# THE RANK OF THE CARTIER OPERATOR ON PICARD CURVES

VAHID NOUROZI AND FARHAD RAHMATI<sup>∗</sup>

ABSTRACT. For an algebraic curve  $\mathcal X$  defined over an algebraically closed field of characteristic  $p > 0$ , a-number  $a(\mathcal{X})$  is the dimension of the space of exact holomorphic differentials on  $X$ . We computed the *a*-number for a family of certain Picard curves using the action of the Cartier operator on  $H^0(\mathcal{X}, \Omega^1)$ .

#### 1. INTRODUCTION

Let  $\mathcal X$  be a geometrically irreducible, projective, and non-singular algebraic curve defined over the finite field  $\mathbb{F}_{\ell}$  of order  $\ell$ . Let  $\mathcal{X}(\mathbb{F}_{\ell})$  denote the set of  $\mathbb{F}_{\ell}$ rational points for  $\mathcal{X}$ . In studying curves over finite fields, determining the size of  $\mathcal{X}(\mathbb{F}_{\ell})$  is a fundamental problem. The exact primary result here is the Hasse-Weil bound, which asserts that

$$
| \# \mathcal{X}(\mathbb{F}_{\ell}) - (\ell + 1) | \leq 2g\sqrt{\ell},
$$

where  $g = g(\mathcal{X})$  is the genus of  $\mathcal{X}$ .

In this paper, we consider Picard curves of genus 3 over  $\mathbb{F}_{q^2}$  of characteristic  $p > 3$ . Let X be a Picard curve. Then X can be defined by an affine equation of the form

<span id="page-0-0"></span>
$$
y^3 = f(x),\tag{1.1}
$$

where  $f(x)$  is a polynomial of degree 4, without multiple roots. It is easy to see that the maximal curve  $\mathcal X$  is super-singular because all the slopes of its Newton polygon are equal to 1/2. This implies that the Jacobian  $X := \text{Jac}(\mathcal{X})$  has no p-torsion points over  $\overline{\mathbb{F}}_p$ . A relevant invariant of the p-torsion group scheme of the Jacobian of the curve is the a-number.

Consider multiplication by p-morphism  $[p] : X \to X$ , a finite flat morphism of degree  $p^{2g}$ . These factors were  $[p] = V \circ F$ . Here,  $F : X \to X^{(p)}$  is the relative Frobenius morphism originating from the p-power map on the sheaf structure, and the Verschiebung morphism  $V: X^{(p)} \to X$  is the dual of F. The multiplicationby-p kernel on X is defined as  $X[p]$ . An important invariant is the a-number  $a(\mathcal{X})$  of curve X defined by

$$
a(\mathcal{X}) = \dim_{\bar{\mathbb{F}}_p} \text{Hom}(\alpha_p, X[p]),
$$

where  $\alpha_p$  is the kernel of the Frobenius endomorphism in the group scheme  $Spec(k[X]/(X^p))$ . Another definition for the *a*-number is

$$
a(\mathcal{X}) = \dim_{\mathbb{F}_p}(\text{Ker}(F) \cap \text{Ker}(V)).
$$

*Key words and phrases.* a-number; Cartier operator; Super-singular Curves; Picard Curves.

<sup>\*</sup> Corresponding author.

A few results on the rank of the Cartier operator (especially a-number) of curves are introduced by Kodama and Washio  $[9]$ , González  $[6]$ , Pries and Weir [\[18\]](#page-5-0), Yui [\[21\]](#page-5-1). Besides that, Vahid talked about the rank of the Cartier of the maximal curves in [\[16\]](#page-5-2), the hyperelliptic curve in [\[13\]](#page-5-3), and the maximal function fields of  $\mathbb{F}_{q^2}$  in [\[12,](#page-4-2) [17\]](#page-5-4). Vahid also wrote about these topics in his [\[15\]](#page-5-5) dissertation.

In Section [3,](#page-2-0) we prove that the  $a$ -number of the Picard curves with Equation  $(1.1)$  is 0 for  $p \equiv 1 \mod 3$ , and is 1 for  $p \equiv 2 \mod 3$ , see Theorem [3.1.](#page-2-1) The proofs directly use the Cartier operator action on  $H^0(\mathcal{X}, \Omega^1)$ . Finally, we provide an example of the a-number of Picard curves obtained from the Hasse-Witt matrix.

### 2. The Cartier operator

Let k be an algebraically closed field of characteristic  $p > 0$ . Let X be a curve defined over k. The Cartier operator is a  $1/p$ -linear operator acting on the sheaf  $\Omega^1 := \Omega^1_{\mathcal{X}}$  of differential forms on  $\mathcal X$  with positive characteristics,  $p > 0$ .

Let  $K = k(\mathcal{X})$  be the function field of curve X of genus g defined over k. The separating variable for K is an element  $x \in K \setminus K^p$ . We can write any function  $f \in K$  uniquely in form

$$
f = f_0^p + f_1^p x + \dots + f_{p-1}^p x^{p-1},
$$

where  $f_i \in K$ , for  $i = 0, \dots, p-1$ .

**Definition 2.1.** (Cartier Operator). Let  $\omega \in \Omega_{K/K_p}$ . There exist  $f_0, \dots, f_{p-1}$ such that  $\omega = (f_0^p + f_1^p x + \cdots + f_{p-1}^{p'} x^{p-1}) dx$ . The Cartier operator  $\mathfrak{C}$  is defined by

$$
\mathfrak{C}(\omega) := f_{p-1} dx.
$$

This definition does not depend on the choice of x (see [\[19,](#page-5-6) Proposition 1]).

We refer the reader to [\[19,](#page-5-6) [2,](#page-4-3) [3,](#page-4-4) [20\]](#page-5-7) for proofs of the following statements.

**Proposition 2.2.** (Global Properties of  $\mathfrak{C}$ ). For all  $\omega \in \Omega_{K/K_q}$  and all  $f \in K$ ,

- $\mathfrak{C}(f^p\omega) = f\mathfrak{C}(\omega);$
- $\mathfrak{C}(\omega) = 0 \Leftrightarrow \exists h \in K, \omega = dh;$
- $\mathfrak{C}(\omega) = \omega \Leftrightarrow \exists h \in K, \omega = dh/h.$

<span id="page-1-1"></span>Remark 2.3. Moreover, one can easily show that

$$
\mathfrak{C}(x^j dx) = \begin{cases} 0 & \text{if } p \nmid j+1\\ x^{s-1} dx & \text{if } j+1 = ps. \end{cases}
$$

If div( $\omega$ ) is effective, then differential  $\omega$  is holomorphic. The set  $H^0(\mathcal{X}, \Omega^1)$  of holomorphic differentials is a *g*-dimensional k-vector subspace of  $\Omega^1$ , such that  $\mathfrak{C}(H^0(\mathcal{X}, \Omega^1)) \subseteq H^0(\mathcal{X}, \Omega^1)$ . If X is a curve, then the a-number of X equals the dimension of the kernel of the Cartier operator  $H^0(\mathcal{X}, \Omega^1)$  (or equivalently, the dimension of the space of the exact holomorphic differentials on  $\mathcal{X}$ ) (see [\[10,](#page-4-5) 5.2.8]).

<span id="page-1-0"></span>The following theorem is based on Gorenstein; see [\[7,](#page-4-6) Theorem 12].

**Theorem 2.4.** A differential  $\omega \in \Omega^1$  is holomorphic if and only if it has the form  $(h(x,y)/F_y)dx$ , where  $H : h(X,Y) = 0$  is a canonical adjoint.

**Theorem 2.5.** [\[11\]](#page-4-7) With the above assumptions,

$$
\mathfrak{C}(h\frac{dx}{F_y}) = \left(\frac{\partial^{2p-2}}{\partial x^{p-1}\partial y^{p-1}}(F^{p-1}h)\right)^{\frac{1}{p}}\frac{dx}{F_y}
$$

for any  $h \in K(\mathcal{X})$ .

The differential operator  $\nabla$  is defined by

$$
\nabla = \frac{\partial^{2p-2}}{\partial x^{p-1} \partial y^{p-1}},
$$

has the property

$$
\nabla(\sum_{i,j} c_{i,j} X^i Y^j) = \sum_{i,j} c_{ip+p-1,jp+p-1} X^{ip} Y^{jp}.
$$
 (2.1)

## 3. The a-number of Picard Curves

<span id="page-2-0"></span>This section considers the Picard curves over a finite field with  $q^2$  elements of characteristic  $p > 3$ . Let X be the Picard curve of genus 3 over  $\mathbb{F}_{q^2}$ . Then X can be defined by an affine equation of the form

$$
y^3 = f(x),\tag{3.1}
$$

where  $f(x)$  is a polynomial of degree 4 without multiple roots. From Theorem [2.4,](#page-1-0) one can find a basis for the space  $H^0(\mathcal{X}, \Omega^1)$  of holomorphic differentials on  $\mathcal{X}$ , namely

$$
\mathcal{B} = \left\{ z_i = \frac{h_i dx}{f_y} \right\},\
$$

<span id="page-2-1"></span>where  $h_1 = 3, h_2 = 3x$  and  $h_3 = 3y$  for  $1 \leq i \leq 3$ . Therefore,  $\mathcal{B} = \{\frac{dx}{y^2}\}$  $\frac{dx}{y^2}$ ,  $\frac{xdx}{y^2}$  $rac{dx}{y^2}, \frac{dx}{y}$  $\frac{dx}{y}$ .

**Theorem 3.1.** Suppose that  $p \neq 0$  mod 3 and  $f(x)$  have a non-zero constantcoefficient, then

- 1. If  $p \equiv 1 \mod 3$ , then  $a(\mathcal{X}) = 0$ .
- 2. If  $p \equiv 2 \mod 3$ , then  $a(\mathcal{X}) = 1$ .

*Proof.* 1. Let us compute the image of  $\mathfrak{C}(\omega)$  for any  $\omega \in \mathcal{B}$ . Taking  $p = 3r+1$ and  $r \in \mathbb{Z}$ . Since  $p - 1 = 3r$ . We get  $2p - 2 = 6r$ . So

$$
\mathfrak{C}(xdx/y^2) = \mathfrak{C}(y^{2p-2}y^{-2p}xdx) = y^{-2}\mathfrak{C}(xf(x)^{2r}dx)
$$
  
= 
$$
y^{-2}\sum_{i=0}^{2r} c_i \mathfrak{C}(x^{i+1}dx) = c_r dx \neq 0.
$$

$$
\mathfrak{C}(dx/y^2) = \mathfrak{C}(y^{2p-2}y^{-2p}dx) = y^{-2}\mathfrak{C}(f(x)^{2r}dx)
$$
  
= 
$$
y^{-2}\sum_{i=0}^{2r} c_i \mathfrak{C}(x^i dx) = c_r dx \neq 0.
$$

Now we let  $p - 1 = 3r$ ,

$$
\mathfrak{C}(dx/y) = \mathfrak{C}(y^{p-1}y^{-p}dx) = y^{-1}\mathfrak{C}(f(x)^r dx)
$$
  
= 
$$
y^{-1}\sum_{i=0}^r c_i \mathfrak{C}(x^i dx) = c_r dx \neq 0.
$$

Thus,  $a(\mathcal{X}) = 0$ .

2. We assume that  $p = 3r + 2$  and  $r \in \mathbb{Z}$ . We get  $p - 2 = 3r$ . Hence

$$
\mathfrak{C}(xdx/y^2) = \mathfrak{C}(y^{p-2}y^{-p}xdx) = y^{-1}\mathfrak{C}(xf(x)^r dx)
$$
  
\n
$$
= y^{-1}\sum_{i=0}^r c_i \mathfrak{C}(x^{i+1}dx) = c_r dx \neq 0.
$$
  
\n
$$
\mathfrak{C}(dx/y^2) = \mathfrak{C}(y^{p-2}y^{-p}dx) = y^{-1}\mathfrak{C}(f(x)^r dx)
$$
  
\n
$$
= y^{-1}\sum_{i=0}^r c_i \mathfrak{C}(x^i dx) = c_r dx \neq 0.
$$

Finally, from Remark [2.3](#page-1-1) we have

$$
\mathfrak{C}(dx/y) = \mathfrak{C}(y^{p-1}y^{-p}dx) = y^{-1}\mathfrak{C}(f(x)^{\frac{3r-1}{3}}dx)
$$
  
= 
$$
y^{-1}\sum_{i=0}^{\frac{3r-1}{3}}c_i\mathfrak{C}(x^i dx) = 0.
$$

Therefore,  $a(\mathcal{X}) = 1$ .

Where the coefficients  $c_i \in k$  are obtained from the expansion

$$
y^{p-1} = f(x)^{(p-1)/2} = \sum_{i=0}^{N} c_i x^i
$$
 with  $N = \frac{p-1}{2}$ .

In [\[4\]](#page-4-8), Estrada Sarlabous showed that if  $F^{p-1} = \sum_{i,j} c_{i,j} x^i y^j$ , then the Hasss-Wit matrix of  $\beta$  is

$$
H = \begin{pmatrix} c_{p-1,p-1} & c_{2p-1,p-1} & c_{p-1,2p-1} \\ c_{p-2,p-1} & c_{2p-2,p-1} & c_{p-2,2p-1} \\ c_{p-1,p-2} & c_{2p-1,p-2} & c_{p-1,2p-2} \end{pmatrix}.
$$

Since  $F = y^3 - f(x)$ ,  $c_{i,j} = 0$  for  $j \not\equiv 0 \mod 3$ . Thus, we have

1.  $p \equiv 1 \mod 3$ . Then

<span id="page-3-1"></span>
$$
H = \begin{pmatrix} c_{p-1,p-1} & c_{2p-1,p-1} & 0\\ c_{p-2,p-1} & c_{2p-2,p-1} & 0\\ 0 & 0 & c_{p-1,2p-2} \end{pmatrix} .
$$
 (3.2)

 $\Box$ 

where  $c_{p-1,p-1}, c_{2p-1,p-1}, c_{p-2,p-1}, c_{2p-2,p-1}$  are the respective coefficients of  $x^{p-1}, x^{2p-1}, x^{p-2}$  and  $x^{2p-2}$  in  $f(x)^{(2p-2)/3}$  mod p.  $c_{p-1,2p-2}$  is the coefficient of  $x^{p-1}$  in  $f(x)^{(p-1)/3}$  mod p.

2.  $p \equiv 2 \mod 3$ . Then

<span id="page-3-0"></span>
$$
H = \begin{pmatrix} 0 & 0 & c_{p-1,2p-1} \\ 0 & 0 & c_{p-2,2p-1} \\ c_{p-1,p-2} & c_{2p-1,p-2} & 0 \end{pmatrix}.
$$
 (3.3)

where  $c_{p-1,2p-1}$  and  $c_{p-2,2p-1}$  are the coefficients of  $x^{p-1}$  and  $x^{p-2}$  in  $f(x)^{(p-2)/3}$ mod p, and  $c_{p-1,p-2}$ , and  $c_{2p-1,p-2}$  are the coefficients of  $x^{p-1}$  and  $x^{2p-1}$  in  $f(x)^{(2p-1)/3} \mod p$ .

Example 3.2. Consider the Picard curves with the following equation:

$$
y^3 = x^4 + 1.
$$

We calculate the a-number with the Hasse-Wit matrix of this curve with  $p = 5$ and  $p = 13$ . Firstly, suppose that  $p = 5$  in this case from equation [\(3.3\)](#page-3-0), we have

$$
H = \left(\begin{array}{rrr} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 3 & 0 & 0 \end{array}\right).
$$

So rank $(H) = 2$ . From the definition of a-number, it is clear that  $a(\mathcal{X}) =$  $g(\mathcal{X})$  – rank $(H)$ . Therefore,  $a(\mathcal{X}) = 1$ . Finally, assuming that  $p = 13$  in this case from equation [\(3.2\)](#page-3-1), we have

$$
H = \left(\begin{array}{rrr} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \end{array}\right).
$$

So rank $(H) = 3$ , hence  $a(\mathcal{X}) = 0$ . In addition, we achieve this result from MAGMA computation [\[1\]](#page-4-9).
