# A CHARACTERIZATION OF POSITROIDS, WITH APPLICATIONS TO AMALGAMS AND EXCLUDED MINORS

JOSEPH E. BONIN

ABSTRACT. A matroid of rank  $r$  on  $n$  elements is a positroid if it has a representation by an r by n matrix over  $\mathbb{R}$ , each r by r submatrix of which has nonnegative determinant. Earlier characterizations of connected positroids and results about direct sums of positroids involve connected flats and non-crossing partitions. We prove another characterization of positroids of a similar flavor and give some applications of the characterization. We show that if  $M$  and  $N$  are positroids and the intersection of their ground sets is an independent set and a set of clones in both M and N, then the free amalgam of M and N is a positroid, and we prove a second result of that type. Also, we identify several multi-parameter infinite families of excluded minors for the class of positroids.

## 1. INTRODUCTION

A *positroid* is a matroid M on a set  $E(M)$ , say of rank r and with  $|E(M)| = n$ , that has a representation by an r by n matrix over  $\mathbb{R}$ , each r by r submatrix of which has nonnegative determinant. Since Blum [\[3\]](#page-34-0) (as base-orderable matroids) and Postnikov [\[23\]](#page-35-0) introduced positroids, many papers have developed this topic, spurred by the important connections with other branches of mathematics that led to the introduction of positroids as well as the wealth of lenses through which they can be viewed (e.g., Grassmann necklaces, reduced plabic graphs, decorated permutations).

Positroids are often defined to have a fixed linear order on the ground set, as is inherent in the columns of a matrix (and so  $E(M)$  is often taken to be  $[n] = \{1, 2, \ldots, n\}$ ). With our focus on matroids per se, we find it useful to separate the matroid and the linear order, so in this paper, a positroid is a matroid  $M$  for which there is a linear order on the ground set  $E(M)$ , which we call a *positroid order* for M, so that the elements, when put in that order, correspond to the columns of a matrix representation of the type described above.

Blum [\[3\]](#page-34-0) and Ardila, Rincón, and Williams [\[2\]](#page-34-1) treat some of the fundamental properties of the class of positroids. In particular, they show that the class of positroids is closed under the operations of minors, duals, and direct sums. Thus, a matroid is a positroid if and only if the restrictions to its connected components are positroids. This raises the issue of determining how to combine the positroid orders on the connected components to get a positroid order on the direct sum. Ardila, Rincón, and Williams settled this question using the well-studied notion of a *non-crossing partition*, that is, a partition  $\{X_1, X_2, \ldots, X_k\}$ of a linearly ordered set E for which, for any two blocks  $X_i$  and  $X_j$ , there is a subset A of E such that  $X_i \subseteq A$ ,  $X_j \subseteq E - A$ , and either A or  $E - A$  is an interval in the linear order. They proved the following result [\[2,](#page-34-1) Theorem 7.6].

<span id="page-0-0"></span>**Theorem 1.1.** Let  $X_1, X_2, \ldots, X_k$  be the connected components of a matroid M. For any positroid order for  $M$ , the partition  $\{X_i\,:\,i\in[k]\}$  of  $E(M)$  is non-crossing. Conversely,

*Date*: June 18, 2024.

*Key words and phrases.* positroid, base-sortable matroid, amalgam, excluded minor.

#### 2 JOSEPH E. BONIN

any linear order on  $E(M)$  for which the induced order on each  $X_i$  is a positroid order for  $M|X_i$  and the partition  $\{X_i : i \in [k]\}$  of  $E(M)$  is non-crossing is a positroid order for M*.*

That result along with the following characterization of positroid orders for connected matroids [\[2,](#page-34-1) Proposition 5.6] give a two-part characterization of positroid orders: Theorem [1.2](#page-1-0) characterizes the orders on the connected components while Theorem [1.1](#page-0-0) characterizes how the orders on those components are assembled globally.

<span id="page-1-0"></span>**Theorem 1.2.** Let M be a connected matroid with  $r(M) \geq 2$ . A linear order  $\leq$  on  $E(M)$ *is a positroid order for* M *if and only if, for every flat* F *such that both*  $M/F$  *and*  $M/F$ *are connected, at least one of* F *and*  $E(M) - F$  *is an interval in*  $\leq$ *.* 

The following similar characterization of positroid orders for connected matroids was given by Rincón, Vinzant, and Yu  $[24,$  Proposition 6.5], and likewise can be paired with Theorem [1.1](#page-0-0) to characterize positroids.

<span id="page-1-1"></span>**Theorem 1.3.** Let M be a rank-r, connected matroid. Fix an integer k with  $1 < k \leq r$ . A *linear order on* E(M) *is a positroid order for* M *if and only if, for each flag*

$$
\emptyset = F_0 \subsetneq F_1 \subsetneq F_2 \subsetneq \cdots \subsetneq F_{k-1} \subsetneq F_k = E(M)
$$

*of flats of M for which each minor*  $M|F_i/F_{i-1}$ *, for*  $i \in [k]$ *, is connected, the set of their ground sets,*  ${F_i - F_{i-1} : i \in [k]}$ *, is a non-crossing partition of*  $E(M)$ *.* 

In Theorem [3.2,](#page-10-0) we give a similar characterization of positroids, namely, the following result, which, along with its corollaries, the rest of the paper exploits.

*Let* M *be a matroid with no loops. A linear order*  $\leq$  *on*  $E(M)$  *is a positroid order if and only if, for each connected flat* F *of* M*, if* K *is a connected component of the contraction*  $M/F$ *, then there is a subset* I *of*  $E(M)$  *such that*  $F \subseteq E(M) - I$ *,*  $K ⊆ I$ *, and either I or*  $E(M) - I$  *is an interval in*  $≤$ *.* 

This result applies to all loopless matroids, whether connected or not, thereby making it easier to use. There is much interest in characterizations of positroid orders; for instance, see Agarwala, Delaney, Yeats [\[1,](#page-34-2) Remark 5.27], which relates Theorem 5.17 in that paper to Theorem [3.2](#page-10-0) in this paper. In Section [3](#page-10-1) we also treat some corollaries of Theorem [3.2](#page-10-0) and, in Theorem [3.5,](#page-13-0) relate it to several earlier characterizations of positroids.

We develop more extensive applications of Theorem [3.2](#page-10-0) in Sections [4](#page-17-0) and [5,](#page-29-0) the first of which concerns free amalgams. The free amalgam of matroids  $M$  and  $N$ , which exists only for certain pairs  $(M, N)$ , is the freest matroid on  $E(M) \cup E(N)$  that has M and N as restrictions. A subset X of  $E(M)$  is a set of clones if each permutation of  $E(M)$  that fixes each element of  $E(M) - X$  is an automorphism of M. We show that if M and N are positroids and  $E(M) \cap E(N)$  is an independent set of clones in both M and N, then the free amalgam of  $M$  and  $N$  exists and is a positroid (Theorem [4.17\)](#page-23-0). We also show that the same conclusion holds under conditions on the independent set  $E(M) \cap E(N)$ that are in one way weaker and in another stronger (Theorem [4.21\)](#page-25-0). A contraction of the free amalgam of  $M$  and  $N$  need not be the free amalgam of the corresponding contractions of  $M$  and  $N$ ; because of this, we introduce and work with a more general way to glue matroids together, one that has useful contraction properties. Defining and developing the basic properties of this construction, which we call bonding, occupies much of Section [4.](#page-17-0) Proving all relevant properties of bonding makes the paper more self-contained; no knowledge of free amalgams is required. In Section [5,](#page-29-0) we identify many excluded minors for the class of positroids, including multi-parameter infinite families of excluded minors. We do not identify all excluded minors for the class of positroids; for some excluded minors not given here, see Park [\[22\]](#page-35-2).

In Section [2](#page-2-0) we review the background that is needed for these results. To make the paper accessible to a wide audience, we give complete background on, for instance, the orders used when treating Grassmann necklaces, as well as sketches of some of the less widely known topics in matroid theory. We assume familiarity with basic matroid theory, as set out in  $[20]$ , and we follow the matroid notation used in  $[20]$ .

# 2. BACKGROUND

<span id="page-2-0"></span>We use  $\mathbb Z$  for the set of integers,  $\mathbb N$  for  $\{n \in \mathbb Z : n > 0\}$ , and  $[n]$  for  $\{1, 2, \ldots, n\}$ .

2.1. Some orders related to a linear order. For a linear order  $\leq$  on a set E, say given by  $e_1 < e_2 < \cdots < e_n$ , its *i*-*shift*  $\leq_i$  is the cyclic shift in which  $e_i$  is least, that is,

 $e_i \leq_i e_{i+1} \leq_i \cdots \leq_i e_n \leq_i e_1 \leq_i \cdots \leq_i e_{i-1}.$ 

A *cyclic interval* of  $\leq$  is an interval in some *i*-shift of  $\leq$ . Elements *e* and *f* of *E* are *cyclically consecutive* in  $\leq$  if  $\{e, f\}$  is a cyclic interval of  $\leq$ . In an ordered set  $(P, \leq)$ , an *ideal* is a subset I of P for which if  $x \in I$  and  $y \in P$  with  $y \leq x$ , then  $y \in I$ ; also,  $F \subseteq P$ is a *filter* if whenever  $x \in F$  and  $z \in P$  with  $x \le z$ , then  $z \in F$ . For a linear order, an ideal is an interval that contains the least element; a filter is an interval that contains the greatest element. Note that for  $A \subseteq E$ , the following statements are equivalent to saying that A is a cyclic interval:  $E - A$  is a cyclic interval; A or  $E - A$  is an interval; A is an ideal of some shift  $\leq_i$  (so  $e_i$  is the least element of A using  $\leq_i$ ); A is a filter of some shift  $\leq_i$  (so  $e_{i-1}$  is the greatest element of A using  $\leq_i$ ).

In some examples we will need to show that no linear order on  $E$  has all sets in some set of sets being cyclic intervals; for instance,  $\{1, 3, 5\}$ ,  $\{2, 3, 4\}$ ,  $\{4, 5, 6\}$ , and  $\{1, 2, 6\}$ cannot all be cyclic intervals in any linear order on [6]. For this, the following observation and lemma are useful. Given two cyclic intervals  $A$  and  $B$  in a linear order on  $E$ , if  $A \cap B \neq \emptyset$ , then either  $A \cup B = E$  or  $A \cap B$  is a cyclic interval.

<span id="page-2-1"></span>**Lemma 2.1.** *Let*  $A$ *,*  $B$ *,*  $C$ *, and*  $D$  *be cyclic intervals in a linear order on*  $E$  *with*  $A \nsubseteq B$ *,*  $A \cup B \neq E$ ,  $A \cap B \neq \emptyset$ ,  $C \nsubseteq B$ ,  $B \cup C \neq E$ ,  $B \cap C \neq \emptyset$ , and  $A \cap B \cap C = \emptyset$ . If D is *disjoint from*  $A \cap B$  *and*  $B \cap C$  *but not from*  $B - (A \cup C)$ *, then*  $D \subseteq B - (A \cup C)$ *.* 

*Proof.* By replacing the order by a cyclic shift if needed, we may assume that  $B$  is an interval. The result follows by observing that, by the hypotheses, one of  $A \cap B$  and  $B \cap C$ is an ideal in the order that is induced on  $B$ , and the other is a filter, so only one of the two cyclic intervals whose union is  $E - (B \cap (A \cup C))$  can contain elements of D.

For a rank-r matroid M, if the matrix representation A shows that  $\leq$  is a positroid order for  $M$ , then the matrix  $A'$  that shifts the first column of  $A$  to be last and multiplies that column by  $(-1)^{r-1}$  shows that  $\leq_2$  is also a positroid order for M since one can shift the first column of an r by r matrix to the last place with  $r - 1$  column transpositions. Thus,  $\leq$  is a positroid order for a matroid  $M$  if and only if  $\leq_i$  is a positroid order for  $M.$ 

Given a linear order  $\leq$  on an *n*-element set E and an integer  $k \in [n]$ , we consider two associated orders on the set of k-element subsets of E: for k-subsets X and Y of E where the elements of X are, in order,  $x_1 < x_2 < \cdots < x_k$ , and likewise  $y_1 < y_2 < \cdots < y_k$ for  $Y$ , we have

- the *Gale order*:  $X \leq_G Y$  if  $x_i \leq y_i$  for all  $i \in [k]$ , and
- the *lexicographic order*:  $X \leq_L Y$  if  $X = Y$  or  $x_i < y_i$  for the least i with  $x_i \neq y_i$ .

While  $\leq_L$  is a linear order,  $\leq_G$  is not except for certain n and k. Also,  $\leq_L$  is an extension of  $\leq_G$ , that is, if  $X \leq_G Y$ , then  $X \leq_L Y$ .

By the next lemma, as one would expect, replacing an element in a set by a smaller element yields a smaller set in the Gale order.

<span id="page-3-0"></span>**Lemma 2.2.** Let  $\leq$  be a linear order on E. Fix a subset X of E and elements  $a \in X$  and  $b \in E - X$ *. If*  $b < a$ *, then*  $(X - a) \cup b <_{G} X$ *. If*  $a < b$ *, then*  $X <_{G} (X - a) \cup b$ *.* 

*Proof.* Assume that  $b < a$ . To get  $(X - a) \cup b <_{G} X$ , compare the elements of X, in order, (the first line below) to those of  $(X - a) \cup b$  (the second line):

$$
x_1 < \cdots < x_{j-1} < x_j < x_{j+1} \cdots < x_{i-1} < a < x_{i+1} < \cdots < x_k
$$

 $x_1 < \cdots < x_{i-1} < b < x_i < \cdots < x_{i-2} < x_{i-1} < x_{i+1} < \cdots < x_k$ 

where j is the least integer with  $b < x_j$ . The second statement follows from the first.  $\square$ 

<span id="page-3-1"></span>The next lemma is from Gale [\[16\]](#page-35-4).

**Lemma 2.3.** Let M be a matroid. Let  $\leq$  be a linear order on  $E(M)$ . If B is the least basis *of*  $M$  *in the lexicographic order, then, in the Gale order,*  $B \leq_G B'$  *for all bases*  $B'$  *of*  $M$ *.* 

*Proof.* We induct on the distance between bases  $B$  and  $B'$  in the lexicographic order. If  $B' = B$ , then  $B \leq_G B'$ , so we may assume that  $B \neq B'$  and, inductively, that  $B \leq_G A$ for all bases A for which  $A \leq_L B'$ . Fix  $a \in B' - B$ . By the symmetric exchange property, for some  $b \in B - B'$ , both  $(B - b) \cup a$  and  $(B' - a) \cup b$  are bases of M. If  $a < b$ , then Lemma [2.2](#page-3-0) would give  $(B - b) \cup a \ltg_B B$ , so  $(B - b) \cup a \lt_L B$ , contrary to B being the least basis in the lexicographic order. Thus,  $b < a$ , so Lemma [2.2](#page-3-0) gives  $(B'-a) \cup b <_G B'$ . By the inductive assumption,  $B \leq_G (B' - a) \cup b$ , so  $B <_G B'$ . .

The least basis of a matroid M in the Gale order induced by a linear order is the *Gale basis* for that order. (In some sources, the Gale basis is taken to be the greatest basis.)

2.2. **Transversal and nested matroids.** Let  $\mathcal{A} = (A_i : i \in [r])$  be an indexed family of subsets of a set E. A *partial transversal* of  $A$  is a subset X of E for which there is an injection  $\phi: X \to [r]$  with  $e \in A_{\phi(e)}$  for all  $e \in X$ . Edmonds and Fulkerson [\[15\]](#page-35-5) showed that the partial transversals of  $A$  are the independent sets of a matroid on  $E$ . This matroid, denoted  $M[A]$ , is a *transversal matroid*, and A is a *presentation* of it. In [\[10\]](#page-35-6), Brylawski showed how to view transversal matroids geometrically: transversal matroids of rank r with no loops are precisely the matroids that have geometric representations on an r-vertex simplex in which, for all  $k \in [r]$ , each circuit of rank k spans a k-vertex face of the simplex (e.g., a 3-element circuit must span an edge of the simplex).

Given a linear order  $\leq$  on E and an r-subset I of E, for each  $i \in I$ , let  $F_i$  be the filter  $\{j : i \leq j\}$ , and let  $\mathcal{A} = (F_i : i \in I)$ . Let  $N(I, \leq)$  be the transversal matroid  $M[\mathcal{A}]$ . Note that if  $i < k$ , then  $F_k \subsetneq F_i$ , so the presentation  $\mathcal{A}$  of  $N(I, \leq)$  is a chain of sets under inclusion. Transversal matroids that have presentations that are chains of sets are called *nested matroids*. (They are also called shifted matroids and Schubert matroids, among other names; see [\[6,](#page-34-3) Section 4].) Note that I is the Gale basis of  $N(I, \leq)$ , and an r-subset J of E is a basis of  $N(I, \leq)$  if and only if  $I \leq_G J$ .

2.3. Grassmann necklaces and base-sortable matroids. For a matroid  $M$  and linear order  $e_1 < e_2 < \cdots < e_n$  on  $E(M)$ , if  $I_i$  is the Gale basis of M using the *i*-shift  $\leq_i$  of  $\leq$ , then the *n*-tuple  $(I_1, I_2, \ldots, I_n)$  of bases has the properties

• if  $e_i \in I_i$ , then  $I_{i+1} = (I_i - e_i) \cup e_j$  for some  $j \in [n]$  (j can be i), and

• if  $e_i \notin I_i$ , then  $I_{i+1} = I_i$ ,

where  $I_{n+1} = I_1$ . An *n*-tuple of *r*-element subsets of a linearly ordered *n*-element set with these properties is a *Grassmann necklace of type*  $(n, r)$ . The next result combines a result of Postnikov [\[23\]](#page-35-0) (the first part) with one of Oh [\[19\]](#page-35-7) (the converse). In this result and the rest of this paper,  $\mathcal{B}(M)$  denotes the set of bases of a matroid M.

<span id="page-4-2"></span>**Theorem 2.4.** Let  $\leq$  be a linear order on E. If  $(I_1, I_2, \ldots, I_n)$  is a Grassmann necklace *of type* (n, r) *on* E*, then*

<span id="page-4-0"></span>
$$
(2.1) \qquad \qquad \bigcap_{i \in [n]} \mathcal{B}\big(N(I_i, \leq_i)\big)
$$

*is the set of bases of a rank-*r *positroid on* E *and* ≤ *is a positroid order for this matroid. Conversely, if*  $\leq$  *is a positroid order for a matroid M, then*  $\mathcal{B}(M)$  *is the intersection* [\(2.1\)](#page-4-0) *where*  $I_i$  *is the Gale basis of*  $M$  *for*  $\leq_i$ *.* 

Positroids first appeared, under the name of base-sortable matroids, in Blum [\[3\]](#page-34-0). Let  $\leq$  be a linear order on the ground set  $E(M)$  of a matroid M of rank r. Given bases B and B' of M, list the elements of the multiset union  $B \cup B'$  in order, taking multiplicities into account, as  $x_1 \le x_2 \le \cdots \le x_{2r}$ . Let  $B_e = \{x_{2i} : i \in [r]\}$ , the set of elements in the even positions in the list, and  $B_0 = \{x_{2i-1} : i \in [r]\}\,$ , the set of elements in the odd positions. Set  $\text{sort}_{\leq}(B, B') = \{B_e, B_o\}$ . Thus,  $\text{sort}_{\leq}(B, B') = \text{sort}_{\leq}(B', B)$ . Under the order dual  $\leq^d$  of  $\leq$  (i.e.,  $e \leq^d f$  if and only if  $f \leq e$ ), the elements in the even positions are switched with those in the odd positions, so  $\text{sort}_{\leq^d}(B, B') = \text{sort}_{\leq}(B, B')$ . Likewise, for the *i*-shift,  $\text{sort}_{\leq i}(B, B') = \text{sort}_{\leq}(B, B').$ 

Definition 2.5. *A matroid* M *is* base-sortable *if there is a linear order on* E(M) *for which, for every pair* B, B' *of bases of* M, the sets  $B_e$  and  $B_o$  in sort $(B, B')$  are bases of M. *Such a linear order on* E(M) *is called a* base-sorting order *for* M*.*

Base-sortable matroids are also often called *sort-closed matroids*. As Blum noted, the observations above about *i*-shifts and the dual order show that  $\leq$  is a base-sorting order for M if and only if  $\leq_i$  is a base-sorting order for M, and likewise for the dual order.

Lam and Postnikov [\[18,](#page-35-8) Corollary 9.4] proved that positroids and base-sortable matroids are the same. (Key results are in [\[17,](#page-35-9) Section 4.2].)

<span id="page-4-3"></span>Theorem 2.6. *Let* M *be a matroid. A linear order on* E(M) *is a positroid order if and only if it is a base-sorting order.*

2.4. Connectivity. For a matroid M, let  $e, f \in E(M)$  be related precisely when  $e = f$  or there is a circuit C of M with  $\{e, f\} \subseteq C$ . This relation is an equivalence relation and the equivalence classes are the *connected components* of M (see [\[20,](#page-35-3) Proposition 4.1.2]). A matroid M is *connected* if it has just one connected component; equivalently, for each pair of distinct elements  $e, f \in E(M)$ , there is a circuit C of M with  $\{e, f\} \subseteq C$ . A *separator* of M is a union of connected components of M. The *trivial separators* are  $\emptyset$  and  $E(M)$ . For a partition  $\{X_1, X_2, \ldots, X_k\}$  of  $E(M)$  with  $k > 1$ , we have

<span id="page-4-1"></span>
$$
(2.2) \t\t\t M = (M|X_1) \oplus (M|X_2) \oplus \cdots \oplus (M|X_k)
$$

if and only if  $M$  and the direct sum have the same circuits, and that holds if and only if each set  $X_i$  is a nontrivial separator of M. Since taking direct sums and the dual commute, it follows that a matroid and its dual have the same connected components, so  $M$  is connected if and only if for each pair of distinct elements  $e, f \in E(M)$ , there is a cocircuit  $C^*$  of M with  $\{e, f\} \subseteq C^*$ .

<span id="page-5-3"></span>**Lemma 2.7.** For a matroid M and a partition  $\{X_1, X_2, \ldots, X_k\}$  of  $E(M)$ , Equation *[\(2.2\)](#page-4-1) holds if and only if*  $r(M) = r(X_1) + r(X_2) + \cdots + r(X_k)$ *.* 

*Proof.* Equation [\(2.2\)](#page-4-1) clearly gives  $r(M) = r(X_1) + \cdots + r(X_k)$ . For the converse, it suffices to prove that if the rank equality holds and C is a circuit of M, then  $C \subseteq X_i$  for some  $i \in [k]$ . Assume that this is false. Set  $Y_i = X_i \cap C$  for  $i \in [k]$ . By our assumption, each set  $Y_i$  is independent. Let  $B_i$  be a basis of  $M|X_i$  with  $Y_i \subseteq B_i$ . This gives the contradiction that  $B_1 \cup \cdots \cup B_k$  spans M, has size  $r(M)$ , but contains the circuit C.

<span id="page-5-1"></span>We say that a set  $X$  in a matroid  $M$  is *connected* if the restriction  $M/X$  is connected.

Lemma 2.8. *Let* F *be a nonempty connected flat of a matroid* M*. If* A *is a nonempty connected flat of the contraction*  $M/F$ *, then either* A *or* A  $\cup$  F *is a connected flat of* M.

*Proof.* Now  $A \cup F$  is a flat of M since A is a flat of  $M/F$ . Let  $M|(A \cup F)$  be the direct sum  $M_1 \oplus M_2 \oplus \cdots \oplus M_k$  where each  $M_i$  is connected. Since F is connected in M, we may assume that  $F \subseteq E(M_1)$ . If  $F = E(M_1)$ , then  $M/F|A = M_2 \oplus \cdots \oplus M_k$ , so, since A is a connected flat of  $M/F$ , we must have  $k = 2$ , and therefore A is a connected flat of M. If  $F \subsetneq E(M_1)$ , then, since  $M/F|A = (M_1/F) \oplus M_2 \oplus \cdots \oplus M_k$  and A is a connected flat of  $M/F$ , we must have  $k = 1$ , so the flat  $A \cup F$  of M is connected.  $\square$ 

<span id="page-5-0"></span>The simple properties in the next lemma will come up at several points.

Lemma 2.9. *All circuits of a restriction of a matroid* M *are circuits of* M*. Dually, all cocircuits of a contraction of* M *are cocircuits of* M*. In particular, coloops of contractions of* M *are coloops of* M*.*

Recall that the closure operator cl of a matroid  $M$  can be cast in terms of circuits as follows: for  $X \subseteq E(M)$ , we have  $cl(X) = X \cup \{e : Y \cup e$  is a circuit for some  $Y \subseteq X\}$ .

<span id="page-5-2"></span>Lemma 2.10. *Let* M *be a matroid with no loops.*

- (1) *If*  $C$  *is a circuit of*  $M$ *, then*  $cl(C)$  *is connected.*
- (2) If M has a spanning circuit C, i.e.,  $r(C) = r(M)$ , then M is connected.
- (3) If some  $e \in E(M)$  is not a coloop and is in no proper connected nonsingleton flat *of* M, then M is connected, as is  $M/F$  *for any flat*  $F$  *of*  $M$  *with*  $e \notin F$ *.*

*Proof.* Part (1) follows from two items recalled above, the equivalence relation, applied to  $M|\text{cl}(C)$ , and the formulation of  $\text{cl}(C)$ . Part (2) follows from that since  $\text{cl}(C) = E(M)$ . For part (3), since e is not a coloop, e is in at least one circuit, say C, and C spans M since  $cl(C)$  cannot be a proper flat, so M is connected by part (2). For the second assertion, it suffices to show that the hypotheses of part (3) hold for  $M/F$ . Now e is not a coloop of  $M/F$  by Lemma [2.9.](#page-5-0) Let the connected components of  $M/F$  be  $F_1, F_2, \ldots, F_t$ . No proper connected nonsingleton flat of  $M/F_1$  contains e since otherwise e would be in a proper connected nonsingleton flat of M by Lemma [2.8.](#page-5-1) The same argument, using  $M/F_1$ , then shows that e is in no proper connected nonsingleton flat of  $M/(F_1 \cup F_2)$ . Iterating this show that, as needed, e is in no proper connected nonsingleton flat of  $M/F$ .

2.5. Cyclic flats, clones, and paving matroids. Some of the excluded minors for the class of positroids that we present in Section [5](#page-29-0) will be defined by giving their cyclic flats and the ranks of those flats, so we briefly review this perspective on matroids. Given a matroid M, a subset A of  $E(M)$  is *cyclic* if the restriction  $M|A$  has no coloops. Equivalently, A is cyclic if it is a (possibly empty) union of circuits. A *cyclic flat* is a flat that is cyclic. Let  $\mathcal{Z}(M)$  denote the set of cyclic flats of M. Note that  $\mathcal{Z}(M)$  is a lattice: the join of cyclic

<span id="page-6-0"></span>FIGURE 1. A graph whose cycle matroid is a positroid.

flats A and B is  $cl(A \cup B)$ , and their meet is  $(A \cap B) - C$  where C is the set of coloops of  $M|(A \cap B)$ . All connected flats F with  $|F| \geq 2$  are cyclic flats, but not conversely.

There is no connection between the terms cyclic interval and cyclic flat, both of which are well established in the literature. For instance, using the usual order, in the cycle matroid of the graph shown in Figure [1,](#page-6-0) which is a positroid, the set  $\{3, 6, 9\}$  is a cyclic flat that is not a cyclic interval, while  $\{6, 7\}$  is a cyclic interval that is a flat, but it is not a cyclic flat.

For any set X in a matroid M, if F is the closure of the union of the circuits of  $M/X$ , then F is a cyclic flat of M and  $r(X) = r(F) + |X - F|$  since the elements of  $X - F$  are coloops of  $M|X$ . If  $A \subseteq E(M)$ , then  $r(X) \le r(X \cap A) + |X - A| \le r(A) + |X - A|$ . Thus,  $r(X) = \min\{r(F) + |X - F| : F \in \mathcal{Z}(M)\}\)$ . So M is determined by its cyclic flats and their ranks, that is, by the set  $\{(A, r(A)) : A \in \mathcal{Z}(M)\}\)$ . The next result, from [\[25,](#page-35-10) [7\]](#page-34-4), provides an axiom scheme for matroids from this perspective.

<span id="page-6-1"></span>**Theorem 2.11.** For a set Z of subsets of a set E and a function  $r : \mathcal{Z} \to \mathbb{Z}$ , there is a *matroid* M on E with  $\mathcal{Z}(M) = \mathcal{Z}$  and  $r_M(X) = r(X)$  for all  $X \in \mathcal{Z}$  if and only if

- (Z0)  $(\mathcal{Z}, \subseteq)$  *is a lattice,*
- (Z1)  $r(0z) = 0$ , where  $0z$  is the least set in  $\mathcal{Z}$ ,

(Z2)  $0 < r(Y) - r(X) < |Y - X|$  for all  $X, Y \in \mathcal{Z}$  with  $X \subseteq Y$ , and

(Z3) *for all sets*  $X, Y$  *in*  $Z$  *(or, equivalently, just incomparable sets in*  $Z$ *),* 

$$
(2.3) \t r(X \vee Y) + r(X \wedge Y) + |(X \cap Y) - (X \wedge Y)| \le r(X) + r(Y).
$$

A set A is cyclic in a matroid M if and only if  $E(M) - A$  is a flat of the dual matroid,  $M^*$ , since A being a union of circuits of M is equivalent to  $E(M) - A$  being an intersection of hyperplanes (cocircuit complements) of  $M^*$ . Thus, X is a cyclic flat of M if and only if  $E(M) - X$  is a cyclic flat of  $M^*$ , and so  $\mathcal{Z}(M^*)$ , the lattice of cyclic flats of  $M^*$ , is isomorphic to the order dual of  $\mathcal{Z}(M)$ . In particular, just as  $\text{cl}_M(\emptyset)$ , the set of loops of M, is the least cyclic flat of M, the set  $E(M) - \text{cl}_{M*}(\emptyset)$  is the greatest cyclic flat of M. The first assertion in the lemma below is easy to see directly, and the second follows by duality.

<span id="page-6-2"></span>**Lemma 2.12.** Let X be a cyclic flat of M. The lattice  $\mathcal{Z}(M|X)$  of cyclic flats of the *restriction*  $M|X$  *is the interval*  $[cl(\emptyset), X]$  *in*  $\mathcal{Z}(M)$ *. The lattice*  $\mathcal{Z}(M/X)$  *of cyclic flats of the contraction*  $M/X$  *is*  ${F - X : F \in \mathcal{Z}(M) \text{ and } X \subseteq F}$ *, which is isomorphic to the upper interval*  $[X, E(M) - \mathrm{cl}_{M^*}(\emptyset)]$  *of cyclic flats that contain* X *in*  $\mathcal{Z}(M)$ *.* 

From the remarks before Theorem [2.11,](#page-6-1) it follows that the automorphisms of M are the permutations of  $E(M)$  that map each cyclic flat of M to a cyclic flat of the same rank. Elements  $e$  and  $f$  in a matroid  $M$  are *clones of*  $M$  if the transposition  $(e, f)$ , which maps  $e$ to f, and f to e, and fixes all other elements of  $E(M)$ , is an automorphism of M. Since M and  $M^*$  have the same automorphisms, two elements are clones in a matroid if and only if

### 8 JOSEPH E. BONIN

they are clones in its dual. A subset X of  $E(M)$  is a *set of clones of* M if  $e, f \in X$  are clones whenever  $e \neq f$ . The next lemma holds since any permutation of  $E(M)$  that fixes each element that is not in a set  $X$  of clones is a composition of transpositions of clones.

<span id="page-7-1"></span>**Lemma 2.13.** *For any matroid* M *and set* X *of clones of* M, *any permutation*  $\phi$  *of*  $E(M)$ *for which*  $\phi(e) = e$  *for all*  $e \in E(M) - X$  *is an automorphism of* M,

Note that  $e$  and  $f$  are clones in  $M$  if and only if they are in the same cyclic flats of  $M$ , and, if M has no loops, that is equivalent to e and f being in the same connected flats  $F$ of M with  $|F| \geq 2$  since such flats, which are cyclic, are the connected components of all cyclic flats. Thus, if X is a set of clones and F is a connected flat with  $|F| \geq 2$ , then either  $X \cap F = \emptyset$  or  $X \subseteq F$ . For any  $Y \subseteq E(M)$ , the closure in M of any cyclic flat of  $M|Y$  is a cyclic flat of M, so clones in M that are in Y are clones in M|Y. By duality, the same holds for  $M/Y$ . Thus, if X is a set of clones of M, then X is a set of clones in any minor M' of M for which  $X \subseteq E(M')$ . The characterization of clones in terms of cyclic flats makes it evident that the relation on  $E(M)$  in which  $e, f \in E(M)$  are related when  $e = f$  or e and f are clones is an equivalence relation; the equivalence classes are the *clonal classes* of M.

A matroid M of rank r is a *paving matroid* if each subset X of  $E(M)$  with  $|X| < r$ is independent. Thus, each set of size at most  $r - 2$  is a flat, so the only flats of a paving matroid M that may be dependent are  $E(M)$  and the hyperplanes. A paving matroid that has no dependent hyperplanes is a uniform matroid: in the *uniform matroid*  $U_{r,n}$  on an *n*-element set  $E$ , the bases are all *r*-subsets of  $E$ . The cyclic flats of a connected paving matroid M are  $\emptyset$ ,  $E(M)$ , and (if any) the dependent hyperplanes. A paving matroid is *sparse paving* if all of its dependent hyperplanes are circuits (that is, circuit-hyperplanes). For example, the rank-3 matroids  $\mathcal{W}_3$  and  $\mathcal{W}^3$  shown in Figure [2](#page-8-0) and discussed in the next subsection are sparse paving matroids; in both,  $\{1, 2, 6\}$ ,  $\{2, 3, 4\}$ , and  $\{4, 5, 6\}$  are circuit-hyperplanes, while  $\{1,3,5\}$  is a circuit-hyperplane of  $\mathcal{W}_3$  but not of  $\mathcal{W}^3.$  It follows from Theorem [2.11](#page-6-1) that a connected paving matroid M on E of rank  $r \geq 2$  that is not uniform can be specified by giving subsets  $H_1, H_2, \ldots, H_t$  (the dependent hyperplanes) of E for which (a)  $r \leq |H_i| \leq |E|-2$ , for all  $i \in [t]$ , and (b)  $|H_i \cap H_j| \leq r-2$ , for all distinct  $i, j \in [t]$ ; given such sets, letting  $\mathcal{Z}$  be  $\{\emptyset, E, H_1, H_2, \ldots, H_t\}$  and setting  $r(\emptyset) = 0, r(H_i) = r - 1$  for all  $i \in [t]$ , and  $r(E) = r$  defines a paving matroid (condition (a) gives property  $(Z2)$  and condition (b) gives the only nontrivial cases of property  $(Z3)$ ).

<span id="page-7-0"></span>2.6. Lattice path and multi-path matroids. Two special classes of positroids are the class of lattice path matroids [\[5\]](#page-34-5) and the larger class of multi-path matroids [\[8\]](#page-34-6). A matroid M is a *lattice path matroid* if and only if it is transversal and there is a linear order on  $E(M)$  and a presentation A of M that is an antichain of intervals in  $E(M)$ , that is, each set in A is an interval in  $E(M)$  and no set in A is a subset of another set in A. A *multipath matroid* is a transversal matroid M that has a presentation by an antichain of cyclic intervals in some linear order on  $E(M)$ .

An important matroid that is a multi-path matroid but not a lattice path matroid is the *n*-whirl,  $W^n$ , for  $n \geq 3$ . This rank-n matroid is formed from the cycle matroid  $W_n$  of an  $n$ -spoke wheel (an  $n$ -vertex cycle with one more vertex, the hub, that is adjacent to all other vertices) by relaxing a circuit-hyperplane. (Only when  $n = 3$  does  $\mathcal{W}_n$  have more than one circuit-hyperplane.) The sets  $\{1, 2, 3\}, \{3, 4, 5\}, \ldots, \{2n-1, 2n, 1\}$  give a presentation of  $\mathcal{W}^n$  by cyclic intervals in the ground set  $[2n]$  under the usual linear order. See Figure [2.](#page-8-0)

By [\[8,](#page-34-6) Theorem 6.3], restricting a multi-path matroid to a proper flat gives a lattice path matroid. The paragraph after that result notes that, with that result, some properties of

<span id="page-8-0"></span>FIGURE 2. The 3-spoke wheel, its cycle matroid  $\mathcal{W}_3$ , and the 3-whirl  $W^3$ . The 3-spoke wheel is the complete graph  $K_4$ , so  $W_3$  is  $M(K_4)$ .

lattice path matroids automatically extend to multi-path matroids. For this paper, the most relevant such property is  $[6,$  Theorem 3.11]: any connected flat in a lattice path matroid M is an interval in the linear order on  $E(M)$ . Thus, any connected flat in a multi-path matroid M is a cyclic interval in the linear order on  $E(M)$ .

2.7. **Amalgams and parallel connections.** For matroids  $M$  and  $N$ , any matroid  $K$  on  $E(M) \cup E(N)$  for which  $K|E(M) = M$  and  $K|E(N) = N$  is an *amalgam* of M and N. The equality  $M|T = N|T$ , where T is  $E(M) \cap E(N)$ , is a necessary (but not sufficient) condition for amalgams to exist. As Figure [3](#page-9-0) shows, when  $M$  and  $N$  have an amalgam, there may be many amalgams; in that example, a different rank-4 amalgam results if  $\{d, f, g, i\}$  is a circuit-hyperplane, and another rank-3 amalgam has, instead of the line  $\{a, e, f, i, h\}$ , the lines  $\{a, e, f\}$  and  $\{a, i, h\}$ . If K is the freest amalgam of M and N (i.e., any set that is independent in any amalgam of M and N is independent in  $K$ ), then K is the *free amalgam* of M and N. Amalgams of M and N may exist without the free amalgam of M and N existing. The next result is one implication in  $[20,$  Proposition 11.4.3].

<span id="page-8-1"></span>**Theorem 2.14.** *Let* K *be an amalgam of* M *and* N, *and set*  $T = E(M) \cap E(N)$ *. If, for each flat* F *of* K*, we have*

$$
r(F) = r(F \cap E(M)) + r(F \cap E(N)) - r(F \cap T),
$$

*then* K *is the free amalgam of* M *and* N*.*

Note that  $[20,$  Proposition 11.4.3] is about the proper amalgam, for which we refer to [\[20,](#page-35-3) Section 11.4] for the definition and a complete account. The proper amalgam, when it exists, is the free amalgam, but the free amalgam can exist without the proper amalgam existing. Two general conditions under which the proper amalgam is known to exist are (a) when T is a modular flat of either M or N, and (b) when the common restriction,  $M/T = N/T$ , is a modular matroid. Condition (b) applies to the amalgams that we consider here since, in what we treat,  $T$  will be independent in both  $M$  and  $N$ .

When T is the singleton  $\{p\}$  and  $r_M(p) = r_N(p)$ , the free amalgam of M and N is the *parallel connection,*  $P(M, N)$ , of M and N at the base point p. (When  $r_M(p) = r_N(p)$ , parallel connection generalizes the operation of gluing two graphs together along an edge. This operation is often defined by giving the set of circuits, as in [\[20,](#page-35-3) Proposition 7.1.4]. By [\[20,](#page-35-3) Exercise 7.1.1] and Theorem [2.14,](#page-8-1) when  $r_M(p) = r_N(p)$ , the parallel connection, as defined in [\[20\]](#page-35-3), is the free amalgam, and thinking about parallel connection as the free amalgam is more useful for this paper, so we take that as the definition.) If  $p$  is a loop of just one of  $M$  and  $N$ , then although there are no amalgams of  $M$  and  $N$ , the parallel

<span id="page-9-0"></span>FIGURE 3. Two rank-3 whirls, their free amalgam (which has rank 4), and a rank-3 amalgam.

connection is still defined: if p is a loop of M but not of N, then  $P(M, N)$  is defined to be  $M \oplus (N/p)$ ; if p is a loop of just N, then  $P(M, N)$  is defined to be  $(M/p) \oplus N$ .

2.8. Principal extension, series extension, quotients, and truncation. A matroid  $N$  is an *extension* of a matroid M if M is a restriction of N. Single-element extensions have been studied extensively, starting with Crapo [\[11\]](#page-35-11) (see also [\[20,](#page-35-3) Section 7.2]). We focus on principal extensions. Given a matroid M, a set  $X \subseteq E(M)$ , and an element  $e \notin E(M)$ , define  $r': 2^{E(M) \cup e} \to \mathbb{Z}$  by, for all  $Y \subseteq E(M)$ , setting  $r'(Y) = r_M(Y)$  and

$$
r'(Y \cup e) = \begin{cases} r_M(Y), & \text{if } X \subseteq \text{cl}_M(Y), \\ r_M(Y) + 1, & \text{otherwise.} \end{cases}
$$

It is routine to show that r' is the rank function of a matroid on  $E(M) \cup e$ . This matroid, which is denoted  $M +_X e$ , is the *principal extension* of M in which e is *added freely* to X. The *free extension* of M by e is  $M +_{E(M)} e$ ; we shorten  $M +_{E(M)} e$  to  $M + e$ . If  $r_M(f) = 1$ , then  $M + fe$  is a *parallel extension* of M. The parallel extension  $M + fe$  is the parallel connection of M and the rank-1 uniform matroid on  $\{e, f\}$ .

Note that e is in the closure of Y in  $M +_X e$  if and only if either  $e \in Y$  or  $X \subseteq cl_M(Y)$ . Also,  $M +_X e = M + c(x) e$ . It is easy to check that if  $e, f \notin E(M)$  and X and Y are subsets of  $E(M)$ , then  $(M +_X e) +_Y f = (M +_Y f) +_X e$ , so we do not need to specify an order for multiple principal extensions. If M has no loops, then the flat cl<sub>M</sub>(X) ∪ e of  $M + Xe$  is connected by Lemma [2.10;](#page-5-2) in particular,  $M + e$  is connected. If M has no loops and  $f \in E(M)$ , then there is a minimum nonsingleton connected flat of M that contains f if and only if M is a principal extension  $(M\backslash f) +_X f$  of  $M\backslash f$  for some  $X \subseteq E(M\backslash f)$ .

*Series extension* (or, more properly, series coextension) is dual to parallel extension:  $M \times_f e = ((M^*) +_f e)^*$ . Thus,  $M \times_f e$  is defined when f is not a coloop of M; also,  $r(M \times_f e) = r(M) + 1$ . The cocircuits of the parallel extension  $M + f e$  are those of M, except that those that contain f are augmented by e, so in the series extension  $M \times_f e$ , the circuits are those of M except that those that contain  $f$  are augmented by  $e$ .

For a matroid M, a matroid Q with  $E(Q) = E(M)$  is a *quotient* of M if, for some extension N of M with  $r(N) = r(M)$ , we have  $Q = N/A$  where  $A = E(N) - E(M)$ . For example, if M is the rank-4 matroid in Figure [3](#page-9-0) and  $X = \{a, e, f, i, h\}$ , the quotient  $(M + X)$  j) is the right-most matroid shown. If  $A = \{e_1, e_2, \ldots, e_k\}$  with  $k \le r(M)$ and  $N = (((M + e_1) + e_2) \cdots) + e_k$ , then  $Q = N/A$  is the *truncation* of M to rank  $r(M) - k$ , and  $r_Q(X) = \min\{r_M(X), r(M) - k\}$  for all  $X \subseteq E(Q)$ . Observe that each basis of a rank-r matroid M is a spanning circuit of its truncation to rank  $r - 1$ , so, if M has no loops, its truncations to positive ranks less than  $r$  are connected by Lemma [2.10.](#page-5-2)

<span id="page-10-1"></span>Theorem [3.2](#page-10-0) below, the proof of which uses Theorem [2.4,](#page-4-2) characterizes positroids with no loops by characterizing positroid orders. The equivalence of statements (1) and (2) is known (Theorem [2.6,](#page-4-3) due to Lam and Postnikov), but we include (2) since it fits naturally into our proof of the equivalence of  $(1)$  and  $(3)$ . Statement  $(4)$ , which uses the following definition, recasts (3) in a way that will prove to be useful.

Definition 3.1. *For a matroid* M *that has no loops, a linear order on* E(M) *has the* cyclic interval property *if, for each proper connected flat*  $F$  *of*  $M$  *with*  $|F| \geq 2$  *and each connected component* K *of the contraction*  $M/F$  *with*  $|K| \geq 2$ *, the set* K *is a subset of a cyclic interval that is disjoint from* F*.*

We require  $|F| > 2$  and  $|K| > 2$  so that we can focus on the substantial cases when applying Theorem [3.2;](#page-10-0) the condition trivially holds if either inequality fails. We assume that M has no loops since otherwise the condition on connected flats would hold vacuously. A matroid is a positroid if and only if the matroid obtained by deleting all of its loops is a positroid, and the placement of loops has no impact on whether a linear order is a positroid order, so the assumption of no loops does not limit the applicability of Theorem [3.2.](#page-10-0) In this result, the matroid is not assumed to be connected.

<span id="page-10-0"></span>**Theorem 3.2.** Let M be a matroid that has no loops and let  $\leq$  be a linear order on  $E(M)$ . *The following statements are equivalent:*

- $(1) \leq$  *is a positroid order for M*,
- $(2) \leq$  *is a base-sorting order for M*,

(3) *if* F is a flat of M for which  $2 \leq |F| \leq |E(M)| - 2$  and M|F is connected, then

$$
(3.1) \tM/F = (M/F|U_1) \oplus (M/F|U_2) \oplus \cdots \oplus (M/F|U_h)
$$

<span id="page-10-2"></span>*where*  $U_1, U_2, \ldots, U_h$  *are the maximal cyclic intervals that are disjoint from F*, *and*

 $(4)$   $\leq$  *has the cyclic interval property.* 

*Proof.* It is easy to see that statements (3) and (4) are equivalent. Below we show that statements (1)–(3) are equivalent. Let  $n = |E(M)|$  and  $r = r(M)$ .

Assume that statement (1) holds. By Theorem [2.4,](#page-4-2) the set of bases of  $M$  is

$$
\bigcap_{i\in[n]} \mathcal{B}\big(N(I_i,\leq_i)\big)
$$

where  $I_i$  is the Gale basis of M in the *i*-shift  $\leq_i$  of  $\leq$ . Let B and B' be bases of M, and let sort  $\leq (B, B') = \{B_e, B_o\}$ . To show that  $B_e$  and  $B_o$  are bases of M, we show that  $B_e, B_o \in \mathcal{B}(N(I_i, \leq_i))$  for all  $i \in [n]$ . Now  $B, B' \in \mathcal{B}(N(I_i, \leq_i))$  since both B and B' are bases of M, so, for each  $j \in [r]$ , each of B and B' has at most  $j - 1$  elements that are less than the *j*th element of  $I_i$  using  $\leq_i$ ; thus, the elements in positions  $2j - 1$  and  $2j$  when we list the elements in the multiset union  $B \cup B'$  in order, using  $\leq_i$ , are both at least the *j*th element of  $I_i$ . The elements in positions  $2j - 1$  and  $2j$  are the *j*th elements of  $B_o$  and  $B_e$ , so  $B_e, B_o \in \mathcal{B}(N(I_i, \leq_i))$ , so statement (2) holds.

Now assume that statement (2) holds. Let  $F$  be a connected flat  $F$  of  $M$  for which  $2 \leq |F| \leq |E(M)| - 2$ . Let  $U_1, U_2, \ldots, U_h$  be the maximal cyclic intervals that are disjoint from F. By replacing  $\leq$  by a shift  $\leq_j$  if needed, we may assume that the elements of  $E(M)$  are, in order,

$$
f_1^1, f_2^1, \ldots, f_{p_1}^1, u_1^1, u_2^1, \ldots, u_{q_1}^1, \ldots, f_1^h, f_2^h, \ldots, f_{p_h}^h, u_1^h, u_2^h, \ldots, u_{q_h}^h,
$$

### 12 JOSEPH E. BONIN

where all  $p_i, q_i \in \mathbb{N}$  and  $f_j^i \in F$ , and  $U_i = \{u_1^i, u_2^i, \dots, u_{q_i}^i\}$ . Set  $F_i = \{f_1^i, f_2^i, \dots, f_{p_i}^i\}$ for  $i \in [h]$ . Statement (3) holds trivially if  $h = 1$ , so assume that  $h > 1$ .

Since  $M|F$  is connected, there is a circuit  $C \subseteq F$  with  $\{f_{p_1}^1, f_1^2\} \subseteq C$ . Let B be a basis of  $M|F$  with  $C - f_{p_1}^1 \subseteq B$ . Let  $B_1$  and  $B_2$  be bases of  $M$  with  $B \subseteq B_1 \cap B_2$ . Let t be  $|B_1 \cap U_1| + |B_2 \cap U_1|$ . We claim that t is even, so  $|B_1 \cap U_1|$  and  $|B_2 \cap U_1|$  have the same parity. To see this, let the elements in the multiset union  $B_1 \cup B_2$ , listed in order, be

$$
a_1 = a_1 < a_2 = a_2 < \dots < a_i = a_i < z_1 \leq z_2 \leq \dots \leq z_t < f_1^2 = f_1^2 < \dots
$$

where  $\{a_1, a_2, \ldots, a_i\} \subseteq F_1 - f_{p_1}^1$  and  $z_j \in U_1$  for  $j \in [t]$ . Since  $\{f_{p_1}^1, f_1^2\} \subseteq C$  and  $C - f_{p_1}^1 \subseteq B$ , the set  $B'_1 = (B_1 - f_1^2) \cup f_{p_1}^1$  is a basis of M. The elements in the multiset union  $B'_1 \cup B_2$ , listed in order, are

$$
a_1 = a_1 < a_2 = a_2 < \cdots < a_i = a_i < f_{p_1}^1 < z_1 \leq z_2 \leq \cdots \leq z_t < f_1^2 < \cdots
$$

Both lists have  $2r(F)$  elements of F, so since the sets in sort $\leq (B_1, B_2)$  and sort $\leq (B'_1, B_2)$ are bases, in each list,  $r(F)$  elements of F are in even positions and the other  $r(F)$  elements of  $F$  are in odd positions. The only difference in the positions of elements in  $F$  in the two lists is that the first copy of  $f_1^2$  in the first list changes to  $f_{p_1}^1$  and moves t places earlier. Therefore t must be even, and so  $|B_1 \cap U_1|$  and  $|B_2 \cap U_1|$  have the same parity.

We next draw a sharper conclusion:  $|B_1 \cap U_1| = |B_2 \cap U_1|$  for any bases  $B_1$  and  $B_2$  of M with  $B \subseteq B_1 \cap B_2$ . This holds since we can get  $B_2$  from  $B_1$  by a sequence of singleelement exchanges, and no such exchange involves elements of F (since  $B \subseteq B_1 \cap B_2$ ), so, by the parity result above, each exchange either exchanges an element in  $U_1$  for an element in  $U_1$ , or an element in  $E(M) - (F \cup U_1)$  for an element in  $E(M) - (F \cup U_1)$ .

For any two bases B and B' of M|F, and any subset I of  $E(M) - F$ , the set  $B \cup I$  is a basis of M if and only if  $B' \cup I$  is a basis of M. This gives the stronger conclusion that for all bases  $B_1$  and  $B_2$  of M that contain bases of  $M|F$ , we have  $|B_1 \cap U_1| = |B_2 \cap U_1|$ .

The same argument applied to cyclic shifts shows that the same result holds for each of  $U_2, \ldots, U_h$ . For each  $j \in [h]$ , let  $s_j = r(F \cup U_j) - r(F)$ , so  $s_j = r(M/F|U_j)$ . We can extend a basis B of M|F to a basis of  $M|(F \cup U_i)$ , and then extend that to a basis of M, so what we just showed implies that for each basis  $B_1$  of M with  $B \subseteq B_1$ , we have  $|B_1 \cap U_j| = s_j$  for each  $j \in [h]$ . Thus,  $r(M) = r(F) + s_1 + s_2 + \cdots + s_h$ , and so

<span id="page-11-0"></span>(3.2) 
$$
r(M/F) = r(M/F|U_1) + r(M/F|U_2) + \cdots + r(M/F|U_h),
$$

and so the direct sum decomposition in statement (3) follows by Lemma [2.7.](#page-5-3)

Now assume that statement (3) holds. Recall that  $n = |E(M)|$  and  $r = r(M)$ . Let  $I_i$ be the Gale basis of M using  $\leq_i$ . By Theorem [2.4,](#page-4-2) the matroid M' for which

$$
\mathcal{B}(M') = \bigcap_{i \in [n]} \mathcal{B}(N(I_i, \leq_i))
$$

is a positroid. Since  $I_i$  is the Gale basis of M using  $\leq_i$ , we have  $\mathcal{B}(M) \subseteq \mathcal{B}(N(I_i, \leq_i))$ by Lemma [2.3,](#page-3-1) so  $\mathcal{B}(M) \subseteq \mathcal{B}(M')$ . Showing equality in that inclusion will give  $M = M'$ , and so M is a positroid and  $\leq$  is a positroid order, thus proving statement (1). To show that equality, it suffices to show that no r-subset of  $E(M)$  that contains a (necessarily non-spanning) circuit of M is in  $\mathcal{B}(M')$ . Let C be a non-spanning circuit of M, let F be the connected flat  $\text{cl}_M(C)$  of M, and let  $C \subseteq D \subseteq E(M)$  where  $|D| = r$ . Let  $U_1, U_2, \ldots, U_h$  be the maximal cyclic intervals that are disjoint from F, and let  $s_j$  be  $r(M/F|U_j)$ . Equation [\(3.1\)](#page-10-2) gives equation [\(3.2\)](#page-11-0), so  $r(M) = r_M(F) + s_1 + s_2 + \cdots + s_h$ . Since  $|D \cap F| \ge |C| > r_M(F)$ , we have  $|D \cap U_j| < s_j$  for at least one set  $U_j$ . Pick the i for which  $U_j$  is a filter in the *i*-order  $\leq_i$ . Equation [\(3.1\)](#page-10-2) gives  $M/F|U_j = M/(E(M)-U_j)$ , so

the Gale basis  $I_i$  must contain  $s_j$  elements of  $U_j$ . Thus, each basis of  $N(I_i, \leq_i)$  contains at least  $s_j$  elements in the filter  $U_j$  of the *i*-order  $\leq_i$ . Since  $|D \cap U_j| < s_j$ , we have  $D \notin \mathcal{B}(\tilde{N}(I_i, \leq_i)),$  so  $D \notin \mathcal{B}(M')$ , as needed.

The corollary below is obtained from condition (3) in Theorem [3.2](#page-10-0) by duality and the following results: F is a flat of M if and only if  $E(M) - F$  is a cyclic set of  $M^*$ ; the positroid orders for  $M$  are the same as the positroid orders for  $M^*$ .

**Corollary 3.3.** Let M be a matroid that has no coloops. A linear order  $\leq$  on  $E(M)$  is a *positroid order for* M *if and only if, for all cyclic sets* A *of* M *for which* M/A *is connected and*  $2 \le |A| \le |E(M)| - 2$ *, we have*  $M|A = (M|V_1) ⊕ (M|V_2) ⊕ \cdots ⊕ (M|V_h)$  *where*  $V_1, V_2, \ldots, V_h$  are the maximal cyclic intervals that are subsets of A.

The next corollary is useful both for limiting the search for potential positroid orders and for deducing that certain matroids are not positroids. This result is part of [\[2,](#page-34-1) Proposition 5.6] by Ardila, Rincón, and Williams, as cast in Theorem [1.2](#page-1-0) above.

<span id="page-12-0"></span>**Corollary 3.4.** Let F be a flat in a matroid M that has no loops. If both  $M/F$  and  $M/F$ *are connected, then* F *is a cyclic interval in any positroid order for* M*.*

*Proof.* This follows since the integer h in condition (3) in Theorem [3.2](#page-10-0) must be 1.  $\Box$ 

For example, the cycle matroid  $M(K_4)$  is not a positroid since the four 3-point lines are connected, as are the corresponding contractions, but, by Lemma [2.1,](#page-2-1) there is no linear order on the ground set in which each of those lines is a cyclic interval. (The example before Lemma [2.1](#page-2-1) uses the 3-point lines of  $M(K_4)$  as labeled in Figure [2.](#page-8-0)) This idea is taken much further in Examples [4–](#page-31-0)[8](#page-32-0) of Section [5.](#page-29-0)

<span id="page-12-1"></span>**Example 1.** Let M be the cycle matroid of the graph in Figure [1,](#page-6-0) which has rank five and is the parallel connection of four copies of the uniform matroid  $U_{2,3}$ , one on each of the sets  $\{3, 6, 9\}$ ,  $\{1, 2, 3\}$ ,  $\{4, 5, 6\}$ , and  $\{7, 8, 9\}$ . By Theorem [3.2,](#page-10-0) M is a positroid since the cyclic interval property clearly holds for each proper connected flat with at least two elements that is a cyclic interval (so,  $\{1, 2, 3\}$ ,  $\{4, 5, 6\}$ , and  $\{7, 8, 9\}$ ), and all other connected flats F with  $|F| \ge 2$  contain  $\{3, 6, 9\}$ , so each connected component of  $M/F$ is one of the intervals  $\{1, 2\}$ ,  $\{4, 5\}$ , and  $\{7, 8\}$ .

To illustrate a point that is used at the end of the proof of Theorem [3.2,](#page-10-0) we explain how each 5-element subset  $X$  of  $E(M)$  that contains a non-spanning circuit of  $M$  fails to be a basis of some matroid  $N(I_i, \leq_i)$ . If  $\{1,2,3\} \subseteq X$ , then X is not a basis of  $N(I_1, \leq_1)$ since  $I_1 = \{1, 2, 4, 5, 7\}$  but at most two elements  $j \in X$  satisfy  $4 \leq_1 j$ . The cases of  $\{4,5,6\} \subseteq X$  (use  $I_4$ ) and  $\{7,8,9\} \subseteq X$  (use  $I_7$ ) are similar. If X contains a 4- or 5circuit, then X is disjoint from  $\{1, 2\}$ ,  $\{4, 5\}$ , or  $\{7, 8\}$ . If  $X \cap \{1, 2\} = \emptyset$ , then X is not a basis of  $N(I_3, \leq_3)$  since the fifth element of X is less than that of  $I_3 = \{3, 4, 5, 7, 1\}$  in  $\leq_3$ . The cases of  $X \cap \{4, 5\} = ∅$  (use  $I_6$ ) and  $X \cap \{7, 8\} = ∅$  (use  $I_9$ ) are similar.

Figure [4](#page-13-1) shows the rank-4 truncation of  $M$ . Applying Corollary [3.4](#page-12-0) to the connected flat  $\{3, 6, 9\}$  shows that the usual order is not a positroid order for the truncation of M to rank 3 or 4. Indeed, these truncations are excluded minors for the class of positroids (see Section [5\)](#page-29-0). Thus, the class of positroids is not closed under truncation.  $\circ$ 

The proof of the next result shows that (1) the cyclic interval property, (2) a condition that Blum conjectured to characterize base-sorting orders [\[3,](#page-34-0) Conjecture 4.9], and (3) a characterization of positroid orders via forbidden induced orders on certain 4-element rank-2 minors can easily be derived from each other. The third characterization, while widely known among researchers in the field, seems to never have appeared in the literature.

<span id="page-13-1"></span>FIGURE 4. A rank-4 excluded minor for the class of positroids that is the truncation of a rank-5 positroid.

<span id="page-13-0"></span>**Theorem 3.5.** Let M be a matroid that has no loops and let  $\leq$  be a linear order on  $E(M)$ . *The following statements are equivalent:*

- $(1)$   $\leq$  *has the cyclic interval property;*
- (2) *for every minor* N *of* M *that has neither loops nor coloops, each circuit-hyperplane of* N is a cyclic interval in the linear order that  $\leq$  *induces on*  $E(N)$ ;
- (3) *for every minor* N *of* M *for which* E(N) *is the disjoint union of a* 2*-element circuit* C *and a* 2*-element cocircuit, the circuit* C *is a cyclic interval in the linear order that*  $\leq$  *induces on*  $E(N)$ *.*

*Proof.* Assume that statement (1) holds, so  $\leq$  is a positroid order by Theorem [3.2.](#page-10-0) Let N be a minor of  $M$  that has neither loops nor coloops and let  $H$  be a circuit-hyperplane of  $N$ . By Corollary [3.4](#page-12-0) applied to the positroid N and its connected flat  $H$ , the set  $H$  is a cyclic interval in the linear order that  $\leq$  induces on  $E(N)$ . Thus, statement (2) holds, as does (3), which is a special case of (2).

Now assume that statement (1) fails. We claim that statement (3), and hence (2), also fail. Let F be a connected flat of M and let K be a connected component of  $M/F$  that is not contained in any cyclic interval of  $E(M)$  that is disjoint from F. Thus, there are elements  $a, b \in F$  and  $e, f \in K$  for which  $\{a, b\}$  is not a cyclic interval in the induced order on  $\{a, b, e, f\}$ . Since F is connected, some circuit C of  $M|F$  has  $a, b \in C$ . Since  $M/F|K$  is connected, some cocircuit  $C^*$  of  $M/F$  has  $e, f \in C^*$ , and  $C^*$  is a cocircuit of *M* by Lemma [2.9.](#page-5-0) Extend  $C - a$  to a basis B of  $M - C^*$ . Set  $N = M/(B - b) | {a, b, e, f}$ . Thus, N has rank two,  $\{a, b\}$  is a circuit of N, and  $\{e, f\}$  is a cocircuit of N. Since  $\{a, b\}$  is not a cyclic interval in the induced order on  $\{a, b, e, f\}$ , statement (3) fails, as claimed.  $\square$ 

Statement (3) in the result above is an excluded-minor characterization of positroids if one considers the linear order to be part of the positroid. In contrast, in this paper, we distinguish between the matroid and positroid orders for it, so the excluded minors that we consider in Section [5](#page-29-0) are for the class of matroids for which positroid orders exist.

The cyclic interval property clearly holds under the hypotheses of the next corollary, which are less restrictive than the hypotheses of  $[3,$  Proposition 4.5].

<span id="page-13-2"></span>**Corollary 3.6.** Let M be a matroid with no loops. If there is a linear order on  $E(M)$  in *which each connected flat of* M *is a cyclic interval, then* M *is a positroid and the linear order is a positroid order.*

In particular, any matroid with no loops in which the proper nonsingleton connected flats are pairwise disjoint is a positroid. Thus, every rank-2 matroid is a positroid.

If a matroid M satisfies the hypothesis of Corollary  $3.6$ , then so do its truncations since all proper connected flats of a truncation are proper connected flats of  $M$ . The same does not apply to quotients other than truncations. Also, the same is not true of Theorem [3.2.](#page-10-0) Indeed, the class of positroids is not closed under truncations, as Example [1](#page-12-1) shows.

Oh [\[19\]](#page-35-7) proved that lattice path matroids are positroids. From Corollary [3.6](#page-13-2) and the remarks in Section [2.6,](#page-7-0) noting our observation on loops at the beginning of this section, it is easy to see that the same is true of the larger class of multi-path matroids (this also follows from Blum [\[3,](#page-34-0) Theorem 5.2]), and likewise for truncations of lattice path matroids (which need not be lattice path), and truncations of multi-path matroids (which need not be multi-path). As an aside, we note that the class of lattice path matroids is closed under direct sums, but that of multi-path matroids is not; also, truncations of direct sums of multipath matroids (e.g., truncations of direct sums of whirls) need not be positroids.

We next show that the class of positroids is closed under circuit-hyperplane relaxation and a more general relaxation operation that we now discuss. Assume that a cyclic flat X of a matroid M is neither  $\text{cl}_M(\emptyset)$  nor  $E(M) - \text{cl}_{M^*}(\emptyset)$ , that the only cyclic flat that properly contains X is  $E(M) - \mathrm{cl}_{M^*}(\emptyset)$ , and that the only cyclic flat that X properly contains is cl<sub>M</sub>( $\emptyset$ ). (Thus, X could be a circuit-hyperplane of a connected matroid of rank at least two, but X is not limited to such sets.) Observe that properties  $(Z0)$ – $(Z3)$  in Theorem [2.11](#page-6-1) hold for  $\mathcal{Z} = \mathcal{Z}(M) - \{X\}$  and  $r : \mathcal{Z} \to \mathbb{Z}$  where  $r(A) = r_M(A)$  for each  $A \in \mathcal{Z}$ . By that result, this reduced cyclic flat and rank data defines another matroid, a generalized relaxation of  $M$ , in which  $X$  is independent.

Corollary 3.7. *Assume that* X *is a proper, nonempty cyclic flat of a matroid* M *that has no loops and no coloops, and that no other proper nonempty cyclic flat of* M *either contains* X or is contained in X. Let M' be the matroid for which  $\mathcal{Z}(M') = \mathcal{Z}(M) - \{X\}$  and  $r_{M'}(A) = r_M(A)$  *for all*  $A \in \mathcal{Z}(M')$ *. If* M *is a positroid, then so is* M', and any *positroid order for* M *is a positroid order for* M′ *. Thus, any circuit-hyperplane relaxation of a connected positroid of rank at least two is a positroid.*

Proof. It follows from Lemma [2.12](#page-6-2) that for any proper, nonempty cyclic flat F of M', we have  $M|F = M'|F$  and  $M/F = M'/F$ . Thus, the proper connected flats F of M' with  $|F| \ge 2$  (all of which are cyclic flats of M') are those of M other than X. For a positroid order for  $M$ , the cyclic interval property holds for  $M$ , so the cyclic interval property also holds for  $M'$ , so the linear order is a positroid order for  $M'$ .

The same result and proof apply to the more general relaxation  $M'$  of M where  $\mathcal{Z}(M')$ is  $\mathcal{Z}(M) - \mathcal{S}$  for some  $\mathcal{S} \subseteq \mathcal{Z}(M) - \{\emptyset, E(M)\}\$  where  $\mathcal{S} \cup \{\emptyset, E(M)\}\$  is both a filter and an ideal of  $\mathcal{Z}(M)$ .

Since the class of positroids is closed under contraction but not under truncation, it is not closed under free extension. (It is therefore also not closed under the operation of free product, of which free extension is a special case; see [\[12,](#page-35-12) [13,](#page-35-13) [20\]](#page-35-3).) The following corollary characterizes when free extensions of positroids are positroids.

<span id="page-14-0"></span>**Corollary 3.8.** Let M be a matroid with no loops, and fix  $e \notin E(M)$ . The free extension  $M + e$  *is a positroid if and only if there is a linear order on*  $E(M)$  *in which each proper connected flat of* M *is an interval.*

*Proof.* First assume that  $M + e$  is a positroid, and let  $\leq$  be a positroid order for  $M + e$ . By replacing  $\leq$  by a cyclic shift if needed, we may assume that e is the greatest element of  $E(M + e)$ . Since e is neither a coloop of  $M + e$  nor in any proper connected nonsingleton flat of  $M + e$ , by Lemma [2.10](#page-5-2) any contraction  $(M + e)/F$  by a flat F with  $e \notin F$  is

connected. Let F be a proper connected flat of M. Then F is a proper connected flat of  $M + e$ , and  $(M + e)/F$  is connected, so F is a cyclic interval in  $\leq$  by Corollary [3.4.](#page-12-0) Therefore F is an interval in  $\leq$  since  $e \notin F$ . Thus, in the positroid order that  $\leq$  induces on  $E(M)$ , every proper connected flat of M is an interval.

The converse follows easily from Corollary [3.6](#page-13-2) since the proper connected nonsingleton flats of M are precisely those of  $M + e$ , so if there is a linear order on  $E(M)$  in which each proper connected flat of M is an interval, then the same holds for  $M + e$  by extending that positroid order for M to make  $e$  the greatest element in the linear order.

**Corollary 3.9.** If the ground sets of  $M_1, M_2, \ldots, M_t$  are pairwise disjoint and the free *extension*  $M_i + e$ , for each  $i \in [t]$ , is a positroid, then any iterated free extension of any *truncation of*  $M_1 \oplus M_2 \oplus \cdots \oplus M_t$  *is a positroid.* 

*Proof.* Let  $N = M_1 \oplus M_2 \oplus \cdots \oplus M_t$ . For each  $i \in [t]$ , since  $M_i + e$  is a positroid, there is a linear order  $e_{i,1}, e_{i,2}, \ldots, e_{i,n_i}$  on  $E(M_i)$  in which each connected flat of  $M_i$  is an interval. Concatenating these linear orders as

```
e_{1,1}, e_{1,2}, \ldots, e_{1,n_1}, e_{2,1}, e_{2,2}, \ldots, e_{2,n_2}, \ldots, e_{t,1}, e_{t,2}, \ldots, e_{t,n_t}
```
gives a linear order on  $E(N)$  in which each connected flat of N is an interval. By Corollary [3.8,](#page-14-0) adding elements freely to N yields a positroid, and contracting some of them gives an iterated free extension of a truncation of  $N$ .

We next identify some cases in which principal extensions of positroids are positroids. The assumption in this result amounts to M being a principal extension of  $M\backslash f$ .

**Corollary 3.10.** Let M be a positroid with no loops. Fix  $e \notin E(M)$ . Assume that for some *nonsingleton connected flat* A *of* M and  $f \in E(M)$ *, for each nonsingleton connected flat*  $F$  *of*  $M$ *, we have*  $f \in F$  *if and only if*  $A \subseteq F$ *. Then the principal extension*  $M + Ae$  *of*  $M$ *is a positroid.*

*Proof.* By construction, e and f are clones in  $M +_{A} e$ . Let  $\leq$  be a positroid order for M. We may assume that f is the greatest element of  $E(M)$  under  $\leq$ . Define  $\leq'$  on  $E(M) \cup e$ by appending e as the new greatest element, so  $E(M)$  is an ideal in the extension  $\leq'$  of  $\leq$ . The connected flats of  $M +_{A} e$  with at least two elements are of two types: (i) connected flats F of M with  $|F| \ge 2$  and  $f \notin F$ , and (ii)  $F \cup e$  where F is a connected flat of M with  $|F| \ge 2$  and  $f \in F$ . For a connected flat F of  $M + A e$  of type (i), the connected components of  $(M +_A e)/F$  are those of  $M/F$ , but with the one that contains f augmented by e. Also, for a connected flat  $F \cup e$  of  $M + A e$  of type (ii), the connected components of  $(M +_A e)/(F \cup e)$  are those of  $M/F$ . With those observations, it is easy to see that  $\leq'$ has the cyclic interval property.

There are infinite antichains of positroids in the minor quasi-order (where  $N \leq M$  if N is isomorphic to a minor of  $M$ ), so the class of positroids is not well-quasi-ordered. Some examples of infinite antichains of positroids are: the excluded minors for the class of nested matroids (the truncation, to rank n, of the direct sum of two n-circuits, for  $n \geq 2$ ; see [\[21\]](#page-35-14)); apart from  $M(K_4)$ , the excluded minors for the class of lattice path matroids (see [\[4\]](#page-34-7)); for all  $n \geq 3$ , the truncation of the rank-n whirl  $\mathcal{W}^n$  to rank 3.

<span id="page-15-0"></span>The next result will be useful in Section [4.](#page-17-0)

**Corollary 3.11.** Let  $X_1, X_2, \ldots, X_d$  be pairwise disjoint sets of clones in a positroid M *for which, in some positroid order for* M, some  $x \in X_1$  and  $y \in X_2$  are cyclically  $consecutive.$  Then there is a positroid order for  $M$  in which each  $X_i,$  for  $i \in [d]$ , is a cyclic

*interval, as is*  $X_1 \cup X_2$ *. In particular, there is a positroid order for* M *in which each clonal class is a cyclic interval.*

*Proof.* Assume that the following linear order,  $\leq$ , on  $E(M)$ , written as a list from the minimum to the maximum element, is a positroid order for M:

 $x_1^1, \ldots, x_{t_1}^1, a_1^1, \ldots, a_{s_1}^1, x_1^2, \ldots, x_{t_2}^2, a_1^2, \ldots, a_{s_2}^2, \ldots, x_1^k, \ldots, x_{t_k}^k, a_1^k, \ldots, a_{s_k}^k,$ 

where all  $t_i$ ,  $s_i$  are in N, each  $x_i^j$  is in  $X_1$ , and each  $a_i^j$  is in  $E(M) - X_1$ . Also, we can take the elements x and y in the hypothesis to be  $x = x_1^1$  and  $y = a_{s_k}^k$ . (By using a cyclic shift and the order dual as needed, any other pair of cyclically consecutive elements  $x \in X_1$ and  $y \in X_2$  can be brought into the analogous position.) Consider the linear order  $\leq_1$  that, written as a list, is given by

$$
x_1^1, \ldots, x_{t_1}^1, x_1^2, \ldots, x_{t_2}^2, \ldots, x_1^k, \ldots, x_{t_k}^k, a_1^1, \ldots, a_{s_1}^1, a_1^2, \ldots, a_{s_2}^2, \ldots, a_1^k, \ldots, a_{s_k}^k,
$$

so  $\le$  and  $\le$ <sub>1</sub> induce the same linear orders on  $X_1$  and on  $E(M) - X_1$ ; also,  $X_1$  is an ideal of  $\leq_1$ . If  $k = 1$ , then  $\leq_1$  is the positroid order  $\leq$  for M. We next show that  $\leq_1$  is a positroid order for M even if  $k > 1$ .

Let F be a connected flat of M with  $|F| \geq 2$  and let K be a connected component of  $M/F$  with  $|K| \ge 2$ . By Theorem [3.2,](#page-10-0) there is a cyclic interval I for  $\le$  so that  $K \subseteq I$  and  $I \cap F = \emptyset$ . We must show that  $K \subseteq I'$  and  $I' \cap F = \emptyset$  for some cyclic interval I' for  $\leq_1$ . If  $X_1 \subseteq F$ , then since F and the cyclic interval I are disjoint,  $I \subseteq \{a_1^i, a_2^i, \ldots, a_{s_i}^i\}$ for some  $i \in [k]$ , and so I is a cyclic interval for  $\leq_1$  and we can take  $I' = I$ . Now assume that  $X_1 \not\subseteq F$ . Then  $X_1 \cap F = \emptyset$  since  $X_1$  is a set of clones of M. Since  $X_1$  is also a set of clones of  $M/F$ , either  $X_1 \cap K = \emptyset$  or  $X_1 \subseteq K$ . First assume that  $X_1 \cap K = \emptyset$ . If  $\{x_1^1, \ldots, x_{t_1}^1\} \cap I = \emptyset$ , then  $I' = I - X_1$  is a cyclic interval for  $\leq_1$  and satisfies  $K \subseteq I'$ and  $I' \cap F = \emptyset$ . If  $\{x_1^1, \ldots, x_{t_1}^1\} \cap I \neq \emptyset$ , then  $I' = I \cup X_1$  is a cyclic interval for  $\leq_1$  and satisfies  $K \subseteq I'$  and  $I' \cap F = \emptyset$ . Now assume that  $X_1 \subseteq K$ . Then  $X_1 \subseteq I$ , so the cyclic interval  $E(M) - I$  for ≤, which contains F, is  $\{a_p^h, a_{p+1}^h, \ldots, a_q^h\}$  for some h, p, and q. Since  $\{a_p^h, a_{p+1}^h, \ldots, a_q^h\}$  is also a cyclic interval for  $\leq_1$ , so is *I*, so we can take  $I' = I$ .

Starting with the dual of  $\leq_1$ , apply the argument above to  $X_2$  in place of  $X_1$ , keeping  $x = x_1^1$  and  $y = a_{s_k}^k$  cyclically consecutive, giving  $\leq_2$ . Since the restrictions of the orders  $\leq_1$  and  $\leq_2$  to  $E(M) - X_2$  are the same,  $X_1$  is a cyclic interval in  $\leq_2$ , as are  $X_2$  and  $X_1 \cup X_2$ . To complete the proof, apply the same modification of the linear order, one step at a time, for each of  $X_3, \ldots, X_d$ .

We close this section with a corollary of Theorem [3.2](#page-10-0) that we will use in Section [5.](#page-29-0)

<span id="page-16-0"></span>Corollary 3.12. *Let* M *be a matroid that has exactly three proper, nonempty cyclic flats,*  $Z_1$ ,  $Z_2$ , and  $Z_3$ . If  $E(M) = Z_1 \cup Z_2 \cup Z_3$  and  $Z_1 \cap Z_2 \cap Z_3 = \emptyset$ , then M is a positroid.

*Proof.* Any proper connected flat with at least two elements is cyclic and so must be  $Z_1$ ,  $Z_2$ , or  $Z_3$ , so, by Corollary [3.6,](#page-13-2) it suffices to find a linear order on  $E(M)$  in which  $Z_1$ ,  $Z_2$ , and  $Z_3$  are cyclic intervals. Consider the following six subsets of  $E(M)$ , some of which may be empty:  $Z_1 \cap Z_3$ ,  $Z_1 - (Z_2 \cup Z_3)$ ,  $Z_1 \cap Z_2$ ,  $Z_2 - (Z_1 \cup Z_3)$ ,  $Z_2 \cap Z_3$ , and  $Z_3 - (Z_1 \cup Z_2)$ ; for each set, pick a linear order on the elements, and then concatenate these six linear orders in the order given for these sets (so, for example,  $Z_1 \cap Z_3$  is an ideal in this linear order). The result is a positroid order for  $M$ .

Similarly, any matroid that has at most four cyclic flats (and so at most one pair of incomparable cyclic flats) is a positroid.

<span id="page-17-1"></span>FIGURE 5. Two rank-2 matroids  $M$  and  $N$ , the matroid  $H$ , and the bonding  $B_T(M, N)$ , which is  $H/{q_1, q_2}\$  { $s_1, s_2$  }.

## 4. BONDING AND ITS APPLICATION TO AMALGAMS OF POSITROIDS

<span id="page-17-0"></span>In this section, we prove Theorem [4.17:](#page-23-0) if M and N are positroids and  $E(M) \cap E(N)$ is an independent set of clones in  $M$  and in  $N$ , then the free amalgam of  $M$  and  $N$  is a positroid. We also prove a second result of this type (Theorem [4.21\)](#page-25-0).

A difficulty that arises is that a contraction of an amalgam of  $M$  and  $N$  need not be an amalgam of the corresponding contractions of  $M$  and  $N$ . To deal with this, we introduce a more general way to glue matroids M and N together along  $T = E(M) \cap E(N)$  that coincides with the free amalgam when  $T$  is independent in both  $M$  and  $N$ , but that has crucial contraction properties that come from the greater generality of the construction.

This section has two parts. In the first, we define the new construction, which we call bonding, and develop the properties of bonding that we need for our work on positroids, and then we treat those applications. In the second, we prove other properties of bonding that may help the future development of this topic.

4.1. Bonding and its application to positroids. The notation that we introduce next is used throughout this section. Let M and N be matroids for which  $E(M) \cap E(N)$  is nonempty; let T denote this intersection. We form the *bonding of* M *and* N *at* T , denoted  $B_T(M, N)$ , via the following steps.

- Say that T is  $\{t_1, t_2, ..., t_k\}$ . Fix sets  $S = \{s_1, s_2, ..., s_k\}$  and  $Q = \{q_1, q_2, ..., q_k\}$ that are disjoint from each other and from  $E(M)$  and  $E(N)$ .
- Form N' from N by, for each  $i \in [k]$ , relabeling  $t_i$  as  $s_i$ . Thus,  $E(M) \cap E(N') = \emptyset$ .
- Extend the direct sum  $M \oplus N'$  by, for each integer  $i \in [k]$ , adding  $q_i$  freely to the flat  $\text{cl}_{M \oplus N'}(\lbrace t_i, s_i \rbrace)$ , giving the matroid H on  $E(M) \cup E(N') \cup Q$ .
- The bonding  $B_T(M, N)$  is the minor  $H/Q \&set S$  of H.

Thus,  $E(B_T(M, N)) = E(M) \cup E(N)$ . Note that  $B_T(M, N) = B_T(N, M)$ . Also, the point  $q_i$  is added freely to the line  $\mathrm{cl}_{M \oplus N'}(\{t_i,s_i\})$  of  $M \oplus N'$  if  $t_i$  is a loop of neither  $M$ nor N, while it is parallel to  $s_i$  if  $t_i$  is a loop of M only, and parallel to  $t_i$  if  $t_i$  is a loop of N only, and  $q_i$  is a loop if  $t_i$  is a loop of both M and N.

Figure [5](#page-17-1) gives a simple example that will show the necessity of certain hypotheses in some results below. Figure [6](#page-18-0) gives an example that is more representative of what we will see: if T is independent in both M and N, then  $B_T(M, N)$  is the free amalgam of M and N; also, if, in addition, T is a set of clones, and M and N are positroids, then  $B_T(M, N)$ is a positroid. That example shows that bonding two transversal matroids (in fact, multipath matroids) need not yield a transversal matroid. If  $M$  and  $N$  are the rank-2 uniform

<span id="page-18-0"></span>FIGURE 6. Two rank-3 positroids M and N, and the bonding (their free amalgam)  $B_T(M, N)$ . Here,  $T = \{1, 2\}$  is an independent set of clones in  $M$  and  $N$ . The bonding is a rank-4 positroid.

matroids on  $[q + 1]$  and  $[2q] - [q - 1]$ , respectively, so  $T = \{q, q + 1\}$ , then  $B_T(M, N)$  is the rank-2 uniform matroid on  $[2q]$ . Thus, bonding need not preserve representability over a fixed finite field. However, bonding preserves membership in classes of matroids that are closed under direct sum, deletion, contraction, and principal extension, such as the class of matroids that are representable over a given infinite field.

The way that bonding interacts with direct sums, which we treat in the next lemma, is crucial in our work.

<span id="page-18-2"></span>**Lemma 4.1.** *Let*  $M$  *be*  $M_1 \oplus M_2 \oplus \cdots \oplus M_s$  *and*  $N$  *be*  $N_1 \oplus N_2 \oplus \cdots \oplus N_t$ . Let  $h \leq \min(s, t)$  *and let*  $\{T_1, T_2, \ldots, T_h\}$  *be a partition of* T. If, for each  $i \in [h]$ *, we have*  $T_i = E(M_i) \cap E(N_i)$ , then the bonding  $B_T(M, N)$  is the direct sum of the bondings  $B_{T_i}(M_i, N_i)$ , for  $i \in [h]$ , along with  $M_{h+1}, \ldots, M_s$  and  $N_{h+1}, \ldots, N_t$ . Also, for i with  $h < i \leq s$ ,  $E(M_i)$  *is a connected component of* M *if and only if*  $E(M_i)$  *is a connected component of*  $B_T(M, N)$ *, and likewise for*  $E(N_i)$  *with*  $h < j \le t$ *.* 

*Proof.* This follows from the construction since the matroid H that is used to construct  $B_T(M, N)$  is the direct sum of its counterparts in the construction of  $B_{T_i}(M_i, N_i)$ , for  $i \in [h]$ , with the other direct sum factors  $M_{h+1}, \ldots, M_s$  and  $N_{h+1}, \ldots, N_t$ .

<span id="page-18-1"></span>We next relate the flats of  $B_T(M, N)$  to those of H.

**Lemma 4.2.** Let F be a flat of  $B_T(M, N)$ , and set  $S_F = \{s_i : t_i \in F \cap T\}$  and  $Q_F = \{q_i\,:\,t_i \in F \cap T\}.$  Then  $F \cup Q \cup S_F$  is a flat of  $H$ , each  $q_j \in Q - Q_F$  is a coloop *of*  $H|(F \cup Q \cup S_F)$ *, and*  $B_T(M, N)|F = H|(F \cup Q_F \cup S_F)/Q_F \backslash S_F$ *.* 

*Proof.* Since F is a flat of  $B_T(M, N)$ , which is  $H\backslash S/Q$ , the set  $F \cup Q$  is a flat of  $H\backslash S$ . Its closure  $\text{cl}_H(F \cup Q)$  in H is  $F \cup Q \cup S_F$  since any two of  $t_i$ ,  $s_i$ , and  $q_i$  have the third in their closure. If  $q_j \in Q - Q_F$ , then  $q_j$  is a coloop of  $H|(F \cup Q \cup S_F)$  since  $q_j$  was added freely to the flat spanned by  $t_j$  and  $s_j$ , which are not in the flat  $F \cup Q \cup S_F$ . Thus,

$$
B_T(M,N)|F = H|(F \cup Q \cup S_F)/Q\backslash S_F = H|(F \cup Q_F \cup S_F)/Q_F\backslash S_F. \quad \Box
$$

The next lemma allows us to deduce that certain flats of  $B_T(M, N)$  are disconnected. In this lemma and throughout this section, for  $X \subseteq E(M) \cup E(N)$ , we shorten  $X \cap E(M)$ to  $X_M$ , and likewise set  $X_N = X \cap E(N)$ .

<span id="page-19-1"></span>**Lemma 4.3.** Let F be a flat of  $B_T(M, N)$ . If there are separators X of  $M|F_M$  and Y of  $N|F_N$ *, not both trivial, for which*  $X \cap T = Y \cap T$ *, then*  $X \cup Y$  *is a nontrivial separator* of  $B_T(M, N)|F$ , so  $B_T(M, N)|F$  is disconnected.

*Proof.* We have  $B_T(M, N)|F = H|(F \cup Q_F \cup S_F)/Q_F \backslash S_F$  where  $S_F$  and  $Q_F$  are as in Lemma [4.2.](#page-18-1) By symmetry, we may assume that the separator X of  $M|F_M$  is neither  $\emptyset$  nor  $F_M$ . Set  $T' = X \cap T = Y \cap T$ , and let  $S_{T'} = \{s_i : t_i \in T'\}$  and  $Q_{T'} = \{q_i : t_i \in T'\}$ . Thus,  $H|(F \cup Q_F \cup S_F)$  is the direct sum

$$
(H|(X \cup Y \cup Q_{T'} \cup S_{T'})) \oplus (H|((F - (X \cup Y)) \cup (Q_F - Q_{T'}) \cup (S_F - S_{T'}))),
$$

and neither  $X \cup Y$  nor  $F - (X \cup Y)$  is empty. Therefore  $X \cup Y$  is a nontrivial separator of  $H|(F \cup Q_F \cup S_F)/Q_F \backslash S_F$ , that is, of  $B_T(M,N)|F$ .

<span id="page-19-2"></span>We next show that bonding and restriction commute when restricting to supersets of  $T$ .

**Lemma 4.4.** *If*  $T \subseteq X \subseteq E(M) \cup E(N)$ *, then*  $B_T(M, N)|X = B_T(M|X_M, N|X_N)$ *.* 

*Proof.* Now  $B_T(M, N)|X = H/Q \setminus S|X = H|(X \cup Q \cup S)/Q \setminus S$  since deletion and contraction commute. With that, the lemma follows by showing that  $H|(X \cup Q \cup S)$  plays the role of H in the construction of  $B_T(M|X_M, N|X_N)$ . That holds since (a)  $H|(X \cup S)$ is  $(M|X_M) \oplus (N'|X_{N'})$  where  $X_{N'} = (X_N - T) \cup S$  and (b) for each  $t_i \in T$ , the point  $q_i$  is added freely to  $\text{cl}_{M\oplus N'}(\{t_i, s_i\})$  in  $M\oplus N'$  to get H, so  $q_i$  is added freely to  $\text{cl}_{H|(X\cup S)}(\{t_i,s_i\})$  in  $H|(X\cup S)$  to get  $H|(X\cup Q\cup S)$ .

<span id="page-19-3"></span>We next treat the counterpart for contraction.

**Lemma 4.5.** *If*  $T \subseteq X \subseteq E(M) \cup E(N)$ *, then*  $B_T(M, N)/X = (M/X_M) \oplus (N/X_N)$ *. Proof.* We show the special case  $B_T(M, N)/T = (M/T) \oplus (N/T)$ , from which the

general result follows. Observe that  $\mathrm{cl}_H(S \cup T) = \mathrm{cl}_H(S \cup Q) = \mathrm{cl}_H(Q \cup T)$ . Thus,

$$
B_T(M, N)/T = H/(Q \cup T) \setminus S
$$
  
=  $H/(S \cup T) \setminus Q$   
=  $H \setminus Q/(S \cup T)$   
=  $(M/T) \oplus (N'/S)$   
=  $(M/T) \oplus (N/T)$ .

We next treat a key contraction property for bonding that shows the traction we gain by using bonding. When T is independent in both M and N, as we will see,  $B_T(M, N)$  is the free amalgam of M and N, but the bonding  $B_T(M/X, N/Y)$  in the next lemma need not be an amalgam of  $M/X$  and  $N/Y$ ; indeed, we may have  $M/X|T \neq N/Y|T$ .

<span id="page-19-0"></span>**Lemma 4.6.** *If*  $X \subseteq E(M) - T$  *and*  $Y \subseteq E(N) - T$ *, then* 

 $B_T(M, N)/(X \cup Y) = B_T(M/X, N/Y).$ 

*Proof.* This holds since deletion and contraction commute:

$$
B_T(M, N)/(X \cup Y) = H/Q \setminus S/(X \cup Y)
$$
  
=  $H/(X \cup Y)/Q \setminus S$   
=  $B_T(M/X, N/Y)$ 

since, to construct  $B_T(M/X, N/Y)$ , the matroid  $H/(X \cup Y)$  plays the role of H.

The next lemma relates  $B_T(M, N)/P$  and  $B_{T-P}(M/P, N/P)$  when  $\emptyset \neq P \subsetneq T$ .

<span id="page-20-1"></span>**Lemma 4.7.** *If*  $\emptyset \neq P \subseteq T$ *, then*  $B_T(M, N)/P = B_{T-P}(M/P, N/P)$ *.* 

*Proof.* It suffices to prove that  $B_T(M,N)/t_1 = B_{T-t_1}(M/t_1,N/t_1)$  for any  $t_1 \in T$ , so we focus on that. Since deletion and contraction commute,

$$
B_T(M,N)/t_1 = H/Q \backslash S/t_1 = H/q_1 \backslash s_1/t_1/(Q-q_1) \backslash (S-s_1).
$$

Thus, it suffices to show that  $H/q_1 \gtrsim 1/t_1$  is the counterpart of H in the construction of  $B_{T-t_1}(M/t_1, N/t_1)$ , that is, it is the direct sum of  $M/t_1$  and  $N'/s_1$  (the copy of  $N/t_1$ where  $T - t_1$  is replaced by  $S - s_1$ ), to which, for i with  $2 \le i \le k$ , the element  $q_i$  is added freely to the flat  $\text{cl}_{(M/t_1)\oplus(N'/s_1)}(\{t_i, s_i\})$ . For a set  $X \subseteq E(H) - \{q_1, s_1, t_1, q_i\}$ where  $2 \le i \le k$ , the following statements are equivalent:

- $q_i \in \text{cl}_{H/q_1 \setminus s_1/t_1}(X)$ ,
- $q_i \in \text{cl}_H(X \cup \{q_1, t_1\}),$
- $t_i, s_i \in \text{cl}_H(X \cup \{q_1, t_1\}),$
- $t_i, s_i \in \text{cl}_{H/q_1 \setminus s_1/t_1}(X)$ .

Thus,  $q_i$  is added freely to the flat  $\text{cl}_{(M/t_1)\oplus(N'/s_1)}(\{t_i, s_i\})$  of  $(M/t_1)\oplus(N'/s_1)$ . Since  $r_H({q_1, t_1}) = r_H({s_1, t_1})$ , we have

$$
r(H/q_1 \setminus s_1/t_1) = r(H) - r_H(\lbrace q_1, t_1 \rbrace)
$$
  
=  $r(M) + r(N') - r_H(\lbrace s_1, t_1 \rbrace)$   
=  $r(M/t_1) + r(N'/s_1)$ .

If  $r_M(t_1) = 1 = r_N(t_1)$ , then  $q_1$  is in the span of neither  $E(M)$  nor  $E(N')$  in H, so M and N' are restrictions of  $H/q_1$ , and so, since  $t_1$  and  $s_1$  are parallel in  $H/q_1$ , both  $M/t_1$  and  $N'/s_1$  are restrictions of  $H/q_1\backslash s_1/t_1$ . If  $r_M(t_1) = 0$  and  $r_N(t_1) = 1$ , then  $q_1$  and  $s_1$  are parallel in H, so  $H/q_1 \backslash s_1 = H \backslash q_1 / s_1$ , and so, with  $t_1$  being a loop,  $N'/s_1$  is a restriction of  $H/q_1 \gtrsim_1/t_1$ , as is  $M/t_1$ . The other two options for  $r_M(t_1)$  and  $r_N(t_1)$  similarly imply that  $M/t_1$  and  $N'/s_1$  are restrictions of  $H/q_1 \gtrsim_1/t_1$ . So, to complete the proof, observe that with the rank equality above, we get  $H/q_1\backslash s_1/t_1\backslash (Q-q_1) = (M/t_1) \oplus (N'/s_1)$ . □

By the next lemma,  $B_T(M, N)$  is an amalgam of M and N if T is independent in both M and N. Figures [5](#page-17-1) (with T dependent) and [6](#page-18-0) (with T independent) illustrate the lemma.

<span id="page-20-0"></span>**Lemma 4.8.** If T is independent in M, then the restriction  $B_T(M, N)|E(N)$  is N. If T *is dependent in* M *and no element of* T *is a loop of* N, then  $B_T(M, N)|E(N)$  *is a proper quotient of* N*.*

*Proof.* Let  $T_0$  be a basis of  $M/T$ . Set  $Q_0 = \{q_i : t_i \in T_0\}$ . For all j, the sets  $\{s_j, q_j\}$  and  ${s_j, t_j}$  have the same closure in H, so the four sets

$$
E(N') \cup Q
$$
,  $E(N') \cup T$ ,  $E(N') \cup T_0$ , and  $E(N') \cup Q_0$ 

have the same closure in  $H$ . The rank of that closure is

$$
r_H(E(N') \cup Q) = r(N) + r_M(T) = r(N) + |T_0| = r(N) + |Q_0|.
$$

Thus,  $Q_0$  is independent in H and  $H/Q_0|E(N')=N'$ .

If T is independent in M, then  $T_0 = T$ , so  $Q_0 = Q$ , and so  $H/Q|E(N')$  is N'. The first assertion follows since  $t_i$  and  $s_i$  are either parallel in  $H/Q$  or, if  $t_i$  is a loop of  $N$ , then  $t_i$  and  $q_i$  are parallel in H, so  $t_i$  is a loop of  $H/Q$ .

Now assume that T is dependent in M and contains no loops of N. Since  $|T_0| < |T|$ , we have  $Q - Q_0 \neq \emptyset$ , so  $H | (E(N') \cup Q)/Q_0$  is a rank- $r(N)$  extension of N'. If  $q_j \in Q - Q_0$ , then  $s_i \notin \text{cl}_H(Q_0)$ , for otherwise there would be a circuit C so that  $s_j \in C \subseteq Q_0 \cup s_j$ , which would give  $q_i \in \text{cl}_H(E(N') \cup (Q_0 - q_i))$  for any  $q_i \in C$ , contrary to the equality

22 JOSEPH E. BONIN

<span id="page-21-0"></span>FIGURE 7. Two connected rank-3 matroids whose bonding at the circuit  $T = \{1, 2\}$  is disconnected;  $B_T(M, N)$  has six connected components, namely,  $\{a, b\}$ ,  $\{c, d\}$ ,  $\{e, f\}$ ,  $\{g, h\}$ ,  $\{1\}$ , and  $\{2\}$ .

 $r(E(N') \cup Q_0) = r(N') + |Q_0|$ ; so  $q_j \notin cl_H(Q_0)$  since  $q_j$  was added freely to the flat spanned by  $s_j$  and  $t_j$ . Thus,  $\text{cl}_H(Q_0) \cap (Q - Q_0) = \emptyset$ , so  $Q - Q_0$  has positive rank in the extension  $H|(E(N') \cup Q)/Q_0$  of  $N'$ . To get  $B_T(M,N)|E(N)$  from that extension of N', besides the relabeling relating N and N', we contract  $Q - Q_0$ , so  $B_T(M, N) | E(N)$ is a proper quotient of N.

<span id="page-21-2"></span>Thus, in general,  $B_T(M, N)$  is an amalgam of quotients of M and N.

Corollary 4.9. *Assume that the set* T *is independent in both* M *and* N*. If* F *is a flat of*  $B_T(M, N)$ , then  $F_M$  is a flat of M and  $F_N$  is a flat of N. If both M and N are connected, *then so is*  $B_T(M, N)$ *.* 

*Proof.* Lemma [4.8](#page-20-0) gives the result about flats. For distinct  $e, f \in E(M) \cup E(N)$ , if  $T \cap \{e, f\} \neq \emptyset$ , then e and f are in a circuit of either M or N; otherwise each of e and f is in a circuit of either M or N with some  $t \in T$ . Such circuits are circuits of  $B_T(M, N)$ , so e and f are in the same component of  $B_T(M, N)$ . Thus,  $B_T(M, N)$  is connected.  $\square$ 

If T is dependent in both M and N, then  $B_T(M, N)$  can be disconnected even if both M and N are connected; see Figure [7](#page-21-0) for an example. Also,  $B_T(M, N)$  may be connected even if both  $M$  and  $N$  are disconnected and  $T$  is independent in both: this occurs, for instance, when M is the direct sum of a 4-circuit on  $\{1, 2, a, b\}$  and a coloop 3, while N is the direct sum of a 4-circuit on  $\{2, 3, c, d\}$  and a coloop 1. Thus, when F is a connected flat of  $B_T(M, N)$ , without additional hypotheses (as in Lemmas [4.16](#page-22-0) and [4.20](#page-25-1) below), we cannot deduce that either  $F_M$  is connected in M or  $F_N$  is connected in N.

<span id="page-21-3"></span>The next result gives the ranks of the flats of  $B_T(M, N)$ .

**Lemma 4.10.** Assume that T is independent in M. The rank  $r(F)$  of a flat F of  $B_T(M, N)$  $is r_M(F_M) + r_N(F_N) - |F \cap T|$ *.* 

*Proof.* Lemma [4.2](#page-18-1) gives  $B_T(M, N)|F = H|(F \cup Q_F \cup S_F)/Q_F \backslash S_F$  where  $Q_F$  and  $S_F$ are defined in that lemma. Since  $\mathrm{cl}_H(F \cup Q_F) = \mathrm{cl}_H(F \cup S_F)$ , we have

$$
r(F) = r(B_T(M, N)|F) = r_H(F \cup S_F) - r_H(Q_F).
$$

By how H is constructed,  $H|(F \cup S_F)$  is the direct sum of  $M|F_M$  and the restriction of  $N'$ that is a relabeling of  $N|F_N$ . As shown in the proof of Lemma [4.8,](#page-20-0) having T independent in M implies that Q is independent in H. Thus,  $r(F) = r_M(F_M) + r_N(F_N) - |Q_F|$ . The equality in the lemma follows since  $|Q_F| = |T \cap F|$ .

<span id="page-21-1"></span>This lemma and Theorem [2.14](#page-8-1) have the following corollary.

**Corollary 4.11.** If T is independent in both M and N, then  $B_T(M, N)$  is the free amalgam *of* M *and* N*.*

The terminology of free amalgams is well established in the literature, so we will use that name when T is independent in both M and N, but, noting Lemma [4.6](#page-19-0) and the remarks before it, we cannot work solely with free amalgams; we sometimes need the more general setting of bonding.

The next result follows from Corollary [4.11](#page-21-1) when  $r_M(p) = 1 = r_N(p)$ . The other cases are easy to verify directly from the definitions of  $B_p(M, N)$  and  $P(M, N)$ .

<span id="page-22-3"></span>**Corollary 4.12.** *If*  $E(M) \cap E(N) = \{p\}$ , then  $B_p(M, N)$  is the parallel connection P(M, N) *of* M *and* N *at the base point* p*.*

We are most interested in connected flats. The next corollary narrows the collection of flats that we must consider.

<span id="page-22-2"></span>Corollary 4.13. *Assume that* T *is independent in both* M *and* N*. If* F *is a flat of*  $B_T(M, N)$  *with*  $F \cap T = \emptyset$  *and neither*  $F_M$  *nor*  $F_N$  *is empty, then*  $F$  *is disconnected.* 

The bonding  $B_T(M, N)$  has additional useful properties when T is a set of clones in both M and N. We first show that clones in both M and N are clones in  $B_T(M, N)$ .

**Lemma 4.14.** If  $t_i, t_j \in T$  are clones in both M and N, then they are clones in  $B_T(M, N)$ . *Thus, if* T *is a set of clones in both* M *and* N, *then* T *is a set of clones in*  $B_T(M, N)$ *.* 

*Proof.* By symmetry, it suffices to show that if F is a cyclic flat of  $B_T(M, N)$  and  $t_i \in F$ , then  $t_i \in F$ . Set  $S_F = \{s_h : t_h \in F \cap T\}$ . By Lemma [4.2,](#page-18-1) the set  $F \cup Q \cup S_F$  is a flat of H. At least one of  $t_i$  and  $s_i$  is not a coloop of  $H|(F \cup S_F)$ , for otherwise  $t_i$  would be a coloop of both  $M|F_M$  and  $N|F_N$ , so  $t_i$  would be a coloop of  $B_T(M,N)|F$  by Lemma [4.3,](#page-19-1) contrary to the flat F being cyclic. If  $t_i$  is not a coloop of  $H|(F \cup S_F)$ , then its clone  $t_j$  in M must be in the flat  $F \cup Q \cup S_F$ , so  $t_j \in F$ ; otherwise  $s_i$  is not a coloop of  $H | (F \cup S_F)$ , so its clone  $s_j$  must be in the flat  $F \cup Q \cup S_F$ , and so  $t_j \in F$ .

Since two elements are clones in  $M$  if and only if they are in the same nonsingleton connected flats of M, we get the next result.

<span id="page-22-1"></span>Lemma 4.15. *If* T *is a set of clones in both* M *and* N*, and if* F *is a connected flat of*  $B_T(M, N)$  *with*  $|F| \geq 2$ *, then either*  $T \subseteq F$  *or*  $F \cap T = \emptyset$ *.* 

We have seen that, when T is independent in M and N, if F is a connected flat of  $B_T(M, N)$  and  $F \cap T = \emptyset$ , then F is a connected flat of one of M or N. The next lemma treats the case of  $T \subsetneq F$ , assuming that T is a set of clones. One can give a shorter proof of this lemma in the case of a connected flat by applying Lemma [4.3](#page-19-1) (and that would suffice for our applications of the next lemma), but the next lemma treats connected sets, not just connected flats. Note also that the lemma does not assume that  $T$  is independent in  $M$  and N, so M and N might not be restrictions of  $B_T(M, N)$ .

<span id="page-22-0"></span>Lemma 4.16. *Assume that* T *is a set of clones in* M *and in* N*. Let* X *be a connected set in*  $B_T(M,N)$  *with*  $T \subsetneq X$ *. If*  $X_M \neq T$ *, then*  $M|X_M$  *is connected, and likewise for*  $N|X_N$ *if*  $X_N \neq T$ *.* 

*Proof.* By symmetry, it suffices to prove the result for  $M|X_M$  when  $X_M \neq T$ . Lemma [4.4](#page-19-2) gives  $B_T(M,N)|X = B_T(M|X_M, N|X_N)$ . Since T is a set of clones in M, either (i)  $|T| \geq 2$  and T contains only loops or only coloops of  $M|X_M$ , or (ii)  $T \subseteq K$  for some connected component K of  $M|X_M$ . Since  $T \neq X_M$ , if option (i) held, then  $M|X_M$ would have more than  $|T|$  connected components, so Lemmas [4.4](#page-19-2) and [4.1](#page-18-2) would give the contradiction that  $B_T(M,N)|X$ , which is connected, is a direct sum of at least two matroids. So option (ii) holds. By Lemmas [4.4](#page-19-2) and [4.1,](#page-18-2) if  $M|X_M$  had any connected components besides K, then  $B_T(M, N) \mid X$  would be a direct sum of at least two matroids, but  $B_T(M, N)|X$  is connected. Thus,  $M|X_M$  is connected.

<span id="page-23-0"></span>We turn to the applications to positroids.

**Theorem 4.17.** Let M and N be positroids with no loops, and let  $E(M) \cap E(N)$  be T. If T *is nonempty,* T *is independent in both* M *and* N*, and* T *is a set of clones in both* M *and* N, then the free amalgam  $B_T(M, N)$  is a positroid.

*Proof.* Let  $T = \{t_1, t_2, \ldots, t_k\}$ . Observe that if the elements of T are coloops of M, then  $B_T(M, N) = (M\ Y) \oplus N$ , in which case the result follows since the class of positroids is closed under deletion and direct sum. Thus, by symmetry and the assumption that  $T$ is a set of clones of both M and N, we may assume that no element of T is a coloop of either M or N. By Lemma [2.13](#page-7-1) and Corollary [3.11,](#page-15-0) some positroid order for M and some positroid order for N have the same restriction to T and have T being an interval. Let

$$
e_1 <_M e_2 <_M \cdots <_M e_m <_M t_1 <_M t_2 <_M \cdots <_M t_k
$$

and

$$
t_1 <_N t_2 <_N \cdots <_N t_k <_N f_1 <_N f_2 <_N \cdots <_N f_n
$$

be such positroid orders for  $M$  and  $N$ , respectively. We claim that the linear order

 $e_1 < e_2 < \cdots < e_m < t_1 < t_2 < \cdots < t_k < f_1 < f_2 < \cdots < f_n$ 

of  $E(B_T(M, N))$  satisfies the cyclic interval property, so  $B_T(M, N)$  is a positroid. Note that each of  $\leq_M$  and  $\leq_N$  is a restriction of  $\leq$  to an interval. The following observations about cyclic intervals in these orders are used below.

- (I<sub>1</sub>) Assume that  $F \subseteq E(M)$  and  $F \cap T = \emptyset$ , and that I is a cyclic interval in  $\leq_M$  with  $I \cap F = \emptyset$ . If  $I \cap T = \emptyset$ , then I is also a cyclic interval in  $\leq$ ; if  $I \cap T \neq \emptyset$ , then  $I \cup E(N)$  is a cyclic interval in  $\leq$  and it is disjoint from F. The same statement holds with the roles of  $M$  and  $N$  reversed.
- (I<sub>2</sub>) If  $T \subseteq F \subseteq E(M) \cup E(N)$ , then any cyclic interval in  $\leq_M$  that is disjoint from F is a cyclic interval in  $\leq$ , as is any cyclic interval in  $\leq_N$  that is disjoint from F.

Let F be a connected flat of  $B_T(M, N)$  with  $|F| \geq 2$ . By the hypotheses about clones and Lemma [4.15,](#page-22-1) either  $F \cap T = \emptyset$  or  $T \subseteq F$ ; we address each case below.

First assume that  $F \cap T = \emptyset$ . By Corollaries [4.9](#page-21-2) and [4.13,](#page-22-2) the set F is a connected flat of either M or N, say of M. No element of T is a coloop of M, so no element of T is a coloop of  $M/F$  by Lemma [2.9,](#page-5-0) and so all elements of T, which are clones in  $M/F$ , are in the same connected component, say X, of  $M/F$ . Lemma [4.6](#page-19-0) gives  $B_T(M, N)/F = B_T(M/F, N)$ . (Unless T is independent in  $M/F$ , there is no amalgam of  $M/F$  and N, but their bonding is defined. While  $M/F$  is a restriction of  $B_T(M/F, N)$ , only when T is independent in  $M/F$  will N be a restriction of  $B_T(M/F, N)$ . Let K be a connected component of  $B_T(M,N)/F$  with  $|K| \geq 2$ . Since T is a set of clones of  $B_T(M,N)$  and so of  $B_T(M, N)/F$ , either  $T \subseteq K$  or  $T \cap K = \emptyset$ . Now either

(a)  $K \subseteq E(N)$ ,

or, by applying Lemma [4.1](#page-18-2) to  $B_T(M/F, N)$ , one of the following statements holds:

- (b) K is a connected component of  $M/F$  for which  $K \cap T = \emptyset$ , or
- (c) K is a connected component of the bonding  $B_T(M/F|X, N|Y)$  for some set Y with  $T \subseteq Y \subseteq E(N)$ .

The cyclic interval property holds in case (a) since  $E(N)$  is a cyclic interval in  $\leq$ . In case (b), there is a cyclic interval I in  $\leq_M$  that contains K and has  $I \cap F = \emptyset$ , so observation  $(I_1)$ above shows that the cyclic interval property holds. In case  $(c)$ , for any cyclic interval  $I$  in  $\leq_M$  that contains X and has  $I \cap F = \emptyset$ , by observation  $(I_1)$ , the cyclic interval  $I \cup E(N)$  $in \le$  shows that the cyclic interval property holds.

Now assume that  $T \subsetneq F$ . By Lemma [4.5,](#page-19-3) we have  $B_T(M, N)/T = (M/T) \oplus (N/T)$ . If  $F \subseteq E(M)$ , then F is a connected flat of M and  $B_T(M, N)/F = (M/F) \oplus (N/T)$ , so each connected component K of  $B_T(M, N)/F$  is a connected component of either  $M/F$ or  $N/T$ ; thus, K is contained either in a cyclic interval in  $\leq_M$  that is disjoint from F, or in the interval  $E(N) - T$ ; such cyclic intervals are cyclic intervals in  $\leq$ , so the cyclic interval property holds. The same idea applies if  $F \subseteq E(N)$ . Now assume that  $F \nsubseteq E(M)$ and  $F \nsubseteq E(N)$ . By Corollary [4.9](#page-21-2) and Lemma [4.16,](#page-22-0) the sets  $F_M$  and  $F_N$  are connected flats of M and N, respectively. Also,  $B_T(M, N)/F = (M/F_M) \oplus (N/F_N)$ . Thus, each connected component of  $B_T(M, N)/F$  is a connected component of one of  $M/F_M$  and  $N/F_N$ , and the cyclic interval property holds since it holds in M and N.

With the assumptions above, while  $B_T(M, N)$  is a positroid, the matroid H that we use to construct  $B_T(M, N)$  need not be a positroid. For instance, H is not a positroid when M and N are both the uniform matroid  $U_{3,4}$  and  $|T| = 3$ .

Corollary [4.12](#page-22-3) and Theorem [4.17](#page-23-0) give one case of the next result on parallel connection; the other case, when p is a loop of one or both of M and N, holds since contractions and direct sums of positroids are positroids. Recall that duals of positroids are positroids, and series connections are dual to parallel connections:  $S(M, N) = (P(M^*, N^*))^*$ . Blum [\[3,](#page-34-0) Corollary 4.2] treated the special cases of parallel and series extension.

<span id="page-24-0"></span>**Corollary 4.18.** *If* M and N are positroids and  $|E(M) \cap E(N)| = 1$ , then the parallel *connection*  $P(M, N)$  *and the series connection*  $S(M, N)$  *are positroids.* 

A *series-parallel network* is a graph that can be obtained from a graph with a single edge (perhaps a loop) by repeatedly applying parallel extension and series extension. Duffin [\[14\]](#page-35-15) proved that a 2-connected graph is a series-parallel network if and only if it has no  $K_4$ minor. Binary matroids with no  $M(K_4)$  minor are graphic since the excluded minors for graphic matroids, other than the excluded minor for binary matroids, have  $M(K_4)$  as a minor. (See Tutte [\[26\]](#page-35-16) for the excluded minors.) So a matroid is the cycle matroid of a series-parallel network if and only if it is connected, binary, and has no  $M(K_4)$ -minor. The next corollary, which is also [\[3,](#page-34-0) Theorem 5.1], follows since the class of positroids is closed under parallel extension and series extension, and  $M(K_4)$  is not a positroid.

Corollary 4.19. *A binary matroid is a positroid if and only if the restriction to each of its connected components is the cycle matroid of a series-parallel network.*

In particular, cycle matroids of series-parallel networks are positroids.

In the proof of Theorem [4.17,](#page-23-0) to get a linear order  $\lt$  that extends both  $\lt_M$  and  $\lt_N$ , we can start with  $E(M) - T$  as an interval followed by  $E(N) - T$ , and then put T either between them (as we did) or after  $E(N) - T$ . Having two options suggests that a similar argument may work if  $T$  is the union of two sets of clones; we may be able to put one set of clones between  $E(M)-T$  and  $E(N)-T$ , and the other after  $E(N)-T$ . Theorem [4.21](#page-25-0) below, which we illustrate in Figure [8,](#page-25-2) treats that. The conditions on  $T$  in Theorem [4.21](#page-25-0) are stronger than those in Theorem [4.17](#page-23-0) in that  $M|\text{cl}_M(T)$  and  $N|\text{cl}_N(T)$  are required to be connected, but weaker in that, instead of requiring  $T$  to be a set of clones,  $T$  is partitioned into two sets of clones, P and  $T - P$ , where all nonsingleton connected flats of either M or N that contain at least one element of  $T - P$  contain all of T.

<span id="page-25-2"></span>FIGURE 8. The free amalgam  $B_T(M, N)$  of the rank-3 positroids M and N, where  $T = \{5, 10\}$ . The free amalgam is a positroid, but 5 and 10 are not clones. The set P in the hypothesis of Theorem [4.21](#page-25-0) is  $\{5\}$ .

Many positroids satisfy the hypotheses of Theorem [4.21.](#page-25-0) For instance, start with an n-spoke wheel, delete at most  $n - 2$  spokes (see Figure [9\)](#page-26-0), take the cycle matroid, and relax the circuit-hyperplane of rim edges. Fix two consecutive spokes that remain, let P contain one of those spokes, and let  $T - P$  be the set of rim edges between those spokes (e.g.,  $T$  can be the set of the thick edges in Figure [9\)](#page-26-0). The set  $T$  is independent, its closure is connected (it is the circuit consisting of the two consecutive spokes and the rim edges between them), and all nonsingleton connected flats that contain one of those rim edges contain that circuit (relaxing the circuit-hyperplane is crucial for that property). To get examples for which both |P| and  $|T - P|$  are arbitrarily large, start with the matroids just constructed and apply the operation of t-expansion, from [\[9\]](#page-35-17), which, given a matroid  $M$ , produces a matroid  $M<sup>t</sup>$  with similar geometric structure, but of larger rank and size. To get  $M^t$ , where  $t \in \mathbb{N}$  and  $t \geq 2$ , first extend M to M' by, for each  $e \in E(M)$ , adding  $t - 1$ elements parallel to e if  $r(e) = 1$ , or as loops if  $r(e) = 0$ ; then  $M<sup>t</sup>$  is the matroid union of t copies of  $M'$ . By [\[9,](#page-35-17) Theorem 3.15] (another corollary of Theorem [3.2\)](#page-10-0), a matroid M is a positroid if and only if its *t*-expansion  $M<sup>t</sup>$  is a positroid.

<span id="page-25-1"></span>We will need the following variation on Lemma [4.16.](#page-22-0)

**Lemma 4.20.** Assume that T is independent in both M and N, that  $\emptyset \neq P \subsetneq T$ , and *that* P is a set of clones in both M and N. Let F be a connected flat of  $B_T(M, N)$  with  $F \cap T = P$ *.* If  $F \subseteq E(M)$ *, then the flat* F *of* M *is connected, and likewise if*  $F \subseteq E(N)$ *. If*  $F \nsubseteq E(M)$  and  $F \nsubseteq E(N)$ , then the flat  $F_M$  of M is connected, as is the flat  $F_N$  of N.

*Proof.* The first assertions are immediate since M and N are restrictions of  $B_T(M, N)$ by Lemma [4.8.](#page-20-0) Now assume that  $F \nsubseteq E(M)$  and  $F \nsubseteq E(N)$ , and, contrary to what we must show, that  $M|F_M$  is disconnected. The elements of P, which are clones in M, either are all coloops of  $M|F_M$  or are all in the same connected component of  $M|F_M$ . Now  $F \nsubseteq E(N)$ , so in either case we have  $M|F_M = (M|X) \oplus (M|(F_M - X))$  for some set X where  $P \subseteq X \subseteq F_M$ . Lemma [4.3](#page-19-1) gives the contradiction that  $B_T(M, N)|F$  is disconnected (as Y in that lemma, use  $F_N$ ). Thus,  $M|F_M$  is connected. By symmetry,  $N|F_N$  is connected.

<span id="page-25-0"></span>**Theorem 4.21.** Let M and N be positroids with no loops and let  $E(M) \cap E(N)$  be T. *Assume that*

<span id="page-26-0"></span>FIGURE 9. A wheel with some spokes deleted. The thick edges are the rim edges between two consecutive spokes along with one of those spokes.

- (1) T *is independent in both* M *and* N*,*
- (2)  $M | cl_M(T)$  *and*  $N | cl_N(T)$  *are connected, and*
- (3) *there is a nonempty proper subset* P *of* T *for which* (3a) P *is a set of clones in both* M *and* N*, and*
	- (3b) *if* F is a nonsingleton connected flat of either M or N with  $F \cap (T P) \neq \emptyset$ , *then*  $T \subset F$ .

*If some positroid order for* M *has some element in* P *and some element in*  $T - P$  *cyclically consecutive, and some positroid order for* N *has some element in* P *and some element in*  $T - P$  *cyclically consecutive, then the free amalgam*  $B_T(M, N)$  *is a positroid.* 

*Proof.* Let  $P = \{p_1, p_2, \ldots, p_h\}$  and  $T - P = \{t_1, t_2, \ldots, t_k\}$ . Assumption (3b) implies that  $T - P$  is a set of clones in both M and N. By that observation, assumption (3a), Lemma [2.13,](#page-7-1) and the hypothesis in the last sentence of the theorem,  $p_h$  and  $t_1$  are cyclically consecutive in some positroid order for M, as are  $t_k$  and  $p_1$  in some positroid order for N. With P and  $T - P$  being sets of clones in both M and N, Lemma [2.13,](#page-7-1) Corollary [3.11,](#page-15-0) and the observation that the order dual of a positroid order is a positroid order, we can assume that the following linear orders are positroid orders for  $M$  and  $N$ , respectively:

 $e_1 <_M e_2 <_M \cdots <_M e_m <_M p_1 <_M p_2 <_M \cdots <_M p_h <_M t_1 <_M t_2 <_M \cdots <_M t_k$ and

 $t_1 <_N t_2 <_N \cdots <_N t_k <_N p_1 <_N p_2 <_N \cdots <_N p_h <_N f_1 <_N f_2 <_N \cdots <_N f_n$ .

The linear order

 $e_1 < e_2 < \cdots < e_m < p_1 < p_2 < \cdots < p_h < f_1 < f_2 < \cdots < f_n < t_1 < t_2 < \cdots < t_k$ has both  $\leq_M$  and a shift of  $\leq_N$  as the induced orders on  $E(M)$  and  $E(N)$ , respectively. We claim that the linear order  $\leq$  on  $E(B_T(M, N))$  satisfies the cyclic interval property, so  $B_T(M, N)$  is a positroid. Note that observations  $(I_1)$  and  $(I_2)$  from the proof of Theorem [4.17](#page-23-0) apply to the linear order  $\lt$  just defined on  $E(B_T(M, N))$ .

Let F be a connected flat of  $B_T(M, N)$  with  $|F| \geq 2$ . If F contained some but not all elements of  $T - P$ , then, by assumption (3b), each  $t_i \in F \cap (T - P)$  would be a coloop of  $M|F_M$  and of  $N|F_N$ , so setting  $X = Y = \{t_i\}$  in Lemma [4.3](#page-19-1) would give the contradiction that  $B_T(M, N)|F$  is disconnected. Thus, by the hypotheses, there are three options:  $F \cap T = \emptyset$ ,  $T \subsetneq F$ , or  $F \cap T = P$ .

The cyclic interval property holds when  $T \subsetneq F$  by the same argument as in the proof of Theorem [4.17](#page-23-0) once we make the following observations. Since  $F$  contains the connected flats  $\text{cl}_M(T)$  of M and  $\text{cl}_N(T)$  of N, there are connected components X of  $M|F_M$  and Y of  $N|F_N$  that contain T. Since  $B_T(M,N)|F$ , which is  $B_T(F_M, F_N)$ , is connected, Lemma [4.1](#page-18-2) implies that  $F_M = X$  and  $F_N = Y$ , so  $F_M$  is a connected flat of M, as is  $F_N$ in N. We turn to the other two cases.

Assume that  $F \cap T = \emptyset$ . As before, F is a connected flat of either M or N, say of M. Thus,  $B_T(M, N)/F = B_T(M/F, N)$ . It follows from Lemma [2.8](#page-5-1) that assumption (3b) also holds for  $M/F$ . Also, since  $\text{cl}_M(T)$  is connected, no element of T is a coloop of  $M$ , so no element of  $T$  is a coloop of  $M/F$ . Thus, all elements of  $T$  are in the same connected component, say  $X$ , of  $M/F$ . It follows that any connected component  $K$  of  $B_T(M, N)/F$  with  $|K| \geq 2$  falls under one of cases (a)–(c) in the proof of Theorem [4.17.](#page-23-0) The cyclic interval property holds in each case by the argument given in that proof.

Now assume that  $F \cap T = P$ . We first treat the case with  $F \nsubseteq E(M)$  and  $F \nsubseteq E(N)$ , in which case, by Lemma [4.20,](#page-25-1) the restrictions  $M|F_M$  and  $N|F_N$  are connected. By applying Lemma [4.7](#page-20-1) and then Lemma [4.6,](#page-19-0) we have

$$
B_T(M, N)/F = (B_{T-P}(M/P, N/P))/(F - T)
$$
  
=  $B_{T-P}(M/F_M, N/F_N)$ .

Since no element of T is a coloop of M, no element of  $T - P$  is a coloop of  $M/F_M$ . Also,  $T - P$  is a set of clones of M and so of  $M/F_M$ . Therefore, some connected component X of  $M/F_M$  has  $T - P \subseteq X$ . Similarly, some connected component Y of  $N/F_N$  has  $T - P \subseteq Y$ . Thus, any connected component of  $B_{T-P}(M, N)/F$  is either

- (a) a connected component of  $M/F_M$  or of  $N/F_N$  that is disjoint from  $T P$ , or
- (b) a connected component of the bonding  $B_{T-P}(M/F_M|X, N/F_N|Y)$ .

For case (a), say K is a connected component of  $M/F_M$ ; then any cyclic interval in  $\leq_M$ that contains K and is disjoint from  $F_M$  is a cyclic interval in  $\leq$ , so the cyclic interval property holds. For a connected component  $K$  that falls under case (b), note that the union of a cyclic interval I in  $\leq_M$  for which  $I \cap T = T - P$  and a cyclic interval J in  $\leq_N$  for which  $J \cap T = T - P$  is a cyclic interval in  $\leq$ . Choosing such I and J for which  $X \subseteq I$ ,  $Y \subseteq J$ , and  $F \cap (I \cup J) = \emptyset$  shows that the cyclic interval property holds in case (b).

Finally, to complete the case with  $F \cap T = P$ , we can assume, by symmetry, that  $F \subseteq E(M)$ , so F is a connected flat of M. Now  $B_T(M,N)/P = B_{T-P}(M/P,N/P)$ by Lemma [4.7,](#page-20-1) so

$$
B_T(M, N)/F = B_{T-P}(M/F, N/P).
$$

As above, all elements of  $T - P$  are in the same connected component of  $M/F$ , say X. Thus, any connected component K of  $B_T(M, N)/F$  falls under one of three cases:

- (a)  $K \subseteq E(N) P$ ,
- (b) K is a connected component of  $M/F$  with  $K \cap (T P) = \emptyset$ , or
- (c) K is a connected component of  $B_{T-P}(M/F|X, N/P|Y)$  for some set Y for which  $T - P \subseteq Y \subseteq E(N) - P$ .

The cyclic interval property holds in case (a) since  $E(N) - P$  is a cyclic interval in  $\leq$ . The argument in case (b) is exactly as for case (a) in the previous paragraph. In case (c),  $X$  is a subset of a cyclic interval I in  $\leq_M$  with  $I \cap F = \emptyset$  and so  $I \cap T = T - P$ . Therefore  $I \cup (E(N) - P)$  is a cyclic interval in  $\leq$ , and it shows that the cyclic interval property holds in this case, thereby completing the proof of the theorem.

4.2. Further properties of bonding. It may be possible to prove other results in the spirit of Theorems [4.17](#page-23-0) and [4.21.](#page-25-0) In this section, we treat some results about bonding that may be useful for the further development of this operation and its applications.

The connected components of bondings play crucial roles above. Even if  $M$  and  $N$  are connected,  $B_T(M, N)$  might be disconnected; see Figure [7.](#page-21-0) The next lemma relates the connected components of M and N to those of  $B_T(M, N)$  under certain hypotheses.

**Lemma 4.22.** *Let* K *be a connected component of* M. If  $T \subseteq K$  and T *is independent in* N, then K is contained in a connected component of  $B_T(M, N)$ , say X, and  $X_M = K$ .

*Proof.* We have  $B_T(M, N)|E(M) = M$  by Lemma [4.8](#page-20-0) since T is independent in N. Thus, any two elements of K are contained in a circuit of  $B_T(M, N)$ , and so are in the same connected component, say X, of  $B_T(M, N)$ . Lemma [4.1](#page-18-2) gives  $X_M = K$ .

The next lemma treats a partial converse of the first assertion in Corollary [4.9.](#page-21-2) Recall that  $(X, Y)$  is a *modular pair* in a matroid M if  $r(X) + r(Y) = r(X \cup Y) + r(X \cap Y)$ . When Y is independent, this equality can be rewritten as  $r(X \cup Y) = r(X) + |Y - X|$ .

<span id="page-28-0"></span>**Lemma 4.23.** *Assume that*  $T$  *is independent in both*  $M$  *and*  $N$ *. Fix*  $F \subseteq E(M) \cup E(N)$ *where*  $F_M$  *is a flat of* M *and*  $F_N$  *is a flat of* N. If  $(F_M, T)$  *is a modular pair in* M *and*  $(F_N, T)$  *is a modular pair in* N, then F *is a flat of*  $B_T(M, N)$ *. In particular, if*  $|T - F| \leq 1$ *, then F is a flat of*  $B_T(M, N)$ *.* 

*Proof.* Recall that  $q_i$ , for each  $i \in [k]$ , is added freely to the line  $\text{cl}_{M \oplus N'}(\lbrace t_i, s_i \rbrace)$  of  $M \oplus N'$  to form H. We may assume that  $F \cap T$  is  $T_h = \{t_1, t_2, \ldots, t_h\}$ , where  $h = 0$ and  $T_0 = \emptyset$  if  $F \cap T = \emptyset$ . Set  $S_h = \{s_1, s_2, \dots, s_h\}$  and  $Q_h = \{q_1, q_2, \dots, q_h\}$ , which are empty if  $h = 0$ . Thus,  $F \cup S_h \cup Q_h$  is a flat of H. Let  $F_{N'} = (F \cap E(N')) \cup S_h$ . By the two assumed modular pairs,

$$
r_H(F \cup T \cup S) = r_M(F_M \cup T) + r_{N'}(F_{N'} \cup S)
$$
  
=  $r_M(F_M) + |T - T_h| + r_{N'}(F_{N'}) + |S - S_h|$   
=  $r_H(F \cup S_h) + 2(k - h).$ 

We claim that  $F \cup S_h \cup Q$  is a flat of H. Assume instead that  $F \cup S_h \cup Q$  is not a flat of H, so for some  $e \notin F \cup S_h \cup Q$ , there is a circuit C with  $e \in C \subseteq F \cup S_h \cup Q \cup e$ . Let  $I = \{i : q_i \in C \cap (Q - Q_h)\}\$ and  $J = [k] - ([h] \cup I)$ . Now  $I \neq \emptyset$  since  $F \cup S_h \cup Q_h$  is a flat of H. If  $i \in I$ , then  $\{t_i, s_i\} \subseteq \mathrm{cl}_H(C)$ , so

$$
\mathrm{cl}_H(F \cup S_h \cup C \cup \{t_j, s_j : j \in J\}) = \mathrm{cl}_H(F \cup T \cup S).
$$

The union of  $\{q_i : i \in I\} \cup \{t_j, s_j : j \in J\}$  and a basis of  $F \cup S_h$  spans  $F \cup T \cup S$ , so  $r_H(F \cup T \cup S) \le r_H(F \cup S_h) + |I| + 2|J|$ . However,  $|I| + 2|J| < 2(k - h)$ , contrary to what we just showed. Thus,  $F \cup S_h \cup Q$  is a flat of H, and so F is a flat of  $B_T(M, N)$ .

The set  $F = \{4, 6, 9, 11\}$  $F = \{4, 6, 9, 11\}$  $F = \{4, 6, 9, 11\}$  in the example in Figure 6 shows that the hypothesis about modular pairs in Lemma [4.23](#page-28-0) is needed. In the proofs of the corollaries below, we will use two observations: (1) if  $(X, Y)$  is a modular pair in M, then so is  $(cl_M(X), Y)$ , and (2) if, in addition, Y is independent, then  $X \cap Y = cl_M(X) \cap Y$ .

<span id="page-28-1"></span>**Corollary 4.24.** *Assume that*  $T$  *is independent in both*  $M$  *and*  $N$ *, and*  $X \subseteq E(M) \cup E(N)$ *.* If  $(X_M, T)$  *is a modular pair in* M *and*  $(X_N, T)$  *is a modular pair in* N, *then the closure*  $\operatorname{cl}_B(X)$  *of* X in  $B_T(M, N)$  is  $\operatorname{cl}_M(X_M) \cup \operatorname{cl}_N(X_N)$ .

*Proof.* We shorten  $B_T(M, N)$  to B. Now  $\text{cl}_M(X_M) \subseteq \text{cl}_B(X)$  since  $B|E(M)$  is M. Likewise,  $\text{cl}_N(X_N) \subseteq \text{cl}_B(X)$ . Thus,  $\text{cl}_M(X_M) \cup \text{cl}_N(X_N) \subseteq \text{cl}_B(X)$ . Since  $(X_M, T)$ is a modular pair in M, so is  $(cl_M(X_M), T)$ , and  $cl_M(X_M) \cap T = X \cap T$ . Likewise,  $(cl_N(X_N), T)$  is a modular pair in N and  $cl_N(X_N) \cap T = X \cap T$ . Thus, by Lemma [4.23,](#page-28-0)

<span id="page-29-1"></span>FIGURE 10. The rank-4 truncation of the positroid in Example [1](#page-12-1) and two of its contractions.

the union  $\text{cl}_M(X_M) \cup \text{cl}_N(X_N)$  is a flat of B. Since this flat of B contains X, we have  $\text{cl}_B(X) \subseteq \text{cl}_M(X_M) \cup \text{cl}_N(X_N)$ . With the inclusion proven above, equality follows.  $\square$ 

**Corollary 4.25.** Assume that T is independent in both M and N, and  $X \subseteq E(M) \cup E(N)$ . *If*  $(X_M, T)$  *is a modular pair in* M *and*  $(X_N, T)$  *is a modular pair in* N, then the rank  $r_B(X)$  *of* X in  $B_T(M, N)$  *is*  $r_M(X_M) + r_N(X_N) - |X \cap T|$ *.* 

*Proof.* We again shorten  $B_T(M, N)$  to B. Corollary [4.24,](#page-28-1) Lemma [4.10,](#page-21-3) and the equality  $\left(\mathrm{cl}_{M}(X_{M})\cup\mathrm{cl}_{N}(X_{N})\right)\cap T=X\cap T$  give

$$
r_B(X) = r_B(\text{cl}_B(X))
$$
  
=  $r_B(\text{cl}_M(X_M) \cup \text{cl}_N(X_N))$   
=  $r_M(\text{cl}_M(X_M)) + r_N(\text{cl}_N(X_N)) - |X \cap T|$   
=  $r_M(X_M) + r_N(X_N) - |X \cap T|$ .

## 5. SOME EXCLUDED MINORS FOR THE CLASS OF POSITROIDS

<span id="page-29-0"></span>As [\[3,](#page-34-0) [2\]](#page-34-1) show, the class of positroids is minor-closed, that is, every minor of a positroid is a positroid. Thus, the class of positroids is characterized by its excluded minors, which are the matroids that are not positroids, but all of their proper minors are positroids. Blum [\[3,](#page-34-0) Corollary 4.12] found the excluded minors for the class of positroids of rank at most three. In this section, we use Theorem [3.2](#page-10-0) and its corollaries to identify infinitely many excluded minors for the class of positroids, focusing on excluded minors of rank greater than three. We do not identify all excluded minors for the class of positroids; indeed, more are given in Park [\[22\]](#page-35-2). We start with the truncation to rank 4 of the positroid in Example [1.](#page-12-1) (The truncation to rank 3 is treated in [\[3\]](#page-34-0).)

**Example 2.** Let M be the rank-4 truncation of the positroid in Example [1,](#page-12-1) labeled as in Figure [10.](#page-29-1) Let  $A = \{a, s, t\}$ ,  $B = \{b, p, q\}$ ,  $C = \{c, u, v\}$ , and  $X = \{a, b, c\}$ . The proper connected flats F of M with  $|F| \geq 2$  are those four sets along with  $A \cup X$ ,  $B \cup X$ , and  $C \cup X$ . For each such F, the contraction  $M/F$  is connected, so by Corollary [3.4,](#page-12-0) if M were a positroid, then there would be a linear order on  $E(M)$  in which each of those flats is a cyclic interval. By Lemma  $2.1$ , there is no such linear order, so  $M$  is not a positroid.

The automorphism group of M is transitive on  $\{s, t, p, q, u, v\}$  and on  $\{a, b, c\}$ , so in order to show that all proper minors of M are positroids, it suffices to show that  $M\setminus u$ ,  $M/u$ ,  $M \backslash c$ , and  $M/c$  are positroids. We show that Corollary [3.6](#page-13-2) applies to these minors.

<span id="page-30-0"></span>FIGURE 11. Two rank-3 positroids  $M$  and  $N$ , and their free amalgam  $B_T(M, N)$ , which is a rank-4 excluded minor for the class of positroids.

- The proper connected flats F of  $M\setminus u$  with  $|F| \geq 2$  are A, B, X, A  $\cup X$ , and B  $\cup X$ , which are intervals in the linear order  $s < t < a < c < b < p < q < v$ .
- The proper connected flats F of  $M\backslash c$  with  $|F| \geq 2$  are A, B, and  $(C \cup X) c$ , which are intervals in the linear order  $s < t < a < u < v < b < p < q$ .
- The proper connected flats F of  $M/u$  with  $|F| \ge 2$  are A, B,  $C u$ , and  $X \cup v$ , which are intervals in the linear order  $s < t < a < c < v < b < p < q$ .
- The proper connected flats F of  $M/c$  with  $|F| \geq 2$  are  $A \cup b$ ,  $B \cup a$ ,  $C c$ , and  $X c$ , which are intervals in the linear order  $s < t < a < b < p < q < u < v$ .

Thus,  $M$  is an excluded minor for the class of positroids.

$$
\mathsf{C}^{\mathsf{L}}
$$

Part of the interest in the next example is to show that the free amalgam of positroids, when the hypotheses of neither Theorem [4.17](#page-23-0) nor Theorem [4.21](#page-25-0) hold, need not yield a positroid; indeed, it may produce an excluded minor for the class of positroids.

**Example 3.** Consider the free amalgam  $B = B_T(M, N)$  of the matroids M and N shown in Figure [11.](#page-30-0) There is no positroid order for  $B$  since, if there were, then by Corollary [3.4,](#page-12-0) the sets  $\{a, b, c\}$ ,  $\{c, d, e\}$ ,  $\{e, g, h\}$ , and  $\{h, i, a\}$  would have to be cyclic intervals in this linear order, but that is impossible since  $f$  would have to be in one of those cyclic intervals. Thus, while  $M$  and  $N$  are positroids, their free amalgam is not. To show that  $B$ is an excluded minor for the class of positroids, by the symmetry of  $B$ , it suffices to show that  $B\$ x and  $B/x$  are positroids for each  $x \in \{a, b, c, f\}$ .

Each contraction  $B/x$  with  $x \in \{a, b, c, f\}$  is a parallel extension of a matroid that either has at most two proper nonempty cyclic flats or satisfies the hypothesis of Corollary [3.12,](#page-16-0) so  $B/x$  is a positroid by Corollary [4.18.](#page-24-0) The deletion  $B \backslash f$  is the whirl  $\mathcal{W}^4$ , which is a multi-path matroid, and  $B\backslash b$  is a parallel connection of  $\mathcal{W}^3$  and  $U_{2,3}$ , and so is a positroid. The deletion  $B\setminus a$  is a positroid since its four proper connected flats F with  $|F| \geq 2$ , namely,  $\{c, d, e\}$ ,  $\{e, g, h\}$ ,  $\{f, b, c, d, e\}$ ,  $\{e, g, h, i, f\}$ , are cyclic intervals in the linear order  $b < c < d < e < g < h < i < f$ . Lastly, for  $B \setminus c$ , the proper connected flats  $\{h, i, a\}, \{e, g, h\}, \{a, b, d, f, e\}$ , and  $\{f, e, g, h, i, a\}$  are cyclic intervals in the linear order  $a < b < d < f < e < g < h < i$ , and for  $F = \{a, f, e\}$ , the only proper connected flat with  $|F| \ge 2$  that is not a cyclic interval, the two connected components of  $(B\setminus c)/F$ , both of rank 1, are  $\{b, d\}$  and  $\{g, h, i\}$ , which, as needed, are cyclic intervals.

Examples [4–](#page-31-0)[12](#page-34-8) give infinite families of excluded minors for the class of positroids, most with multiple parameters. Example [4](#page-31-0) includes  $M(K_4)$  and Example [9](#page-33-0) includes free extensions of rank-3 truncations of whirls.

<span id="page-31-0"></span>**Example 4.** Let  $\mathcal{L}$  be  $\{ \{1,3,5\}, \{2,3,4\}, \{4,5,6\}, \{1,2,6\} \}$ , the set of 3-point lines of the cycle matroid  $M(K_4)$  as labeled in Figure [2.](#page-8-0) Let  $X_1, X_2, \ldots, X_6$  be pairwise disjoint nonempty sets that satisfy the following conditions. Let  $x_i = |X_i|$ . The set  $X_2$  is arbitrary. Pick  $X_1$ ,  $X_3$ ,  $X_4$ , and  $X_6$  so that  $x_3 + x_4 = x_1 + x_6$ . Let r be  $x_2 + x_3 + x_4$ , which is also  $x_1 + x_2 + x_6$ . We may assume that  $x_1 + x_3 \le x_4 + x_6$ . Choose  $X_5$  so that  $x_1 + x_3 + x_5 \le r \le x_4 + x_5 + x_6$ . Let  $E = X_1 \cup \cdots \cup X_6$ , and let  $\mathcal Z$  consist of  $\emptyset$ , E, and the four sets  $X_i \cup X_j \cup X_k$  for  $\{i, j, k\} \in \mathcal{L}$ , and let the ranks of these sets be as given in the table below.

Properties (Z0) and (Z1) in Theorem [2.11](#page-6-1) clearly hold. The only case of property (Z2) that is not immediate is when  $X = X_1 \cup X_3 \cup X_5$  and  $Y = E$ , in which case we need  $r(Y) - r(X) < |Y - X|$ , that is,  $r - (x_1 + x_3 + x_5 - 1) < x_2 + x_4 + x_6$ , that is,  $r + 1 < |E|$ , which is clear. Thus, property  $(Z2)$  holds. Each instance of the inequality in property  $(Z3)$ for two incomparable cyclic flats other than  $X_1 \cup X_3 \cup X_5$  is an inequality of the form  $r + x_i \leq 2(r - 1)$ , i.e.,  $x_i \leq r - 2$ , which holds since the sum of  $x_i$  and two other positive integers is at most  $r$ . The inequality required for property  $(Z3)$  in each case that involves  $X_1 \cup X_3 \cup X_5$  has the form  $r + x_i \leq r - 1 + x_1 + x_3 + x_5 - 1$  with  $i \in \{1, 3, 5\}$ , i.e.,  $x_i \leq x_1 + x_3 + x_5 - 2$ , which holds since  $x_1, x_3, x_5 \in \mathbb{N}$ . Thus, the cyclic flats and ranks given above define a matroid  $M$  on  $E$ .

We now show that  $M$  is an excluded minor for the class of positroids. By Lemma [2.12,](#page-6-2) the restriction to and contraction by  $X_i \cup X_j \cup X_k$ , for each  $\{i, j, k\} \in \mathcal{L}$ , is a uniform matroid of positive nullity, and so is connected. If  $M$  were a positroid, then each of these connected flats would be a cyclic interval in any positroid order for  $M$ ; that is impossible by Lemma [2.1,](#page-2-1) so M is not a positroid. Each cyclic flat  $X_i \cup X_j \cup X_k$  for  $\{i, j, k\} \in \mathcal{L} - \{\{4, 5, 6\}\}\$ is a circuit ( $X_4 \cup X_5 \cup X_6$  might be a circuit) and each cyclic flat  $X_i \cup X_j \cup X_k$  for  $\{i, j, k\} \in \mathcal{L} - \{\{1, 3, 5\}\}\$ is a hyperplane ( $X_1 \cup X_3 \cup X_5$  might be a hyperplane). Thus, each element  $e$  is in either one or two cyclic flats that are circuits, and not in either one or two cyclic flats that are hyperplanes. So  $M\$ e either has only four cyclic flats or the hypotheses of Corollary [3.12](#page-16-0) apply, and likewise for  $M/e$ , so these minors of M are positroids. Thus, M is an excluded minor for the class of positroids.  $\circ$ 

In Example [4,](#page-31-0) the proper, nonempty cyclic flat (if any) that is not a circuit and the one (if any) that is not a hyperplane are not equal. In the next example, they are the same.

**Example 5.** Fix  $a, b, c, s, r \in \mathbb{N}$  for which (i)  $\max(a, b, c) < s < a + b + c$ , (ii) r has the same parity as  $a + b + c$ , and (iii) max $(s, a + b - c, a + c - b, b + c - a) < r$ . Let  $\mathcal L$  be as in Example [4.](#page-31-0) Pick pairwise disjoint sets  $X_1, X_2, \ldots, X_6$  for which  $|X_4| = a, |X_5| = c$ ,  $|X_6| = b$ , and

$$
|X_1| = \frac{r+a-b-c}{2}, \qquad |X_2| = \frac{r-a-b+c}{2} \qquad |X_3| = \frac{r-a+b-c}{2}.
$$

Thus,  $|X_4 \cup X_5 \cup X_6| = a+b+c$  and  $|X_i \cup X_j \cup X_k| = r$ , for  $\{i, j, k\} \in \mathcal{L} - \{\{4, 5, 6\}\}.$ Let  $E = X_1 \cup \cdots \cup X_6$ , and let Z consist of  $\emptyset$ , E, and the four sets  $X_i \cup X_j \cup X_k$  for  $\{i, j, k\} \in \mathcal{L}$ , and let the ranks of these sets be as given in the table below.

Properties (Z0) and (Z1) in Theorem [2.11](#page-6-1) clearly hold. The only case of property (Z2) that is not transparent is when  $X = X_4 \cup X_5 \cup X_6$  and  $Y = E$ , for which we must show that  $r(Y) - r(X) < |Y - X|$ , that is,  $r - s < |X_1 \cup X_2 \cup X_3|$ . That inequality simplifies to  $a + b + c < r + 2s$ , which holds since  $a + b + c < 3s < r + 2s$  by conditions (i) and (iii). Thus, property (Z2) holds. Each instance of the inequality in property (Z3) for two incomparable cyclic flats other than  $X_4 \cup X_5 \cup X_6$  is an inequality of the form  $r + |X_i| \le 2(r-1)$ , i.e.,  $|X_i| \le r-2$ , which holds since  $|X_i|$  and two other positive integers add to  $r$ . The inequality required for property  $(Z3)$  in each case that involves  $X_4 \cup X_5 \cup X_6$  has the form  $r + |X_i| \le r - 1 + s$  with  $i \in \{4, 5, 6\}$ , i.e.,  $|X_i| < s$ , which holds by the inequality  $\max(a, b, c) < s$  in condition (i). Thus, the cyclic flats and their ranks define a matroid  $M$  on  $E$ . The same argument as used in the last example shows that  $M$  is an excluded minor for the class of positroids.  $\circ$ 

We next give three more infinite families of excluded minors for the class of positroids, along with their duals, that are different variations on the idea in Example [4.](#page-31-0) We omit the proofs that these are excluded minors since no new ideas are required.

**Example 6.** Fix  $a, b, c, k \in \mathbb{N}$  and let  $X_1, \ldots, X_6$  be pairwise disjoint sets with  $|X_3| = a$ ,  $|X_6| = a + k$ ,  $|X_4| = b$ ,  $|X_1| = b + k$ ,  $|X_5| = c$ , and  $|X_2| = c + k$ . Fix an element p that is in none of  $X_1, \ldots, X_6$ , and let  $E = X_1 \cup \cdots \cup X_6 \cup p$ . Let the paving matroid M of rank  $a+b+c+k+1$  on E have as its dependent hyperplanes the three circuit-hyperplanes  $X_1 \cup X_3 \cup X_5 \cup p$ ,  $X_2 \cup X_3 \cup X_4 \cup p$ , and  $X_4 \cup X_5 \cup X_6 \cup p$ , along with  $X_1 \cup X_2 \cup X_6$ , which has nullity  $2k$ . It is easy to check that  $M$  is an excluded minor for the class of positroids. In the dual,  $M^*$ , of M, which has rank  $a + b + c + 2k$ , the sets  $X_2 \cup X_4 \cup X_6$ ,  $X_1 \cup X_5 \cup X_6$ , and  $X_1 \cup X_2 \cup X_3$  are circuit-hyperplanes, while  $X_3 \cup X_4 \cup X_5 \cup p$  is a circuit but not a hyperplane.

**Example 7.** Fix  $a, b, c \in \mathbb{N}$  and let the sets  $X_1, \ldots, X_6$  be pairwise disjoint and satisfy  $|X_3| = |X_6| = a, |X_1| = b + 1, |X_4| = b$ , and  $|X_2| = |X_5| = c$ . Fix elements p and q that are in none of  $X_1, \ldots, X_6$ , and let  $E = X_1 \cup \cdots \cup X_6 \cup \{p, q\}$ . The sets

 $X_1 \cup X_3 \cup X_5 \cup p$ ,  $X_2 \cup X_3 \cup X_4 \cup \{p,q\}$ ,  $X_4 \cup X_5 \cup X_6 \cup \{p,q\}$ ,  $X_1 \cup X_2 \cup X_6 \cup q$ 

are the circuit-hyperplanes of a sparse paving matroid M of rank  $a + b + c + 2$  on E. It is easy to check that  $M$  is an excluded minor for the class of positroids. The sparse paving matroid  $M^*$  has rank  $a + b + c + 1$  and its circuit-hyperplanes are  $X_2 \cup X_4 \cup X_6 \cup q$ ,  $X_1 \cup X_5 \cup X_6$ ,  $X_1 \cup X_2 \cup X_3$ , and  $X_3 \cup X_4 \cup X_5 \cup p$ .

<span id="page-32-0"></span>**Example 8.** Fix  $a, b, c \in \mathbb{N}$  and let the sets  $X_1, \ldots, X_6$  be pairwise disjoint and satisfy  $|X_3| = |X_6| = a, |X_1| = |X_4| = b$ , and  $|X_2| = |X_5| = c$ . Fix four elements p, q, s, t that are in none of  $X_1, \ldots, X_6$ , and let  $E = X_1 \cup \cdots \cup X_6 \cup \{p, q, s, t\}$ . The sets

are the circuit-hyperplanes of a sparse-paving matroid M on E of rank  $a + b + c + 3$ . It is easy to check that  $M$  is an excluded minor for the class of positroids. The sparsepaving matroid  $M^*$  has the circuit-hyperplanes  $X_2 \cup X_4 \cup X_6 \cup p$ ,  $X_1 \cup X_5 \cup X_6 \cup q$ ,  $X_1 \cup X_2 \cup X_3 \cup s$ , and  $X_3 \cup X_4 \cup X_5 \cup t$ , and its rank is  $a+b+c+1$ .

Let L be the lattice of flats of  $M(K_4)$  and let M be a loopless matroid whose lattice of cyclic flats is isomorphic to  $L$ . Note that if the cyclic flats of a matroid  $N$  are either (i) just  $\emptyset$  and  $E(N)$ , or (ii) just  $\emptyset$ ,  $E(N)$ , and three other sets, none of which contains either of the other two, then  $N$  is connected since its lattice of cyclic flats is not a direct

<span id="page-33-1"></span>FIGURE 12. The matroids in Example [10](#page-34-9) for ranks 3 and 4, with the 4-circuits in the rank-4 matroid drawn in the faces of a triangular prism.

product of two other lattices. By Lemma [2.12,](#page-6-2) for any cyclic flat  $F_1$  of M that corresponds to a point of  $M(K_4)$  and any cyclic flat  $F_2$  of M that corresponds to a 3-point line of  $M(K_4)$ , condition (i) holds for  $\mathcal{Z}(M|F_1)$  and  $\mathcal{Z}(M/F_2)$  while condition (ii) holds for  $\mathcal{Z}(M/F_1)$  and  $\mathcal{Z}(M/F_2)$ , so all such minors are connected. As above, it follows that M is not a positroid. Thus, while every lattice is isomorphic to the lattice of cyclic flats of some matroid [\[7\]](#page-34-4), the same is not true for positroids.

The rank-n whirl,  $W<sup>n</sup>$ , is a multi-path matroid, so it and its rank-3 truncation are positroids, but the free extension of the rank-3 truncation of  $\mathcal{W}^n$  is an excluded minor for the class of positroids. The next example treats these excluded minors and many more.

<span id="page-33-0"></span>**Example 9.** Fix  $n, r, x_1, x_2, \ldots, x_{2n} \in \mathbb{N}$ , with  $n \geq 3$ , that satisfy the properties below, where we interpret indices modulo 2n and set  $m_i = x_{2i-2} + x_{2i-1} + x_{2i}$  for all  $i \in [n]$ :

- (i)  $3 \leq m_i \leq r$  for all  $i \in [n]$ ,
- (ii) if  $n = 3$ , then all  $m_i$  are r, while if  $n > 3$ , then  $m_i = r = m_j$  for at least two elements i and j of  $[n]$  that are not cyclically consecutive,

(iii) if 
$$
i, j \in [n]
$$
 with  $j \neq i$  and  $j \neq i + 1$ , then  $r < x_{2i} + x_{2j} + \sum_{k=i+1}^{j} x_{2k-1}$ .

(To be clear, the sum in property (iii) is over the odd terms in a cyclic interval in  $[2n]$ .) Let  $e_1, e_2, \ldots, e_{2n}$  be the elements of the *n*-whirl  $\mathcal{W}^n$ , labeled so that, for each  $i \in [n]$ , the set  $\{e_{2i-2}, e_{2i-1}, e_{2i}\}$  is a 3-circuit, where  $e_0 = e_{2n}$ . For each  $i \in [2n]$ , apply series extension  $x_i - 1$  times to  $e_i$ , so the 3-circuit  $\{e_{2i-2}, e_{2i-1}, e_{2i}\}$  of  $\mathcal{W}^n$  yields an  $m_i$ -circuit  $C_i$ . Let M' denote the resulting matroid. Truncate the free extension  $M' + f$  to rank r to get a matroid  $M$ . We claim that  $M$  is an excluded minor for the class of positroids.

The circuits of the *n*-whirl  $\mathcal{W}^n$  are the symmetric differences of consecutive 3-circuits, so the circuits of  $M'$  are the symmetric differences of the form  $C_i \triangle C_{i+1} \triangle \cdots \triangle C_j$ , where we interpret the subscripts modulo n. Thus, by property (iii), the only circuits of  $M$  of rank less than r are the circuits  $C_i$  for  $i \in [n]$ , so they are the only proper connected flats F of M with  $|F| \ge 2$ . Also,  $M/C_i$  is connected by part (3) of Lemma [2.10.](#page-5-2) So if M were a positroid, each circuit  $C_i$  would have to be an interval in any positroid order for  $M$ , but, since f is in no circuit  $C_i$  and  $C_i \cap C_{i+1} \neq \emptyset$  for all  $i \in [n]$ , there is no positroid order for  $M$ , so  $M$  is not a positroid.

For each  $e \in E(M)$ , at least one circuit  $C_i$  of M fails to be a circuit of  $M/e$  by property (ii), so a now-routine use of Corollary [3.6](#page-13-2) implies that  $M/e$  is a positroid. The same holds for  $M\backslash e$  if  $e \neq f$ . Adapting a positroid order for a whirl to  $M\backslash f$  shows that it too is a positroid. Thus,  $M$  is an excluded minor for the class of positroids.  $\circ$ 

The next infinite family of excluded minors for the class of positroids can be seen as a variation on a 3-whirl, but with two r-circuits and a 3-circuit, and instead of taking a free extension, another 3-circuit is added.

<span id="page-34-9"></span>**Example 10.** Fix an integer  $r \geq 3$ , take the parallel connection of two *r*-circuits, A and B, with base point e, truncate to rank r, fix  $a_1, a_2 \in A - e$  and  $b_1, b_2 \in B - e$ , and then, using principal extension, add a point  $p_1$  to the line  $\{a_1, b_1\}$  and a point  $p_2$  to the line  ${a_2, b_2}$ . The resulting matroid M has rank r and its proper, nonempty connected flats, each of which is a circuit, are A, B,  $\{a_1, b_1, p_1\}$ , and  $\{a_2, b_2, p_2\}$ . (See Figure [12](#page-33-1) for the cases  $r = 3$  and  $r = 4$ .) Contracting any of the proper, nonempty connected flats yields a connected matroid, and, by Lemma [2.1,](#page-2-1) no linear order on  $E(M)$  has each of A, B,  ${a_1, b_1, p_1}$ , and  ${a_2, b_2, p_2}$  being a cyclic interval, so M is not a positroid. It is routine to check that all proper minors of  $M$  are positroids.  $\circ$ 

We close with two more infinite families of excluded minors for the class of positroids. With the ideas above, verifying that these are excluded minors is routine. Also, applying duality yields more excluded minors.

**Example 11.** For integers  $n \geq k \geq 3$ , take the parallel connection of two *n*-circuits and a k-circuit (or three *n*-circuits if  $n = k$ ) at a common base point, and then truncate to rank n. The matroid obtained is an excluded minor for the class of positroids.

<span id="page-34-8"></span>**Example 12.** For integers  $n \geq k \geq 3$ , take two *n*-circuits and a *k*-circuit (or three *n*circuits if  $n = k$ ) and a 3-point line; for each of the first three circuits, take its parallel connection with the line, using three different base points on the line, and then truncate to rank *n*. The resulting matroid is an excluded minor for the class of positroids.

## ACKNOWLEDGMENTS

The author thanks Kolja Knauer for pointing out the work of Blum and the result of Lam and Postnikov that base-sortable matroids are the same as positroids. The author thanks Felipe Rinc of for pointing him to Theorems  $1.2$  and  $1.3$  and recasting those results, which were originally stated in terms of matroid polytopes, in a form closer to what is given here, and for a useful discussion about Blum's conjecture that led to Theorem [3.5.](#page-13-0) The author also thanks both referees for their careful reading and helpful comments that should result in making this paper accessible to a wider audience.
