Resolution of Non-Singularities and the Absolute Anabelian Conjecture

Emmanuel Lepage

June 13, 2023

Introduction

Grothendieck anabelian conjecture is concerned with the recovery, for smooth curves over number fields, of a curve from its étale fundamental group. More precisely, it conjectures that if X and Y are two hyperbolic curves over a number field K with absolute Galois group G_K , then $\text{Isom}_K(X, Y) \to \text{Isom}_{G_K}(\pi_1^{\text{alg}}(X), \pi_1^{\text{alg}}(Y))/ \sim \text{is}$ bijective, where ∼ is given by composing with inner automorphisms. This conjecture was proved by S. Mochizuki in [\[4\]](#page-10-0), where it is proved much more generally for sub-padic fields.

In this article we will only be interested in the case where K is a p-adic field. In [\[7\]](#page-10-1), Mochizuki then asks if one can remove the assumption of lying over an isomorphism of absolute Galois groups. This gives us the following conjecture:

Conjecture 0.1. Let K, L be finite extensions of \mathbb{Q}_p , and X/L , Y/K be two hyperbolic *curves. Then the map* $\text{Isom}(X, Y) \to \text{Isom}(\pi_1^{\text{alg}}(X), \pi_1^{\text{alg}}(Y))/ \sim$ *is bijective.*

The conjecture was proved by Mochizuki in [\[7\]](#page-10-1) in the case where X and Y are of quasi-Belyi type. This quasi-Belyi type condition doesn't contain any proper curve. The goal of this paper is to extend this result to a wider family of curves, that in particular contains every Mumford curve :

Theorem 0.2. *Let* K, *L be finite extensions of* \mathbb{Q}_p *, and* X/L *,* Y/K *be two hyperbolic curves satisfying resolution of non singularities (see definition [1.1\)](#page-2-0), for example two hyperbolic Mumford curves. Then the map* $\text{Isom}(X, Y) \to \text{Isom}(\pi_1^{\text{alg}}(X), \pi_1^{\text{alg}}(Y))/ \sim$ *is bijective.*

A theorem of Mochizuki ([\[7,](#page-10-1) Thm 2.9]) claims that to prove that it is sufficient to characterize group-theoretically among the partial Galois sections $G_{K'} \to \pi_1^{\rm alg}(X)$ those which come from a closed point $x \in X(K')$ for any finite extension K' of K. The idea of the proof then relies on the reconstruction of the Berkovich space $|X|$ (as a topological space) of the curve from the étale fundamental group, as was done in [\[3,](#page-10-2) Thm. 3.10] for the geometric tempered fundamental group. From a result of Mochizuki ([\[5,](#page-10-3) Thm 2.7]), one can recover from $\pi_1^{\text{alg}}(X)$ the dual graph $\mathbb{G}(X)$ of the special fiber of the stable model of $X_{\overline{K}}$. By applying this reconstruction to

all the finite étale coverings, the recovering of the Berkovich space follows from a homeomorphism $|\overline{X}| = (\varprojlim_{Z} |G(Z)|)/\pi_1^{\text{alg}}(X)$, where Z goes through connected pointed finite étale covers of X and \overline{X} is the smooth compactification of X. It is then sufficient to characterized rigid points inside the Berkovich space $|X|$.

The Berkovich points on curves are traditionally classified into four classes, where the type 1 points correspond to \mathbb{C}_p -points. The type 2 points are type 3 points are easy to distinguish from the others by the local topological behavior. The main issue is then to distinguish between type 4 and type 1 points. In this paper, we present two different ways of doing it. First through a metric characterization, using Mochizuki's recovery of the log-structure of the special fiber of the stable model [\[5,](#page-10-3) Thm 2.7]). Secondly, by showing that the geometric decomposition group of type 4 points is non trivial. More precisely, we will see that a \mathbb{Z}_p -torsor of $X_{\mathbb{C}_p}$ does not decompose at a type 4 points if it is not a topological torsor. Locally in a small disk, this \mathbb{Z}_p -torsor comes from Kummer classes of invertible functions, and by applying the log-differential, whose image is bounded, one gets that these invertible functions cannot have $pⁿ$ th root for big enough $n.$ Then the rigid points are characterized among type 1 points by the fact that their image in the absolute Galois group G_K is open.

1 Resolution of Non-Singularities

Let K be a complete nonarchimedean field of mixed characteristics $(0, p)$. Let O_K be its ring of integers and \tilde{K} be its residue field.

Let $X = \overline{X} \backslash D$ be a hyperbolic curve over K. Let X^{an} be the associated Berkovich space. As a set, X^{an} can be seen as the union of the set of closed points of X and the set of R-valued valuations v on the fraction field $K(X)$ extending the valuation on K. The completion of $K(X)$ for this valuation will be denoted by $\mathcal{H}(v)$. Since $K(X)/K$ is an extension of transcendance degree one, for every such valuation v, $r(v) + t(v) \leq 1$ where $r(v) = \text{rk}(v(K(X)^{\times})/v(K^{\times}))$ and $t(v)$ is the transcendance degree of the residue field $\mathcal{H}(v)$ of $\mathcal{H}(v)$ as an extension of \widetilde{K} .

A type 2 point of X^{an} then corresponds to a valuation v such that $t(v) = 1$, and a type 3 point corresponds to a valuation v such that $r(v) = 1$. If a point x of X^{an} is a rigid point or comes from a valuation such that $K(X)$ embeds isometrically into the completion of an algebraic closure of K , then x is said to be of type 1. Otherwise it is of type 4.

If \overline{X} has a stable model $\mathfrak X$ over O_K , there is a natural specialization map sp : $X^{\text{an}} \to \mathfrak{X}_s$ where $\mathfrak{X}_s = \mathfrak{X}_{\widetilde{K}}$ is the special fiber of \mathfrak{X} . Then the generic point z of any irreducible component of \mathfrak{X}_s has a unique preimage v_z and this preimage is a type 2 point, and the residue field $\mathcal{H}(v_z)$ is isomorphic to $k(z)$. Such a type 2 point will be called a skeletal point of X^{an} , and the set of skeletal points will be denoted by $V(X)$. Skeletal points are the vertices of the minimal triangulation of X^{an} in the sense of [\[1,](#page-10-4) §5.1.13]. The connected components of $X^{\text{an}}\backslash V(X)$ are given by the preimages by sp of the closed points in \mathfrak{X}_s . Moreover, if K is algebraically closed and x is a closed point of \mathfrak{X}_s , then $sp^{-1}(x)$ is analytically isomorphic to :

• a punctured open disk if x is a cusp;

- an open disk if x is a smooth point;
- an open annulus if x is a node.

In particular if v is a type two point of X^{an} such that $\mathcal{H}(v)$ is the fraction field of a curve of genus > 0 , then v is skeletal.

Definition 1.1. ([\[3,](#page-10-2) Def. 2.1])

Let C be an algebraically closed complete nonarchimedean field of mixed characteristics $(0, p)$. Let X be a hyperbolic curve over C. X is said to satisfy *resolution of non-singularities* (or $RNS(X)$ for short) if for every point x of type 2 of X^{an} , there exists a finite étale cover $f: Y \to X$ such that $f^{-1}(x) \cap V(Y) \neq \emptyset$.

More generally, if X is a hyperbolic curve over a complete field K of mixed characteristics $(0, p)$, then we will write $RNS(X)$ for $RNS(X_C)$, where C is the completion of an algebraic closure of K.

Proposition 1.1. *Let* $f : X \to Y$ *be a map of hyperbolic curves over* K.

- *1.* If $f: X \to Y$ is a dominant map, then $RNS(Y)$ implies $RNS(X)$.
- *2. If* $f : X \to Y$ *is finite étale, then* $RNS(X)$ *and* $RNS(Y)$ *are equivalent.*

Proof. One can assume K to be algebraically closed.

- 1. Let $x \in X^{\text{an}}$ be a point of type 2, and let $y = f(x)$. Then y is also of type 2, and by RNS(Y), there exists a finite étale cover $g: Z \to Y$ and $z \in g^{-1}(y) \cap V(Z)$. Let $f_Z : X \times_Y Z \to Z$ be the map obtained by pulling back f and g_X : $X \times_Y Z \to X$ be the finite étale cover obtained by pulling back g. Then there exists $z' \in g_X^{-1}(x) \cap f_Z^{-1}(z) \subset g_X^{-1}(x) \cap f_Z^{-1}(V(Z)) \subset g_X^{-1}(x) \cap V(X \times_Y Z)$.
- 2. By (i), $RNS(Y)$ implies $RNS(X)$. Let us assume $RNS(X)$ and let $y \in Y^{an}$ be a point of type 2, and let $x \in X^{\text{an}}$ be a preimage of y by f. Then there exists a finite étale cover $g: Z \to X$ and $z \in g^{-1}(x) \cap V(Z)$. Then $fg: Z \to Y$ is a finite étale cover and $z \in (fg)^{-1}(y) \cap V(Z)$, so that $RNS(Y)$ is true.

Proposition 1.2. *([\[3,](#page-10-2) Th. 0.1])*

- *1. If* \overline{X} *is a Mumford curve over* $\overline{\mathbb{Q}}_p$ *and* $X\subset \overline{X}_{\mathbb{C}_p}$ *is a Zariski open subset of* $X_{\mathbb{C}_p}$ which is a hyperbolic curve over \mathbb{C}_p , then $\mathrm{RNS}(X_{\mathbb{C}_p})$ is true.
- *2. If X* is a \mathbb{C}_p -curve of quasi-Belyi type, then $RNS(X)$ is true.

The case of Mumford curves over $\overline{\mathbb{Q}}_p$ follows from a more general criterion in terms of the following Hodge-Tate map. Let X be a smooth adic space over K , and let ν : $X_{\text{pro-\'et}} \rightarrow X_{\text{\'et}}$ be the natural map from its pro-étale site to its étale site. Then the short exact sequence on $X_{\text{pro-\'et}}$:

$$
1 \to \mathbb{Z}_p(1) \to \lim_{\times p} \mathcal{O}_X^{\times} \to \mathcal{O}_X^{\times} \to 1
$$

induces a boundary map $\kappa : \mathcal{O}_X^{\times}$ $X_{\xi_{\text{\'et}}} = \nu_* \mathcal{O}_X^{\times} \to R^1 \nu_* \mathbb{Z}_p(1)$. There exists a unique $\mathcal{O}_{X_{\text{\'et}}}$ -linear map $\phi : \Omega^1_{X_{\text{\'et}}} \to R^1\nu_*\widehat{\mathcal{O}}^{\times}_{X_{\text{\'et}}}$ such that the following diagram commutes (see [\[8,](#page-10-5) Lem. 3.24]):

$$
\mathcal{O}_{X_{\text{\'et}}}^{\times} \xrightarrow{\kappa} R^1 \nu_* \mathbb{Z}_p(1)
$$
\n
$$
\downarrow^{dlog} \qquad \qquad \downarrow^{i}
$$
\n
$$
\Omega^1_{X_{\text{\'et}}} \xrightarrow{\phi} R^1 \nu_* \widehat{\mathcal{O}}_{X_{\text{\'et}}}^{\times}
$$

and ϕ is an isomorphism. By taking global sections of $\phi^{-1}i$, one gets a map:

$$
\operatorname{HT}_X: H^1(X, \mathbb{Z}_p(1)) \to H^0(X, \Omega^1_X).
$$

- **Definition 1.2.** 1. Let $HTvLoc_1(X) \subset X(K)$ (for Hodge-Tate vanishing locus of X) be the set of points such that there exists $c \in H^1(Y, \mathbb{Z}_p(1))$ such that $HT_Y(c)$ has vanishing order $e < +\infty$ at y such that $e + 1$ is not a power of p.
	- 2. Let $HTvLoc_1^{f\text{-\'et}}(X) = \bigcup_{f:Y\to X} f(HTvLoc_1(Y)) \subset X(K)$, where the union is indexed through all finite étale covers of X.
	- 3. Let $HTv_1(X)$ be the following property: $HTvLoc_1^{\text{f-\'et}}(X)$ is dense in $X(K)$.

Proposition 1.3. Let X be a hyperbolic curve over K. Then $HTv_1(X)$ implies $RNS(X)$.

Proof. By the argument of [\[3,](#page-10-2) Prop. 2.2] it is enough to show that for every disk D in X, there exists a finite étale cover $g: Z \to X$ such that $g^{-1}(D) \cap V(Z) \neq \emptyset$.

By definition of HTv₁(X), there exists a finite étale cover $f: Y \to X, y \in$ $f^{-1}(D)$ and $c \in H^1(Y, \mathbb{Z}_p(1))$ such that the vanishing order e of $HT_Y(c)$ at y is not of the form $p^n - 1$ for any $n \in \mathbb{N}$.

For $n \in N$, let $c_n \in H^1(Y, \mu_{p^n})$ be the image of c by the map induced from the surjection $\mathbb{Z}_p(1) \to \mu_{p^n}$ and let $g_n : Y_n \to Y$ be the corresponding μ_{p^n} -torsor. Let D' be a discal neighborhood of y in $f^{-1}(D)$. Since $H^1(D', \mathbf{G}_m) = 0$, the restriction $c_{n,D'}$ of c_n to D' is in the image of the Kummer map $\kappa_n : \mathcal{O}^{\times}(D') \to H^1(D', \mu_{p^n})$. Let $a_n \in \mathcal{O}^{\times}(D')$ such that $\kappa_n(a_n) = c_{n,D'}$ and $a_n(y) = 1$. There exists $b_n \in \mathcal{O}^{\times}(D')$ such that $a_n = b_n^{p^n} a_{n+1}$ and $b_n(y) = 1$. After replacing D' by a smaller disk D'', there exists $r < 1$ such that for every $n \in \mathbb{N}$, $|b_n - 1|_{D'} \le r$, and therefore $(b_n^{p^n})_n$ converges uniformly to 1 on D'. Therefore $(a_{n,D'})_n$ converges to $a \in \mathcal{O}^{\times}(D'')$ and $c_{D''}$ is the image of a by the boundary map $\kappa : \mathcal{O}_Y^{\times}$ $Y_{Y_{\text{\'et}}} \to \nu_* \mathcal{O}_Y^{\times} \to R^1 \nu_* \mathbb{Z}_p(1)$. Therefore $HT_Y(c)_{D^{\prime\prime}} = dlog(a)$ and [\[3,](#page-10-2) Prop. 2.4] shows that, for n big enough, there exists $y_n \in V(Y_n) \cap g_n^{-1}(D'') \subset V(Y_n) \cap (fg_n)^{-1}(D).$ П

2 Reconstruction of the Berkovich topology

If X is a hyperbolic curve over K, let \overline{X} be its smooth compactification, so that $X =$ $\overline{X} \backslash D_X$ for some divisor D_X on \overline{X} . Let |X| be the Berkovich space of X, considered as a topological space.

If \widetilde{X} is a universal pro-object in the category of finite étale cover of X, we will use the following notations : $|X| = \lim_{\substack{\longleftarrow \\ \longleftarrow}} \widetilde{X} \rightarrow Y} |Y|$ and $|X|_c = \lim_{\substack{\longleftarrow \\ \longleftarrow}} \widetilde{X} \rightarrow Y} |Y|$, where Y goes through \tilde{X} -pointed finite étale cover of X.

Proposition 2.1. *Let* X_1/K *and* X_2/K_2 *be two p-adic hyperbolic curves satisfying rns* and let X_i/K_i be a universal pro-cover of X_i/K_i . Let $\alpha : \pi_1(X_1, X_1) \to \pi_1(X_2, X_2)$ *be an isomorphism of fundamental groups. Then there is a unique homeomorphism of pro-Berkovich spaces* $\tilde{\alpha}: |\tilde{X}_1| \to |\tilde{X}_2|$ *and* $\tilde{\alpha}_c: |\tilde{X}_1|_c \to |\tilde{X}_2|_c$ *which are equivariant in the sense that the following diagram commutes:*

$$
\pi_1(X_1, \widetilde{X}_1) \times |\widetilde{X}_1|_c \longrightarrow |\widetilde{X}_1|_c
$$
\n
$$
\downarrow \alpha \times \widetilde{\alpha} \qquad \qquad \downarrow \widetilde{\alpha}
$$
\n
$$
\pi_1(X_2, \widetilde{X}_2) \times |\widetilde{X}_2|_c \longrightarrow |\widetilde{X}_2|_c
$$

In particular, by quotienting by the étale fundmental group and the geometric étale fundamental groups, one gets homeomorphisms:

$$
\bar{\alpha} : \overline{X}_1^{\text{an}} \to \overline{X}_2^{\text{an}},
$$

$$
\bar{\alpha}_{\mathbb{C}_p} : \overline{X}_{1,\mathbb{C}_p}^{\text{an}} \to \overline{X}_{2,\mathbb{C}_p}^{\text{an}}
$$

,

Proof. Let $\Pi_i = \pi_1(X_i, X_i)$, $\Delta_i = \pi_1(X_{i, \overline{K}_i}, X_i) \subset \pi_1(X_i, X_i)$ and $G_i = \Pi_i/\Delta_i \simeq$ $Gal(\overline{K}_i/K_i)$. Then $\alpha(\Delta_1) = \Delta_2$ by [\[5,](#page-10-3) Lem. 1.1.4] and therefore α induces an isomorphism $\alpha_G : G_1 \to G_2$.

Let $\Delta_i^{(p')}$ be the maximal pro-prime-to-p quotient of Δ_i and $\Pi_i^{(p')} = \Pi_i / \text{Ker}(\Delta_i \rightarrow$ $\Delta_i^{(p')}$) be the maximal geometrically pro-prime-to-p quotient of Π_i . Let $\alpha_{geom}^{(p')}$: $\Delta_1^{(p')} \rightarrow \Delta_2^{(p')}$ and $\alpha^{(p')} : \Pi_1^{(p')} \rightarrow \Pi_2^{(p')}$ be the morphisms induced by α .

Let H_1 be an open subgroup of Π_1 , and let $H_2 = \alpha(H_1)$. Let Y_1 be the connected finite étale cover of X_1 corresponding to H_1 and let Y_2 be the cover of X_2 corresponding to H_2 . Denote by L_i the field of constants of Y_i . Then cofinally on Y_1 , both Y_1/L_1 and Y_2/L_2 have stable reduction. Denote by \mathfrak{Y}_1 and \mathfrak{Y}_2 the corresponding stable models endowed with the natural log-structure. According to [\[5,](#page-10-3) Thm 2.7], α induces natural isomorphisms of log-special fibers $\alpha_{H_1,\log} : \mathfrak{Y}_{1,s} \to \mathfrak{Y}_{2,s}$. More precisely, when one identifies the prime-to- p geometric log fundamental group $\pi_1^{\log\text{-geom}}(\mathfrak{Y}_{1,s})$ of $\mathfrak{Y}_{i,s}$ with $(H_i \cap \Delta_i)^{(p')}$ along the specialisation map, the morphism $\pi_1^{\text{log-geom}}(\mathfrak{Y}_{1,s}) \rightarrow \pi_1^{\text{log-geom}}(\mathfrak{Y}_{1,s})$ induced by $\alpha_{H_1,\text{log}}$ coincides with $\alpha_{H_1,geom}^{(p')}$: $(H_1 \cap \Delta_1)^{(p')} \to (H_2 \cap \Delta_2)^{(p')}$. In particular, one gets an isomorphism of the geometric dual graphs $\mathbb{G}_{Y_1} \to \mathbb{G}_{Y_2}$ such that if z_1 is an edge or a vertex in \mathbb{G}_{Y_1} with image z_2 in \mathbb{G}_{Y_2} , then $\alpha_{H_1,geom}^{(p')}(D_{z_1})=D_{z_2}$ where D_{z_i} is the decomposition group of z_i in $(H_i \cap \Delta_i)^{(p')}$. The construction (and unicity) of $\bar{\alpha}$ is then perfectly similar to the one in [\[3,](#page-10-2) Thm. 3.10], that we now recall.

If K_i is an open subgroup of Δ_i , let $\tilde{V}(K_i)$ (resp. $\tilde{E}(K_i)$) be the set of decomposition groups of vertices of \mathbb{G}_{Y_i} in $K_i^{(p')},$ where $Y_i \rightarrow X_i$ is the finite étale cover

corresponding to H_i , where H_i is any open subgroup of Π_i such that $K_i = H_i \cap \Delta_i$ and Y_i has stable reduction $(\tilde{V}(K_i))$ and $\tilde{E}(K_i)$ do not depend on the choice of H_i). Let $V(K_i) = V(K_i)/K_i$ and $E(K_i) = E(K_i)/K_i$ be the set of conjugation classes.

Let $K''_i \subset K'_i \subset K_i$ be three open subsets of Δ_i such that K'_i and K''_i are normal in K_i . let $j_{K''_i, K'_i}: (K''_i)^{(p')} \to (K'_i)^{(p')}$ be the induced map. Then for every $D \in \tilde{V}(K'_i)$ there exists a unique $D' \in \tilde{V}(K_i'')$ up to conjugation in K_i such that $j_{K_i'', K_i'}(D')$ is open in D. This induces an injection $i_{K''_i, K'_i}: V(K'_i)/K_i \to V(K''_i)/K_i$.

Let $D \in E(K_i)$. Let K' be a normal open subgroup of K_i and let $j: K'^{(p')} \to$ $K^{(p')}$ be the induced map. One denotes by

 $A_{D,K'} := \{D' \in \tilde{V}(K') | j(D') \text{ is conjugate to an open subgroup of } D\}/K_i \subset V(K')/K_i.$ If $K'' \subset K'$, then $i_{K'',K'}$ maps $A_{D,K''}$ to $A_{D,K'}$, and let

$$
A_D = \lim_{K'} A_{D,K'}.
$$

Let $D_1 \in \tilde{V}(K_i)$ such that $D \subset D_1$ and let D_2 be the only other subgroup in $V(K_i)$ such that $D \subset D_2$. The full subgraph $\mathbb{G}(A_{D,K'})$ of $\mathbb{G}_{K'}/K_i$ with vertices

$$
A_{D,K'} \cup \{i_{K',K_i}(D_1), i_{K',K_i}(D_2)\}
$$

is a line, so that $A_{D,K'}$ is naturally an ordered set for which D_1 is the minimal element and D_2 is the maximal. If one exchanges the role of D_1 and D_2 , the order is reversed.

The injective map $A_{D,K''} \rightarrow A_{D,K'}$ is increasing, so that one obtains an order on A_D , which is then, non-canonically, isomorphic to $\mathbf{Q} \cap (0,1)$ as an ordered set. Let A_D be the Dedekind completion of A_D : A_D is an ordered topological space noncanonically isomorphic to [0, 1] as an ordered set. One denotes by $e(D_1)$ the minimal element of A_D . As a set A_D does not depend on D_1 but the order is reversed when one replace D_1 by D_2 . One then defines the topological space

$$
S(K_i) := \left(V(K_i) \coprod_{D \in E(K_i)} \widehat{A}_D\right)/\sim
$$

where \sim is generated by

 $\forall D \subset D_1, \quad D_1 \sim e(D_1).$

Since \widehat{A}_D is (a priori non canonically) homeomorphic to [0, 1], $S(K_i)$ is (a priori non canonically) homeomorphic to the geometric realization of $\mathbb{G}(K_i)$.

Let $B_i = \underline{\lim}_{K_i} S(K_i)$. Then one has a natural homeomorphism $|X_1|_c \to B_i$ (see [\[3,](#page-10-2) Lem. 3.9]). Then the family of isomorphisms of graphs $\mathbb{G}(K_1) \to \mathbb{G}(K_2)$ induce a homeomorphism $B_1 \to B_2$, and therefore one gets a homeomorphism $\tilde{\alpha}_c : |X_1|_c \to$ $|\widetilde{X}_2|_c$. It preserves cusps, for example by [\[6\]](#page-10-6), so that it also induces a homeomorphism $\tilde{\alpha}: |X_1| \to |X_2|$. The action of Π_i on itself by conjugacy induce an action of Π_i on B_i , so that the homeomorphism $\underline{\lim}_{K_i} S(K_i) \to |X_1|_c$ is Π_i -equivariant, and $B_1 \to B_2$ is also equivariant.

The uniqueness is identical to [\[3,](#page-10-2) Prop. 3.11].

The map $\bar{\alpha}_{C_p}$ is deduced from the fact that $\alpha(\Delta_1) = \Delta_2$.

3 The canonical metric

Let $\mathbb G$ be a finite connected graph. A metric on $\mathbb G$ is just a map $l : E(\mathbb G) \to \mathbb R_{>0}$ where $E(\mathbb{G})$ is the set of edges of \mathbb{G} . If x, y are two vertices of \mathbb{G} , a path from x to y is a sequence $p = (x = x_0, e_1, x_1, \dots, e_n, x_n = y)$ where for all i, x_i is a vertex of G and e_i is an edge of $\mathbb G$ abutting at x_{i-1} and x_i . We then set $d(x, y) = \inf_p l(p)$ where the infimum goes through all paths from x to y and $l(p) = \sum_{i=1}^{n} l(e_i)$ if $p = (x =$ $x_0, e_1, x_1, \cdots, e_n, x_n = y$ is a path.

Let X^{\log}/k^{\log} be a semistable log curve over a log point, and let \mathbb{G}_X be the dual graph of X. Let us fix $\pi \in M_{k^{\log}} \setminus \{0\}$. Let e be a node of X^{\log} , then $\overline{M}_{X,e}$ is isomorphic to $\overline{M}_{k^{\log}} \oplus \mathbb{N}u \oplus \mathbb{N}v$ / $(u + v = a)$ for some $a \in \overline{M}_{k^{\log}} \setminus \{0\}$. Note that u and v are characterized as the generators of the faces of $\overline{M}_{X,e}$ isomorphic to N, so that, in particular, a is preserved by automorphisms of $\overline{M}_{X,e}$. Then $a = \pi^r$ for a unique $r \in \mathbb{Q}_{>0}$, and one can set $l_{X^{\log} \pi}(e) = r$ to get a metric $d_{X^{\log} \pi}$ on \mathbb{G}_X .

If X is an analytic \mathbb{C}_p -curve in the sense of Berkovich, the set $X_{[2]}$ of points of type 2 is endowed with a canonical metric (see [\[1,](#page-10-4) Prop. 4.5.7]). If $x, y \in X_{[2]}$, let an annular path from x to y be a sequence $p = (x = x_0, A_1, x_1, A_2, \dots, A_n, x_n =$ y), where for all i, $x_i \in X_2$ and A_i is a annulus embedded in X with endpoints x_{i-1} and x_i . The length of the path $p = (x = x_0, A_1, x_1, A_2, \dots, A_n, x_n = y)$ is then defined to be $\ell(p) = \sum_{i=1}^{n} r_{\text{norm}}(A_i)$ and the distance between x and y is $d(x, y) = \inf_{p} l(p)$ where the infimum goes through all annular paths from x to y. If X is topologically simply connected, $d(x, y) = l(p)$ for all annular path $p = (x =$ $x_0, A_1, x_1, A_2, \cdots, A_n, x_n = y$ such that, for all $i \neq j$, $A_i \cap A_j = \emptyset$.

Let $\mathfrak X$ be a proper semistable log curve over $\mathbb C_p$ with smooth generic fiber. Let π : $\mathfrak{X}_\eta^{\rm an} \to \mathfrak{X}_s$ be the specialisation map from the analytic generic fiber to the special fiber. Let $V(\mathfrak{X}_s)$ be the set of generic points of \mathfrak{X}_s , $N(\mathfrak{X}_s)$ be the set of nodal points of \mathfrak{X}_s and $S(\mathfrak{X}) = \pi^{-1}(V(\mathfrak{X}_s))$. Then π induces a bijection $S(\mathfrak{X}) \to V(\mathfrak{X}_s)$ and $S(\mathfrak{X})$ is a triangulation of $\mathfrak{X}_\eta^{\rm an}$ in the sense of [\[1,](#page-10-4) §5.1.13]. If $z \in N(\mathfrak{X}_s)$, then $\pi^{-1}(z)$ is an open annulus and $r_{\text{norm}}(\pi^{-1}(z)) = l_{\mathfrak{X}_s^{\log}/p}(z)$. Moreover, the distance between two points of $S(\mathfrak{X})$ is reached by an annular path $p = (x = x_0, A_1, x_1, A_2, \dots, A_n, x_n = y)$ such that for all *i* there exists $z_i \in N(\mathfrak{X}_s)$ such that $A_i = \pi^{-1}(z_i)$. When one identifies $S(\mathfrak{X})$ and $V(\mathfrak{X}_s)$ along π , $d_{\mathfrak{X}_s^{\log},p}$ and the restriction of the canonical distance $d_{\mathfrak{X}_\eta^{\rm an}}$ to $S(\mathfrak{X})$ therefore coincide.

Proposition 3.1. *Keep the assumptions and the notations of proposition* [\(2.1\)](#page-4-0)*. Then* $\bar{\alpha}$ *preserves the points of type* 2 *and* 3 *and preserves the canonical distance on points of type* 2*: if* $x, y \in X_{1,2}$ *, then* $d(\bar{\alpha}(x), \bar{\alpha}(y)) = d(x, y)$ *.*

Proof. In $\overline{X}_1^{\text{an}}$ $\frac{a_n}{1}$, a point x is of type 2 if and only if $\overline{X}_1^{\text{an}}$ $\binom{1}{1}$ as more than two connected components and is of type 3 if and only if $\overline{X}_1^{\text{an}}\setminus\{x\}$ has exactly two connected component. In particular points of type 2 (resp. 3) are preserved by arbitrary automorphisms, and therefore by $\bar{\alpha}$.

Let $x, y \in X^{\text{an}}_{1,[2]}$ and let $p = (x = x_0, A_1, x_1, A_2, \dots, A_n, x_n = y)$ be an annular path. By resolution of non singularities, there exists a finite étale cover $f: Y_1 \to X_1$ such that for every $i \leq n$, $f^{-1}(x_i) \cap V(Y_1) \neq \emptyset$. One can moreover assume that $f: Y_1 \to X_1$ is a Galois cover, and let $G = \text{Gal}(Y_1/X_1)$. Then, since $V(Y_1)$ is Gequivariant, for every $i, f^{-1}(x_i) \subset V(Y_1)$. Up to refining p, one may assume that one

can lift p to a path $(y_0, B_1, y_1, B_2, \dots, B_n, y_n)$ of Y_1 such that $B_i = sp_{Y_1}^{-1}(e_i)$ where e_i is a node of the special fiber $\mathfrak{Y}_{1,s}$ of the stable model of Y_1 . Then $r_{\text{norm}}(A_i)$ = $l_{\mathfrak{Y}_{1,s}^{\log}}(e_i)/|\mathrm{Stab}_G(\tilde{e}_i)|$, and $l(p) = \sum_i l_{\mathfrak{Y}_{1,s}^{\log}}(e_i)/|\mathrm{Stab}_G(\tilde{e}_i)|$. Let Y_2 be the corresponding cover of X_2 . Since the isomorphism of graphs $\mathbb{G}_{Y_1} \to \mathbb{G}_{Y_2}$ is G -equivariant and actually comes from an isomorphism of log-schemes $\mathfrak{Y}_{1,s}^{\log} \to \mathfrak{Y}_{2,s}^{\log}$, one deduces that $\bar{\alpha}$ preserves the length of p, and therefore the metric.

Proposition 3.2. *Keep the assumptions and the notations of proposition* [\(2.1\)](#page-4-0)*. Then* $\bar{\alpha}$ *preserves the types of the points.*

Proof. In $\overline{X}_1^{\text{an}}$ $\frac{1}{1}$, a point x is of type 2 if and only if $\frac{1}{X}$ $\frac{1}{1}$ $\binom{1}{1}$ as more than two connected components and is of type 3 if and only if $\overline{X}_1^{\text{an}}$ $\binom{1}{1}$ as exactly two connected component. In particular points of type 2 (resp. 3) are preserved by arbitrary automorphisms, and therefore by $\bar{\alpha}$. We still need to distinguish points of type 1 from points of type 4. (X_i^{an}) $\sum_{i=1}^{\text{an}}$ (2) is endowed with a natural metric d_i and a point x of $\overline{X}_i^{\text{an}}$ $\sum_{i=1}^{n}$ is of type 1 if and only if for every sequence $(x_n) \in (\overline{X}_i^{\text{an}})$ $\binom{\text{an}}{i}$ ($\binom{3}{2}$ that converges to x , $d(x_0, x_n)$ goes to infinity. But the restriction of d_i to $V(X_i)$ can be recovered (up to a multiplicative constant, which is determined by the absolute ramification index of K_i , which can be recovered from $\pi_1(X_i)$) by the log-structure on $\mathfrak{X}_{i,s}$. By doing so for every $\mathfrak{Y}_{i,s}$, one gets that for every $x, x' \in (\overline{X}_1^{\text{an}})$ $\binom{a_{1}}{1}$ ₍₂₎, $d_{1}(x, x') = d_{2}(\bar{\alpha}(x), \bar{\alpha}(x'))$. But a point x of $\overline{X}_i^{\rm an}$ $\sum_{i=1}^{a}$ is of type 1 if and only if for every sequence $(x_n) \in (\overline{X}_i^{\text{an}})$ $\binom{an}{i}\binom{N}{2}$ that converges to x, $d(x_0, x_n)$ goes to infinity. Therefore, $\overline{\alpha}$ also preserves points of type 1. 口

Theorem 3.3. Let X_1/K_1 and X_2/K_2 be two p-adic hyperbolic curves satisfying rns *and let* $\widetilde{X}_i/\widetilde{K}_i$ *be a universal cover of* X_1/K_1 *. Let* $\alpha : \pi_1(X_1, \widetilde{X}_1) \to \pi_1(X_2, \widetilde{X}_2)$ *be an isomorphism of fundamental groups. Then* α *is induced by a unique isomorphism* $X_1 \rightarrow X_2$.

Proof. Let \tilde{x}_1 be a closed point of \tilde{X}_1 . Then the decomposition group $D_{\tilde{x}_1}$ is the stabilizer of \tilde{x}_1 for the action of $\pi_1(X_1)$ on $\tilde{X}_1|_c$. Therefore, the equivariance of $\bar{\alpha}$ tells us that $\alpha(D_{\tilde{x}_1}) = D_{\bar{\alpha}(\tilde{x}_1)}$. According to Prop. [2.1,](#page-4-0) $\bar{\alpha}(\tilde{x}_1)$ is of type 1, so that $\mathcal{H}(x_1)$ is a closed subfield of \mathbb{C}_p . Since $k(x_1)$ is a finite extension of \mathbb{Q}_p , the image of $D_{\tilde{x}_1}$ inside G_{K_1} is open, therefore $\alpha(D_{\tilde{x}_1}) = D_{\bar{\alpha}(\tilde{x}_1)}$ maps to an open subgroup of G_{K_2} , so that $\mathcal{H}(x_2)$ is a finite extension of \mathbb{Q}_p . Therefore $\alpha(D_{\tilde{x}_1})$ is the decomposition group of a closed point of \tilde{X}_2 . The result then follows from [\[7,](#page-10-1) Thm 2.9]. \Box

4 Geometric characterization of the type of points

Let C be a algebraically closed complete non archimedean field of mixed characteristics $(0, p)$.

Proposition 4.1. *Let* $D = \mathcal{M}(\mathrm{C}\{T\})$ *be a disk; let* η *be its Gauss point, and let* $c \in H^1(D, \mathbb{Z}_p(1)) = \text{Hom}(\pi_1^{\text{\'et}}(D), \mathbb{Z}_p(1)).$ For $n \geq 1$, let $f_n : Y_n \to D$ be the *corresponding* μ_{p^n} *-torsor, so that* $\pi_1^{\text{\'et}}(Y_n) = c^{-1}(p^n \mathbb{Z}_p(1)) \subset \pi_1^{\text{\'et}}(D)$.

1. $\left| \frac{HT_D(c)}{dT} \right|_{\eta} \leq 1;$

2. For every $n \geq 1$, if f_n splits over η , then $\left|\frac{HT_D(c)}{dT}\right|_{\eta} \leq \frac{1}{p^n}$.

Proof. 1. If $c = \kappa(f)$ with $f \in O^{\times}(D)$, then $HT_D(c) = \frac{df}{f}$. Up to multiplying f by a constant in C, one can assume that $|f|_{\eta} = 1$. Then $\left| \frac{HT_D(c)}{dT} \right|_{\eta} = \left| \frac{df}{dT} \right|_{\eta} \leq 1$. In general, the restriction of c to any proper closed disk is in the image of the Kummer map. In particular, if z is the Gauss point of a closed disk of radius $r \in$ $(0,1) \cap |C^{\times}|$, one deduce from the previous argument applied to the parameter $a^{-1}T$ where $|a| = r$ that $\left|\frac{HT_D(c)}{dT}\right|_{\eta_r} \leq \frac{1}{r}$. When r converges to 1, one gets that $\left|\frac{HT_D(c)}{dT}\right|_{\eta} \leq 1.$

2. Assume f_n splits over η . Then it splits over a neighborhood of η , which contains a small annulus $\{r \leq |T| \leq 1\}$. By gluing with the trivial μ_{p^n} -torsor over the disk $\{0 \leq |\frac{1}{T}| \leq \frac{1}{r}\}$ centered at infinity, one obtains a μ_{p^n} -torsor over \mathbb{P}^1 , which is necessarily trivial. Therefore f_n is a trivial μ_{p^n} -torsor.

The pullback $f_n^*c \in \text{Hom}(\pi_1^{\text{alg}}(Y_n), \mathbb{Z}_p(1))$ has its image in $\text{Hom}(\pi_1^{\text{alg}}(Y_n), p^n\mathbb{Z}_p(1)),$ so there exists $c' \in \text{Hom}(\pi_1^\text{alg}(Y_n), \mathbb{Z}_p(1))$ such that $f_n^*c = p^n c'$, and so $f_n^* H T_{Y_n}(c) =$ $p^n HT_{Y_n}(c')$. If f_n is a trivial cover, let $s: D \to Y_n$ be a section of f_n . Then $HT_D(c) = p^n HT_D(s^*c')$ and therefore $\left|\frac{HT_D(c)}{dT}\right|_{\eta} = \frac{1}{p^n} \left|\frac{HT_D(s^*c')}{dT}\right|_{\eta} \le \frac{1}{p^n}$.

Proposition 4.2. *Let* X *be a hyperbolic curve over* C*. Let* $x \in X^{an}$ *be a type* 4 *point.* Let $c \in Hom(\pi_1^{\text{\'et}}(X), \mathbb{Z}_p(1))$ *such that* $\text{HT}_X(c) \neq 0$ *. Then* c *is not split over* x*: its restriction* $c_{D_x} \in \text{Hom}(D_x, \mathbb{Z}_p(1))$ *to the decomposition group* D_x *is non-zero.*

Proof. Let $f_n: Y_n \to X$ be the μ_{p^n} -torsor induced by c.

The point x is contained in a closed disk. Since $HT(c)$ vanishes in D only at finitely many points of type 1, one can assume after replacing D by a smaller disk that $HT(c)$ does not vanish on D. Let T be a parameter on D. Then $\frac{HT(c)}{dT}$ has constant norm λ on D. Let us normalize the radii of subdisks of D such that $r({|T - a| \le \alpha}) = \alpha$. Then if $f_n: Y_n \to X$ is split over a strict closed disk D then $r(D) \leq \frac{\lambda}{p^n}$. Then there exists a decreasing sequence of strict closed disks $(D_k)_{k\in\mathbb{N}}$ in D such that $x = \lim_k \eta_{D_k}$ where η_{D_k} is the Gauss point of D_k . Since x if of type 4, $r := \lim_k r(D_k) > 0$. In particular, there exists $n \in \mathbb{N}$ such that $\frac{\lambda}{p^n} < r$. Therefore, for every $k \in \mathbb{N}$, $\frac{\lambda}{p^n} < r(D_k)$, so that $Y_n \to X$ does not split over x_k . Therefore it does not split over x either. In particular $c_{D_x} \neq 0.$ П

This criterion gives another proof of proposition [3.2](#page-7-0) that does not use the recovery of the log structure on the special fiber. This allows to deduce the following purely geometric analogue of [3.2.](#page-7-0)

Definition 4.1. Let Π be a topological group.

One denotes by $RNS(\Pi)$ the following property: there exists a hyperbolic curve X over an algebraically closed complete non-archimedean field C of mixed characteristics $(0, p)$ which satisfies resolution of non-singularity and an isomorphism $a : \Pi \rightarrow$ $\pi_1^{\text{temp}}(X,\widetilde{X}).$

Such an isomorphism $a: \Pi \to \pi_1^{\text{temp}}(X, \widetilde{X})$ will be called a geometric setting of Π.

Let Π be a topological group such that $RNS(\Pi)$ is true. By [\[2,](#page-10-7) Th. 3.39], one has a group-theoretical graph that recovers the graph of the stable reduction in the same way as in [\[6\]](#page-10-6) over discretely valued fields. More precisely, one sets $\mathbb{G}(\Pi)$ to be the graph whose vertices are conjugacy classes of maximal compact subgroups of Πprime−to−^p and whose edges are conjugacy classes of non-trivial intersections of two distinct maximal compact subgroups of $\Pi^{\text{prime-to-p}}$. Then any geometric setting a : $\Pi \to \pi_1^{\text{temp}}(X)$ induces an isomorphism $\mathbb{G}(\Pi) \to \mathbb{G}(X)$.

Then, the construction of [\[3,](#page-10-2) §3.3] (or the construction in the proof of [2.1\)](#page-4-0) extends without modification to this context (the only slight difference is that in the notations of [\[3,](#page-10-2) §3.3], A_e is no longer isomorphic to $\mathbb{Q} \cap (0,1)$ in general, but to $v(\mathbb{C}^\times) \cap (0,1)$ where $v(C^{\times})$ is the value group of C): one obtains a topological space $\widetilde{X}_c(\Pi)$ endowed with a continuous action of Π , and for every geometric setting $a:\Pi \to \pi_1^\mathrm{temp}(X, \widetilde{X})$ a unique equivariant homeomorphism $\tilde{a}_c : \tilde{X}_c(\Pi) \to |\tilde{X}^{\rm an}|_c$.

Let $\overline{X}(\Pi) = \widetilde{X}_c(\Pi)/\Pi$. If $\tilde{x} \in \widetilde{X}_c(\Pi)$, let $D_{\tilde{x}} = \text{Stab}_{\Pi}(\tilde{x})$. If $x \in \overline{X}(\Pi)$, let $D_x = D_{\tilde{x}}$, where \tilde{x} is a preimage of x in $\tilde{X}(\Pi)$, so that it is only well-defined up to conjugation. If $\Pi = \pi_1^{\text{temp}}(X)$, then D_x coincides with the image of the outer morphism $G_{\mathcal{H}(x)} \to \Pi_X$ induced by the morphism of analytic spaces $\mathcal{M}(\mathcal{H}(x)) \to$ X^{an} , where $G_{\mathcal{H}(x)}$ is the absolute Galois group of $\mathcal{H}(x)$.

Cusps of $\overline{X}(\Pi)$ are end-points x of $\overline{X}(\Pi)$ (in the sense that the set of open neighborhoods U of x such that $U \setminus \{x\}$ is connected are cofinal among open neighborhoods of x) such that D_x is isomorphic to $\hat{\mathbb{Z}}$, and we denote by $X(\Pi) = \overline{X}(\Pi)\setminus{\text{cusps}}$. Then for every geometric setting $a: \Pi \to \pi_1^{\text{temp}}(X, \widetilde{X})$, \tilde{a}_c restricts to a homeomorphism $X(\Pi) \to |X^{\text{an}}|$ (it follows for example from the following proposition [4.3\)](#page-9-0).

Definition 4.2. Let $x \in X(\Pi)$. Let l be a prime number different from p. Then x is said to be of type:

- 1 if $D_x = \{1\};$
- 2 if D_x has a non abelian pro-l subquotient;
- 3 if D_x has a non trivial pro-l subquotient but every pro-l subquotient of D_x is abelian.
- 4 if D_x is a non-trivial pro-p group.

Proposition 4.3. For any geometric setting $a : \Pi \to \pi_1^{\text{temp}}(X)$, the isomorphism $\bar{a}: X(\Pi) \simeq |X^{\text{an}}|$ preserves the types of points. In particular, the type of a point in *definition [4.2](#page-9-1) is independent from* l*.*

Proof. From the definition [4.2,](#page-9-1) it is clear that a point in $X(\Pi_Z)$ cannot be of two different types. It is therefore sufficient to show that if $x \in Z^{an}$ is of a given type, $D_x \subset \Pi_Z$ satisfies the corresponding property in definition [4.2.](#page-9-1)

1. Assume x is of type 1. Then $D_x = \{1\}$ because $\mathcal{H}(x) = C$ is algebraically closed.

- 2. Assume x is of type 2. By resolution of non-singularities, there exists a finite cover $f: Y \to Z$ and $y \in f^{-1}(\{x\}) \cap V(Y)$. Then $D_y = D_x \cap \Pi_Y$ (for some choice of D_x inside its conjugacy class), and the image of D_y in $\Pi_Y^{\text{prime-to-p}}$ is isomorphic to $\pi_1^{\text{\'et}}(U)^{\text{prime-to}-p}$ where U is the smooth locus in the irreducible component of the special fiber of the stable model of Y corresponding to the specialisation of y. Since U is an hyperbolic curve over the residue field C of C, D_y has a non abelian pro-l quotient.
- 3. Assume x is of type 3. By resolution of non-singularities, there exists a finite Galois cover $f: Y \to Z$ and $y \in f^{-1}(\lbrace x \rbrace)$ such that y belongs to the skeleton of Y^{an} . Then the image of D_y in $\Pi_Y^{\text{prime-to-p}}$ is isomorphic to $\mathbb{Z}(1)^{\text{prime-to-p}}$, and therefore has a non trivial pro-l quotient.

Since $\mathcal{H}(x)$ has an algebraically closed residue field, the absolute galois group $G_{\mathcal{H}(x)}$ of $\mathcal{H}(x)$ is equal to its inertia subgroup $I_{\mathcal{H}(x)}$. Since the wild inertia subgroup $W_{\mathcal{H}(x)}$ is a pro-p group, every subquotient of $G_{\mathcal{H}(x)}$ is isomorphic to a subquotient of $I_{\mathcal{H}(x)/W_{\mathcal{H}(x)}}$ and is therefore abelian (cf. [\[1,](#page-10-4) §2.3.19]).

4. Assume x is of type 4. Then according to proposition [4.2,](#page-8-0) D_x is non trivial. Since D_x is a quotient of the absolute Galois group of $\mathcal{H}(x)$, it is enough to show that its absolute galois group $G_{\mathcal{H}(x)}$ is a p-group. Since the residue field of $\mathcal{H}(x)$ is algebraically closed and its value group is divisible, $G_{\mathcal{H}(x)}$ is equal to its wild inertia subgroup $W_{\mathcal{H}(x)}$, which is a pro-p group.
