

# Improving SINR Performance Deploying IRS in 6G Wireless Networks

Mobasshir Mahbub, Raed M. Shubair

# 1. Introduction

Over the past thirty years, wireless discoveries and methodologies, along with their prospective applications, have seen exponential progress and improvement. They include transmitter design as well as broadcast properties [1-18], THz interfacing and signal enhancement properties [19-31], as well as interior location strategies and problems [32-50].

Deploying miniature cells, aka small cells [51], within a very distracted network represents one of the simplest ways for meeting the demands of huge data traffic currently. To improve cellular services, such ground stations are put on-premises near resource-hungry equipment, generally in a smaller indoor/outdoor region. Furthermore, such base stations have higher coverage, ensuring adequate transmission. Because micro cells are located near to customers, a low-power transmission capacity (relative to large base stations) may ensure a better throughput to the gadgets [52].

The sixth version of wireless networking technologies aspires to build a data-driven, economically viable future enabled by near-instant, secure, unlimited, and environmentally friendly communication [53]. To accomplish this, industry and academics have established stringent performance criteria for se-

curity and reliability, speed, sensory capabilities, dependability, flexibility, and consuming energy. As a consequence, the 6G or sixth-generation cellular framework must be developed to meet growing requirements and standards, such as larger coverage, improved capacity, ubiquitous connection, and so on [54].

A planar metasurface made of an extensive number of reflecting components that has recently piqued academic attention due to its ability to significantly boost network energy as well as spectrum productivity by modifying wireless transmission settings termed as IRS. IRS segments with the appropriate phase shift may be able to relay the arriving wave [55]. By dynamically adjusting reflected signal communications, IRS creates constructive signal aggregation as well as harmful interference reduction at reception. As a result, the receiver's quality of experience (QoE) may improve.

As a consequence, the study evaluated the performance of normal miniature cellular connection with IRS-enhanced miniature cellular connectivity with regard to SINR in the case of services and applications.

## **2. Related Literature**

Wu et al. [56] investigated power regulation in the upstream for IRS-assisted connected devices under the restrictions of user-end

level of performance (QoS). The study aimed to reduce users' overall power consumption by adjusting the phase transitions of IRS reflecting components and base station reception beamforming while keeping the SINR restriction in mind. Hao et al. [57] investigated an IRS-empowered multiuser MIMO system using orthogonal frequency-division multi-access (OFDMA) across the THz range. The scattered radio frequency, or RF, antenna design was used in the study to lower the network's energy use. The goal of the study is to optimize the sum-rate by enhancing hybrid beam formation simultaneously.

### 3. Measurement Model

Let's consider,  $P_t^D$  is the amount of power employed for transmission.

#### A. Conventional Model

For this instance, the power obtained by a typical miniature cell is depicted as follows (Eq. 1) [58], [59],

$$P_r^{DL} = \frac{\lambda L P_t^{DL}}{r^\alpha 16\pi^2} \quad (1)$$

where  $r = \sqrt{(x^s - x^{ue})^2 + (y^s - y^{ue})^2 + (z^s - z^{ue})^2}$ .  $\alpha$  is the fading level.  $L$  represents a Rayleigh decay factor having an exponential form that follows a unit mean dispersion.  $\lambda = c/f$

denotes the wavelength related to the carrier.  $c$  is the velocity of the sunlight in  $ms^{-1}$ . The carrier resonance is represented by  $f$  in Hz.

The equation beneath is used to compute the downstream SINR (Eq. 2),

$$S^{DL} = \frac{P_r^{DL}}{Intf. + n_w} \quad (2)$$

where  $Intf.$  denotes the interfering signal.  $n_w$  is noise.

### B. IRS-Empowered Model

In the case of an IRS-assisted small cell for IoT components, the obtained power in the downstream is computed as follows (Eq. 2) [60],

$$P_r^{DL(IRS)} = \frac{l_x w_y m^2 n^2 \lambda^2 G_T G_R G \cos(\theta_T) \cos(\theta_R) A^2}{64\pi^3 (r_1 r_2)^2} P_t^{DL(IRS)} \quad (3)$$

where  $A$  is the numerical value that represents the refraction index.  $\theta_T$  is the direction for transmitting and  $\theta_R$  is the direction of reception.  $l_x$  and  $w_y$  are the length and width of IRS components.  $G = \frac{4\pi l_x w_y}{\lambda^2}$  represents the IRS's dispersal gain.  $m$  and  $n$  represent the total quantity of pairs of transmitting and receiving elements.  $G_T$  refers to the transmitting gain and  $G_R$  refers to the recipient's gain.  $r_1 = \sqrt{(x^s - x_i^i)^2 + (y^s - y_i^i)^2 + (z^s - z_i^i)^2}$

indicates the distance that lies between the signal's transmitter and the receiver at  $(x^s, y^s, z^s)$  coordinates and corresponding IRS at  $(x_i^i, y_i^i, z_i^i)$  coordinates.

$r_2 = \sqrt{(x_i^i - x_n^{ue})^2 + (y_i^i - y_n^{ue})^2 + (z_i^i - z_n^{ue})^2}$  is the separation between the IRS and the devices at  $(x^{ue}, y^{ue}, z^{ue})$ .

The subsequent equation yields the downstream SINR (Eq. 4),

$$S^{DL(IRS)} = \frac{P_r^{DL(IRS)}}{Intf. + n_w} \quad (4)$$

## 4. Numerical Results and Discussions

The measurement findings produced through MATLAB-based modelling implementing the measurement concept are included in this portion of the article, as are remarks on the generated results.

### A. Results for Conventional Model

Fig. 1 visualizes the measurement of downlink SINR for conventional micro cells.

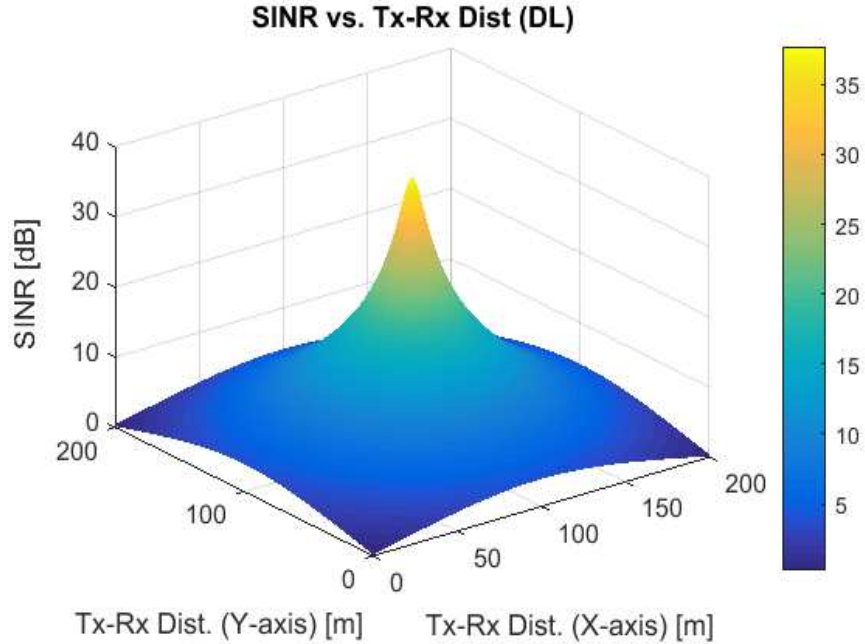

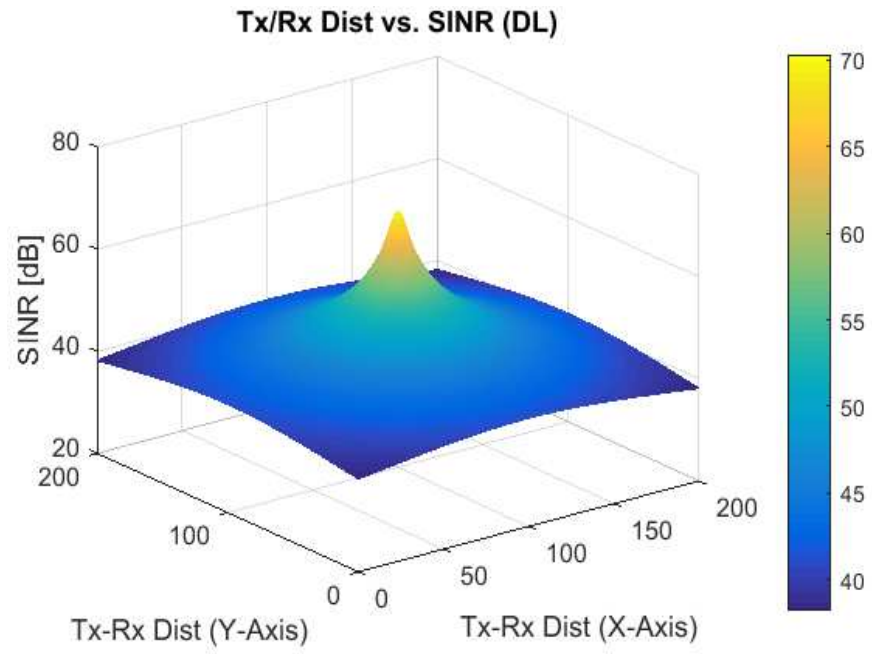

Fig. 1. Transmitter-receiver separation distance vs. SINR  
(non-IRS DL)

According to the observation in Fig. 1, the devices located within 10 – 15 m will achieve around 24 dB SINR and the devices 40 m away from the base station will obtain around 14 dB SINR. The cell edge devices will obtain 0.4 - 4 dB of SINR approximately.

### B. Results for IRS-Assisted Model

Fig. 2 (a), (b), and (c) show the downlink SINR for the whole coverage region in terms of varied transmit-receive angles. Fig.

2 (d) visualizes the SINR placing the IRS 50 m away from the cell edge.

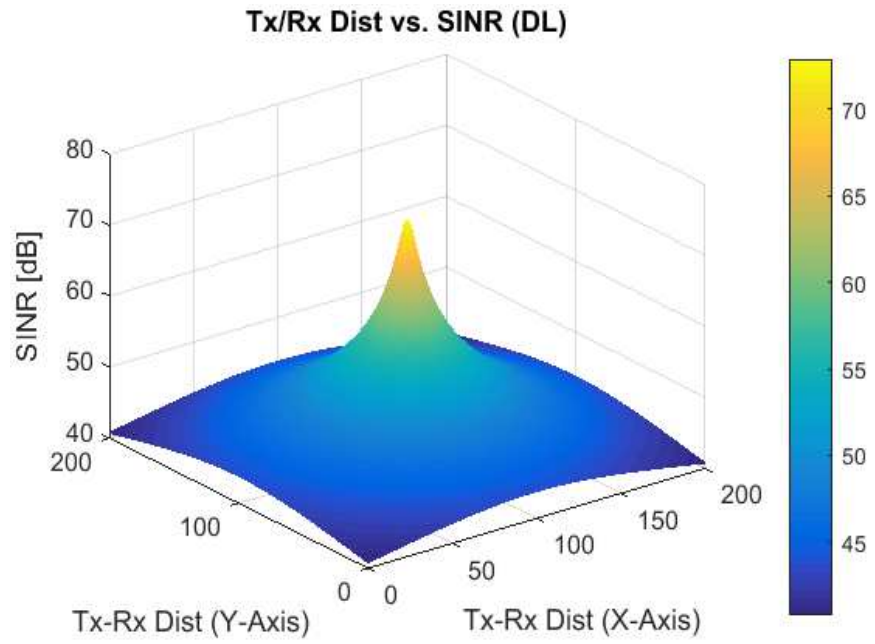

(a)

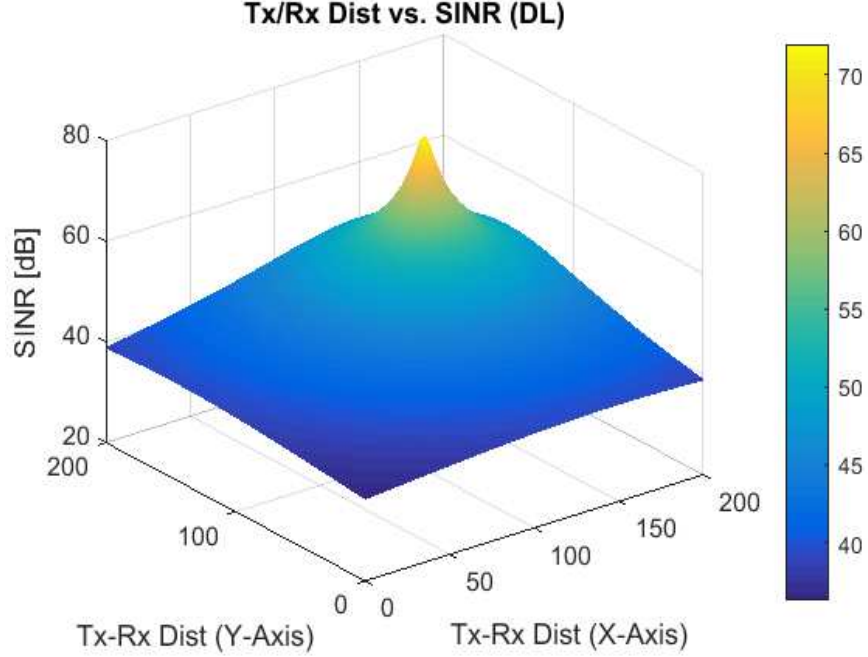

(b)

(c)

(d)

Fig. 2. (a) Transmitter-receiver separation vs. SINR ( $\theta_t = 45^\circ$ ,  $\theta_r = 45^\circ$ ), (b) Transmitter-receiver separation vs. SINR ( $\theta_t = 60^\circ$ ,  $\theta_r = 60^\circ$ ), (c) Transmitter-receiver separation vs. SINR ( $\theta_t = 45^\circ$ ,  $\theta_r = 60^\circ$ ), (d) Transmitter-receiver separation vs. SINR ( $\theta_t = 60^\circ$ ,  $\theta_r = 60^\circ$  and IRS placed at 50 m away from cell edge)

The observation of Fig. 2 (a)-(c) states that the  $60^\circ$  transmit-receive angles (from the base station to IRS and IRS to device) outperform other considered angles in terms of downlink received power. Afterward,  $45^\circ$  of transmitting and  $60^\circ$  of re-

ceiving angles perform better than other considered transmit-receive angles. In the case of the  $60^\circ$  transmit-receive angles, the devices located 15 m away from the IRS achieve around -25 dBm of received power, at 50 m the received power in downlink becomes -35 dBm, and at the cell edge, it is -41 to -44 dBm.

Inspecting Fig. 2 (a), (b), and (c) it is feasible that,  $60^\circ$  of transmit-receive angles outperforms other angles in terms of downlink SINR (maximum 75 dB and minimum 44 dB). When the devices are randomly distributed over a coverage region it is favorable to place IRS in the mid of the coverage region to offer a favorable coverage to all devices according to the comparison between Fig. 2 (b) and (d). The placement of IRS near the receiver may be favorable for a clustered group of devices located in a specific region.

## 5. Conclusion

The study aimed to improve coverage in the environment of upcoming 6G networks by installing IRS in a miniature cell. A literature assessment of related current research was conducted to give insight and identify research constraints or gaps. It developed a measurement approach for both traditional and IRS-assisted miniature cellular networks, which includes numerous equations for measuring SINR.
