Abstract

The fair allocation of mixed goods, consisting of both divisible and indivisible goods, has been a prominent topic of study in economics and computer science. We define an allocation as fair if its utility vector minimizes a symmetric strictly convex function. This fairness criterion includes standard ones such as maximum egalitarian social welfare and maximum Nash social welfare. We address the problem of minimizing a given symmetric strictly convex function when agents have binary valuations. If only divisible goods or only indivisible goods exist, the problem is known to be solvable in polynomial time. In this paper, firstly, we demonstrate that the problem is NP-hard even when all indivisible goods are identical. This NP-hardness is established even for maximizing egalitarian social welfare or Nash social welfare. Secondly, we provide a polynomial-time algorithm for the problem when all divisible goods are identical. To accomplish these, we exploit the proximity structure inherent in the problem. This provides theoretically important insights into the hybrid domain of convex optimization that incorporates both discrete and continuous aspects.

1 Introduction

The fair allocation of resources is a fundamental problem that arises in various real-life scenarios, such as dividing tasks among team members, distributing inheritance, or allocating land. In many of these situations, the resources can be of mixed types: divisible and indivisible. The investigation of fair allocation mechanisms for mixed goods has thus gained considerable interest recently [4, 6, 7, 26, 28, 35, 27].

In this paper, we study the following fair allocation problem of mixed goods. We are given a set $N = \{1, 2, \dots, n\}$ of n agents and a set $E = C \cup M$, where C and M are the sets of divisible and indivisible goods, respectively. We are also given a *symmetric strictly convex* function $\Phi: \mathbb{R}^N \rightarrow \mathbb{R}$. Each agent i has a binary valuation $v_{ie} \in \{0, 1\}$ for each good e , meaning that for each good, each agent either desires it or not. An allocation is a matrix $\pi \in [0, 1]^{N \times E}$ such that $\pi_{ie} \in \{0, 1\}$ for all $i \in N$ and $e \in M$. Throughout this paper, we only consider utilitarian optimum allocations, that is, $\pi_{ie} > 0$ only if $v_{ie} = 1$. The entry π_{ie} means the allocated amount of good e to agent i . Agents have additive utility, and the utility of agent i in allocation π is $\pi_i(E) = \sum_{e \in E} v_{ie} \pi_{ie}$. For an allocation π , a vector $z = (\pi_1(E), \dots, \pi_n(E))$ is called a utility vector of π . We say that

an allocation π is Φ -fair if its utility vector z minimizes $\Phi(z)$ among allocations. The goal of our problem is to find a Φ -fair allocation.

This problem is a generalization of maximizing fairness measures such as the *Nash welfare* and the *egalitarian social welfare* (max-min fairness), as we will see in Section 2. Roughly speaking, the former notion is defined as the product of positive utilities $\prod_{i \in N: z_i > 0} z_i$, and the latter is the minimum utility among agents $\min_{i \in N} z_i$.

There is a vast body of literature on the allocation of goods in cases where only divisible or indivisible goods are present. In such cases, it suffices to find a feasible minimizer (utility vector) of Φ because we can find an allocation achieving the utilities by solving the maximum flow problem (see also Section 2). In the continuous case, where there are only divisible goods, the set of possible utility vectors forms an *integral base-polyhedron*¹. It is known that an integral base-polyhedron has a common unique minimizer independent of Φ , and the minimizer can be characterized by a structure called the *principal partition* [16, 29] (see Section 3.3 for the definition and details). Since there exist polynomial-time algorithms to find an allocation achieving the maximum Nash welfare (MNW) [36, 41], a minimizer of Φ can be found in polynomial time. In the discrete case, where there are only indivisible goods, the set of possible utility vectors forms an *M-convex set*, which is the set of integral vectors in an integral base-polyhedron. It is known that a minimizer of Φ on an M-convex set can be characterized by the *canonical partition* [13], which is an aggregation of the principal partition. Additionally, the set of minimizers of a symmetric strictly convex function does not depend on the function [13] and a minimizer (utility vector) can be found in polynomial time [14]. Furthermore, a *proximity theorem* has been established [15]. This theorem states that a minimizer of Φ in an M-convex set lies within a unit hypercube that contains the minimizer in the corresponding integral base-polyhedron.

Our problem is regarded as the hybrid of continuous and discrete optimization problems; finding an allocation whose utility vector z minimizes $\Phi(z)$ under the constraint that z belongs to the Minkowski sum of an integral base-polyhedron and an M-convex set. Unfortunately, the hybrid case may not inherit nice properties of continuous or discrete cases. When there are both divisible and indivisible goods, the set of possible utility vectors is not necessarily an integral base-polyhedron or an M-convex set. It also does not work to find allocations of divisible and indivisible goods separately and combine them. We can observe these from the following example.

Example 1.1. *Suppose that there are one indivisible good g , one divisible good c , and three agents who desire both goods. Let $\Phi(z) = -z_1 \cdot z_2 \cdot z_3$. In this case, allocating c equally to the three agents minimizes Φ when considering only c . However, allocating g to agent 1 and c to agents 2 and 3 equally minimizes Φ for mixed goods. In addition, the set of possible utility vectors is not an M-convex set since it contains fractional utility vectors and not an integral base-polyhedron since it is not convex (see Figure 1).*

Therefore, existing results are not applicable to our problem. In addition, even if we obtain a minimizer of Φ , it is not clear how to derive an allocation that achieves the utility vector. Thus, investigating a structure and establishing a polynomial-time algorithm for the hybrid problem is much more challenging.

¹An integral base-polyhedron is a polyhedron that can be represented as $\{x \in \mathbb{R}^N : x(N) = f(N) \text{ and } x(X) \leq f(X) (\forall X \subseteq N)\}$ by an integer-valued submodular function $f: 2^N \rightarrow \mathbb{Z}$ with $f(\emptyset) = 0$. See Section 3.1 for details.

1.1 Our contribution

First, we investigate the structure of the fair allocation of mixed goods. Unfortunately, certain nice properties that hold in the divisible case or the indivisible case no longer hold in the mixed case, as we will see in Examples 2.3 and 2.4. Nevertheless, we demonstrate that a proximity theorem (Theorem 4.1) holds in the mixed case. The proximity theorem states that a minimizer of Φ for mixed goods lies within a unit box containing the minimizer of Φ assuming that every good is divisible. This generalizes a proximity theorem for the discrete case [15]. It is worth mentioning that our theorem holds even when each agent evaluates indivisible goods with a matroid rank function and divisible goods with the concave closure of a matroid rank function. By the proximity theorem, an optimal integral solution is a good approximation solution for mixed goods, in the sense that the ℓ_∞ distance from the optimal solution is at most 1.

Note that our proof does not depend on the fair allocation setting. Therefore, these properties are fundamental even for the hybrid of continuous and discrete optimization. Our proximity theorem cannot be proven by directly applying the proof to the discrete-only or the continuous-only case since the structure is different. To prove it, we introduce new exchange properties. The main idea is to see an optimality criterion in terms of an exchange graph. Unlike the discrete case, the situation of the mixed case is much complicated. Our main contribution to this paper is to provide an elaborate analysis of the graph. As a consequence, we can show that the hybrid case still retains a structure of the canonical partition (Lemma 4.11).

Next, by utilizing the proximity theorem, we show that our problem is NP-hard even when indivisible goods are *identical*, i.e., for each agent i , either $v_{ie} = 1$ ($\forall e \in M$) or $v_{ie} = 0$ ($\forall e \in M$).

Theorem 1.2. *For any fixed symmetric strictly convex function Φ , finding a Φ -fair allocation is NP-hard even when indivisible goods are identical.*

We also prove that computing an MNW allocation and an optimal egalitarian allocation are both NP-hard. These results highlight the difficulty of the mixed goods case because the problems can be solved in polynomial time when there are only divisible goods or only indivisible goods.

Finally, we show the following tractability when divisible goods are identical.

Theorem 1.3. *Let Φ be a symmetric strictly convex function. There exists a polynomial-time algorithm that finds a Φ -fair allocation if all the divisible goods are identical.*

A key tool to construct our algorithm is the canonical partition for the mixed goods. By applying it, we can partition goods as E_1, \dots, E_q and agents as N_1, \dots, N_q so that goods in E_j

are allocated to agents in N_j in a Φ -fair allocation (Theorem 4.12). Thanks to this structure, a minimizer of Φ can be found by independently solving the subproblems of assigning E_j to N_j for $j = 1, 2, \dots, q$. In each subproblem, the utility of every agent is almost the same. However, unlike the continuous or discrete case, an optimal allocation depends on Φ (see Examples 2.3 and 2.4). Thus, it is not easy to obtain a full characterization of minimizers.

1.2 Related work

For the fair allocation of divisible homogeneous goods with additive valuations (not restricted to binary), an MNW allocation corresponds to a market equilibrium of a special case of the Fisher’s market model (see, e.g., [34]). Moreover, an MNW allocation is *envy-free* (EF) [38, 40], that is, no agent envies any other agent. It is known that this problem can be solved in strongly polynomial-time [36, 41].

For the fair allocation of indivisible goods with additive valuations, Caragiannis et al. [7] proved that an MNW allocation is *envy-free up to one good* (EF1), that is, each agent i does not envy another agent j if some indivisible good is removed from the bundle of agent j . Since computing an MNW allocation is hard in general [25], there is a series of research to design an approximation algorithm [1, 8, 9, 10, 20]. Benabbou et al. [5] proved that the set of MNW allocations coincides with that of minimizers of any symmetric strictly convex function, even when the utility of each agent is represented by a matroid rank function.² Harvey et al. [23] proposed efficient algorithms for computing an allocation that minimizes a certain symmetric strictly convex function. When agents’ valuations are matroid rank function, Goko et al. [21] presented a truthful and EF mechanism by subsidizing each agent with at most 1. Note that subsidies can be viewed as divisible goods that every agent desires. When agents have binary additive valuations, an MNW allocation can be computed in polynomial time [3, 11]. Truthful mechanisms to find an MNW allocation are also proposed [22, 2].

Fair allocation with a mixture of divisible and indivisible goods has recently gained attention and has been the subject of research. Bei et al. [4] introduced a fairness notion called *envy-freeness for mixed goods* (EFM) as a generalization of EF and EF1 notions. Caragiannis et al. [7] mentioned that an MNW allocation is *envy-free up to one good for mixed goods* (EF1M), which is a relaxation of EFM. Very recently, Li et al. [26] proposed a truthful mechanism that outputs an EFM allocation for the case where agents have binary additive valuations on indivisible goods and a common valuation on a single divisible good (e.g., money). They also showed that their mechanism runs in polynomial time, and its output achieves MNW. We remark that their algorithm does not work in our problem even when divisible goods are identical because we allow some agents to have value 0 on them. For more details, see a survey paper by Liu et al. [27].

The (integral) base-polyhedron has been studied in the theory of matroids and submodular functions [17]. The concept of M-convex sets was introduced by Murota [31] and is defined as a set of integral vectors satisfying certain exchange axioms. *Discrete convex analysis* [32] is a framework of convex analysis in discrete settings, including M-convexity.

The concepts of continuous/discrete hybrid convexity have been proposed by Takamatsu et al. [39] and Moriguchi et al. [30]. In particular, Moriguchi et al. [30] provided an optimality criterion for an integral polyhedral hybrid M-convex function minimization. However, the functions treated

²Note that Theorem 4.1 is an extension of this result. Specifically, we construct an “augmenting” path of [5, Section 3.2] for a hybrid situation.

in the present paper are hybrid M-convex functions that are not necessarily integral polyhedral.

1.3 Organization

The rest of this paper is organized as follows. Firstly, the formal definition of our problem is provided in Section 2. Next, in Section 3, we introduce integral base-polyhedra and M-convex sets. We formulate our fair allocation problem with these concepts. Then, in Section 4, we present a proximity structure that aids in understanding the problem. Section 5 provides a polynomial-time algorithm for the case where all divisible goods are identical. Section 6 proves NP-hardness even when all indivisible goods are identical. We defer some proofs to Appendix.

2 Preliminaries

For $k \in \mathbb{N}$, we denote $[k] = \{1, 2, \dots, k\}$. Let $N = [n]$ represent the set of n agents. We have two types of goods: $M = \{g_1, g_2, \dots, g_m\}$ represents the set of indivisible goods, and $C = \{c_1, c_2, \dots, c_r\}$ denotes the set of homogeneous divisible goods, that is, the valuation for a piece of a good is proportional to its fraction. The set of all goods is denoted by $E = M \cup C$. Let v_{ie} be the valuation of good $e \in E$ for agent $i \in N$. Throughout this paper, we assume that agents have binary valuations, that is, the valuation v_{ie} for the whole of good e is either 0 or 1 for all $i \in N$ and $e \in E$. An instance of the fair allocation we deal with in this paper is described as (N, M, C, v) . Without loss of generality, we assume that, for any $e \in E$, there exists $i \in N$ such that $v_{ie} = 1$.

A *relaxed allocation* is defined as a matrix $\pi \in [0, 1]^{N \times E}$ that satisfies (i) $\sum_{i \in N} \pi_{ie} = 1$ for all $e \in E$ and (ii) $\pi_{ie} = 0$ for any $i \in N$ and $e \in E$ with $v_{ie} = 0$. In a relaxed allocation π , each agent i receives each good e in the proportion of π_{ie} . Relaxed allocations treat indivisible goods as divisible. A relaxed allocation π is an *allocation* if it additionally satisfies $\pi_{ie} \in \{0, 1\}$ for all $i \in N$ and $e \in M$. A relaxed allocation π is an *integral allocation* if it additionally satisfies $\pi_{ie} \in \{0, 1\}$ for all $i \in N$ and $e \in E$. For an allocation π , an agent $i \in N$, and a subset of goods $E' \subseteq E$, let $\pi_i(E') = \sum_{e \in E'} \pi_{ie}$, which is the valuation of agent i 's bundle from E' . For an allocation π , the utility of agent $i \in N$ is defined as $\pi_i(E)$. Our goal is to find a fair allocation. As fairness measures, we employ Φ -fairness defined below.

For an allocation π , let $\pi(E)$ be the utility vector $(\pi_1(E), \dots, \pi_n(E))$. For a utility vector x , let x^\downarrow be the vector obtained from x by rearranging its components in the decreasing order. We call two vectors $x, y \in \mathbb{R}^N$ *value-equivalent* if $x^\downarrow = y^\downarrow$. A vector $x \in \mathbb{R}^N$ is *decreasingly smaller* than a vector $y \in \mathbb{R}^N$ if x^\downarrow is lexicographically smaller than y^\downarrow (i.e., $x_1^\downarrow < y_1^\downarrow$, or $x_1^\downarrow = y_1^\downarrow$ and $x_2^\downarrow < y_2^\downarrow$, etc). An allocation π is called *decreasingly minimal* (*dec-min*, for short) if $\pi(E)$ is decreasingly smaller than or value-equivalent to $\pi'(E)$ for every allocation π' . In other words, an allocation π is dec-min if its largest utility is as small as possible, within this, its second largest utility (with the same or smaller value than the largest one) is as small as possible, and so on. Similarly, an allocation π is called *increasingly maximal* (*inc-max*, for short) if its smallest utility is as large as possible, within this, its second smallest utility is as large as possible, and so on.

We say that a function $\Phi: \mathbb{R}^N \rightarrow \mathbb{R}$ is *symmetric* if

$$\Phi(z_1, z_2, \dots, z_n) = \Phi(z_{\sigma(1)}, z_{\sigma(2)}, \dots, z_{\sigma(n)})$$

for all permutations σ of $(1, 2, \dots, n)$. We say that a function $\Phi: \mathbb{R}^N \rightarrow \mathbb{R}$ is strictly *convex* if

$$\lambda\Phi(z) + (1 - \lambda)\Phi(z') > \Phi(\lambda z + (1 - \lambda)z')$$

for all $z, z' \in \mathbb{R}^N$ and $\lambda \in (0, 1)$. A typical example of symmetric strictly convex functions is the square-sum $\Phi(z) = \sum_{i \in N} z_i^2$. In general, for $z \in \mathbb{R}^N$ and $i, j \in N$ with $z_i > z_j$, we have $\Phi(z - \varepsilon(\chi_i - \chi_j)) < \Phi(z)$ for any $\varepsilon \in (0, z_i - z_j)$ because

$$\begin{aligned} \Phi(z) &= \lambda \Phi(z - (z_i - z_j)(\chi_i - \chi_j)) + (1 - \lambda) \Phi(z) \\ &> \Phi(\lambda(z - (z_i - z_j)(\chi_i - \chi_j)) + (1 - \lambda)z) = \Phi(z - \lambda(z_i - z_j)(\chi_i - \chi_j)) \end{aligned} \quad (1)$$

for any $\lambda \in (0, 1)$. Here, χ_i represents a unit vector where only the i th component is equal to 1, while all other components are equal to 0. An allocation π is called Φ -fair if the utility vector $(\pi_1(E), \dots, \pi_n(E))$ minimizes Φ among allocations.

Our problem is to find a Φ -fair allocation. When there are only divisible goods or only indivisible goods, it suffices to find a utility vector z^* that minimizes Φ , because once we obtain z^* , a Φ -fair allocation is obtained from the maximum flow problem as shown below. Let $G = (\{s, t\} \cup E \cup N, A)$ be a directed graph, where $A = \{(s, e) : e \in E\} \cup \{(e, i) : v_{i,e} = 1\} \cup \{(i, t) : i \in N\}$. The capacity c is defined as $c(s, e) = 1$ for $e \in E$, $c(e, i) = 1$ for $(e, i) \in A \cap (E \times N)$, and $c(i, t) = z_i^*$ for $i \in N$. For a maximum flow f from s to t , let π be the allocation defined as $\pi_{ie} = f(e, i)$ ($e \in E, i \in N$). Then, we can see that $\pi_i(E) = z_i^*$ for each agent $i \in N$. Since we can find an integral maximum flow in the indivisible goods case, π can be an integral allocation. However, when both types of goods exist, it is not straightforward to construct an allocation from a given utility vector. Indeed, checking the existence of an allocation achieving a given utility vector is NP-hard, as shown in Appendix (see Theorem B.1).

As we will see in the next section, the set of possible utility vectors forms an integral base-polyhedron (or M-convex set) if there are only divisible (or indivisible) goods. By using the properties known for integral base-polyhedrons (M-convex sets), we can prove that the dec-min allocations coincide with the inc-max allocations and the Φ -fair allocations for any symmetric strictly convex function Φ .

Theorem 2.1 (Fujishige [16] and Maruyama [29]³). *If there are only divisible goods (i.e., $M = \emptyset$), the dec-min allocations have the same utility vector up to value equivalence. Also, the utility vector is the unique utility vector for inc-max allocations and Φ -fair allocations for any symmetric strictly convex functions Φ .*

Theorem 2.2 (Frank and Murota [13]). *If there are only indivisible goods (i.e., $C = \emptyset$), the set of utility vectors of the dec-min allocations forms an M-convex set. The set is identical for the set of utility vectors of inc-max allocations or Φ -fair allocations for any symmetric strictly convex functions Φ .*

However, this is not the case when both types of goods exist (i.e., $M \neq \emptyset$ and $C \neq \emptyset$).

Example 2.3. *Consider an instance with five agents $N = \{1, 2, 3, 4, 5\}$, five indivisible goods $M = \{g_1, g_2, g_3, g_4, g_5\}$, and three divisible goods $C = \{c_1, c_2, c_3\}$. Suppose that agents 1, 2, 3, and 4 desire all the goods, but agent 5 desires only the indivisible goods (see Table 1). Then, an allocation π with $\pi(E) = (7/4, 7/4, 7/4, 7/4, 1)$ is dec-min. However, an allocation ρ with $\rho(E) = (6/4, 6/4, 6/4, 6/4, 2)$ is inc-max and square-sum minimizer. Indeed, $\sum_{i \in N} \pi_i(E)^2 = 13.25$ and $\sum_{i \in N} \rho_i(E)^2 = 13$.*

³See also Nagano [33, Corollary 13].

Example 2.4. Consider an instance with five agents $N = \{1, 2, 3, 4, 5\}$, five indivisible goods $M = \{g_1, g_2, g_3, g_4, g_5\}$, and two divisible goods $C = \{c_1, c_2\}$. Suppose that agents 1, 2, 3, and 4 desire all the goods, but agent 5 desires only the indivisible goods (see Table 2). Then, an allocation π with $\pi(E) = (6/4, 6/4, 6/4, 6/4, 1)$ is dec-min and square-sum minimizer. However, an allocation ρ with $\rho(E) = (5/4, 5/4, 5/4, 5/4, 2)$ is inc-max. Indeed, $\sum_{i \in N} \pi_i(E)^2 = 10$ and $\sum_{i \in N} \rho_i(E)^2 = 10.25$.

Table 1: Agents' valuations in Example 2.3.

agents	g_1	g_2	g_3	g_4	g_5	c_1	c_2	c_3
1	1	1	1	1	1	1	1	1
2	1	1	1	1	1	1	1	1
3	1	1	1	1	1	1	1	1
4	1	1	1	1	1	1	1	1
5	1	1	1	1	1	0	0	0

Table 2: Agents' valuations in Example 2.4.

agents	g_1	g_2	g_3	g_4	g_5	c_1	c_2
1	1	1	1	1	1	1	1
2	1	1	1	1	1	1	1
3	1	1	1	1	1	1	1
4	1	1	1	1	1	1	1
5	1	1	1	1	1	0	0

Nevertheless, a certain symmetric strictly convex function Φ induces the dec-min and inc-max solution as a Φ -fair allocation.

Proposition 2.5. Let (N, M, C, v) be a fair allocation instance. There exists a symmetric strictly convex function Φ such that a dec-min allocation is Φ -fair. In addition, there exists a symmetric strictly convex function Φ' such that an inc-max allocation is Φ' -fair.

Proof. When we fix an allocation of the indivisible goods, we can observe that the utility vector of the dec-min allocations is uniquely determined by treating each indivisible good as a divisible one such that only the agent who receives it desires it and applying Theorem 2.1. Let U be the set of the utility vectors obtained in this way for all possible allocations of indivisible goods. Since the number of possible allocations of indivisible goods is finite, $|U|$ is also finite.

Let x be the utility vector of a dec-min allocation. Without loss of generality, we may assume that $y^\downarrow \neq x^\downarrow$ for some $y \in U$ since otherwise the claim of this proposition holds for any symmetric strictly convex function Φ . Let $\varepsilon = \min\{y_i^\downarrow - x_i^\downarrow : y \in U, i \in [n], y_i^\downarrow > x_i^\downarrow\}$. We show that x minimizes $\Phi(z) = \sum_{i \in N} (2n)^{z_i/\varepsilon}$ over U . Take any $y \in U$ with $y^\downarrow \neq x^\downarrow$. Then, there exists an index $k \in [n]$ such that $y_i^\downarrow = x_i^\downarrow$ for $i = 1, 2, \dots, k-1$ and $y_k^\downarrow \geq x_k^\downarrow + \varepsilon$ since x is the utility vector of a dec-min allocation. Hence, we obtain

$$\Phi(y) - \Phi(x) = \sum_{i \in N} (2n)^{y_i/\varepsilon} - \sum_{i \in N} (2n)^{x_i/\varepsilon} \geq (2n)^{y_k^\downarrow/\varepsilon} - n \cdot (2n)^{(y_k^\downarrow - \varepsilon)/\varepsilon} = \frac{1}{2} \cdot (2n)^{y_k^\downarrow/\varepsilon} > 0.$$

The inc-max case is also proven in a similar way by setting $\Phi'(z) = \sum_{i \in N} (2n)^{-z_i/\varepsilon'}$ with $\varepsilon' = \min\{x_i^\downarrow - y_i^\downarrow : y \in U, i \in [n], x_i^\downarrow > y_i^\downarrow\}$. \square

This proposition implies that dec-min and inc-max allocations can be viewed as minimizers of some symmetric strictly convex function. We remark that some prominent fairness notions are naturally represented as Φ -fairness for some symmetric strictly convex function Φ . An allocation π is said to achieve the *maximum Nash welfare* (MNW) if the number of agents with positive utilities is maximized, and subject to that, the Nash welfare $\prod_{i \in N: \pi_i(E) > 0} \pi_i(E)$ is maximized. Finding a utility vector of an MNW allocation is equivalent to minimizing $\prod_{i \in N: z_i > 0} (z_i + \varepsilon)$ for some

sufficiently small $\varepsilon > 0$. See Appendix A for the detail. The egalitarian social welfare is defined by the smallest utility among agents. Maximizing the egalitarian social welfare is a weaker notion of inc-max, and thus we can apply Proposition 2.5. Hence, we mainly consider Φ -fair allocations in the following.

3 Integral base-polyhedra and M-convex sets

In this section, we formulate our fair allocation problem in terms of convex analysis. Then we introduce known results and tools for continuous or discrete cases.

3.1 Definitions and properties

In this subsection, we introduce the definitions and properties of integral base-polyhedra and M-convex sets that we will use later. A set function f over N is called *supermodular* if

$$f(X) + f(Y) \leq f(X \cup Y) + f(X \cap Y) \quad (\forall X, Y \subseteq N)$$

and *submodular* if

$$f(X) + f(Y) \geq f(X \cup Y) + f(X \cap Y) \quad (\forall X, Y \subseteq N).$$

For a subset $X \subseteq N$ and a vector $x \in \mathbb{R}^N$, we denote $x(X) = \sum_{i \in X} x_i$. For an integer-valued supermodular set function f on N for which $f(\emptyset) = 0$ (normalized), the *integral base-polyhedron* $\bar{\mathbf{B}}$ of f is defined as

$$\bar{\mathbf{B}} = \{x \in \mathbb{R}^N : x(N) = f(N) \text{ and } x(X) \geq f(X) \ (\forall X \subseteq N)\}.$$

In addition, we call the set $\ddot{\mathbf{B}}$ of the integer vectors in an integral base-polyhedron $\bar{\mathbf{B}}$ an *M-convex set*. Note that an M-convex set $\ddot{\mathbf{B}}$ induces an integral base-polyhedron $\bar{\mathbf{B}}$ as its convex hull.

For an integral base-polyhedra $\bar{\mathbf{B}}$ defined by a supermodular function $f: 2^N \rightarrow \mathbb{Z}$, we have the following facts.

Proposition 3.1 ([17, Lemma 3.2]). *For any $X \subseteq N$, there exists $x \in \ddot{\mathbf{B}}$ such that $x(X) = f(X)$.*

Proposition 3.2 ([17, Lemma 2.2]). *For $x \in \bar{\mathbf{B}}$, letting $\mathcal{D}(x) = \{X \subseteq N : x(X) = f(X)\}$, we have*

$$X, Y \in \mathcal{D}(x) \implies X \cup Y, X \cap Y \in \mathcal{D}(x).$$

An M-convex set $\ddot{\mathbf{B}}$ satisfies the *exchange property* (B-EXC[\mathbb{Z}]) stated as follows.

Proposition 3.3 ([32]). *For any $x, y \in \ddot{\mathbf{B}}$ and $i \in \text{supp}^+(x - y)$, there exists some $j \in \text{supp}^-(x - y)$ such that $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$ and $y + \chi_i - \chi_j \in \ddot{\mathbf{B}}$.*

An integral base-polyhedra $\bar{\mathbf{B}}$ satisfies the following exchange property (B-EXC[\mathbb{R}]).

Proposition 3.4 ([32]). *For any $x, y \in \bar{\mathbf{B}}$ and $i \in \text{supp}^+(x - y)$, there exists some $j \in \text{supp}^-(x - y)$ and a positive real α_0 such that $x - \alpha(\chi_i - \chi_j) \in \bar{\mathbf{B}}$ and $y + \alpha(\chi_i - \chi_j) \in \bar{\mathbf{B}}$ for all $\alpha \in [0, \alpha_0]$.*

In addition, the following variants of exchange properties also hold. Suppose that $\bar{\mathbf{B}}$ and $\ddot{\mathbf{B}}$ are induced by a supermodular function $f: 2^N \rightarrow \mathbb{Z}$.

Proposition 3.5. *For any $x, y \in \ddot{\mathbf{B}}$ and $X \subseteq N$ with $x(X) > y(X)$, there exist $i \in X$ and $j \in N \setminus X$ such that $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$. Moreover, if $x(X) > f(X)$, there exist $i \in X$ and $j \in N \setminus X$ such that $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$.*

Proof. Suppose to the contrary that $x - \chi_i + \chi_j \notin \ddot{\mathbf{B}}$ for any $i \in X$ and $j \in N \setminus X$. For each $i \in X$ and $j \in N \setminus X$, let Y_{ij} be a subset of N such that $x(Y_{ij}) = f(Y_{ij})$, $i \in Y_{ij}$, and $j \notin Y_{ij}$. Then, $Y_i := \bigcap_{j \in N \setminus X} Y_{ij}$ satisfies $i \in Y_i$, $Y_i \subseteq X$, and $x(Y_i) = f(Y_i)$ for each $i \in N$ by Proposition 3.2. Furthermore, $Y := \bigcup_{i \in X} Y_i$ satisfies $Y = X$ and $x(Y) = f(X)$ by Proposition 3.2. Hence, we obtain $f(X) = x(X) > y(X) \geq f(X)$, which is a contradiction.

In addition, the latter statement holds by setting y such that $y(X) = f(X)$, whose existence is guaranteed by Proposition 3.1. \square

Proposition 3.6. *For any $x, y \in \bar{\mathbf{B}}$ and $X \subseteq N$ with $x(X) > y(X)$, there exist $i \in X$, $j \in N \setminus X$, and $\varepsilon > 0$ such that $x - \varepsilon(\chi_i - \chi_j) \in \bar{\mathbf{B}}$. Moreover, if $x(X) > f(X)$, there exist $i \in X$, $j \in N \setminus X$, and $\varepsilon > 0$ such that $x - \varepsilon(\chi_i - \chi_j) \in \bar{\mathbf{B}}$.*

Proof. The proof is done in a similar way to Proposition 3.5. \square

Proposition 3.7. *For any $x \in \ddot{\mathbf{B}}$ and disjoint subsets $I, J \subseteq N$ such that $x(J) < f(I \cup J) - f(I)$, there exist $i \in I$ and $j \in J$ such that $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$.*

Proof. Since $f(I \cup J) \leq x(I \cup J) < x(I) + f(I \cup J) - f(I)$, we have $x(I) > f(I)$.

Suppose to the contrary that $x - \chi_i + \chi_j \notin \ddot{\mathbf{B}}$ for any $i \in I$ and $j \in J$. For each $i \in I$ and $j \in J$, let T_{ij} be a subset of N such that $x(T_{ij}) = f(T_{ij})$, $i \in T_{ij}$, and $j \notin T_{ij}$. Then, $T := \bigcup_{i \in I} \bigcap_{j \in J} T_{ij}$ satisfies $I \subseteq T \subseteq N \setminus J$ and $x(T) = f(T)$ by Proposition 3.2.

By Proposition 3.5 and $x(I) > f(I)$, there exist $i_1 \in I$ and $j_1 \in N \setminus I$ such that $x^{(1)} := x - \chi_{i_1} + \chi_{j_1} \in \ddot{\mathbf{B}}$. Here, j_1 must be in T since otherwise $x^{(1)}(T) = x(T) - 1 \geq f(T)$, which is a contradiction. Let $s := f(I) - x(I)$. Similarly, for each $k = 1, 2, \dots, s$, since $x^{(k-1)}(I) > f(I)$, we can choose $i_k \in I$ and $j_k \in T \setminus I$ such that $x^{(k)} := x^{(k-1)} - \chi_{i_k} + \chi_{j_k} \in \ddot{\mathbf{B}}$. However, we have $x^{(s)}(I \cup J) = f(I) + x(J) < f(I \cup J)$, which contradicts $x^{(s)} \in \ddot{\mathbf{B}}$. \square

Proposition 3.8. *For any $x \in \ddot{\mathbf{B}}$ and $y \in \bar{\mathbf{B}}$, and $i \in \text{supp}^+(x - y)$, there exists $j \in \text{supp}^-(x - y)$ such that $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$. Also, for any $x \in \ddot{\mathbf{B}}$ and $y \in \bar{\mathbf{B}}$, and $i \in \text{supp}^-(x - y)$, there exists $j \in \text{supp}^+(x - y)$ such that $x + \chi_i - \chi_j \in \ddot{\mathbf{B}}$.*

Proof. We only provide a proof for the former part, as the latter part can be demonstrated in a similar manner. By Proposition 3.4, there exists some $j \in \text{supp}^-(x - y)$ and a positive real α_0 such that $x' := x - \alpha_0(\chi_i - \chi_j) \in \bar{\mathbf{B}}$. For any $X \subseteq N$ with $i \in X$ and $j \notin X$, we have $x'(X) = x(X) - \alpha_0 \geq f(X)$, and hence $x(X) - 1 \geq f(X)$ since $x(X)$ and $f(X)$ are integers. Therefore, $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$ holds. \square

Moreover, the following properties also hold.

Proposition 3.9. *For any $x \in \ddot{\mathbf{B}}$, if $x - \chi_i + \chi_j \in \ddot{\mathbf{B}}$ and $x - \chi_j + \chi_k \in \ddot{\mathbf{B}}$, then it holds that $x - \chi_i + \chi_k \in \ddot{\mathbf{B}}$.*

Proof. Let $x' := x - \chi_i + \chi_j$ and $y' := x - \chi_j + \chi_k$. We apply Proposition 3.3 to x' and y' . Since $\text{supp}^+(x' - y') = \{j\}$ and $\text{supp}^-(x' - y') = \{i, k\}$, we have two possibilities. In both cases, we have $x' - \chi_j + \chi_k \in \ddot{\mathbf{B}}$. \square

Proposition 3.10 ([17, Lemma 4.5]). *Let $x \in \ddot{\mathbf{B}}$. Suppose that there exist a sequence $i_1, j_1, \dots, i_r, j_r$ of $2r$ distinct elements in N such that $x - \chi_{i_h} + \chi_{j_k} \in \ddot{\mathbf{B}}$ if $h = k$ and $x - \chi_{i_h} + \chi_{j_k} \notin \ddot{\mathbf{B}}$ if $h > k$ for $h, k \in [r]$. Then, it holds that $x - \sum_{k \in [r]} (\chi_{i_k} - \chi_{j_k}) \in \ddot{\mathbf{B}}$.*

Proposition 3.11 (integrally convexity [32]).

$$x \in \bar{\mathbf{B}} \implies x \in \text{conv}(\bar{\mathbf{B}} \cap \{y \in \mathbb{Z}^N : \|x - y\|_\infty < 1\}).$$

3.2 The hybrid problem and relation to fair allocation

Here, we explain how integral base-polyhedra and M-convex sets appear in a fair allocation with binary additive valuations. For a subset $X \subseteq N$ of agents, we define $f_M, f_C, f_E: 2^N \rightarrow \mathbb{Z}_+$ as follows:

- $f_M(X) = |\{g \in M : v_{ig} = 0 \ (\forall i \notin X)\}|$ is the number of indivisible goods that must be allocated to agents in X ,
- $f_C(X) = |\{c \in C : v_{ic} = 0 \ (\forall i \notin X)\}|$ is the number of divisible goods that must be allocated to agents in X , and
- $f_E(X) = f_M(X) + f_C(X)$ is the number of goods that must be allocated to agents in X .

It is not difficult to see that the functions f_M, f_C, f_E are normalized integer-valued supermodular.⁴ Let $\ddot{\mathbf{B}}_M$ and $\bar{\mathbf{B}}_C$ be the M-convex set of f_M and the integral base-polyhedron of f_C , respectively. In addition, let \mathbf{B}_E be the Minkowski sum of $\ddot{\mathbf{B}}_M$ and $\bar{\mathbf{B}}_C$, i.e., $\mathbf{B}_E = \{x + y : x \in \ddot{\mathbf{B}}_M, y \in \bar{\mathbf{B}}_C\}$. Then, \mathbf{B}_E is the set of possible utility vectors.

Recall that $\bar{\mathbf{B}}_M = \text{conv}(\ddot{\mathbf{B}}_M)$ and $\ddot{\mathbf{B}}_C = \bar{\mathbf{B}}_C \cap \mathbb{Z}^N$. We denote $\bar{\mathbf{B}}_E = \text{conv}(\mathbf{B}_E)$, and $\ddot{\mathbf{B}}_E = \mathbf{B}_E \cap \mathbb{Z}^N$. Note that \mathbf{B}_E is not necessarily an M-convex set or an integral base-polyhedron as we have seen in Example 1.1.

Then we can rewrite finding a Φ -fair allocation for a symmetric strictly convex function $\Phi: \mathbb{R}^N \rightarrow \mathbb{R}$ as the problem of finding a vector z that attains

$$\min_{z \in \mathbf{B}_E} \Phi(z) \ (= \min_{x \in \ddot{\mathbf{B}}_M} \min_{y \in \bar{\mathbf{B}}_C} \Phi(x + y)).$$

This formulation is not restricted to the fair allocation. An optimal solution z is called Φ -*minimizer* (on \mathbf{B}_E). We omit the feasible region if it is clear. If $M = \emptyset$ or $C = \emptyset$, this minimization problem can be solved in polynomial time, as shown in the next subsection.

3.3 Principal Partition and Canonical Partition

In this subsection, we summarize the structures of Φ -minimizers on integral base-polyhedra or M-convex sets.

Consider the integral base-polyhedron $\bar{\mathbf{B}}$ and the M-convex set $\ddot{\mathbf{B}}$ of a supermodular function $f: 2^N \rightarrow \mathbb{Z}_+$. For any real number λ , let $\mathcal{L}(\lambda)$ be the set of all maximizers of $f(X) - \lambda|X|$, i.e., $\mathcal{L}(\lambda) = \arg \max_{X \subseteq N} (f(X) - \lambda|X|)$. Note that \mathcal{L} has a lattice structure (see Proposition 3.2), i.e.,

⁴Most of our results can be extended to the case when each agent evaluates indivisible goods with a matroid rank function and divisible goods with the concave closure of a matroid rank function because the functions f_M, f_C, f_E continue to be normalized integer-valued supermodular in this scenario.

\mathcal{L} is closed under union and intersection. Let $L(\lambda)$ be the smallest member in $\mathcal{L}(\lambda)$. It is known that $L(\lambda) \subseteq L(\lambda')$ for any $\lambda > \lambda'$ (see, e.g., [15, Proposition 3.1]).

Fujishige [16] characterized the optimal utility vectors by the *principal partition* of N . There are at most $|N|$ number of λ for which $|\mathcal{L}(\lambda)| \geq 2$. Let us denote such numbers as $\lambda_1 > \lambda_2 > \dots > \lambda_r$, which are called the *critical values*. The principal partition $\hat{N}_1, \hat{N}_2, \dots, \hat{N}_r$ is a partition of N defined by

$$\hat{N}_j = L(\lambda'_j) - L(\lambda_j) \quad (j = 1, 2, \dots, r),$$

where λ'_j is an arbitrary real satisfying $\lambda_j > \lambda'_j > \lambda_{j+1}$ (assuming that $\lambda_{r+1} = -\infty$).

Theorem 3.12 (Fujishige [16] and Maruyama [29]). *The unique minimizer x^* of $\min_{x \in \bar{\mathbf{B}}} \Phi(x)$ satisfies $x_i^* = \lambda_j$ for each $i \in \hat{N}_j$ and $j \in [r]$. The principal partition and critical values can be found in strongly polynomial time.*

For more details of the principal partition, see a book and a survey of Fujishige [17, 18].

Frank and Murota [13] characterized the optimal utility vectors by the *canonical partition* of N . There are at most $|N|$ number of $\beta \in \mathbb{Z}$ for which $L(\beta) \neq L(\beta - 1)$. Let us denote such numbers as $\beta_1 > \beta_2 > \dots > \beta_q$, which are called the *essential values*. The canonical partition N_1, N_2, \dots, N_q is a partition of N defined by

$$N_i = L(\beta_i - 1) - L(\beta_i) \quad (i = 1, 2, \dots, q).$$

Alternatively, the canonical partition and the essential values can be obtained by the following procedure [15, Section 3]: for $j = 1, 2, \dots, q$, define

$$\beta_j = \max \left\{ \left\lceil \frac{f(X \cup \bigcup_{j'=1}^{j-1} N_{j'}) - f(\bigcup_{j'=1}^{j-1} N_{j'})}{|X|} \right\rceil : \emptyset \neq X \subseteq N \setminus \bigcup_{j'=1}^{j-1} N_{j'} \right\}, \quad (2)$$

$$h_j(X) = f(X \cup \bigcup_{j'=1}^{j-1} N_{j'}) - (\beta_j - 1)|X| - f(\bigcup_{j'=1}^{j-1} N_{j'}) \quad (\forall X \subseteq N \setminus \bigcup_{j'=1}^{j-1} N_{j'}), \text{ and}$$

$$N_j = \text{smallest subset of } N \setminus \bigcup_{j'=1}^{j-1} N_{j'} \text{ maximizing } h_j.$$

They provided a strongly polynomial-time algorithm to compute the canonical partition and the essential values by using this structure and a strongly polynomial-time algorithm for the submodular function minimization [24, 37].

Theorem 3.13 (Frank and Murota [13, 14, 15]). *The essential values $\beta_1 > \beta_2 > \dots > \beta_q$ are obtained from the critical values $\lambda_1 > \lambda_2 > \dots > \lambda_r$ as the distinct members of the rounded-up integers $\lceil \lambda_1 \rceil \geq \lceil \lambda_2 \rceil \geq \dots \geq \lceil \lambda_r \rceil$. Moreover, the canonical partition is an aggregation of the principal partition as $N_i = \bigcup_{j: \lceil \lambda_j \rceil = \beta_i} \hat{N}_j$ for each $i \in [q]$. Any minimizer y^* of $\min_{y \in \bar{\mathbf{B}}} \Phi(y)$ satisfies $\beta_j - 1 \leq y_i^* \leq \beta_j$ for each $i \in N_j$ and $j \in [q]$. The minimizer y^* , the canonical partition, and essential values can be found in strongly polynomial time with respect to $|N|$.*

4 Structure of Φ -minimizers

In this section, we prove a proximity theorem and a structure based on the canonical partition. Let f_M and f_C be two supermodular functions over M and C , respectively. Let also $f_E = f_M +$

f_C . Recall that $\ddot{\mathbf{B}}_M$ and $\bar{\mathbf{B}}_C$ are a corresponding M-convex set and integral base-polyhedron, respectively. In addition, \mathbf{B}_E is the Minkowski sum of $\ddot{\mathbf{B}}_M$ and $\bar{\mathbf{B}}_C$. Note that, in this section, we consider general integral supermodular functions, not restricted to the ones appearing in Section 3.2.

Theorem 4.1. *Let Φ be a symmetric strictly convex function. For any $z^* \in \arg \min_{z \in \mathbf{B}_E} \Phi(z)$ and $\bar{z} \in \arg \min_{z \in \bar{\mathbf{B}}_E} \Phi(z)$, we have*

$$\lfloor \bar{z}_i \rfloor \leq z_i^* \leq \lceil \bar{z}_i \rceil \quad (i \in N).$$

It should be noted that, for the integral base-polyhedron $\bar{\mathbf{B}}$ and the M-convex set $\ddot{\mathbf{B}}$ of a common supermodular function, the following proximity theorem has been shown by Frank and Murota [15].

Theorem 4.2 ([15, Theorem 4.1]). *Let Φ be a symmetric strictly convex function. For any $x^* \in \arg \min_{x \in \ddot{\mathbf{B}}} \Phi(x)$ and $y^* \in \arg \min_{y \in \bar{\mathbf{B}}} \Phi(y)$, we have*

$$\lfloor y_i^* \rfloor \leq x_i^* \leq \lceil y_i^* \rceil \quad (i \in N).$$

Note that Theorem 4.2 is a special case of our Theorem 4.1 when $f_C(X) = 0$ ($\forall X \subseteq N$). We prove Theorem 4.1 following the same approach as for Theorem 4.2. However, we need to conduct a more detailed analysis to handle $\bar{\mathbf{B}}_C$.

Throughout this section, we fix a symmetric strictly convex function $\Phi: \mathbb{R}^N \rightarrow \mathbb{R}$ and its minimizer $z^* \in \arg \min_{z \in \mathbf{B}_E} \Phi(z)$. By definition, z^* can be represented as $x^* + y^*$ by $x^* \in \ddot{\mathbf{B}}_M$ and $y^* \in \bar{\mathbf{B}}_C$. Moreover, let N_1, \dots, N_q and β_1, \dots, β_q be the canonical partition and the essential values of the M-convex set $\ddot{\mathbf{B}}_E$.

In subsequent subsections, we prove Theorem 4.1 through the following steps. First, in Section 4.1, we demonstrate that z_i^* lies within the interval $[\beta_1 - 1, \beta_1]$ for $i \in N_1$. Then, in Section 4.2, we decompose the problem of finding z^* into two independent problems on N_1 and $N \setminus N_1$. By iteratively applying the same procedure, we obtain the desired structure. In Section 4.3, we show an additional result when \mathbf{B}_E emerges from the fair allocation.

4.1 The peak-set N_1

In this subsection, we prove that $\beta_1 \geq z_i^* \geq \beta_1 - 1$ and $z^*(N_1) = f_E(N_1)$.

We first observe that we can transfer some amounts from elements with high value to those with low value.

Lemma 4.3. *If $y^* + \varepsilon(\chi_i - \chi_j) \in \bar{\mathbf{B}}_C$ for some $i, j \in N$ and $\varepsilon > 0$, then $z_i^* = x_i^* + y_i^* \geq x_j^* + y_j^* = z_j^*$. In addition, for any $\beta \in \mathbb{R}$, it holds that $y^*(N') = f_C(N')$ with $N' = \{i \in N : z_i^* \geq \beta\}$.*

Proof. For the former statement, suppose to the contrary that $y^* + \varepsilon(\chi_i - \chi_j) \in \bar{\mathbf{B}}_C$ for some $i, j \in N$ such that $x_i^* + y_i^* < x_j^* + y_j^*$ and $\varepsilon > 0$. Then, $y = y^* + \min\{\varepsilon, (y_j^* - y_i^*)/2\} \cdot (\chi_i - \chi_j) \in \bar{\mathbf{B}}_C$ and $\Phi(x^* + y) < \Phi(x^* + y^*)$ by (1). This contradicts the assumption that $z^* = x^* + y^*$ is a Φ -minimizer.

For the latter statement, suppose that $y^*(N') > f_C(N')$ for some $N' = \{i \in N : z_i^* \geq \beta\}$ with $\beta \in \mathbb{R}$. Then, by Proposition 3.6, there exist $i \in N'$, $j \in N \setminus N'$, and $\varepsilon > 0$ such that $y^* + \varepsilon(\chi_j - \chi_i) \in \bar{\mathbf{B}}_C$. By the former statement, this implies $z_j^* \geq z_i^*$, which contradicts $j \notin N'$. \square

Lemma 4.4. Let β be an integer and $N' \subseteq N$. Define $N^> = \{i \in N : z_i^* > \beta\}$, $N^= = \{i \in N : z_i^* = \beta\}$, and $N^< = \{i \in N : z_i^* < \beta\}$. Construct a graph

$$G = (N', \{(i, j) \in N' \times N' : x^* - \chi_i + \chi_j \in \ddot{\mathbf{B}}_M \text{ or } y^* - \chi_i + \chi_j \in \bar{\mathbf{B}}_C\}).$$

If G has a path from some $i \in N' \cap N^>$ to some $j \in N' \cap N^<$, then there exists a vector z'' such that $\Phi(z'') < \Phi(z^*)$.

Proof. We first observe that Lemma 4.3 implies $y^*(N^>) = f_C(N^>)$ and $y^*(N^> \cup N^=) = f_C(N^> \cup N^=)$.

Let $P = (i_1, i_2, \dots, i_k)$ be a shortest path from some $i_1 \in N' \cap N^>$ to some $i_k \in N' \cap N^<$. Then we have $i_1 \in N^>$, $i_2, \dots, i_{k-1} \in N^=$, and $i_k \in N^<$. Since $z_{i_2}^* < z_{i_1}^*$, Lemma 4.3 implies that $y^* - \chi_{i_1} + \chi_{i_2} \notin \bar{\mathbf{B}}_C$, and thus $x^* - \chi_{i_1} + \chi_{i_2} \in \ddot{\mathbf{B}}_M$. If $x^* - \chi_{i_2} + \chi_{i_3} \in \ddot{\mathbf{B}}_M$, then $x^* - \chi_{i_1} + \chi_{i_3} \in \ddot{\mathbf{B}}_M$ by Proposition 3.9, which leads to a shortcut of P . Thus, we have $x^* - \chi_{i_2} + \chi_{i_3} \notin \ddot{\mathbf{B}}_M$ and instead, $y^* - \chi_{i_2} + \chi_{i_3} \in \bar{\mathbf{B}}_C$ holds. Next, let us assume that $y^* - \chi_{i_3} + \chi_{i_4} \in \bar{\mathbf{B}}_C$ and $i_4 \in N^=$, and derive a contradiction. Consider

$$\bar{\mathbf{B}}^= = \{\tilde{y} \in \mathbb{R}^{N^=} : \tilde{y}(N^=) = f_C(N^= \cup N^>) - f_C(N^>) \text{ and } \tilde{y}(X) \geq f_C(X \cup N^>) - f_C(N^>) (\forall X \subseteq N^=)\},$$

which is also an integral base-polyhedron of a supermodular function. Since β is an integer, $y_{N^=}^*$ is also integral. Thus, the vectors $y_{N^=}^* - \chi_{i_2} + \chi_{i_3}$ and $y_{N^=}^* - \chi_{i_3} + \chi_{i_4}$ are contained in $\bar{\mathbf{B}}^=$, since $y^*(N^>) = f_C(N^>)$ and $i_2, i_3, i_4 \in N^=$. Then $y_{N^=}^* - \chi_{i_2} + \chi_{i_4} \in \bar{\mathbf{B}}^=$ follows from Proposition 3.9, which means that $y^* - \chi_{i_2} + \chi_{i_4} \in \bar{\mathbf{B}}_C$ ⁵. However, this implies a shortcut of P . Therefore, if $i_4 \in N^=$, then $y^* - \chi_{i_3} + \chi_{i_4} \notin \bar{\mathbf{B}}_C$, and hence $x^* - \chi_{i_3} + \chi_{i_4} \in \ddot{\mathbf{B}}_M$. By the same argument, we have $x^* - \chi_{i_\ell} + \chi_{i_{\ell+1}} \in \ddot{\mathbf{B}}_M$ if ℓ is an odd number and $i_{\ell+1} \in N^=$, and $y^* - \chi_{i_\ell} + \chi_{i_{\ell+1}} \in \bar{\mathbf{B}}_C$ if ℓ is an even number. Note that k must be an even number, because $y^* - \chi_{i_{k-1}} + \chi_{i_k} \notin \bar{\mathbf{B}}_C$ follows from Lemma 4.3 and $z_{i_k}^* < z_{i_{k-1}}^*$. Moreover, for any integers ℓ and h with $\ell \geq h + 2$, we have $x^* - \chi_{i_\ell} + \chi_{i_h} \notin \ddot{\mathbf{B}}_M$ and $y^* - \chi_{i_\ell} + \chi_{i_h} \notin \bar{\mathbf{B}}_C$. Let

$$x' = x^* - \sum_{\ell: \text{odd}} (\chi_{i_\ell} - \chi_{i_{\ell+1}}), \quad y' = y^* - \sum_{\ell: \text{even}} (\chi_{i_\ell} - \chi_{i_{\ell+1}}),$$

and $z' = x' + y'$. By Proposition 3.10, we have $x' \in \ddot{\mathbf{B}}_M$, $y' \in \bar{\mathbf{B}}_C$, and $z' \in \mathbf{B}_E$. Note that $z' = z^* - \chi_{i_1} + \chi_{i_k}$, $y'(N^>) = y^*(N^>)$ ($= f_C(N^>)$) and $y'(N^> \cup N^=) = y^*(N^> \cup N^=)$ ($= f_C(N^> \cup N^=)$) by the construction. For notational convenience, we denote $i^* = i_1$ and $j^* = i_k$ in the following.

If $z_{i^*}^* > z_{j^*}^* + 1$, then $\Phi(z') < \Phi(z^*)$. Thus, suppose that $z_{i^*}^* \leq z_{j^*}^* + 1$ ($< \beta + 1$). In this case, $\beta - 1 < z_{i^*}^* < \beta$ and $\beta < z_{j^*}^* < \beta + 1$. By Proposition 3.11, y' can be represented by a convex combination of its integral neighbors in $\bar{\mathbf{B}}_C$. Let $y' = \sum_{t=1}^r \lambda^{(t)} \cdot y^{(t)}$, where $y^{(t)} \in \bar{\mathbf{B}}_C \cap \{y \in \mathbb{Z}^N : \|y - y'\| < 1\}$ ($\forall t \in [r]$), $\sum_{t=1}^r \lambda^{(t)} = 1$, and $\lambda^{(t)} \geq 0$ ($\forall t \in [r]$). Define $z^{(t)} = x' + y^{(t)}$ for each t . Thus, we also obtain $z' = \sum_{t=1}^r \lambda^{(t)} \cdot z^{(t)}$. Note that $z_{i^*}^{(t)} \in \{\beta - 1, \beta\}$ and $z_{j^*}^{(t)} \in \{\beta, \beta + 1\}$ for each t . In addition, for each t , it holds that $y^{(t)}(N^>) = f_C(N^>)$ because $\sum_{t=1}^r \lambda^{(t)} \cdot y^{(t)}(N^>) = y'(N^>) = y^*(N^>) = f_C(N^>)$ and $y^{(t)}(N^>) \geq f_C(N^>)$. Similarly, we can see that $y^{(t)}(N^> \cup N^=) = f_C(N^> \cup N^=)$ for each t .

⁵We need to check for each X such that $i_2 \in X$ but $i_4 \notin X$. The case when $X \supseteq \{i_2, i_3\}$ follows by $y^* - \chi_{i_3} + \chi_{i_4} \in \bar{\mathbf{B}}_C$, and the case when $i_2 \in X$ but $i_3 \notin X$ follows by $y^* - \chi_{i_2} + \chi_{i_3} \in \bar{\mathbf{B}}_C$.

Let us choose an arbitrary t with $z_{i^*}^{(t)} = \beta - 1$. Let

$$\bar{\mathbf{B}}^> = \{\tilde{y} \in \mathbb{R}^{N^>} : \tilde{y}(N^>) = f_C(N^>) \text{ and } \tilde{y}(X) \geq f_C(X) (\forall X \subseteq N^>)\}$$

(the restriction of $\bar{\mathbf{B}}_C$ to $N^>$), and $\check{\mathbf{B}}^>$ be the M-convex set induced from $\bar{\mathbf{B}}^>$. Then it holds that $y_{N^>}^{(t)} \in \check{\mathbf{B}}^>$, $y'_{N^>} \in \bar{\mathbf{B}}^>$ and $i^* \in \text{supp}^-(y_{N^>}^{(t)} - y'_{N^>})$. We apply Proposition 3.8 to them. Then we can choose an index $i^{(t)} \in \text{supp}^+(y_{N^>}^{(t)} - y'_{N^>})$ such that $y_{N^>}^{(t)} + \chi_{i^*} - \chi_{i^{(t)}} \in \bar{\mathbf{B}}^>$. We show that this implies

$$\hat{y}^{(t)} := y^{(t)} + \chi_{i^*} - \chi_{i^{(t)}} \in \bar{\mathbf{B}}_C.$$

Indeed, for any X with $i^* \notin X$ and $i^{(t)} \in X$ (the other cases are trivial), since $y^{(t)}(X \cap N^>) - 1 \geq f_C(X \cap N^>)$, we have

$$y^{(t)}(X) = y^{(t)}(X \cap N^>) + y^{(t)}(X \cup N^>) - y^{(t)}(N^>) > f_C(X \cap N^>) + f_C(X \cup N^>) - f_C(N^>) \geq f_C(X),$$

which implies that $\hat{y}^{(t)}(X) \geq f_C(X)$. In addition, we observe that $z_{i^{(t)}}^{(t)} = y_{i^{(t)}}^{(t)} + x'_{i^{(t)}} > y'_{i^{(t)}} + x'_{i^{(t)}} = z'_{i^{(t)}} = z_{i^{(t)}} > \beta$. Thus, since $z_{i^{(t)}}^{(t)}$ is an integer,

$$\hat{y}_{i^{(t)}}^{(t)} + x'_{i^{(t)}} = z_{i^{(t)}}^{(t)} - 1 \geq \beta. \quad (3)$$

On the other hand, for each t with $z_{i^*}^{(t)} = \beta$, we denote $\hat{y}^{(t)} = y^{(t)}$. We also remark that $\hat{y}^{(t)}(N^> \cup N^=) = y^{(t)}(N^> \cup N^=)$ and $\hat{y}_i^{(t)} = y_i^{(t)}$ for each t and $i \in N \setminus N^>$.

We will do similar operations for indices in $N^<$. Let us choose an arbitrary t with $z_{j^*}^{(t)} = \beta_1 + 1$. We show that we can choose $j^{(t)} \in N^<$ with $z_{j^{(t)}}^{(t)} \leq \beta_1 - 1$ such that $\hat{y}^{(t)} - \chi_{j^*} + \chi_{j^{(t)}} \in \bar{\mathbf{B}}_C$ by applying Proposition 3.8. We denote $N^{\geq} = N^> \cup N^=$. Let also

$$\bar{\mathbf{B}}^< = \{\tilde{y} \in \mathbb{R}^{N^<} : \tilde{y}(N^<) = f_C(N) - f_C(N^{\geq}) \text{ and } \tilde{y}(X) \geq f_C(X \cup N^{\geq}) - f_C(N^{\geq}) (\forall X \subseteq N^<)\}.$$

(the contraction of $\bar{\mathbf{B}}_C$ by N^{\geq}), and $\check{\mathbf{B}}^<$ be the M-convex set induced from $\bar{\mathbf{B}}^<$. Then it holds that $\hat{y}_{N^<}^{(t)} \in \check{\mathbf{B}}^<$, $y'_{N^<} \in \bar{\mathbf{B}}^<$ and $j^* \in \text{supp}^+(\hat{y}_{N^<}^{(t)} - y'_{N^<})$. We apply Proposition 3.8 to them. Then we can choose an index $j^{(t)} \in \text{supp}^-(\hat{y}_{N^<}^{(t)} - y'_{N^<})$ such that $\hat{y}_{N^<}^{(t)} - \chi_{j^*} + \chi_{j^{(t)}} \in \bar{\mathbf{B}}^<$. Then we can observe that

$$\hat{y}^{(t)} - \chi_{j^*} + \chi_{j^{(t)}} \in \bar{\mathbf{B}}_C.$$

Indeed, for any X with $j^* \in X$ and $j^{(t)} \notin X$, since $y^{(t)}(X \cap N^<) - 1 \geq f_C((X \cap N^<) \cup N^{\geq}) - f_C(N^{\geq})$ and $y^{(t)}(X \cap N^{\geq}) \geq f_C(X \cap N^{\geq})$, we have

$$y^{(t)}(X) = y^{(t)}(X \cap N^<) + y^{(t)}(X \cap N^{\geq}) > f_C(X \cap N^<) - f_C(N^{\geq}) + f_C(X \cup N^{\geq}) \geq f_C(X).$$

Moreover, $z_{j^{(t)}}^{(t)} < y'_{j^{(t)}} + x'_{j^{(t)}} = z'_{j^{(t)}} = z_{j^{(t)}} < \beta$, which implies that

$$\hat{y}_{j^{(t)}}^{(t)} + 1 + x'_{j^{(t)}} = z_{j^{(t)}}^{(t)} + 1 \leq \beta. \quad (4)$$

For simplicity, let $j^{(t)} = j^*$ for each t with $z_{j^*}^{(t)} = \beta$. Then,

$$y'' := \sum_{t=1}^r \lambda^{(t)} \cdot (\hat{y}^{(t)} - \chi_{j^*} + \chi_{j^{(t)}}) \in \bar{\mathbf{B}}_C.$$

Let $z'' = x' + y''$. Note that this operation to produce z'' first reduces the value of elements more than β while keeping them at least β by (3), and then increases the value of elements less than β while keeping them at most β by (4). In other words, $\beta_1 \leq z''_i \leq z^*_i$ for $i \in N^>$, $z''_i = z^*_i$ for $i \in N^=$, and $z^*_i \leq z''_i \leq \beta_1$ for $i \in N^<$. Therefore, $\Phi(z'') < \Phi(z^*)$ holds. This contradicts to the optimality of z^* . \square

Next, we show that z^*_i is at most β_1 for all $i \in N$. Recall that $\beta_1 = \max\{[f_E(X)/|X|] : \emptyset \neq X \subseteq N\}$ by (2).

Lemma 4.5. $z^*_i \leq \beta_1$ for all $i \in N$.

Proof. Define the sets $N^> = \{i \in N : z^*_i > \beta_1\}$, $N^= = \{i \in N : z^*_i = \beta_1\}$, and $N^< = \{i \in N : z^*_i < \beta_1\}$. By Lemma 4.3, $y^*(N^>) = f_C(N^>)$ and $y^*(N^> \cup N^=) = f_C(N^> \cup N^=)$.

Suppose to the contrary that $N^>$ is nonempty. We construct a graph

$$G = (N, \{(i, j) \in N^2 : x^* - \chi_i + \chi_j \in \ddot{\mathbf{B}}_M \text{ or } y^* - \chi_i + \chi_j \in \bar{\mathbf{B}}_C\}).$$

We observe that for any Z with $N^> \subseteq Z \subseteq N^> \cup N^=$, it holds that

$$z^*(Z) > f_E(Z) \tag{5}$$

because $f_M(Z) + f_C(Z) = x^*(Z) + y^*(Z) = z^*(Z) > \beta_1 \cdot |Z| \geq f_E(Z) = f_M(Z) + f_C(Z)$, where the last inequality holds by the definition of β_1 . This implies the following claim.

Claim 4.6. For any Z satisfying (5), there exists an edge from some vertex $i \in Z$ to some $j \in N \setminus Z$.

Proof. Let us fix Z . Suppose to the contrary that $x^* - \chi_i + \chi_j \notin \ddot{\mathbf{B}}_M$ and $y^* - \chi_i + \chi_j \notin \bar{\mathbf{B}}_C$ for all $i \in Z$ and $j \in N \setminus Z$. In a similar way to Proposition 3.5, for each $i \in Z$ and $j \in N \setminus Z$, let X_{ij} be a subset of N such that $x^*(X_{ij}) = f_M(X_{ij})$, $i \in X_{ij}$, and $j \notin X_{ij}$. Then, since $\bigcup_{i \in Z} \bigcap_{j \in N \setminus Z} X_{ij}$ coincides with Z , we have $x^*(Z) = f_M(Z)$ by Proposition 3.2. For each $i \in Z$ and $j \in N \setminus Z$ let Y_{ij} be a subset of N such that $y^*(Y_{ij}) \in [f_C(Y_{ij}), f_C(Y_{ij}) + 1)$, $i \in Y_{ij}$, and $j \notin Y_{ij}$. Let $Y'_{ij} := (Y_{ij} \cup N^>) \setminus N^<$. Then, we have

$$\begin{aligned} y^*(Y'_{ij}) &= y^*(N^>) + y^*(Y_{ij}) - y^*(Y_{ij} \setminus N^=) \\ &< f_C(N^>) + f_C(Y_{ij}) + 1 - y^*(Y_{ij} \setminus N^=) \\ &\leq f_C(N^> \cup Y_{ij}) + f_C(N^> \cap Y_{ij}) + 1 - y^*(Y_{ij} \setminus N^=) \\ &\leq f_C(N^> \cup Y_{ij}) - y^*(N^< \cap Y_{ij}) + 1 \\ &\leq f_C(Y'_{ij}) + f_C(N^> \cup N^= \cup Y_{ij}) - f_C(N^> \cup N^=) - y^*(N^< \cap Y_{ij}) + 1 \\ &= f_C(Y'_{ij}) + f_C(N^> \cup N^= \cup Y_{ij}) - y^*(N^> \cup N^= \cup Y_{ij}) + 1 \leq f_C(Y'_{ij}) + 1. \end{aligned}$$

Since $y^*_i = \beta_1 - x^*_i$ is an integer for any $i \in N^=$ by the choice, $y^*(N^>) = f_C(N^> \cup N^=) - y^*(N^=)$ is also an integer. This implies that $y^*(Y'_{ij}) = y^*(N^>) + y^*(Y_{ij} \cap N^=)$ is an integer, and hence we obtain $y^*(Y'_{ij}) = f_C(Y'_{ij})$. Thus, $\bigcup_{i \in Z \cap N^=} \bigcap_{j \in N^> \setminus Z} Y'_{ij}$ coincides with Z , and we have $y^*(Z) = f_M(Z)$ by Proposition 3.2. However, this contradicts to (5). \square

Claim 4.7. *There exist paths in G from some vertex in $N^>$ to some vertex in $N^<$.*

Proof. By setting $Z = N^>$, Claim 4.6 implies that the graph G has an edge from some $i_1 \in N^>$ to some $i_2 \in N^< \cup N^=$. If $i_2 \in N^<$, we have done. Let us assume $i_2 \in N^=$. Taking $Z = N^> \cup \{i_2\}$, we also use Claim 4.6 to see that G has an edge from some $i_3 \in N^> \cup \{i_2\}$ to some $i_4 \in (N^< \cup N^=) \setminus \{i_2\}$. If $i_4 \in N^<$, then either path i_3, i_4 ($i_3 \in N^>$) or i_1, i_2, i_4 ($i_2 = i_3$) is the one what we look for. Otherwise, we see that a path from some vertex in $N^>$ (i_1 or i_3) to i_4 .

After repeating this procedure k times, we obtain an edge (i_{2k-1}, i_{2k}) in G . If $i_{2k} \in N^<$, we obtain a path from some vertex in $N^>$ to i_{2k} via i_{2k-1} ; otherwise, we obtain a path from some vertex in $N^>$ to i_{2k} . Since i_2, i_4, \dots, i_{2k} are all distinct, we can find $i_{2k} \in N^<$ after at most $|N^=| + 1$ repetitions. This completes the proof of the claim. \square

By the above claim and Lemma 4.4 with $N' = N$ and $\beta = \beta_1$, there exists a vector z with $\Phi(z) < \phi(z^*)$, which contradicts to the optimality of z^* . This completes the proof of Lemma 4.5. \square

We then prove that z_i^* is at least $\beta_1 - 1$ for all $i \in N_1$. Recall that N_1 is the smallest subset of N maximizing $f_E(X) - (\beta_1 - 1)|X|$.

Lemma 4.8. *$z_i^* \geq \beta_1 - 1$ for all $i \in N_1$.*

Proof. Let $N_1^> := \{i \in N_1 : z_i^*(E) > \beta_1 - 1\}$, $N_1^= := \{i \in N_1 : z_i^*(E) = \beta_1 - 1\}$, and $N_1^< := \{i \in N_1 : z_i^* < \beta_1 - 1\}$. Suppose to the contrary that $N_1^<$ is nonempty. We construct a graph

$$G = (N_1, \{(i, j) \in N_1 \times N_1 : x^* - \chi_i + \chi_j \in \bar{\mathbf{B}}_M \text{ or } y^* - \chi_i + \chi_j \in \bar{\mathbf{B}}_C\}).$$

Recall that N_1 is the smallest subset of N maximizing $f_E(S) - (\beta_1 - 1)|S|$. For any X with $N_1^< \subseteq X \subseteq N_1^< \cup N_1^=$, we have $f_E(N_1 \setminus X) - (\beta_1 - 1)|N_1 \setminus X| \leq f_E(N_1) - (\beta_1 - 1)|N_1|$, which implies $f_E(N_1) - f_E(N_1 \setminus X) \geq (\beta_1 - 1)|X| > z^*(X)$. In other words,

$$z^*(Z) = z^*(N_1) - z^*(N_1 \setminus Z) \geq f_E(N_1) - z^*(N_1 \setminus Z) > f_E(Z)$$

holds for any Z with $N_1^> \subseteq Z \subseteq N_1^> \cup N_1^=$. By a similar proof of Claim 4.6, we see that there exists an edge from some vertex in Z to $N_1 \setminus Z$ for any Z with $N_1^> \subseteq Z \subseteq N_1^> \cup N_1^=$.

Therefore, by a similar way to Claim 4.7, we can find a path from some vertex in $N_1^>$ to some in $N_1^<$. Then, by applying Lemma 4.4 with $N' = N_1$ and $\beta = \beta_1 - 1$, we can reduce the value of Φ , which is a contradiction. Hence, $N_1^<$ is empty and $z_i^* \geq \beta_1 - 1$ for all $i \in N_1$. \square

Finally, we show that we cannot decrease the values of elements in N_1 (which have high values) anymore. In the words of fair allocation, this means that goods not required to be assigned to N_1 are not assigned to N_1 .

Lemma 4.9. *$x^*(N_1) = f_M(N_1)$, $y^*(N_1) = f_C(N_1)$, and $z^*(N_1) = f_E(N_1)$.*

Proof. It is sufficient to prove that $z^*(N_1) = f_E(N_1)$. Let $N^> := \{i \in N : z_i^* > \beta_1 - 1\}$, $N^= := \{i \in N : z_i^* = \beta_1 - 1\}$, and $N^< := \{i \in N : z_i^* < \beta_1 - 1\}$.

Suppose to the contrary that $z^*(N_1) > f_E(N_1)$. We construct a graph

$$G = (N, \{(i, j) \in N \times N : x^* - \chi_i + \chi_j \in \ddot{\mathbf{B}}_M \text{ or } y^* - \chi_i + \chi_j \in \bar{\mathbf{B}}_C\}).$$

Since $N_1 \in \arg \max_{S \subseteq N} f_E(S) - (\beta_1 - 1)|S|$, we have $f_E(N_1) - (\beta_1 - 1)|N_1| \geq f_E(X) - (\beta_1 - 1)|X|$ for any $X \subseteq N$. For any X with $N^> \subseteq X \subseteq N^> \cup N^=$, it holds that

$$\begin{aligned} z^*(X) &= z^*(N^>) + z^*(X \setminus N^>) \\ &= z^*(N^>) + (\beta_1 - 1) \cdot (|X| - |N^>|) \\ &\geq z^*(N^> \cap N_1) + (\beta_1 - 1) \cdot (|X| - |N^> \cap N_1|) \\ &= z^*(N_1) - (\beta_1 - 1) \cdot (|N_1| - |N^> \cap N_1|) + (\beta_1 - 1) \cdot (|X| - |N^> \cap N_1|) \quad (\text{by Lemma 4.8}) \\ &= z^*(N_1) - (\beta_1 - 1)|N_1| + (\beta_1 - 1)|X| \\ &> f_E(N_1) - (\beta_1 - 1)|N_1| + (\beta_1 - 1)|X| \quad (\text{by assumption}) \\ &\geq f_E(X) - (\beta_1 - 1)|X| + (\beta_1 - 1)|X| = f_E(X). \end{aligned}$$

Hence, by the same proofs of Claims 4.6 and 4.7, there exist paths in G from an agent in $N^>$ to an agent in $N^<$. Then, by applying Lemma 4.4 with $N' = N$ and $\beta = \beta_1 - 1$, we can decrease the value of Φ , which is a contradiction. Hence, we obtain $z^*(N_1) = f_E(N_1)$. This implies that $x^*(N_1) = f_M(N_1)$ and $y^*(N_1) = f_C(N_1)$. \square

4.2 Decomposition

We have shown that $\beta_1 - 1 \leq z_i^* \leq \beta_1$ for all $i \in N_1$ in Lemmas 4.5 and 4.8. We describe that we can derive a similar result for N_2, \dots, N_q .

Let $N'_1 = N \setminus N_1$. For a supermodular function f , we denote $f^{(1)}: 2^{N'_1} \rightarrow \mathbb{Z}$ to be the supermodular function obtained from f by contracting N_1 , i.e., $f^{(1)}(X) = f(X \cup N_1) - f(N_1)$ for each $X \subseteq N'_1$. We consider the M-convex set $\ddot{\mathbf{B}}_M^{(1)}$ of $f_M^{(1)}$, integral base-polyhedra $\bar{\mathbf{B}}_C^{(1)}$ of $f_C^{(1)}$, and $\mathbf{B}_E^{(1)} = \ddot{\mathbf{B}}_M^{(1)} + \bar{\mathbf{B}}_C^{(1)}$.

By Lemma 4.9, we have $z_{N'_1}^* \in \mathbf{B}_E^{(1)}$. In addition, for any $z_{N'_1} \in \mathbf{B}_E^{(1)}$, an extended vector $z = (z_{N_1}^*, z_{N'_1})$ is contained in \mathbf{B}_E because

$$z(X) \geq f_E(X \cap N_1) + f_E^{(1)}(X \cap N'_1) = f_E(X \cap N_1) + f_E(X \cup N_1) - f(N_1) \geq f_E(X)$$

for all $X \subseteq N$ by the supermodularity of f_E . Hence, we obtain the following lemma. Let $\Phi': \mathbb{R}^{N'_1} \rightarrow \mathbb{R}$ be the symmetric strictly convex function such that $\Phi'(z_{N'_1}) = \Phi(z_{N_1}^*, z_{N'_1})$.

Lemma 4.10. *For any $z_{N'_1} \in \mathbf{B}_E^{(1)}$, a vector $z = (z_{N_1}^*, z_{N'_1})$ is a Φ -minimizer of \mathbf{B}_E if and only if $z_{N'_1}$ is a Φ' -minimizer of $\mathbf{B}_E^{(1)}$.*

Therefore, we can apply the results in Section 4.1 to N'_1 , $f_M^{(1)}$, $f_C^{(1)}$ and $f_E^{(1)}$, and repeat the same procedure. By the definition of the canonical partition and the essential values, we obtain the following lemma.

Lemma 4.11. *For each $j = 1, \dots, q$, it holds that $\beta_j - 1 \leq z_i^* \leq \beta_j$ for every $i \in N_j$.*

Now, we are ready to prove Theorem 4.1.

Proof of Theorem 4.1. Recall that the partition N_1, \dots, N_q is the canonical partition of \mathbf{B}_E , and β_1, \dots, β_q are the corresponding essential values. Let $\hat{N}_1, \dots, \hat{N}_r$ be the principal partition of \mathbf{B}_E , and let $\lambda_1, \dots, \lambda_r$ be the critical values. We fix $i \in N$ arbitrarily. Let $j \in [q]$ and $k \in [r]$ be the unique indices such that $i \in N_j$ and $i \in \hat{N}_k$. By invoking Theorem 3.13, we have $\beta_j = \lceil \lambda_k \rceil$. Consequently, by Theorem 3.12 and Lemma 4.11, we obtain $z_i^* \leq \beta_j = \lceil \lambda_k \rceil = \lceil \bar{z}_i \rceil$.

To show the other inequality, let $\Phi': \mathbb{R}^N \rightarrow \mathbb{R}$ be a symmetric strictly convex function such that $\Phi'(z) = \Phi'(-z)$ for $z \in \mathbb{R}^N$. Let $\mathbf{B}'_E = -\mathbf{B}_E$ and $\bar{\mathbf{B}}'_E = -\bar{\mathbf{B}}_E$. Then, $-z^*$ and $-\bar{z}$ are Φ' -minimizers of \mathbf{B}'_E and $\bar{\mathbf{B}}'_E$, respectively. By applying the same argument as above, we obtain $-z_i^* \leq \lceil -\bar{z}_i \rceil$, which is equivalent to $z_i^* \geq \lfloor \bar{z}_i \rfloor$. \square

4.3 Structures in Fair Allocation

Before concluding this section, we discuss additional structures that can be established in the case of fair allocations. We partition the goods according to the canonical partition as follows. Let M_1 and C_1 denote the subset of indivisible goods M and divisible goods C , respectively, that must be allocated to agents in N_1 . We iteratively define M_j and C_j as the subset of $M \setminus \bigcup_{j'=1}^{j-1} M_{j'}$ and $C \setminus \bigcup_{j'=1}^{j-1} C_{j'}$, respectively, that must be allocated to agents in $\bigcup_{j'=1}^j N_{j'}$. In other words, M_j and C_j ($j = 1, \dots, q$) is defined as

$$M_j = \left\{ g \in M \setminus \bigcup_{j'=1}^{j-1} M_{j'} : v_{ig} = 0 \ (\forall i \in N \setminus \bigcup_{j'=1}^j N_{j'}) \right\}, \quad (6)$$

$$C_j = \left\{ c \in C \setminus \bigcup_{j'=1}^{j-1} C_{j'} : v_{ic} = 0 \ (\forall i \in N \setminus \bigcup_{j'=1}^j N_{j'}) \right\}. \quad (7)$$

We refer M_1, \dots, M_q and C_1, \dots, C_q as the canonical partitions of the indivisible goods and the divisible goods, respectively.

Theorem 4.12. *For any allocation π^* whose utility vector is a Φ -minimizer over \mathbf{B}_E , it holds that $\sum_{i \in N_j} \pi_{ie}^* = 1$ for every good $e \in M_j \cup C_j$ and $j = 1, 2, \dots, q$.*

Proof. Let z^* be the utility vector of π^* . Let x^* and y^* be the utility vectors for indivisible and divisible goods in π^* , respectively. Thus, $z^* = x^* + y^*$.

First, since $f_M(N_1) = |M_1|$ and $f_C(N_1) = |C_1|$, we have $z^*(N_1) = |M_1 \cup C_1|$ by Lemma 4.9. Next, let $N'_j = N \setminus \bigcup_{j'=1}^j N_{j'}$ for $j = 1, \dots, q-1$. By Lemma 4.10, $z_{N'_j}^*$ is a Φ' -minimizer, where $\Phi'(z) = \phi(z_{N'_1}^*, z)$. Thus by the definition of N_2 and Lemma 4.9 again, $x_{N'_1}^*(N_2) = f_M^{(1)}(N_2) = f_M(N_1 \cup N_2) - f_M(N_1) = |M_2|$ and $y_{N'_1}^*(N_2) = f_C^{(1)}(N_2) = |C_2|$. By iteratively applying this argument, we observe that $z^*(N_j) = |M_j \cup C_j|$ for $j = 2, \dots, q$.

Because agents in N_q want only the goods in $M_q \cup C_q$, these goods are allocated to the agents in N_q . Then, for each $j = q-1, \dots, 1$, since agents in N_j want only the goods in $\bigcup_{j'=j}^q (M_{j'} \cup C_{j'})$ but the goods in $\bigcup_{j'=j+1}^q (M_{j'} \cup C_{j'})$ are allocated to agents in $N_{j+1} \cup \dots \cup N_q$, the goods in $M_j \cup C_j$ are allocated to agents in N_j . Therefore, the theorem holds. \square

5 Tractability for Identical Divisible Goods

In this section, we focus on the setting where all the divisible goods are identical, i.e., $v_{ic} = v_{ic'}$ for any $c, c' \in C$ and $i \in N$. Assume that C is non-empty, and let Φ be a symmetric strictly convex function. The main result of this section is a polynomial-time algorithm to find a Φ -fair allocation (i.e., an allocation whose utility vector is a Φ -minimizer). This implies that we can find an allocation that maximizes the Nash welfare for mixed goods in polynomial time when the divisible goods are identical.

Our algorithm utilizes the structures discussed in the previous section. Namely, we seek allocations whose utility vectors satisfy the statements in Lemma 4.11 and Theorem 4.12, which are necessary conditions to be optimal. Then, we find the best allocation from them. In the following, we describe our algorithm, which is summarized in Algorithm 1.

The algorithm first finds a discrete Φ -minimizer $\tilde{z}^* \in \arg \min_{z \in \mathbf{B}_E} \Phi(z)$, the canonical partition N_1, \dots, N_q , and the essential values β_1, \dots, β_q of \mathbf{B}_E . These can be computed in polynomial time by Theorem 3.13. Note that \tilde{z}^* is an optimal utility vector if every good is assumed to be indivisible. In addition, the canonical partition of the indivisible goods M_1, \dots, M_q and that of the divisible ones C_1, \dots, C_q can be calculated easily by (6) and (7). Since all divisible goods are identical, only one of C_1, \dots, C_q is non-empty. Let j^* be the index such that $C_{j^*} = C$.

Next, we decide on an allocation for agents in N_j for each $j \neq j^*$. Let us fix $j \neq j^*$. Theorem 4.12 implies that in an optimal allocation, the agents in N_j receive only the indivisible goods in M_j . Moreover, by Lemma 4.11, some agents in N_j must receive β_j goods and the others must receive $\beta_j - 1$. Because $\beta_j - 1 \leq \tilde{z}_i^* \leq \beta_j$ holds by Theorem 3.13, we allocate goods in M_j so that each agent $i \in N \setminus N_{j^*}$ receives \tilde{z}_i^* goods. Such an allocation can be computed by solving a bipartite matching problem.⁶ For agents in N_j , the utility vector of this allocation is value-equivalent to an optimal one. Thus, we have found an optimal allocation for agents in N_j .

The remaining task is to determine the allocation of $M_{j^*} \cup C$ to agents N_{j^*} . Since the optimal allocation of $M_{j^*} \cup C$ depends on Φ as we saw in Examples 2.3 and 2.4, we conduct an enumeration-based approach rather than performing a full characterization.

Let π^* be an optimal allocation. Let $N_{j^*}^+$ be the set of agents in N_{j^*} who desire the divisible goods, i.e., $N_{j^*}^+ = \{i \in N_{j^*} : v_i(c) = 1 (\forall c \in C)\}$. Let $N_{j^*}^- = N_{j^*} \setminus N_{j^*}^+$. The following lemma indicates that there are a finite number of candidates for a Φ -minimizer.

Lemma 5.1. *All the agents who receive divisible goods (i.e., $\pi_i^*(C) > 0$) have the same utility.*

Proof. Assume that there exist two agents $i, i' \in N_{j^*}^+$ with $\pi_i^*(E) > \pi_{i'}^*(E)$, $\pi_i^*(C) > 0$, and $\pi_{i'}^*(C) > 0$. Then by equation (1), we can decrease the value of Φ by transferring a fraction $\varepsilon \in (0, \pi_i^*(E) - \pi_{i'}^*(E))$ of a divisible good from agent i to agent i' . This contradicts that the utility vector of π^* is a Φ -minimizer. \square

Let k be the number of agents in $N_{j^*}^+$ who receive β_{j^*} indivisible goods and let ℓ be the total number of indivisible goods received by agents in $N_{j^*}^+$. Note that $k < |N_{j^*}^+|$. The key observation is the following lemma.

Lemma 5.2. *The following properties hold:*

1. $|N_{j^*}^+| \cdot (\beta_{j^*} - 1) + k \leq \ell + |C| \leq |N_{j^*}^+| \cdot \beta_{j^*}$;

⁶It can also be calculated directly with a method of Harvey et al. [23].

2. there exist $X \subseteq N_{j^*}^+$ such that $|X| = k$ and

(a) for each $i \in X$: $\pi_i^*(M_{j^*}) = \beta_{j^*}$ and $\pi_i^*(C) = 0$;

(b) for each $i \in N_{j^*}^+ \setminus X$: $\pi_i^*(M_{j^*}) \leq \beta_{j^*} - 1$ and $\pi_i^*(E) = \beta_{j^*} - (|N_{j^*}^+| \cdot \beta_{j^*} - \ell - |C|) / (|N_{j^*}^+| - k)$;

3. $\pi_i^*(M_{j^*}) \in \{\beta_{j^*}, \beta_{j^*} - 1\}$ and $\pi_i^*(C) = 0$ for each $i \in N_{j^*}^-$.

Proof. Let $X = \{i \in N_{j^*}^+ : \pi_i^*(M_{j^*}) = \beta_{j^*}\}$. By Lemma 4.11, it holds that $\beta_{j^*} - 1 \leq \pi_i^*(E) \leq \beta_{j^*}$ for each $i \in N_{j^*}^+$. Hence, it is easy to see properties 2(a) and 3. In addition, by the definitions of k and ℓ , we have $|N_{j^*}^+| \cdot (\beta_{j^*} - 1) + k \leq \sum_{i \in N_{j^*}^+} \pi_i^*(E) = \ell + |C|$, and $\sum_{i \in N_{j^*}^+} \pi_i^*(E) \leq |N_{j^*}^+| \cdot \beta_{j^*}$.

It remains to see property 2(b). By definition of X , we have $\pi_i^*(M_{j^*}) \leq \beta_{j^*} - 1$ for each $i \in N_{j^*}^+ \setminus X$. Let Y be the set of agents in $N_{j^*}^+ \setminus X$ who receive divisible goods. By Lemma 5.1, $\pi_i^*(E) = \pi_{i'}^*(E)$ for any $i, i' \in Y$. If $Y \neq N_{j^*}^+ \setminus X$ and $\pi_i^*(E) > \beta_{j^*} - 1$ for some $i \in Y$, then giving some portion of a divisible good from agent i to agent in $N_{j^*}^+ \setminus (X \cup Y)$ decreases the value of Φ by (1), which is a contradiction. Thus, $Y = N_{j^*}^+ \setminus X$ or $\pi_i^*(E) = \beta_{j^*} - 1$ for all $i \in Y$. Hence, in either case, all the agents in $N_{j^*}^+ \setminus X$ have the same utility. Therefore, it holds that

$$\pi_i^*(E) = \frac{\ell + |C| - k \cdot \beta_{j^*}}{|N_{j^*}^+| - k} = \beta_{j^*} - \frac{|N_{j^*}^+| \cdot \beta_{j^*} - \ell - |C|}{|N_{j^*}^+| - k} \quad (\forall i \in N_{j^*}^+ \setminus X),$$

and property 2(b) is satisfied. \square

Since Lemma 5.2 specifies the utility vector (i.e., $\pi_i^*(E)$ for each $i \in N_{j^*}^+$) of an optimal allocation up to value-equivalence, it suffices to find an allocation whose utility vector satisfies the statement in Lemma 5.2. In fact, if we are given ℓ , an optimal allocation can be computed as follows. For each $k = 0, \dots, |N_{j^*}^+|$ such that property 1 in Lemma 5.2 is satisfied,

1. find an allocation $\pi^{k, \ell} \in \{0, 1\}^{N_{j^*}^+ \times M_{j^*}}$ of indivisible goods in M_{j^*} such that (a) $|\{i \in N_{j^*}^+ : \pi_i(M_{j^*}) = \beta_{j^*}\}| \leq k$, (b) $\pi_i(M_{j^*}) \leq \beta_{j^*}$ for each $i \in N_{j^*}^+$, (c) $\sum_{i \in N_{j^*}^+} \pi_i(M_{j^*}) = \ell$, (d) $\pi_i(M_{j^*}) \in \{\beta_{j^*}, \beta_{j^*} - 1\}$ for each $i \in N_{j^*}^-$;
2. if $\pi^{k, \ell}$ exists, let $\hat{\pi}^{k, \ell}$ be the allocation by allocating indivisible goods according to $\pi^{k, \ell}$, and allocating divisible goods by a water-filling policy so that

$$\hat{\pi}_i^{k, \ell}(c) = \frac{1}{|C|} \cdot \left(\beta_{j^*} - \frac{|N_{j^*}^+| \cdot \beta_{j^*} - \ell - |C|}{|N_{j^*}^+| - k} - \pi_i^{k, \ell}(M) \right)$$

for each $i \in N_{j^*}^+$ such that $\pi_i^{k, \ell}(M) < \beta_{j^*}$ and $c \in C$.

Let us see that this indeed works. Since $\Phi(\hat{\pi}^{k, \ell}) \leq \Phi(\hat{\pi}^{k+1, \ell})$ holds (if $\pi^{k, \ell}$ exists), the smallest k such that $\pi^{k, \ell}$ exists is the number in Lemma 5.2. For such an integer k , we have $|\{i \in N_{j^*}^+ : \pi_i(M_{j^*}) = \beta_{j^*}\}| = k$, and the properties in Lemma 5.2 are satisfied except the allocation of divisible goods. Once we have decided on an allocation of indivisible goods, an optimal allocation of divisible goods is found by the water-filling policy.

Now, we explain how to find an allocation $\pi^{k, \ell}$ at step 1 in polynomial time. We reduce this problem to the submodular flow problem, which can be solved in polynomial time (see, e.g.,

Murota [32]). Let $G = (V, A)$ be a directed graph constructed as follows. The set of vertices V is $M_{j^*} \cup N_{j^*} \cup N'_{j^*}$ where N'_{j^*} is a set of copy i' of each $i \in N_{j^*}$. The set of edges A is $A_1 \cup A_2 \cup A_3$ where $A_1 = \{(g, i') \in M_{j^*} \times N'_{j^*} : v_i(g) = 1\}$, $A_2 = \{(i', i) : i \in N_{j^*}^+\}$, and $A_3 = \{(i', i) : i \in N_{j^*}^-\}$. We define $\underline{c}, \bar{c}: A \rightarrow \mathbb{Z}$ as $\underline{c}(a) = 0$ and $\bar{c}(a) = 1$ for each $a \in A_1$; $\underline{c}(a) = 0$ and $\bar{c}(a) = \beta_{j^*}$ for each $a \in A_2$; $\underline{c}(a) = \beta_{j^*} - 1$ and $\bar{c}(a) = \beta_{j^*}$ for each $a \in A_3$. In addition, let $f_{k,\ell}: 2^V \rightarrow \mathbb{Z}$ be a function such that

$$f_{k,\ell}(X) = \varphi_{k,\ell}(|X \cap N_{j^*}^+|) + (|M_{j^*}| - \ell) \mathbf{1}_{X \cap N_{j^*}^- \neq \emptyset} - |X \cap M_{j^*}| \quad (\forall X \subseteq V),$$

where $\varphi_{k,\ell}(h) = \min\{\beta_{j^*}h, (\beta_{j^*} - 1)h + k, \ell\}$, and $\mathbf{1}_{X \cap N_{j^*}^- \neq \emptyset}$ takes the value 1 if $X \cap N_{j^*}^- \neq \emptyset$ and 0 otherwise. We remark that $f_{k,\ell}$ is a submodular function, and $f_{k,\ell}(V) = 0$ since $\ell \leq \sum_{i \in N_{j^*}^+} \pi_i^*(M_{j^*}) \leq (\beta_{j^*} - 1)|N_{j^*}^+| + k \leq \beta_{j^*}|N_{j^*}^+|$.

Lemma 5.3. *There exists an allocation $\pi \in \{0, 1\}^{N_{j^*} \times M_{j^*}}$ satisfying (a)–(d) if and only if there exists an integral flow $\xi: A \rightarrow \mathbb{Z}$ satisfying $\underline{c}(a) \leq \xi(a) \leq \bar{c}(a)$ (capacity constraints) and a constraint (called supply specification) that the boundary $\partial\xi \in \mathbb{Z}^V$ of the flow ξ , which is defined by*

$$\partial\xi(v) = \sum_{a=(v,u) \in A} \xi(a) - \sum_{a=(u,v) \in A} \xi(a),$$

is in the M -convex set $\mathring{B} = \{x \in \mathbb{Z}^V : x(V) = f_{k,\ell}(V) \text{ and } x(X) \leq f_{k,\ell}(X) \text{ } (\forall X \subseteq V)\}$.

Proof. Let π be an allocation satisfying (a)–(d). Let ξ be an integral flow such that $\xi(g, i') = \pi_i(g)$ for each $i \in N_{j^*}, g \in M_{j^*}$, and $\xi(i', i) = \sum_g \xi(g, i')$ for each $i \in N_{j^*}$. Since $\xi(i', i) = \pi_i(M_{j^*})$, the conditions (b) and (d) ensure the capacity constraints. By construction, $\partial\xi(g) = -1$ for each $g \in M_{j^*}$, $\partial\xi(i') = 0$ for each $i' \in N'_{j^*}$, and $\partial\xi(i) = \pi_i(M_{j^*})$ for each $i \in N_{j^*}$. To see that $\partial\xi \in \mathring{B}$, fix $X \subseteq V$. We have $\partial\xi(X) = \sum_{i \in X \cap N_{j^*}^+} \pi_i(M_{j^*}) + \sum_{i \in X \cap N_{j^*}^-} \pi_i(M_{j^*}) - |X \cap M_{j^*}|$. Here, we have $\sum_{i \in X \cap N_{j^*}^+} \pi_i(M_{j^*}) \leq \beta_{j^*}|X \cap N_{j^*}^+|$ by condition (b), $\sum_{i \in X \cap N_{j^*}^+} \pi_i(M_{j^*}) \leq (\beta_{j^*} - 1)|X \cap N_{j^*}^+| + k$ by conditions (a) and (b), and $\sum_{i \in X \cap N_{j^*}^+} \pi_i(M_{j^*}) \leq \ell$ by condition (c). Moreover, $\sum_{i \in X \cap N_{j^*}^-} \pi_i(M_{j^*}) \leq (|M_{j^*}| - \ell) \mathbf{1}_{X \cap N_{j^*}^- \neq \emptyset}$ by condition (c). Thus, we have $\partial\xi(X) \leq f_{k,\ell}(X)$. In addition, $\partial\xi(V) = 0$, and hence $\partial\xi \in \mathring{B}$.

Conversely, let ξ be a feasible integral flow. Define π by $\pi_i(g) = \xi(g, i')$ for each $i \in N_{j^*}$ and $g \in M_{j^*}$. For each $i \in N_{j^*}$ and $g \in M_{j^*}$, we have $\xi(g, i') \in \{0, 1\}$ by the capacity constraint, and $\partial\xi(g) \leq -1$ by the supply specification with $X = \{g\}$. In addition, we have $\partial\xi(M_{j^*}) \leq f_{k,\ell}(M_{j^*}) = -|M_{j^*}|$, $\partial\xi(N_{j^*} \cup N'_{j^*}) \leq |M_{j^*}|$ and $\partial\xi(V) = 0$, we have $\partial\xi(M_{j^*}) = -|M_{j^*}|$. Thus, $\sum_i \pi_i(g) = 1$ for each $g \in M_{j^*}$, and hence π is an allocation of M_{j^*} .

We observe that $\partial\xi(i') = \sum_{g: v_i(g)=1} \xi(g, i') - \xi(i', i) \leq f_{k,\ell}(\{i'\}) = 0$ for each $i' \in N'_{j^*}$. Moreover, since $\partial\xi(M_{j^*} \cup N_{j^*}) \leq 0$ and $\partial\xi(V) = 0$, we have $\partial\xi(i') = 0$ for each $i' \in N'_{j^*}$, which implies that $\pi_i(M_{j^*}) = \sum_{g: v_i(g)=1} \xi(g, i') = \xi(i', i)$. Then we can see that each condition is satisfied.

(d) The capacity constraint for A_3 implies that $\pi_i(M_{j^*}) = \xi(i', i) \in \{\beta_{j^*} - 1, \beta_{j^*}\}$.

(c) We have $\sum_{i \in N_{j^*}^+} \pi_i(M_{j^*}) = \partial\xi(N_{j^*}^+) \leq f_{k,\ell}(N_{j^*}^+) = \ell$. Moreover, $\partial\xi(N_{j^*}^+) = -\partial\xi(V \setminus N_{j^*}^+) \geq \ell$ since $\partial\xi(V \setminus N_{j^*}^+) \leq -\ell$.

(b) The capacity constraint for A_2 implies that $\pi_i(M_{j^*}) = \xi(i', i) \leq \beta_{j^*}$ for each $i \in N_{j^*}^+$.

- (a) It holds that $\sum_{i \in N_{j^*}^+} \pi_i(M_{j^*}) = \partial \xi(N_{j^*}^+) \leq \phi_{k,\ell}(N_{j^*}^+) \leq (\beta_{j^*} - 1)|N_{j^*}^+| + k = (\beta_{j^*} - 1)(|N_{j^*}^+| - k) + k\beta_{j^*}$. By (b), at most k agents have the utility β_{j^*} .

This completes the proof. \square

It is known that the feasibility of the submodular flow problem can be determined in polynomial time [17]. Hence, by Lemma 5.3, the existence of an allocation satisfying conditions (a)–(d) can be determined in polynomial time. Moreover, if such an allocation exists, we can find one of such allocations in polynomial time.

Finally, because we do not know ℓ in advance, we enumerate all possibilities. That is, find a best allocation $\pi^{k,\ell}$ for each $\ell = 0, 1, \dots, |M_{j^*}|$ by the above procedure, and choose the best one. Then the resulting allocation is as good as an optimal allocation π^* .

Algorithm 1: Allocation algorithm when the divisible goods are identical

 - 7 **for** $k \leftarrow 0, 1, \dots, |N_{j^*}^+|$ **and** $\ell \leftarrow 0, 1, \dots, |M_{j^*}|$ **do**
 - 8 **if** $|N_{j^*}^+| \cdot (\beta_{j^*} - 1) + k \leq \ell + |C| \leq |N_{j^*}^+| \cdot \beta_{j^*}$ **then**
 - 9 Determine the existence an allocation $\pi^{k,\ell} \in \{0, 1\}^{N_{j^*}^+ \times M_{j^*}}$ satisfying the following conditions via the submodular flow problem: $\{i \in N_{j^*}^+ : \pi_i(M_{j^*}) = \beta_{j^*}\} \leq k$, $\pi_i(M_{j^*}) \leq \beta_{j^*}$ for each $i \in N_{j^*}^+$, $\sum_{i \in N_{j^*}^+} \pi_i(M_{j^*}) = \ell$, $\pi_i(M_{j^*}) \in \{\beta_{j^*}, \beta_{j^*} - 1\}$ for each $i \in N_{j^*}^-$;
 - 10 **if** *Such an allocation $\pi^{k,\ell}$ exists* **then**
 - 11 Let π be an allocation such that indivisible goods are allocated according to line 4 and $\pi^{k,\ell}$, and the divisible goods are allocated to agents in $N_{j^*}^+$ by a water-filling policy;
 - 12 $\Pi \leftarrow \Pi \cup \{\pi\}$;
 - 13 **return** $\pi^* \in \arg \min_{\pi \in \Pi} \Phi(\pi(E))$;
-

By summarizing the discussions so far, we obtain the main result in this section.

Theorem 5.4 (restatement of Theorem 1.3). *Let Φ be a symmetric strictly convex function. If all the divisible goods are identical, Algorithm 1 finds a Φ -fair allocation in polynomial time.*

6 Hardness for Identical Indivisible Goods

In this section, we show a hardness result when divisible goods are non-identical but indivisible goods are identical.

We prove the NP-hardness of finding a Φ -fair allocation by using the 3-dimensional matching (3DM) problem, which is known to be NP-hard [19]. In the 3DM problem, we are given three sets of elements, $X = \{x_1, \dots, x_n\}$, $Y = \{y_1, \dots, y_n\}$, and $Z = \{z_1, \dots, z_n\}$. We are also given a set of hyperedges $T = \{t_1, \dots, t_m\}$ where $t \in T$ is an ordered triplets in $X \times Y \times Z$. The goal of the problem is to determine if there exists a subset T' of T such that each element from X , Y , and Z appears exactly once in T' . In other words, our task is to find a perfect matching that covers all the elements in X , Y , and Z without any repetitions.

Theorem 6.1 (restatement of Theorem 1.2). *For any fixed symmetric strictly convex function Φ , finding a Φ -minimizer is NP-hard even when indivisible goods are identical. Hence, finding a Φ -fair allocation is NP-hard.*

Proof. Let us fix a symmetric strictly convex function Φ . Given an instance of 3DM $(X, Y, Z; T)$, we construct an instance of fair allocation (N, M, C, v) . Without loss of generality, we assume $m \geq n$, since otherwise, the 3DM instance is a no-instance. We construct two agents s and s' for each $s \in X \cup Y \cup Z$ and five agents $t, t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}$ for each $t \in T$. Thus, we have the set N of $6n + 5m$ agents: $N = \bigcup_{s \in X \cup Y \cup Z} \{s, s'\} \cup \bigcup_{t \in T} \{t, t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}\}$. We create n indivisible goods $M = \{g_1, g_2, \dots, g_n\}$, which correspond to the hyperedges chosen as a matching. We set the valuations so that only the agents in T desire the indivisible goods, i.e., $v_t(g) = 1$ ($t \in T$) and $v_i(g) = 0$ ($i \in N \setminus T$) for every $g \in M$. We construct two types of divisible goods. First, for each $s \in X \cup Y \cup Z$, we create a good c_s , which is desired by only s and s' . Second, for each hyperedge $t = (x, y, z) \in T$, we create goods $c_t^{(1)}, c_t^{(2)}, c_t^{(3)}$, which are desired by only 8 agents $t, t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}, x, y, z$. Thus, we have the set of $3n + 3m$ divisible goods, denoted by $C = \bigcup_{s \in X \cup Y \cup Z} \{c_s\} \cup \bigcup_{t \in T} \{c_t^{(1)}, c_t^{(2)}, c_t^{(3)}\}$. We summarize the valuation of each agent for each good in Table 3.

Table 3: Agents' valuations in the proof of Theorem 6.1.

agents	g_i ($i \in [n]$)	$c_{\hat{s}}$ ($\hat{s} \in X \cup Y \cup Z$)	$c_{\hat{t}}^{(1)}, c_{\hat{t}}^{(2)}, c_{\hat{t}}^{(3)}$ ($\hat{t} \in T$)
s ($s \in X \cup Y \cup Z$)	0	1 if $s = \hat{s}$ and 0 otherwise	1 if $s \in \hat{t}$ and 0 otherwise
s' ($s \in X \cup Y \cup Z$)	0	1 if $s = \hat{s}$ and 0 otherwise	0
t ($t \in T$)	1	0	1 if $t = \hat{t}$ and 0 otherwise
$t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}$ ($t \in T$)	0	0	1 if $t = \hat{t}$ and 0 otherwise

We can observe that there always exists an integral allocation such that the utility of each agent is at most 1 as follows: allocate indivisible good $g_i \in M$ to agent $t_i \in N$ for each $i \in [n]$, divisible good $c_s \in C$ to agent $s \in N$ for each $s \in X \cup Y \cup Z$, divisible good $c_t^{(j)} \in C$ to agent $t^{(j)} \in N$ for each $t \in T$ and $j \in \{1, 2, 3\}$. Thus, in any dec-min *relaxed* allocation, the largest utility is at most 1. Hence, the utility of each agent is at most 1 in any Φ -fair relaxed allocation since Φ -fair and dec-min allocations coincide in relaxed allocations by Theorem 2.1. By the proximity (Theorem 4.1), the utility of each agent is also at most 1 in any Φ -fair allocation.

We demonstrate that the 3DM instance is a yes-instance if and only if there exists an allocation such that only n agents have utility 1 and the other agents have utility 0.6. Note that, if such an allocation exists, it must be a Φ -fair allocation. This is because at least n agents have utility 1 as there are n indivisible goods.

Suppose that the 3DM instance is a yes-instance. Let T' be a subset of T such that each element in $X \cup Y \cup Z$ appears exactly once. We construct a desired allocation π^* as follows. For the indivisible goods M , we distribute one to each agent in T' (i.e., $\pi_{t_{\tau(i)}}^*(g_i) = 1$ for each $i \in [n]$, where $T' = \{t_{\tau(1)}, \dots, t_{\tau(n)}\}$). For each divisible good c_s with $s \in X \cup Y \cup Z$, we allocate 0.4 fraction of c_s to agent $s \in N$ and 0.6 fraction to agent $s' \in N$ (i.e., $\pi_s^*(c_s) = 0.4$ and $\pi_{s'}^*(c_s) = 0.6$). For each $t = (x, y, z) \in T'$ and $j \in \{1, 2, 3\}$, we allocate 0.2/3 fraction of $c_t^{(j)}$ to each of agents x, y, z (i.e., $\pi_x^*(c_t^{(j)}) = \pi_y^*(c_t^{(j)}) = \pi_z^*(c_t^{(j)}) = 0.2/3$) and 0.2 fraction to each of agents $t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}$ (i.e., $\pi_{t^{(1)}}^*(c_t^{(j)}) = \pi_{t^{(2)}}^*(c_t^{(j)}) = \pi_{t^{(3)}}^*(c_t^{(j)}) = \pi_{t^{(4)}}^*(c_t^{(j)}) = 0.2$). For each $t \in T \setminus T'$ and $j \in \{1, 2, 3\}$, we allocate 0.2 of $c_t^{(j)}$ to each of agents $t, t^{(1)}, t^{(2)}, t^{(3)}$, and $t^{(4)}$ (i.e., $\pi_t^*(c_t^{(j)}) = \pi_{t^{(1)}}^*(c_t^{(j)}) = \pi_{t^{(2)}}^*(c_t^{(j)}) = \pi_{t^{(3)}}^*(c_t^{(j)}) = \pi_{t^{(4)}}^*(c_t^{(j)}) = 0.2$). Then, we can see that $\pi_i^*(E)$ is 1 if $i \in T'$ and 0.6 otherwise.

Conversely, suppose that there exists an allocation π^\dagger such that $\pi_i^\dagger(E)$ is 1 for n agents of $i \in N$ and 0.6 for the other agents. Let N^\dagger be the set of agents $i \in N$ with $\pi_i^\dagger(E) = 1$. As there are n indivisible goods M , each agent $i \in N^\dagger$ must receive one indivisible good, and hence $N^\dagger \subseteq T$. Thus, we identify N^\dagger with a set of hyperedges. We prove that N^\dagger is a perfect matching for the 3DM instance. Suppose to the contrary that N^\dagger is not a perfect matching in the 3DM instance. Then, there exist two distinct agents (corresponding to hyperedges) $t = (x, y, z)$ and $\hat{t} = (\hat{x}, \hat{y}, \hat{z})$ in N^\dagger such that they have an intersection. Then, we have $k := |\{x, y, z, \hat{x}, \hat{y}, \hat{z}\}| \in \{3, 4, 5\}$. Thus, the $k + 6$ divisible goods $\bigcup_{s \in \{x, y, z, \hat{x}, \hat{y}, \hat{z}\}} \{c_s\} \cup \{c_t^{(1)}, c_t^{(2)}, c_t^{(3)}\} \cup \{c_{\hat{t}}^{(1)}, c_{\hat{t}}^{(2)}, c_{\hat{t}}^{(3)}\}$ must be allocated to $2k + 8$ agents $\bigcup_{s \in \{x, y, z, \hat{x}, \hat{y}, \hat{z}\}} \{s, s'\} \cup \{t^{(1)}, t^{(2)}, t^{(3)}, t^{(4)}\} \cup \{\hat{t}^{(1)}, \hat{t}^{(2)}, \hat{t}^{(3)}, \hat{t}^{(4)}\}$. However, we have $(k + 6)/(2k + 8) > 0.6$ since $k \in \{3, 4, 5\}$. Therefore, at least one of the $2k + 8$ agents must have a utility greater than 0.6 in the allocation π^\dagger , which is a contradiction. \square

By the proof of this theorem, we can also prove the following.

Corollary 6.2. *The problems of finding an MNW allocation and an optimal egalitarian allocation are both NP-hard, even when indivisible goods are identical.*

A The Nash welfare and a symmetric strictly convex function

In this section, we describe the detail of the Nash welfare for binary additive valuations and a symmetric strictly convex function. Namely, we can find the utility vector of an MNW allocation by minimizing some symmetric strictly convex functions.

Recall that an MNW allocation π is the one such that the number of agents with positive utilities is maximized, and subject to that, the Nash welfare $\prod_{i \in N: \pi_i(E) > 0} \pi_i(E)$ is maximized. Maximizing the product of utilities is equivalent to maximizing the sum of the logarithm of utilities. To minimize the number of agents with zero utilities, we set a symmetric strictly convex function $\Phi(z) = -\sum_{i \in N} \log(z_i + \varepsilon)$, where ε is a positive real that is smaller than $\frac{1}{(2|E|n!)^{n+1}}$. We show that Φ -minimizer for this function indeed implies an MNW allocation. To this end, we see a property of an MNW allocation.

Suppose that the allocation of indivisible goods in an MNW allocation is given. We may remove agents who do not receive indivisible goods and do not desire divisible goods because the utility of such agents cannot be positive. Then we can find an MNW allocation by assuming that each indivisible good is divisible and desired by only the agent who receives it. For the setting where only divisible homogeneous goods exist, Devanur et al. [12] proposed an algorithm to find an MNW allocation. We may assume that every agent has a positive valuation for at least one divisible good, and hence there exists an allocation in which every agent has a positive utility. By applying

Lemma 7.1 in [12] to when all the agents have binary additive utility functions, there is an MNW allocation in which each agent's utility is a rational value with a denominator at most n . Moreover, by Theorem 2.1, every MNW allocation satisfies the above property, and so does every Φ -fair allocation.

Therefore, in a similar way to the proof of Proposition 2.5, we obtain the following lemma.

Lemma A.1. *In every Φ -fair allocation, each agent's utility is a rational value with a denominator at most n , and hence it is zero or a positive rational value at least $1/n$.*

We focus only on the utility vectors that satisfy the property in this lemma. Let x be the utility vector of an allocation π in which s (≥ 1) agents have zero utility, and let y be the utility vector of an allocation in which t ($< s$) agents have zero utility. Suppose that x and y satisfy the property. Then, we have

$$\begin{aligned} \Phi(y) - \Phi(x) &= - \sum_{i \in N} \log(y_i + \varepsilon) + \sum_{i \in N} \log(x_i + \varepsilon) \\ &\leq (s - t) \log \varepsilon + (n - s) \log(|E|/(n - s) + \varepsilon) - (n - t) \log(1/n) \\ &= (s - t) \log(n\varepsilon) + (n - s) \log(n|E|/(n - s) + n\varepsilon) \\ &\leq \log(n\varepsilon) + n \log(n|E| + 1) \\ &\leq \log(n(n|E| + 1)^n \varepsilon) < \log((2n|E|)^{n+1} \varepsilon) < 0, \end{aligned}$$

where the second inequality holds by $\log(n\varepsilon) < 0$. Thus, Φ is minimized at allocations that maximize the number of agents with positive utilities. Let u and v be the corresponding utility vectors of two such allocations. By Lemma A.1, $u' = n! \cdot u$ and $v' = n! \cdot v$ are integral vectors. Let $A = \prod_{i \in N: u'_i > 0} (u'_i + n!\varepsilon) - \prod_{i \in N: v'_i > 0} (v'_i + n!\varepsilon)$ and $B = \prod_{i \in N: u'_i > 0} u'_i - \prod_{i \in N: v'_i > 0} v'_i$. Then, we have

$$\begin{aligned} |A - B| &\leq \left| \prod_{i \in N: u'_i > 0} (u'_i + n!\varepsilon) - \prod_{i \in N: v'_i > 0} (v'_i + n!\varepsilon) \right| + \left| \prod_{i \in N: u'_i > 0} u'_i - \prod_{i \in N: v'_i > 0} v'_i \right| \\ &\leq \varepsilon \cdot 2^n \prod_{i \in N: u'_i > 0} u'_i + \varepsilon \cdot 2^n \prod_{i \in N: v'_i > 0} v'_i \\ &\leq \varepsilon \cdot 2 \cdot (2|E|n!)^n < (2|E|n!)^{n+1} \cdot \varepsilon < 1. \end{aligned}$$

This implies that if $A > 0$, then $B \geq 0$ because B is integral. In other words, if $\Phi(u) < \Phi(v)$ then $\prod_{i \in N: u_i > 0} u_i \geq \prod_{i \in N: v_i > 0} v_i$.

Therefore, any Φ -fair allocation is an MNW allocation.

B Hardness of allocation for a specified utility vector

In this section, we demonstrate NP-hardness of checking existence of an allocation whose utility vector is equal to a given vector. We remark that, when there are only divisible goods or only indivisible goods, the problem can be solved in polynomial time via the maximum flow problem.

Theorem B.1. *It is NP-hard to determine whether a given utility vector $u \in \mathbb{R}^N$ can be achieved by an allocation, even when the indivisible goods are identical.*

Proof. We provide a reduction from the 3DM problem. For a given instance of 3DM $(X, Y, Z; T)$, we construct an instance of fair allocation (N, M, C, v) as follows. Suppose that $X = \{x_1, \dots, x_n\}$, $Y = \{y_1, \dots, y_n\}$, $Z = \{z_1, \dots, z_n\}$, and $T = \{t_1, \dots, t_m\} \subseteq X \times Y \times Z$. The set of agents is defined as $N = X \cup Y \cup Z \cup T$. We create n indivisible goods $M = \{g_1, g_2, \dots, g_n\}$, which will correspond to the hyperedges chosen as a matching. We set the valuations so that only agents in T desire the indivisible goods, i.e., $v_t(g) = 1$ ($\forall t \in T$) and $v_s(g) = 0$ ($\forall s \in X \cup Y \cup Z$) for all $g \in M$. Additionally, we create m divisible goods $C = \{c_1, c_2, \dots, c_m\}$. For each $i \in [m]$, the divisible good c_i is desired by only four agents t_i, x, y, z , where $t_i = (x, y, z)$. Moreover, we set the utility vector u as $u_t = 1$ for all $t \in T$ and $u_s = 1/3$ for all $s \in X \cup Y \cup Z$. We summarize the valuation of each agent for each good and the given utilities in Table 4.

Table 4: Agents' valuations and utilities in the proof of Theorem B.1.

agents	g_i ($i \in [n]$)	c_i ($i \in [m]$)	u
$s \in X \cup Y \cup Z$	0	1 if $s \in t_i$ and 0 otherwise	1/3
$t_j \in T$	1	1 if $i = j$ and 0 otherwise	1

We demonstrate that the 3DM instance is a yes-instance if and only if there is an allocation such that its utility vector is u .

Suppose that the 3DM instance is a yes-instance. Let T' be a subset of T such that each element in $X \cup Y \cup Z$ appears exactly once. We construct a desired allocation π^* as follows. For the indivisible goods M , we distribute one to each agent in T' . For each $t_i \in T'$ with $t_i = (x, y, z)$, we allocate 1/3 fraction of c_i to each of agents x, y, z . For each $t_i \in T \setminus T'$, we assign the entire c_i to t_i . Then, it is not difficult to see that $\pi^*(E)$ is the desired vector u .

Conversely, suppose that π^* is an allocation such that $\pi^*(E) = u$. Let $T^\dagger \subseteq T$ be the set of agents who receive indivisible goods. We prove that T^\dagger is a perfect matching for the 3DM instance. Suppose to the contrary that T^\dagger is not a perfect matching in the 3DM instance. Then, there exist two distinct agents $t_i = (x, y, z)$ and $t_j = (x', y', z')$ in T^\dagger such that they have an intersection. Then, we have $k := |\{x, y, z, x', y', z'\}| < 6$. As c_i and c_j must be allocated to someone in $\{x, y, z, x', y', z'\}$, we have $\sum_{s \in \{x, y, z, x', y', z'\}} \pi_s^*(E) \geq 2$. In contrast, we also have $\sum_{s \in \{x, y, z, x', y', z'\}} u_s = k/3 < 2$. This contradicts the assumption that $\pi^*(E) = u$. \square
