

TRUNCATED SECOND MAIN THEOREM FOR NON-ARCHIMEDEAN MEROMORPHIC MAPS

SI DUC QUANG

ABSTRACT. Let \mathbb{F} be an algebraically closed field of characteristic $p \geq 0$, which is complete with respect to a non-Archimedean absolute value. Let V be a projective subvariety of $\mathbb{P}^M(\mathbb{F})$. In this paper, we will prove some second main theorems for non-Archimedean meromorphic maps of \mathbb{F}^m into V intersecting a family of hypersurfaces in N -subgeneral position with truncated counting functions.

1. INTRODUCTION AND MAIN RESULTS

Let \mathbb{F} be an algebraically closed field of characteristic $p \geq 0$, which is complete with respect to a non-Archimedean absolute value. Let $N \geq n$ and $q \geq N + 1$. Let H_1, \dots, H_q be hyperplanes in $\mathbb{P}^n(\mathbb{F})$. The family of hyperplanes $\{H_i\}_{i=1}^q$ is said to be in N -subgeneral position in $\mathbb{P}^n(\mathbb{F})$ if $H_{j_0} \cap \dots \cap H_{j_N} = \emptyset$ for every $1 \leq j_0 < \dots < j_N \leq q$.

In 2017, Yan [6] proved a truncated second main theorem for a non-Archimedean meromorphic map into $\mathbb{P}^n(\mathbb{F})$ with a family of hyperplanes in subgeneral position. With the standart notations on the Nevanlinna theory for non-Archimedean meromorphic maps, his result is stated as follows.

Theorem A (cf. [6, Theorem 4.6]) *Let \mathbb{F} be an algebraically closed field of characteristic $p \geq 0$, which is complete with respect to a non-Archimedean absolute value. Let $f : \mathbb{F}^m \rightarrow \mathbb{P}^n(\mathbb{F})$ be a linearly non-degenerate non-Archimedean meromorphic map with index of independence s and $\text{rank } f = k$. Let H_1, \dots, H_q be hyperplanes in $\mathbb{P}^n(\mathbb{F})$ in N -subgeneral position ($N \geq n$). Then, for all $r \geq 1$,*

$$(q - 2N + n - 1)T_f(r) \leq \sum_{i=1}^q N_f^{(a)}(H_i, r) - \frac{N + 1}{n + 1} \log r + O(1),$$

where

$$a = \begin{cases} p^{s-1}(n - k + 1) & \text{if } p > 0, \\ n - k + 1 & \text{if } p = 0. \end{cases}$$

Here, the index of independence s and the $\text{rank } f$ are defined in Section 2 (Definition 3).

Also, in 2017, An and Quang [2] proved a truncated second main theorem for meromorphic mappings from \mathbb{C}^m into a projective variety $V \subset \mathbb{P}^M(\mathbb{C})$ with hypersurfaces. Motivated by the methods of Yan [6] and An-Quang [2], our aim in this article is to generalize Theorem A to the case where the map f is from \mathbb{F}^m into an arbitrary projective

Key words and phrases. non-Archimedean, second main theorem, meromorphic mapping, Nevanlinna, hypersurface, subgeneral position.

variety V of dimension n in $\mathbb{P}^M(\mathbb{F})$ and the hyperplanes are replaced by hypersurfaces of $\mathbb{P}^M(\mathbb{F})$ in N -subgeneral position with respect to V .

Firstly, we give the following definitions.

Definition B. *Let V be a projective subvariety of $\mathbb{P}^M(\mathbb{F})$ of dimension n ($n \leq M$). Let Q_1, \dots, Q_q ($q \geq n+1$) be q hypersurfaces in $\mathbb{P}^M(\mathbb{F})$. The family of hypersurfaces $\{Q_i\}_{i=1}^q$ is said to be in N -subgeneral position with respect to V if*

$$V \cap \left(\bigcap_{j=1}^{N+1} Q_{i_j} \right) = \emptyset \quad \text{for any } 1 \leq i_1 < \dots < i_{N+1} \leq q.$$

If $N = n$, we just say $\{Q_i\}_{i=1}^q$ is in general position with respect to V .

Now, let V be as above and let d be a positive integer. We denote by $I(V)$ the ideal of homogeneous polynomials in $\mathbb{F}[x_0, \dots, x_M]$ defining V and by H_d the \mathbb{F} -vector space of all homogeneous polynomials in $\mathbb{F}[x_0, \dots, x_M]$ of degree d . Define

$$I_d(V) := \frac{H_d}{I(V) \cap H_d} \quad \text{and} \quad H_V(d) := \dim_{\mathbb{F}} I_d(V).$$

Then $H_V(d)$ is called the Hilbert function of V . Each element of $I_d(V)$ which is an equivalent class of an element $Q \in H_d$, will be denoted by $[Q]$,

Definition C. *Let $f : \mathbb{F}^m \rightarrow V$ be a non-Archimedean meromorphic map with a reduced representation $\mathbf{f} = (f_0, \dots, f_M)$. We say that f is degenerate over $I_d(V)$ if there is $[Q] \in I_d(V) \setminus \{0\}$ such that $Q(\mathbf{f}) \equiv 0$. Otherwise, we say that f is non-degenerate over $I_d(V)$.*

We will generalize Theorem A to the following.

Theorem 1. *Let V be a projective subvariety of $\mathbb{P}^M(\mathbb{F})$ of dimension n ($n \leq M$). Let $\{Q_i\}_{i=1}^q$ be hypersurfaces of $\mathbb{P}^M(\mathbb{F})$ in N -subgeneral position with respect to V with $\deg Q_i = d_i$ ($1 \leq i \leq q$). Let d be the least common multiple of d_i 's. Let f be a non-Archimedean meromorphic map of \mathbb{F}^m into V , which is non-degenerate over $I_d(V)$ with the d^{th} -index of non-degeneracy s and $\text{rank } f = k$. Then, for all $r \geq 1$,*

$$\left(q - \frac{(2N + n - 1)H_d(V)}{n + 1} \right) T_f(r) \leq \sum_{i=1}^q \frac{1}{d_i} N_f^{(\kappa_0)}(Q_i, r) - \frac{N(H_d(V) - 1)}{nd} \log r + O(1),$$

where

$$\kappa_0 = \begin{cases} p^{s-1}(H_d(V) - k) & \text{if } p > 0, \\ H_d(V) - k & \text{if } p = 0. \end{cases}$$

Here, the d^{th} -index of non-degeneracy s is defined in Section 2 (Definition 3). Note that, in the case where $V = \mathbb{P}^n(\mathbb{C})$, $d = 1$, $H_d(V) = n + 1$, our result will give back Theorem A.

For the case of counting function without truncation level, we will prove the following.

Theorem 2. *Let V be a arbitrary projective subvariety of $\mathbb{P}^M(\mathbb{F})$. Let $\{Q_i\}_{i=1}^q$ be hypersurfaces of $\mathbb{P}^M(\mathbb{F})$ in N -subgeneral position with respect to V . Let f be a non-constant non-Archimedean meromorphic map of \mathbb{F}^m into V . Then, for any $r > 0$,*

$$(q - N)T_f(r) \leq \sum_{i=1}^q \frac{1}{\deg Q_i} N_f(Q_i, r) + O(1),$$

where the quantity $O(1)$ depends only on $\{Q_i\}_{i=1}^q$.

We see that, the above result is a generalization of the previous results in [1, 5].

2. BASIC NOTIONS AND AUXILIARY RESULTS

In this section, we will recall some basic notions from Nevanlinna theory for non-Archimedean meromorphic maps due to Cherry-Ye [3] and Yan [6].

2.1. Non-Archimedean meromorphic function. Let \mathbb{F} be an algebraically closed field of characteristic p , complete with respect to a non-Archimedean absolute value $|\cdot|$. We set $\|z\| = \max_{1 \leq i \leq m} |z_i|$ for $z = (z_1, \dots, z_m) \in \mathbb{F}^m$ and define

$$\mathbb{B}^m(r) := \{z \in \mathbb{F}^m; \|z\| < r\}.$$

For a multi-index $\gamma = (\gamma_1, \dots, \gamma_m) \in \mathbb{Z}_{\geq 0}^m$, define

$$z^\gamma = z_1^{\gamma_1} \cdots z_m^{\gamma_m}, \quad |\gamma| = \gamma_1 + \cdots + \gamma_m, \quad \gamma! = \gamma_1! \cdots \gamma_m!.$$

For an analytic function f on \mathbb{F}^m (i.e., entire function) given by a formal power series

$$f = \sum_{\gamma} a_{\gamma} z^{\gamma}$$

with $a_{\gamma} \in \mathbb{F}$ such that $\lim_{|\gamma| \rightarrow \infty} |a_{\gamma}| r^{|\gamma|} = 0$ ($\forall r \in \mathbb{F}^* = \mathbb{F} \setminus \{0\}$), define

$$|f|_r = \sup_{\gamma} |a_{\gamma}| r^{|\gamma|}.$$

We denote by \mathcal{E}_m the ring of all analytic functions on \mathbb{F}^m .

We define a meromorphic function f on \mathbb{F}^m to be the quotient of two analytic functions $g, h \in \mathcal{E}_m$ such that g and h have no common factors in \mathcal{E}_m , i.e., $f = \frac{g}{h}$. We define

$$|f|_r = \frac{|g|_r}{|h|_r}.$$

We denote by \mathcal{M}_m the field of all meromorphic functions on \mathbb{F}^m , which is the fractional field of \mathcal{E}_m .

2.2. Derivatives and Hasse derivatives. For a meromorphic function $f \in \mathcal{M}_m$ and a multi-index $\gamma = (\gamma_1, \dots, \gamma_m)$, we set

$$\partial^{\gamma} f = \frac{\partial^{|\gamma|} f}{\partial z_1^{\gamma_1} \cdots \partial z_m^{\gamma_m}}.$$

Let $\alpha = (\alpha_1, \dots, \alpha_m)$ and $\beta = (\beta_1, \dots, \beta_m)$ be multi-indices. We say that $\alpha \geq \beta$ if $\alpha_i \geq \beta_i$ for all $i = 1, \dots, m$. If $\alpha \geq \beta$, we define

$$\alpha - \beta = (\alpha_1 - \beta_1, \dots, \alpha_m - \beta_m), \quad \binom{\alpha}{\beta} = \binom{\alpha_1}{\beta_1} \cdots \binom{\alpha_m}{\beta_m}.$$

For an analytic function $f = \sum_{\alpha} a_{\alpha} z^{\alpha}$ and a multi-index γ , we define the Hasse derivative of multi-index γ of f by

$$D^{\gamma} f = \sum_{\alpha \geq \gamma} \binom{\alpha}{\gamma} a_{\alpha} z^{\alpha - \gamma}.$$

We may verify that $D^\alpha D^\beta f = \binom{\alpha+\beta}{\beta} D^{\alpha+\beta} f$ for all $f \in \mathcal{E}_m$. Therefore, the Hasse derivative D can be extended to meromorphic functions in the following way:

- For a multi-index $e_i = (0, \dots, 0, \overset{j^{th}\text{-position}}{1}, 0, \dots, 0)$, we set $D_j^k f := D^{ke_i}(f)$.
- For a meromorphic function $f = \frac{g}{h}$ ($g, h \in \mathcal{E}_m$), we define

$$D^{e_i} f = D_j^1 f := \frac{hD_i^1 g - gD_i^1 h}{h^2}, \quad j = 1, \dots, m.$$

- For $\gamma = (\gamma_1, \dots, \gamma_m)$, we may choose a sequence of multi-indices $\gamma = \alpha^1 > \alpha^2 > \dots > \alpha^{|\gamma|}$ such that $\alpha^i = \alpha^{i+1} + e_{j_i}$ ($j_i \in \{1, \dots, m\}$) for $1 \leq i \leq |\gamma| - 1$ and $\alpha^{|\gamma|} = e_{j_{|\gamma|}}$ ($j_{|\gamma|} \in \{1, \dots, m\}$) and define

$$D^{\alpha^i} h = \frac{1}{\binom{\alpha_{i+1} + e_{j_i}}{\alpha_{i+1}}} D^{e_{j_i}} D^{\alpha_{i+1}} h, \quad \forall i = |\gamma| - 1, |\gamma| - 2, \dots, 1.$$

We summarize here the fundamental properties of the Hasse derivative from [6] as follows:

- (i) $D^\gamma(f + g) = D^\gamma f + D^\gamma g$, $f, g \in \mathcal{M}_m$.
- (ii) $D^\gamma(fg) = \sum_{\alpha, \beta} D^\alpha f D^\beta g$, $f, g \in \mathcal{M}_m$.
- (iii) $D^\alpha D^\beta f = \binom{\alpha+\beta}{\beta} D^{\alpha+\beta} f$, $f \in \mathcal{M}_m$.
- (iv) (Lemma on the logarithmic derivative) For $f \in \mathcal{E}_m$,

$$|D^\gamma f|_r \leq \frac{|f|_r}{r^{|\gamma|}}, \quad |\partial^\gamma f|_r \leq \frac{|f|_r}{r^{|\gamma|}}.$$

(v) For $f \in \mathcal{E}_m$ and a multi-index γ , let P be an irreducible element of \mathcal{E}_m that divides f with exact multiplicity e . If $e > |\gamma|$, then $P^{e-|\gamma|}$ divides $D^\gamma f$.

For each integer $k \geq 2$, let

$$\mathcal{M}_m[k] = \{Q \in \mathcal{M}_m : D_j^i Q \equiv 0 \text{ for all } 0 < i < k \text{ and } 1 \leq j \leq m\}.$$

If F has characteristic 0, then $\mathcal{M}_m[k] = \mathbb{F}$ for all $k \geq 2$. If \mathbb{F} has characteristic $p > 0$ and if $s \geq 1$ is an integer, then $\mathcal{M}_m[p^s]$ is the fraction field of \mathcal{E}_m , where $\mathcal{E}_m[p^s] = \{g^{p^s} : g \in \mathcal{E}_m\}$ is a subring of \mathcal{E}_m . Moreover,

$$\mathcal{M}_m[p^{s-1} + 1] = \mathcal{M}_m[p^s].$$

2.3. Non-Archimedean Nevanlinna's function.

Let $f = \sum_\gamma a_\gamma z^\gamma \in \mathcal{E}_m$ be an holomorphic function. The counting function of zeros of f is defined as follows:

$$N_f(0, r) = n_f(0, 0) \log r + \int_0^r (n_f(0, t) - n_f(0, 0)) \frac{dt}{t} \quad (r > 0),$$

where

$$n_f(0, r) = \sup\{|\gamma|; |a_\gamma| r^{|\gamma|} = |f|_r\} \text{ and } n_f(0, 0) = \min\{|\gamma|; a_\gamma \neq 0\}.$$

Let f be a meromorphic function on \mathbb{F}^m . Assume that $f = \frac{g}{h}$, where g, h are holomorphic functions without common factors. We define

$$N_f(0, r) = N_g(0, r) \text{ and } N_f(\infty, r) = N_h(0, r).$$

The Poisson-Jensen-Green formula (see [3, Theorem 3.1]) states that

$$N_f(0, r) - N_f(\infty, r) = \log |f|_r + C_f \quad \text{for all } r > 0,$$

where C_f is a constant depending on f but not on r .

Suppose that $f \not\equiv a$ for $a \in \mathbb{F}$. The counting function of f with respect to the point a is defined by

$$N_f(a, r) = N_{f-a}(0, r).$$

The proximity functions of f with respect to ∞ and a are defined respectively as follows

$$m_f(\infty, r) = \max\{0, \log |f|_r\} = \log^+ |f|_r \quad \text{and} \quad m_f(a, r) = m_{1/(f-a)}(\infty, r).$$

The characteristic function of f is defined by

$$T_f(r) = m_f(\infty, r) + N_f(\infty, r).$$

Note that, if $f = \frac{g}{h}$ as above then $T_f(r) = \max\{\log |g|_r, \log |h|_r\} + O(1)$.

The first main theorem is stated as follows:

$$T_f(r) = m_f(a, r) + N_f(a, r) + O(1) \quad (\forall r > 0).$$

2.4. Truncated counting function.

Let $f \in \mathcal{E}_m$. For $j = 1, \dots, m$, define

$$g_j = \gcd(f, D_j^1(f)) \quad \text{and} \quad h_j = \frac{f}{g_j}.$$

The radical $R(f)$ of f is defined to be the least common multiple of h_j 's.

Case 1: \mathbb{F} has characteristic $p = 0$. The truncated counting function of zeros of f is defined by

$$N_f^{(l)}(0, r) = N_{\gcd(f, R(f)^l)}(0, r).$$

In particular,

$$N_f^{(1)}(0, r) = N_{R(f)}(0, r).$$

Case 2: \mathbb{F} has characteristic $p > 0$. We define $R_{p^s}(f)$ by induction in $s = 0, 1, \dots$. For $s = 0$, set $R_{p^0}(f) = R(f)$. For $s \geq 1$, assume that $R_{p^{s-1}}(f)$ has been defined. We set

$$\bar{f} = \frac{f}{\gcd(f, R_{p^{s-1}}(f)^{p^s})}, \quad g_i = \gcd(\bar{f}, D_i^{p^s} \bar{f}), \quad h_i = \frac{\bar{f}}{g_i}$$

for $i = 1, \dots, m$. Let H be the least common multiple of h_i 's, and set

$$G = \frac{H}{\gcd(H, R_{p^{s-1}}(H)^{p^{s-1}})},$$

which is a p^s th power. Let R be the p^s th root of G and define the higher p^s -radical $R_{p^s}(f)$ of f to be the least common multiple of $R_{p^{s-1}}(f)$ and R .

Take a sequence $\{r_j\}_{j \in \mathbb{N}} \subset |\mathbb{F}^*|$ such that $r_j \rightarrow \infty$. Take s_j such that if $P \in \mathcal{E}_m$ is irreducible such that $P|f$ and P is not unit on $\mathbb{B}^m(r_j)$ then $P|R_{p^s}(f)$ for $s > s_j$. Let u_j be a unit on $\mathbb{B}^m(r_j)$ such that

$$R_{p^{s_j}}(f) = u_j R_{p^{s_j+1}}(f).$$

Define $v_j = \prod_{l=j}^{\infty} u_l$, which is unit on $\mathbb{B}^m(r_j)$, and

$$S(f) = \lim_{j \rightarrow \infty} \frac{R_{p^{s_j}}(f)}{v_j} \in \mathcal{E}_m,$$

which is called the square free part of f . The truncated (to level l) counting function of zeros of f is defined by

$$N_f^{(l)}(0, r) = N_{\gcd(f, S(f)^l)}(0, r).$$

2.5. Non-Archimedean meromorphic maps and family of hypersurfaces.

Let V be a projective subvariety of $\mathbb{P}^M(\mathbb{F})$ of dimension n ($n \leq M$). For a positive integer d , take a basis $\{[A_1], \dots, [A_{H_d(V)}]\}$ of $I_d(V)$, where $A_i \in \mathcal{H}_d[x_0, \dots, x_M]$. Let $f : \mathbb{F}^m \rightarrow \mathbb{P}^M(\mathbb{F})$ be a non-Archimedean meromorphic map with a reduced representation $\mathbf{f} = (f_0, \dots, f_M)$, which is non-degenerate over $I_d(V)$. We have the following definition.

Definition 3. *Assume that \mathbb{F} has the character $p > 0$. Denote by s the smallest integer such that any subset of $\{A_1(\mathbf{f}), \dots, A_{H_d(V)}(\mathbf{f})\}$ linearly independent over \mathbb{F} remains linearly independent over $\mathcal{M}_m[p^s]$. We call s is the d^{th} -index of non-degeneracy of f .*

We see that the above definition does not depend on the choice of the basis $\{[A_i]; 1 \leq i \leq H_d(V)\}$ and the choice of the reduced representation \mathbf{f} . If $V = \mathbb{P}^M(\mathbb{F})$ and $d = 1$ then s is also called the index of independence of f (see [6, Definition 4.1]).

The following three lemmas are proved in [2] for the case of $\mathbb{F} = \mathbb{C}$ and the canonical absolute value. However, with the same proof, they also hold for arbitrary algebraic closed field \mathbb{F} of character $p \geq 0$ and complete with an arbitrary absolute value. We state them here without the proofs.

Throughout this paper, we sometimes identify each hypersurface in a projective variety with its defining homogeneous polynomial. The following lemma of An-Quang [2] may be considered as a generalization of the lemma on Nochka weights in [4].

Lemma 4 (cf. [2, Lemma 3]). *Let V be a projective subvariety of $\mathbb{P}^M(\mathbb{F})$ of dimension n ($n \leq M$). Let Q_1, \dots, Q_q be q ($q > 2N - k + 1$) hypersurfaces in $\mathbb{P}^M(\mathbb{F})$ in N -subgeneral position with respect to V of the common degree d . Then there are positive rational constants ω_i ($1 \leq i \leq q$) satisfying the following:*

i) $0 < \omega_i \leq 1, \forall i \in \{1, \dots, q\}$,

ii) Setting $\tilde{\omega} = \max_{j \in Q} \omega_j$, one gets

$$\sum_{j=1}^q \omega_j = \tilde{\omega}(q - 2N + n - 1) + n + 1.$$

iii) $\frac{n+1}{2N-n+1} \leq \tilde{\omega} \leq \frac{n}{N}$.

iv) For $R \subset \{1, \dots, q\}$ with $\sharp R = N + 1$, then $\sum_{i \in R} \omega_i \leq n + 1$.

v) Let $E_i \geq 1$ ($1 \leq i \leq q$) be arbitrarily given numbers. For $R \subset \{1, \dots, q\}$ with $\sharp R = N + 1$, there is a subset $R^o \subset R$ such that $\sharp R^o = \text{rank}_{\mathbb{F}}\{[Q_i]; i \in R^o\} = n + 1$ and

$$\prod_{i \in R} E_i^{\omega_i} \leq \prod_{i \in R^o} E_i.$$

Let Q be a hypersurface in $\mathbb{P}^n(\mathbb{F})$ of degree d defined by $\sum_{I \in \mathcal{I}_d} a_I x^I = 0$, where $\mathcal{I}_d = \{(i_0, \dots, i_M) \in \mathbb{N}_0^{M+1} : i_0 + \dots + i_M = d\}$, $I = (i_0, \dots, i_M) \in \mathcal{I}_d$, $x^I = x_0^{i_0} \cdots x_M^{i_M}$ and $(x_0 : \dots : x_M)$ is homogeneous coordinates of $\mathbb{P}^M(\mathbb{F})$. Let f be a non-Archimedean meromorphic map from \mathbb{F}^m into a projective subvariety V of $\mathbb{P}^M(\mathbb{F})$ with a reduced representation $\mathbf{f} = (f_0, \dots, f_M)$. We define

$$Q(\mathbf{f}) = \sum_{I \in \mathcal{I}_d} a_I f^I,$$

where $f^I = f_0^{i_0} \cdots f_n^{i_n}$ for $I = (i_0, \dots, i_n)$. We have the following lemma.

Lemma 5 (cf. [2, Lemma 4]). *Let $\{Q_i\}_{i \in R}$ be a set of hypersurfaces in $\mathbb{P}^n(\mathbb{F})$ of the common degree d and let f be a meromorphic mapping of \mathbb{F}^m into $\mathbb{P}^n(\mathbb{F})$ with a reduced representation $\mathbf{f} = (f_0, \dots, f_M)$. Assume that $\bigcap_{i \in R} Q_i \cap V = \emptyset$. Then, there exist positive constants α and β such that*

$$\alpha \|\mathbf{f}\|_r^d \leq \max_{i \in R} |Q_i(\mathbf{f})|_r \leq \beta \|\mathbf{f}\|_r^d \text{ for any } r > 0.$$

Lemma 6 (cf. [2, Lemma 5]). *Let $\{Q_i\}_{i=1}^q$ be a set of q hypersurfaces in $\mathbb{P}^M(\mathbb{F})$ of the common degree d . Then there exist $(H_V(d) - n - 1)$ hypersurfaces $\{T_i\}_{i=1}^{H_V(d) - n - 1}$ in $\mathbb{P}^M(\mathbb{F})$ such that for any subset $R \in \{1, \dots, q\}$ with $\sharp R = \text{rank}_{\mathbb{F}}\{[Q_i]; i \in R\} = n + 1$, we get $\text{rank}_{\mathbb{F}}\{[Q_i]; i \in R\} \cup \{[T_i]; 1 \leq i \leq H_d(V) - n - 1\} = H_V(d)$.*

2.5. Value distribution theory for non-Archimedean meromorphic maps.

Let $f : \mathbb{F}^m \rightarrow V \subset \mathbb{P}^M(\mathbb{F})$ be a non-Archimedean meromorphic map with a reduced representation $\mathbf{f} = (f_0, \dots, f_N)$. The characteristic function of f is defined by

$$T_f(r) = \log \|\mathbf{f}\|_r,$$

where $\|\mathbf{f}\|_r = \max_{1 \leq i \leq n} |f_i|_r$. This definition is well-defined upto a constant.

Let Q be a hypersurface in $\mathbb{P}^n(\mathbb{F})$ of degree d defined by $\sum_{I \in \mathcal{I}_d} a_I x^I = 0$, where $a_I \in \mathbb{F}$ ($I \in \mathcal{I}_d$) and are not all zeros. If $Q(\mathbf{f}) \not\equiv 0$ then we define the proximity function of f with respect to Q by

$$m_f(Q, r) = \log \frac{\|\mathbf{f}\|_r^d \cdot \|Q\|}{|Q(\mathbf{f})|_r},$$

where $\|Q\| := \max_{I \in \mathcal{I}_d} |a_I|$. We see that the definition of $m_f(Q, r)$ does not depend on the choices of the presentations of f and Q .

The truncated (to level l) counting function of f with respect to Q is defined by

$$N_f^{(l)}(Q, r) := N_{Q(\mathbf{f})}^{(l)}(0, r).$$

For simplicity, we will omit the character $^{(l)}$ if $l = \infty$.

The first main theorem for non-Archimedean meromorphic maps states that

$$dT_f(r) = m_f(Q, r) + N_f(Q, r) + O(1).$$

Proposition 7 (cf. [6, Propositions 4.3, 4.4]). *Let p be the character of \mathbb{F} . Assume that $f : \mathbb{F}_m \rightarrow \mathbb{P}^n(\mathbb{F})$ is a non-Archimedean meromorphic map, which is linearly non-degenerate*

over \mathbb{F} , with a reduced representation $\mathbf{f} = (f_0, \dots, f_n)$. Then there exist multi-indices $\gamma^0 = (0, \dots, 0), \gamma^1, \dots, \gamma^n$ with

$$|\gamma^0| \leq \dots \leq |\gamma^n| \leq \kappa_0 \leq \begin{cases} p^{s-1}(n-k+1) & \text{if } p > 0, \\ n-k+1 & \text{if } p = 0 \end{cases}$$

where s is the index of independence of f and $k = \text{rank} f$, such that the generalized Wronskian

$$W_{\gamma^0, \dots, \gamma^n}(f_0, \dots, f_n) = \det \left(D^{\gamma^i} f_j \right)_{0 \leq i, j \leq n} \neq 0.$$

Here $\text{rank} f$ is defined by

$$\text{rank} f = \text{rank}_{\mathcal{M}_m} \{(D^\gamma f_0, \dots, D^\gamma f_n); |\gamma| \leq 1\} - 1.$$

3. PROOF OF MAIN THEOREMS

Proof of Theorem 1. By replacing Q_i with Q_i^{d/d_i} if necessary, we may assume that all Q_i ($i = 1, \dots, q$) do have the same degree d . It is easy to see that there is a positive constant β such that $\beta \|\mathbf{f}\|^d \geq |Q_i(\mathbf{f})|$ for every $1 \leq i \leq q$. Set $Q := \{1, \dots, q\}$. Let $\{\omega_i\}_{i=1}^q$ be as in Lemma 4 for the family $\{Q_i\}_{i=1}^q$. Let $\{T_i\}_{i=1}^{H_d(V)-n-1}$ be $(H_d(V) - n - 1)$ hypersurfaces in $\mathbb{P}^M(\mathbb{F})$, which satisfy Lemma 6.

Take a \mathbb{F} -basis $\{[A_i]\}_{i=1}^{H_V(d)}$ of $I_d(V)$, where $A_i \in H_d$. Since f is non-degenerate over $I_d(V)$, it implies that $\{A_i(\mathbf{f}); 1 \leq i \leq H_V(d)\}$ is linearly independent over \mathbb{F} . By Proposition 7, there multi-indices $\{\gamma^1 = (0, \dots, 0), \gamma^2, \dots, \gamma^{H_V(d)}\} \subset \mathbb{Z}_+^m$ such that $|\gamma^0| \leq \dots \leq |\gamma^{H_d(V)}| \leq \kappa_0$, where

$$\kappa_0 \leq \begin{cases} p^{s-1}(H_V(d) - k) & \text{if } p > 0, \\ H_d(V) - k & \text{if } p = 0 \end{cases}$$

and the generalized Wronskian

$$W = \det \left(D^{\gamma^i} A_j(\mathbf{f}) \right)_{1 \leq i, j \leq H_d(V)} \neq 0.$$

Here, we note that

$$\begin{aligned} k &= \text{rank}_{\mathcal{M}_m} \{(D^\gamma f_0, \dots, D^\gamma f_M); |\gamma| \leq 1\} - 1 \\ &= \text{rank}_{\mathcal{M}_m} \left\{ \left(D^\gamma \left(\frac{f_1}{f_0} \right), \dots, D^\gamma \left(\frac{f_M}{f_0} \right) \right); |\gamma| \leq 1 \right\} \\ &\leq \text{rank}_{\mathcal{M}_m} \left\{ \left(D^\gamma \left(\frac{A_2(\mathbf{f})}{A_1(\mathbf{f})} \right), \dots, D^\gamma \left(\frac{A_{H_d(V)}(\mathbf{f})}{A_1(\mathbf{f})} \right) \right); |\gamma| \leq 1 \right\} \\ &= \text{rank}_{\mathcal{M}_m} \{(D^\gamma(A_1(\mathbf{f})), \dots, D^\gamma(A_{H_d(V)}(\mathbf{f}))); |\gamma| \leq 1\} - 1. \end{aligned}$$

For each $R^\circ = \{r_1^0, \dots, r_{n+1}^0\} \subset \{1, \dots, q\}$ with $\text{rank}_{\mathbb{F}} \{Q_i\}_{i \in R^\circ} = \#R^\circ = n+1$, set

$$W_{R^\circ} \equiv \det \left(D^{\gamma^j} Q_{r_v^0}(\mathbf{f})(1 \leq v \leq n+1), D^{\gamma^l} T_l(\mathbf{f})(1 \leq l \leq H_V(d) - n - 1) \right)_{1 \leq j \leq H_V(d)}.$$

Since $\text{rank}_{\mathbb{F}} \{[Q_{r_v^0}](1 \leq v \leq n+1), [T_l](1 \leq l \leq H_V(d) - n - 1)\} = H_V(d)$, there exists a nonzero constant $C_{R^\circ} \in \mathbb{F}$ such that $W_{R^\circ} = C_{R^\circ} \cdot W$.

We denote by \mathcal{R}^o the family of all subsets R^o of $\{1, \dots, q\}$ satisfying

$$\text{rank}_{\mathbb{F}}\{[Q_i]; i \in R^o\} = \#R^o = n + 1.$$

For each $r > 0$, there exists $\bar{R} \subset Q$ with $\#\bar{R} = N + 1$ such that $|Q_i(\mathbf{f})|_r \leq |Q_j(\mathbf{f})|_r, \forall i \in \bar{R}, j \notin \bar{R}$. We choose $R^o \subset R$ such that $R^o \in \mathcal{R}^o$ and R^o satisfies Lemma 4(v) with respect to numbers $\left\{\frac{\beta\|\mathbf{f}\|_r^d}{|Q_i(\mathbf{f})|_r}\right\}_{i=1}^q$. Since $\bigcap_{i \in \bar{R}} Q_i = \emptyset$, by Lemma 5, there exists a positive constant $\alpha^{\bar{R}}$ such that

$$\alpha^{\bar{R}}\|\mathbf{f}\|_r^d \leq \max_{i \in \bar{R}} |Q_i(\mathbf{f})|_r.$$

Then, we get

$$\begin{aligned} \frac{\|\mathbf{f}\|_r^{d(\sum_{i=1}^q \omega_i)} |W|_r}{|Q_1(\mathbf{f})|_r^{\omega_1} \cdots |Q_q(\mathbf{f})|_r^{\omega_q}} &\leq \frac{|W|_r}{\alpha^{\bar{R}^{q-N-1}} \beta^{N+1}} \prod_{i \in \bar{R}} \left(\frac{\beta\|\mathbf{f}\|_r^d}{|Q_i(\mathbf{f})|_r} \right)^{\omega_i} \\ &\leq A_{\bar{R}} \frac{|W|_r \cdot \|\mathbf{f}\|_r^{d(n+1)}}{\prod_{i \in \bar{R}^o} |Q_i(\mathbf{f})|_r} \\ &\leq B_{\bar{R}} \frac{|W_{\bar{R}^o}|_r \cdot \|\mathbf{f}\|_r^{dH_V(d)}}{\prod_{i \in \bar{R}^o} |Q_i(\mathbf{f})|_r \prod_{i=1}^{H_V(d)-n-1} |T_i(\mathbf{f})|_r}, \end{aligned}$$

where $A_{\bar{R}}, B_{\bar{R}}$ are positive constants.

Therefore, for every $r > 0$,

$$\begin{aligned} \log \frac{\|\mathbf{f}\|_r^{d(\sum_{i=1}^q \omega_i - H_d(V))} |W|_r}{|Q_1(\mathbf{f})|_r^{\omega_1} \cdots |Q_q(\mathbf{f})|_r^{\omega_q}} &\leq \max_{\bar{R}} \log \frac{|W_{\bar{R}}|_r}{\prod_{i \in \bar{R}} |Q_i(\mathbf{f})|_r \prod_{i=1}^{H_V(d)-n-1} |T_i(\mathbf{f})|_r} + O(1) \\ &\leq - \sum_{j=1}^{H_d(V)} |\gamma^j| \log r + O(1), \end{aligned}$$

where the maximum is taken over all subsets $R \subset \{1, \dots, q\}$ such that $\#R = n + 1$ and $\text{rank}_{\mathbb{F}}\{[Q_i]; i \in R\} = n + 1$. Here, the last inequality comes from the lemma on logarithmic derivative. By the Poisson-Jensen-Green formula, the definitions of the approximation function and the characteristic function, we have

$$\sum_{i=1}^q \omega_i m_f(Q_i, r) - dH_d(V)T_f(r) - N_W(0, r) \leq -(H_d(V) - 1) \log r + O(1),$$

(note that $\sum_{i=1}^{H_d(V)} |\gamma^i| \leq H_d(V) - 1$). Then, by the first main theorem, we obtain

$$(8) \quad \left(\sum_{i=1}^q \omega_i - H_d(V) \right) dT_f(r) \leq \sum_{i=1}^q \omega_i N_f(Q_i, r) - N_W(0, r) - (H_d(V) - 1) \log r + O(1).$$

Claim. $\sum_{i=1}^q \omega_i N_f(Q_i, r) - N_W(0, r) \leq \sum_{i=1}^q \omega_i N_f^{(\kappa_0)}(Q_i, r) + O(1)$.

Indeed, set $\tilde{G}_j = \text{gcd}(Q_j(\mathbf{f}), S(Q_j(\mathbf{f}))^{\kappa_0})$. Since ω_i ($1 \leq i \leq q$) are rational numbers, there exists an integer A such that $\tilde{\omega}_i = A\omega_i$ ($1 \leq i \leq q$) are integers.

Let $P \in \mathcal{E}_m$ be an irreducible element with $P \mid \prod_{i=1}^q Q_i(\mathbf{f})^{\tilde{\omega}_i}$. There exists a subset R of $\{1, \dots, q\}$ with $\sharp R = N + 1$ such that P is not a division of $Q_i(\mathbf{f})$ for any $i \notin R$. Denote by e_i the largest integer such that $P^{e_i} \mid Q_i(\mathbf{f})$ for each $i \in R$. Then, there is a subset $R^o \subset R$ with $\sharp R^o = n + 1$, $W_{R^o} \neq 0$ and

$$\sum_{i \in R} \omega_i \max\{0, e_i - \kappa_0\} \leq \sum_{i \in R^o} \max\{0, e_i - \kappa_0\}.$$

Also, since $W = C_{R^o} \cdot W_{R^o}$, it clear that P divides W with multiplicity at least

$$\begin{aligned} \min_{\{j_1, \dots, j_{n+1}\} \subset \{1, \dots, H_d(V)\}} \sum_{i \in R^o} \min\{0, e_i - |\gamma^{j_i}|\} &\geq \sum_{i \in R^o} \min\{0, e_i - \kappa_0\} \\ &\geq \sum_{i \in R} \omega_i \max\{0, e_i - \kappa_0\} \\ &= \sum_{i \in R} \omega_i (e_i - \min\{e_i, \kappa_0\}). \end{aligned}$$

This implies that

$$P^{\sum_{i \in R} \tilde{\omega}_i e_i} \mid W^A \cdot P^{\sum_{i \in R} \tilde{\omega}_i \min\{e_i, \kappa_0\}}.$$

We note that $P^{\tilde{\omega}_i \min\{e_i, \kappa_0\}} \mid G_i^{\tilde{\omega}_i}$. Therefore,

$$P^{\sum_{i \in R} \tilde{\omega}_i e_i} \mid W^A \cdot \prod_{i \in R} G_i^{\tilde{\omega}_i}.$$

This holds for every such irreducible element P . Then it yields that

$$\prod_{i=1}^q Q_i(\mathbf{f})^{\tilde{\omega}_i} \mid W^A \cdot \prod_{i=1}^q G_i^{\tilde{\omega}_i}.$$

Hence,

$$\sum_{i=1}^q N_f(Q_i, r) \leq N_W(0, r) + \sum_{i=1}^q N_f^{(\kappa_0)}(Q_i, r).$$

The claim is proved.

From the claim, Lemma 4(ii) and the inequality (8), we obtain

$$\begin{aligned} &(\tilde{\omega}(q - 2N + n - 1) - H_d(V) + n + 1)dT_f(r) \\ &\leq \sum_{i=1}^q \omega_i N_f^{(\kappa_0)}(Q_i, r) - (H_d(V) - 1) \log r + O(1). \end{aligned}$$

Note that, $\omega_i \leq \tilde{\omega}$ ($1 \leq i \leq q$) and $\frac{n+1}{2N-n+1} \leq \tilde{\omega} \leq \frac{n}{N}$. Then, the above inequality implies that

$$\left(q - \frac{(2N - n + 1)H_d(V)}{n + 1} \right) \leq \sum_{i=1}^q \frac{1}{d} N_f^{(\kappa_0)}(Q_i, r) - \frac{N(H_d(V) - 1)}{nd} \log r + O(1).$$

The theorem is proved. \square

Proof of Theorem 2. For $r > 0$, without loss of generality, we may assume that

$$|Q_1(\mathbf{f})|_r^{1/\deg Q_1} \leq |Q_2(\mathbf{f})|_r^{1/\deg Q_2} \leq \dots \leq |Q_q(\mathbf{f})|_r^{1/\deg Q_{N+1}}.$$

Since $\bigcap_{i=1}^{N+1} Q_i = \emptyset$, by Lemma 5, there exists a positive constant C such that

$$C\|\mathbf{f}\|_r \leq \max_{1 \leq i \leq N+1} |Q_i(\mathbf{f})|_r^{1/\deg Q_i} = |Q_{N+1}(\mathbf{f})|_r^{1/\deg Q_{N+1}}.$$

Then, we get

$$\begin{aligned} \sum_{i=1}^q \frac{m_f(Q_i, r)}{\deg Q_i} &= \log \frac{\|\mathbf{f}\|_r^q}{|Q_1(\mathbf{f})|_r^{1/\deg Q_1} \dots |Q_q(\mathbf{f})|_r^{1/\deg Q_q}} + O(1) \\ &\leq \log \prod_{i=1}^N \frac{\|\mathbf{f}\|_r}{|Q_i(\mathbf{f})|_r^{1/\deg Q_i}} + O(1) \\ &= \sum_{i=1}^N \frac{m_f(Q_i, r)}{\deg Q_i} + O(1) \\ &\leq N \cdot T_f(r) + O(1). \end{aligned}$$

Therefore,

$$(q - N)T_f(r) \leq \sum_{i=1}^q \frac{1}{\deg Q_i} N_f(Q_i, r) + O(1) \quad (r > 0).$$

The theorem is proved. \square
