol{H}_{\boldsymbol{y}} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}^{-1}}\right)^{2}} \\
& \geq \frac{\left(\|\boldsymbol{u}\|_{\boldsymbol{X}^{-1}}-\frac{1}{400 \cdot B^{20}}\|\boldsymbol{u}\|_{2}\right)^{2}}{\left(\|\boldsymbol{u}\|_{2}+\frac{1}{400 \cdot B^{20}}\|\boldsymbol{u}\|_{2}\right)^{2}} \\
& \geq \frac{\left(\|\boldsymbol{u}\|_{\boldsymbol{X}^{-1}}-B^{2} \cdot \frac{1}{400 \cdot B^{20}}\|\boldsymbol{u}\|_{\left.\boldsymbol{X}^{-1}\right)^{2}}^{\left(\|\boldsymbol{u}\|_{2}+\frac{1}{400 \cdot B^{20}}\|\boldsymbol{u}\|_{2}\right)^{2}}\right.}{} \\
& \geq\left(1-\frac{1}{B^{17}}\right) \cdot \frac{\|\boldsymbol{u}\|_{\boldsymbol{X}^{-1}}^{2}}{\|\boldsymbol{u}\|_{2}^{2}} \geq\left(1-\frac{1}{B^{17}}\right) \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}
\end{aligned}
$$

Additionally, from Lemma 36 we obtain an approximation $\|\boldsymbol{u}\|_{2} \leq n_{\boldsymbol{y}}(\boldsymbol{u}) \leq\left(\frac{1}{1-\frac{1}{1000}}\right)^{2}\|\boldsymbol{u}\|_{2}$. We now show that $n_{y}(\boldsymbol{u})$ is a good approximation of $\left\|\boldsymbol{u}^{\prime}\right\|_{2}$. Indeed following the same approach as before, we have

$$
\left|\left|\boldsymbol{u}^{\prime}\left\|_{2}-\right\| \boldsymbol{u}\left\|_{2} \mid \leq\right\| \boldsymbol{u}^{\prime}-\boldsymbol{u}\left\|_{2} \leq\right\| p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\left\|_{\boldsymbol{H}_{y}^{-1}} \leq \frac{1}{400 \cdot B^{20}}\right\| \boldsymbol{u} \|_{2},\right.\right.
$$

and so,

$$
\|\boldsymbol{u}\|_{2}\left(1-\frac{1}{400 \cdot B^{20}}\right) \leq\left\|\boldsymbol{u}^{\prime}\right\|_{2} \leq\|\boldsymbol{u}\|_{2}\left(1+\frac{1}{400 \cdot B^{20}}\right)
$$

which gives:

$$
\begin{aligned}
\left\|\boldsymbol{u}^{\prime}\right\|_{2} \leq\left(1+\frac{1}{400 \cdot B^{20}}\right) & n_{y}(\boldsymbol{u}) \leq\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} \cdot \frac{1+\frac{1}{40 \cdot \cdot B^{20}}}{1-\frac{1}{400 \cdot B^{20}}} \cdot\left\|\boldsymbol{u}^{\prime}\right\|_{2} \\
& \leq\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} \cdot\left(1+\frac{1}{100 \cdot B^{20}}\right) \cdot\left\|\boldsymbol{u}^{\prime}\right\|_{2}
\end{aligned}
$$

Thus per the first case of Lemma 35 , updating $\widetilde{\boldsymbol{H}}$ to $\widetilde{\boldsymbol{H}}^{\prime}$ such that

$$
\boldsymbol{X}^{\prime}:=\boldsymbol{H}_{y}^{-1 / 2} \widetilde{\boldsymbol{H}}^{\prime} \boldsymbol{H}_{y}^{-1 / 2}=\boldsymbol{H}_{\boldsymbol{y}}^{-1 / 2} \widetilde{\boldsymbol{H}} \boldsymbol{H}_{\boldsymbol{y}}^{-1 / 2}+\frac{\boldsymbol{H}_{y}^{-1 / 2} p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right) p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top} \boldsymbol{H}_{y}^{-1 / 2}}{\left(1+\frac{1}{\left.400 \cdot B^{20}\right)^{2} \cdot n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \nabla g(\boldsymbol{y})\right)^{2}}\right.}
$$

and equivalently setting

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}+\frac{p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} r\right) p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top}}{\left(1+\frac{1}{400 \cdot B^{20}}\right)^{2} n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \nabla g(\boldsymbol{y})\right)^{2}}
$$

improves excentricity. in the sense that

$$
\frac{\mathcal{E}\left(\boldsymbol{X}^{\prime}\right)}{\mathcal{E}(\boldsymbol{X})} \leq \frac{2}{\sqrt{1+\left(\frac{1}{\left(\frac{1}{1-\frac{1}{1000}}\right)^{2} \cdot\left(1+\frac{1}{100 \cdot B^{20}}\right)}\right)^{2} \frac{1}{\sqrt{\frac{20}{9} \beta}}}} \leq \frac{2}{\sqrt{1+\frac{99}{100} \cdot \frac{1}{\sqrt{\frac{20}{9} \beta}}}} .
$$

Again, we note that the time to implement this update is dominated by making a constant number of gradient queries, and performing a constant number of matrix-vector multiplications involving $\widetilde{\boldsymbol{H}}$ and $\widetilde{\boldsymbol{H}}^{-1}$, which takes $O\left(n^{2}\right)$ time.

Change in preconditioner norm. For the purpose of this proof we only require slightly weaker guarantees on the norm increases suffered by $\|\widetilde{\boldsymbol{H}}\|$ or $\left\|\widetilde{\boldsymbol{H}}^{-1}\right\|$. Whenever the preconditioner norm increases, it is because of a type 2 certificate, in which case we have:

$$
\widetilde{\boldsymbol{H}}^{\prime}=\widetilde{\boldsymbol{H}}+\frac{p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right) p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{\top}}{\left(1+\frac{1}{400 \cdot B^{20}}\right)^{2} n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}},
$$

so

$$
\left\|\widetilde{\boldsymbol{H}}^{\prime}-\widetilde{\boldsymbol{H}}\right\| \leq \frac{\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)\right\|_{2}^{2}}{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} r\right)^{2}}
$$

and using Lemma 37, we know that

$$
\begin{aligned}
\left\|p_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)-\boldsymbol{H}_{y} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}^{-1}} & \leq \frac{1}{400 \cdot B^{20}}\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}, \\
\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} & \leq\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}\left(1+\frac{1}{400 \cdot B^{20}}\right), \\
\left\|p_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)\right\|_{2} & \leq\left\|\boldsymbol{H}_{y}^{-1}\right\| \cdot\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}\left(1+\frac{1}{400 \cdot B^{20}}\right),
\end{aligned}
$$

Also since by Lemma $36,\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{\boldsymbol{y}}} \leq n_{\boldsymbol{y}}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right) \leq\|\boldsymbol{u}\|_{2} \cdot\left(\frac{1}{1-\frac{1}{1000}}\right)^{2}$, we conclude that

$$
\left\|\widetilde{\boldsymbol{H}}^{\prime}-\widetilde{\boldsymbol{H}}\right\| \leq \frac{\left(\left\|\boldsymbol{H}_{y}^{-1}\right\| \cdot\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}\left(1+\frac{1}{400 \cdot B^{20}}\right)\right)^{2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{2}}=\left\|\boldsymbol{H}_{y}^{-1}\right\|^{2}\left(1+\frac{1}{400 \cdot B^{20}}\right)^{2} .
$$

Similarly, in the case where $\widetilde{\boldsymbol{H}}^{\prime-1}$ increases, it is because of a type 1 certificate, in which case we have:

$$
\widetilde{\boldsymbol{H}}^{\prime-1}=\widetilde{\boldsymbol{H}}^{-1}+\frac{\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r} \boldsymbol{r}^{\top} \widetilde{\boldsymbol{H}}^{-1}}{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}}
$$

and thus

$$
\left\|\widetilde{\boldsymbol{H}}^{\prime^{-1}}-\widetilde{\boldsymbol{H}}^{-1}\right\| \leq \frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}^{2}}{n_{y}\left(\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right)^{2}} \leq \frac{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}^{2}}{\left\|\widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}}^{2}}=\frac{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{\boldsymbol{H}_{y}^{-1}}^{2}}{\left\|\boldsymbol{H}_{y}^{1 / 2} \widetilde{\boldsymbol{H}}^{-1} \boldsymbol{r}\right\|_{2}^{2}} \leq\left\|\boldsymbol{H}_{y}^{-1}\right\| .
$$

## D Proof from Section 5

Lemma 38. Let $g_{\mu}$ be self-concordant. Suppose that $\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}} \leq 1 / 20$ and $\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}\right\|_{\boldsymbol{H}_{\boldsymbol{y}}^{-1}} \leq \varepsilon \leq 1 / 20$. Then setting $\boldsymbol{y}^{\prime}=\boldsymbol{y}-\boldsymbol{x}$,

$$
\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{\prime}}} \leq 2 \varepsilon+7 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\boldsymbol{y}}^{-1}}^{2}
$$

Furthermore,

$$
\left\|\boldsymbol{y}^{\prime}-\boldsymbol{y}\right\|_{\boldsymbol{H}_{\boldsymbol{y}}} \leq \varepsilon+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}} .
$$

Proof. Let $\overline{\boldsymbol{H}}=\int_{0}^{1} \boldsymbol{H}_{y+\left(y^{\prime}-y\right) t} d t$, for which we know from self-concordance that

$$
\max \left\{\left\|\boldsymbol{H}_{y}^{-1 / 2} \boldsymbol{H}_{\boldsymbol{y}^{\prime}} \boldsymbol{H}_{y}^{-1 / 2}\right\|,\left\|\boldsymbol{H}_{y}^{-1 / 2} \overline{\boldsymbol{H}} \boldsymbol{H}_{y}^{-1 / 2}\right\|\right\} \leq\left(\frac{1}{1-\left\|\boldsymbol{y}^{\prime}-\boldsymbol{y}\right\|_{\boldsymbol{H}_{y}}}\right)^{2}=\left(\frac{1}{1-\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}}\right)^{2}
$$

Additionally we write

$$
\begin{equation*}
\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}=\left\|\boldsymbol{H}_{y} \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}} \leq\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{\boldsymbol{y}} \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}}+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}} \leq \varepsilon+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{\boldsymbol{y}^{-1}}} \leq \frac{1}{10} \tag{20}
\end{equation*}
$$

Using these, we can bound the new gradient as:

$$
\begin{aligned}
\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} & =\left\|\nabla g_{\mu}(\boldsymbol{y})+\overline{\boldsymbol{H}}\left(\boldsymbol{y}^{\prime}-\boldsymbol{y}\right) d t\right\|_{\boldsymbol{H}_{y}^{-1}} \\
& =\left\|\nabla g_{\mu}(\boldsymbol{y})-\overline{\boldsymbol{H}} \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}} \\
& =\left\|\nabla g_{\mu}(\boldsymbol{y})-\boldsymbol{H}_{y} \boldsymbol{x}+\left(\boldsymbol{H}_{\boldsymbol{y}}-\overline{\boldsymbol{H}}\right) \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}} \\
& \leq \varepsilon+\left\|\left(\boldsymbol{H}_{\boldsymbol{y}}-\overline{\boldsymbol{H}}\right) \boldsymbol{x}\right\|_{\boldsymbol{H}_{y}^{-1}} \\
& =\varepsilon+\left\|\left(\boldsymbol{I}-\boldsymbol{H}_{y}^{-1 / 2} \overline{\boldsymbol{H}} \boldsymbol{H}_{y}^{-1 / 2}\right) \boldsymbol{H}_{y}^{1 / 2} \boldsymbol{x}\right\|_{2} \\
& \leq \varepsilon+\left\|\boldsymbol{I}-\boldsymbol{H}_{y}^{-1 / 2} \overline{\boldsymbol{H}} \boldsymbol{H}_{y}^{-1 / 2}\right\|\left\|\boldsymbol{H}_{y}^{1 / 2} \boldsymbol{x}\right\|_{2} \\
& \leq \varepsilon+\left(1-\left(\frac{1}{1-\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}}\right)^{2}\right)\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}} \\
& \leq \varepsilon+\frac{2\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}^{2}}{\left(1-\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}\right)^{2}} \\
& \leq \varepsilon+\left(\frac{10}{9}\right)^{2} \cdot 2\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}^{2} .
\end{aligned}
$$

Using (20) we obtain that

$$
\begin{aligned}
\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} & \leq \varepsilon+\left(\frac{10}{9}\right)^{2} \cdot 2\left(\varepsilon+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}\right)^{2} \\
& \leq \varepsilon+\left(\frac{10}{9}\right)^{2} \cdot 4\left(\varepsilon^{2}+\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}^{2}\right) \\
& \leq \varepsilon\left(1+\left(\frac{10}{9}\right)^{2} \cdot \frac{1}{5}\right)+\left(\frac{10}{9}\right)^{2} \cdot 4 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}^{2} \\
& \leq \varepsilon\left(1+\frac{1}{4}\right)+5 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}^{2}
\end{aligned}
$$

Finally, changing the norm we have

$$
\begin{aligned}
\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{y^{\prime}}^{-1}} & \leq\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} \cdot\left\|\boldsymbol{H}_{y}^{1 / 2} \boldsymbol{H}_{\boldsymbol{y}^{\prime}}^{-1} \boldsymbol{H}_{y}^{1 / 2}\right\| \\
& \leq\left\|\nabla g_{\mu}\left(\boldsymbol{y}^{\prime}\right)\right\|_{\boldsymbol{H}_{y}^{-1}} \cdot\left(\frac{1}{1-\|\boldsymbol{x}\|_{\boldsymbol{H}_{y}}}\right)^{2} \\
& \leq\left(\varepsilon\left(1+\frac{1}{4}\right)+5 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y^{-1}}}^{2}\right) \cdot \frac{100}{81} \\
& \leq 2 \varepsilon+7 \cdot\left\|\nabla g_{\mu}(\boldsymbol{y})\right\|_{\boldsymbol{H}_{y}^{-1}}^{2} .
\end{aligned}
$$

Lemma 39. Let $g_{\mu}(\boldsymbol{y})=\frac{\langle\boldsymbol{c}, \boldsymbol{y}\rangle}{\mu}+\phi(\boldsymbol{y})$. Then $\nabla g_{\mu /(1-\delta)}(\boldsymbol{y})=(1+\delta) \nabla g_{\mu}(\boldsymbol{y})-\delta \nabla \phi(\boldsymbol{y})$.

Proof. We prove the identity as follows:

$$
\begin{aligned}
\nabla g_{\mu(1-\delta)}(\boldsymbol{y}) & =\frac{\boldsymbol{c}}{\mu /(1+\delta)}+\nabla \phi(\boldsymbol{y})=(1+\delta)\left(\frac{\boldsymbol{c}}{\mu}+\nabla \phi(\boldsymbol{y})\right)-\delta \nabla \phi(\boldsymbol{y}) \\
& =(1+\delta) \nabla g_{\mu}(\boldsymbol{y})-\delta \nabla \phi(\boldsymbol{y}) .
\end{aligned}
$$
