# Connectivity of graphs that do not have the edge-Erd˝os-P´osa property

Henning Bruhn and Raphael Steck

July 24, 2023

#### Abstract

We show that we can assume graphs that do not have the edge-Erdős-Pósa property to be connected. Then we strengthen this result to 2connectivity under the additional assumptions of a minor-closed property and a generic counterexample.

A class F has the edge-Erdős-Pósa property if there exists a function f:  $\mathbb{N} \to \mathbb{R}$  such that for every graph G and every integer k, there are k edgedisjoint graphs in G each isomorphic to some graph in  $\mathcal F$  or there is an edge set  $X \subseteq E(G)$  of size at most  $f(k)$  meeting all subgraphs in G isomorphic to some graph in  $\mathcal F$ . The edge set X is called the *hitting set*. If we replace vertices with edges in the above definition, that is, we look for a vertex hitting set or vertexdisjoint graphs, then we obtain the vertex-Erdős-Pósa property. The class  $\mathcal F$ that is studied in this paper arises from taking minors: For a fixed graph  $H$ , we define the set

 $\mathcal{F}_H = \{G \mid H \text{ is a minor of } G\}.$ 

In other words,  $\mathcal{F}_H$  is the set of H-expansions. The vertex-Erdős-Pósa property for  $\mathcal{F}_H$  is well understood: Robertson and Seymour [\[1\]](#page-5-0) proved that the class  $\mathcal{F}_H$  has the vertex-Erdős-Pósa property if and only if H is planar. This implies that the vertex-Erdős-Pósa property is closed under taking minors, which in turn implies that

> <span id="page-0-0"></span>If for a graph H the class  $\mathcal{F}_H$  has the vertex-Erdős-Pósa property, then so does the class  $\mathcal{F}_C$  for every component C of H. (1)

For the edge-Erdős-Pósa property, it is not known whether it is minor-closed or not, and it is not at all clear whether it should be. Thus, we tackle [\(1\)](#page-0-0) for the edge-Erdős-Pósa property. We show that

<span id="page-0-1"></span>**Theorem 1.** If for a graph H the class  $\mathcal{F}_H$  has the edge-Erdős-Pósa property, then so does  $\mathcal{F}_C$  for every component C of H.

Interestingly, Robertson and Seymour proved their result about the vertex-Erdős-Pósa property of planar graphs in two steps: First, they proved it for every connected planar graph. In a second step, they lifted the connectivity requirement. Thus Theorem [1](#page-0-1) might also provide some help in verifying for which graphs H the class  $\mathcal{F}_H$  has the edge-Erdős-Pósa property. For example, it might help to prove that  $\mathcal{F}_H$  does not have the edge-Erdős-Pósa property if H has large treewidth (for larger or arbitrary maximum degree of  $H$ ).

To this end, we also attempt a strengthening of Theorem [1](#page-0-1) which allows us to not only focus on connected, but 2-connected graphs  $H$ . This, however, is not achieved in full generality, and we prove it only by imposing some additional assumptions (see Theorem [3\)](#page-3-0).

For a graph H, a connected graph  $G \subseteq H$  with at least one vertex  $v \in V(G)$ with  $d_H(v) \geq 3$  and an integer  $r \in \mathbb{N}$ , we define  $G^{\times}$  to be the following graph: Starting with the empty graph, we add a copy of every vertex  $v \in V(G)$  with  $d_H(v) \geq 3$  to  $G^{\times}$ . For every non-trivial path P of length l in G between two vertices such vertices, we add r internally disjoint paths of length  $\max\{l, 2\}$ between their corresponding copies in  $G^{\times}$ . Finally, for every path P of length l in G between a vertex u with  $d_G(u) = 1$ ,  $d_H(u) \leq 2$  and its closest vertex  $v \in V(G)$  with  $d_H(v) \geq 3$ , we add r paths of length l which are disjoint except for the copy of  $v$ . See Figure [1](#page-1-0) for an example.

<span id="page-1-0"></span>Figure 1: Construction of  $G^{\times}$ , with  $u \in V(H) \setminus V(G)$ .

Let us check that for every edge set X of size at most  $r-1$ ,  $G^{\times} - X$  contains a G-expansion. Every  $v \in V(G)$  with  $d_H(v) \geq 3$  can be mapped to its copy  $v' \in V(G^{\times})$ . Every u-v path between two such vertices can be mapped to one of its copies in  $G^{\times}$  that is disjoint from X. For every vertex  $u \in V(G)$  with  $d_G(u) = 1$  and  $d_H(u) \leq 2$ , there is vertex  $v \in V(G)$  with  $d_H(v) \geq 3$  that is closest to u. Among all copies of the  $u-v$  path, we pick a copy  $P'$  that is disjoint from X and map P to P' such that v is mapped to v'. The prerequisite of G being connected and containing a vertex v with  $d_H(v) \geq 3$  implies that every  $v \in V(G)$  with  $d_G(v) = d_H(v) = 2$  lies on a path in G between vertices of degree other than  $2$  in  $H$ , with at least one endvertex of the path having degree at least 3 in H. We conclude that the above mapping yields a G-expansion in  $G^{\times} - X$ .

For  $r \geq 3$ , the number of vertices of degree at least 3 in  $G^{\times}$  is the same as the number of vertices v with  $d_H(v) \geq 3$  in G.

<span id="page-1-1"></span>**Remark 2.** Let H be a connected graph for which  $\mathcal{F}_H$  does not have the edge- $Erd\tilde{o}s-P\tilde{o}sa$  property. Then  $H$  contains vertices of degree at least 3.

*Proof.* Suppose  $H$  would only contain vertices of degree 2 or less. Since  $H$  is connected, H must be a cycle, a path or an isolated vertex. However, for all of those graphs,  $\mathcal{F}_H$  is already known to have the edge-Erdős-Pósa property.  $\Box$ 

For two graphs A and B, we define  $\preceq$  by

$$
A \preceq B \Leftrightarrow A \text{ is a minor of } B.
$$

Similarly, we define  $\preceq$  by

$$
A \nleq B \Leftrightarrow A
$$
 is not a minor of B.

#### 1 1-Connectivity

*Proof of Theorem [1.](#page-0-1)* Let A be some component of H such that  $\mathcal{F}_A$  does not have the edge-Erdős-Pósa property. Thus, there exists an integer  $k \in \mathbb{N}$  such that for every  $r \in \mathbb{N}$ , there exists a graph  $A_r^*$  such that  $A_r^*$  neither contains k edge-disjoint expansions of A nor an edge set X of size at most  $r-1$  such that  $A_r^* - X$  contains no expansion of A. We separate the other components of H into two disjoint sets  $\beta$  and  $\beta$ , which we define by

> $\mathcal{B} = \{B \text{ component of } H \mid A \nless B\}$  and  $C = \{C \text{ component of } H | A \preceq C\} \setminus \{A\}.$

To prove that  $\mathcal{F}_H$  does not have the edge-Erdős-Pósa property, let r be given. We prove that there exists a graph  $H^*$  that contains neither  $k$  edge-disjoint H-expansions nor an edge set X of size at most  $r-1$  such that  $H^* - X$  contains no  $H$ -expansion. We define  $H^*$  to be the disjoint union of

- $A^* = A_r^*$ ,
- for every  $B \in \mathcal{B}$ : r distinct copies of B and
- for every  $C \in \mathcal{C}$ : one  $C^{\times}$ .

First we show that  $H^*$  does not contain an edge-hitting set meeting all  $A$ expansions. Let  $X \subseteq E(H^*)$  be an edge set of size at most  $r-1$ . We claim that  $H^* - X$  still contains an H-expansion: Indeed, there is an A-expansion in  $A^* - X$  by choice of  $A^*$ . For every  $B \in \mathcal{B}$ , at least one of the r copies of B in H is disjoint from  $X$ . Thus, there is a  $B$ -expansion in that copy. Finally, for every  $C \in \mathcal{C}$ , there is a C-expansion in  $C^{\times} - X$  by construction of  $C^{\times}$ . Together, this yields an H-expansion in  $H^* - X$ .

We claim

<span id="page-2-0"></span>Every H-expansion in 
$$
H^*
$$
 contains an A-expansion in  $A^*$ . (2)

Note that  $(2)$  finishes the proof of the theorem: Indeed, by choice of  $A^*$ , there can be no  $k$  edge-disjoint A-expansions in  $A^*$ . To prove the claim, consider an expansion  $H'$  in  $H^*$ , and suppose that [\(2\)](#page-2-0) is false for  $H'$ .

Since every component of  $H'$  is connected, it must be contained in a single component of  $H^*$ . Further note that every expansion of a  $C \in \mathcal{C}$  in some component of  $H^*$  contains an expansion of A by definition of C. Thus, by definition of B, no A-expansion (and thus no C-expansion for any  $C \in \mathcal{C}$ ) can be contained in some copy of some  $B \in \mathcal{B}$ . On top of that, if an A-expansion (or a C-expansion for any  $C \in \mathcal{C}$ ) is embedded in  $A^*$ , this proves the above claim. Thus, suppose all A-expansion in  $H'$  (and thus all  $C$ -expansions for every  $C \in \mathcal{C}$  are contained in  $\bigcup C^{\times}$ . Every H-expansion in  $H^*$  contains at least one vertex of degree  $\geq 3$  in  $H^*$  for every vertex of degree  $\geq 3$  in H. However, by construction of  $C^{\times}$ ,  $\bigcup$  $C \in \mathcal{C}$  $C^{\times}$  contains no more vertices of degree  $\geq 3$  than  $\bigcup_{C \in \mathcal{C}} C$ . Since A contains vertices of degree  $\geq 3$  by Remark [2](#page-1-1) and the branch sets of all vertices in  $A \cup \left( \begin{array}{c} \bigcup \end{array} \right)$  $C$  must be contained in  $\bigcup_{C \in \mathcal{C}}$  $C^{\times}$ , this is a contradiction.  $C \in \mathcal{C}$ Thus [\(2\)](#page-2-0) holds, proving the theorem.  $\Box$ 

### 2 2-Connectivity

If we want to prove that for some graph  $H$ ,  $\mathcal{F}_H$  does not have the edge-Erdős-Pósa property, the above theorem implies that it suffices to check the components of  $H$  individually. Thus, without loss of generality, we can assume that  $H$ is 1-connected. To improve this to 2-connectivity of  $H$ , we need two additional assumptions.

First, we define a graph property P to be *hereditary* if  $\overline{P}$  is closed under taking minors, that is, for every graph  $H$  without property  $P$ , no minor of  $H$ has property  $P$ . An example for a hereditary property would be large treewidth: If a graph  $H$  does not have treewidth at least  $t$ , then no minor of  $H$  has treewidth at least t.

Second, for a block  $A$  of a graph  $H$ , let  $S$  be the set of cutvertices of  $H$  that lie in A. We say that there is a generic counterexample for A if there exists some  $k \in \mathbb{N}$  such that for every  $r \in \mathbb{N}$ , there is a graph  $A^*$  with the following properties: There are no  $k$  edge-disjoint A-expansions in  $A^*$ . Furthermore, for every  $s \in S$ , there is a  $s' \in V(A^*)$  such that for every edge set X of size at most  $r-1$ , there is an embedding of A in  $A^*$  such that for every vertex  $s \in S$ , the branch set  $B_s$  contains s'. (Together, this implies that  $\mathcal{F}_A$  does not have the edge-Erdős-Pósa property.) Every known construction that shows that some class  $\mathcal{F}_A$  does not have the edge-Erdős-Pósa property is a generic counterexample.

<span id="page-3-0"></span>**Theorem 3.** Let  $P$  be a hereditary graph property and let  $H$  be a graph that contains a block with property  $P$ . Furthermore, for every block A of H with property  $P$ , let there be a generic counterexample.

Then  $\mathcal{F}_H$  does not have the edge-Erdős-Pósa property.

An example for an application of Theorem[\\*3](#page-3-0) could be the following. Suppose we want to show that:

<span id="page-3-1"></span>For every graph H of treewidth at least  $10^{100}$ ,  $\mathcal{F}_H$  does not have For every graph 11 of treewant at teast 10  $\rightarrow$ ,  $\rightarrow$  H abes not have (3)<br>the edge-Erdős-Pósa property.

Having large treewidth is a hereditary graph property. Assume we were able to show that for every 2-connected graph H of treewidth at least  $10^{100}$ ,  $\mathcal{F}_H$ does not have the edge-Erdős-Pósa property. Then we will most likely do that by giving a generic counterexample. Thus we can apply Theorem [3](#page-3-0) to drop the connectivity requirement and we obtain [\(3\)](#page-3-1). Now let us prove Theorem [3.](#page-3-0)

*Proof.* We can assume  $H$  to be 1-connected: Indeed, if  $H$  contains a block  $A$  with property  $P$ , then there is a component  $Q$  of  $H$  that contains  $A$ . Furthermore, if all block of H with property  $P$  allow for a generic counterexample, then this includes the blocks of Q. If we are able to prove that  $\mathcal{F}_Q$  does not have the edge-Erdős-Pósa property, then using Theorem [1,](#page-0-1) we conclude that  $\mathcal{F}_H$  does not have the edge-Erdős-Pósa property.

We consider the block tree T of H. Let  $T_p$  be the minimal subtree of T that contains all blocks with property  $P$ . We pick A to be a leaf of  $T_P$ . Note that A is a block of H that has the property  $P$ . Observe that A is not a trivial block, i.e.  $A$  is not a  $K_2$  due to Remark [2.](#page-1-1)

We define

$$
C = \{ C \text{ block of } H \mid A \preceq C \} \setminus \{ A \}.
$$

Since P is hereditary, it holds for every  $C \in \mathcal{C}$  that C has the property P, too. Let  $T_{\mathcal{C}}$  be the minimal subtree of T that contains all blocks of  $\mathcal{C} \cup \{A\}$ . We observe that  $T_{\mathcal{C}}$  is a subgraph of  $T_{\mathcal{P}}$ . Thus,

$$
A \t is \t a \t leaf \t of \t T_{\mathcal{C}}.
$$
\n
$$
\tag{4}
$$

<span id="page-4-0"></span>We define

$$
\mathcal{B} = \{B \text{ block of } H \mid A \nleq B\} \cap V(T_{\mathcal{C}}) \text{ and}
$$
  

$$
\mathcal{D} = \{D \text{ component of } \bigcup_{\substack{B \text{ block of } H \\ B \notin V(T_{\mathcal{C}})}} B\}.
$$

Note that since T is a tree,  $T - T_C$  is a forest. For each component T' in  $T - T_C$ ,  $V(T')$  are the blocks and cutvertices of one element of  $D$ .

To show that H does not have the edge-Erdős-Pósa property, let  $r \geq 3$  be some integer. We define our counterexample graph  $H^*$  to be the union of

- $\bullet$   $A^*$ ,
- for every  $C \in \mathcal{C}$ : one  $C^{\times}$ ,
- for every  $D \in \mathcal{D}$ : r distinct copies of D,
- for every non-trivial  $B \in \mathcal{B}$ : one  $B^{\times}$  and
- for every component  $P$  of  $\bigcup$  $B\in\mathcal{B}_B$ <br>B=K<sub>2</sub> B: one  $P^{\times}$ .

We pick the above graphs to be disjoint except for those vertices which are copies of the same vertex  $v \in H$ , which we identify with each other in  $H^*$ , too. In  $A^*$ , we pick the vertex s' for every  $s \in S$  and identify it with all copies of s. Note that for all blocks  $B \in \mathcal{B}$ , there is a path P in H whose endvertices are in a block in  $\{A\} \cup C$  and P contains an edge of B. With A and C being non-trivial blocks for all  $C \in \mathcal{C}$ , their cutvertices have degree at least 3 in H. Thus the union of all trivial blocks in  $B$  is a collection of paths  $P$  whose endvertices are in non-trivial blocks and have degree at least  $3$  in  $H$ . We denote the union of all  $P^{\times}$  and all  $B^{\times}$  for every non-trivial  $B \in \mathcal{B}$  by  $\mathcal{B}^{\times}$ . Note that every vertex v' in  $\mathcal{B}^{\times} \cup \bigcup_{C \in \mathcal{C}} C^{\times}$  with  $d_{H^*}(v') \geq 3$  is the copy of some vertex v in  $\bigcup_{B \in \mathcal{B}} B \cup \bigcup_{C \in \mathcal{C}} C$  with  $d_H(v) \geq 3$ .

Now we show that  $H^*$  does not contain an edge-hitting set meeting all  $A$ expansions. Let  $X \subseteq E(H^*)$  be an edge set of size at most  $r-1$ . We claim that  $H^* - X$  still contains an embedding of H: Indeed, we can embed A in  $A^* - X$ such that for every  $s \in S$ , its branch set  $B_s$  contains s' by choice of  $A^*$ . For every  $D \in \mathcal{D}$ , at least one of the r copies of D is disjoint from X. Thus, we

can embed D in that copy. For every non-trivial  $B \in \mathcal{B} \cup \mathcal{C}$ , we can embed B in  $B^{\times} - X$  by construction of  $B^{\times}$ . We observed above that trivial blocks of B are contained in some paths between vertices of degree at least 3, which can be embedded in their copy in  $H^* - X$ . Together, this yields an embedding of H in  $H^* - X$  by construction of  $H^*$ .

It remains to show that there are no  $k$  edge-disjoint embeddings of  $H$  in  $H^*$ . For this, we claim:

#### <span id="page-5-1"></span>Every H-expansion in  $H^*$  contains an A-expansion in  $A^*$  $(5)$

Note that  $(5)$  proves the theorem: Indeed, by choice of  $A^*$ , there can be no k edge-disjoint embeddings of A in  $A^*$ . Let us prove [\(5\)](#page-5-1). Way say that a block B of H is embedded in a block  $B^*$  of  $H^*$ , when for every  $v \in V(B)$  with  $d_H(v) \geq 3$ , the branch set  $B_v$  contains a vertex  $v^* \in V(B^*)$  with  $d_{B^*} \geq 3$ . In this sense, every block  $B$  of  $H$  is embedded in a single block  $B^*$  of  $H^*$ . Note that every embedding of a  $C \in \mathcal{C}$  in some block of  $H^*$  contains an embedding of A by definition of C. Thus neither A nor any  $C \in \mathcal{C}$  can be embedded in any copy of some  $D \in \mathcal{D}$ . Additionally, if some  $C \in \mathcal{C}$  is embedded in  $A^*$ , this includes an embedding of  $A$  in  $A^*$ , which was what we wanted. Thus, we may assume that neither A nor any  $C \in \mathcal{C}$  is embedded in  $A^*$ .

We conclude that  $A \cup \bigcup C$  is embedded in  $\mathcal{B}^{\times} \cup \bigcup C^{\times}$ . Let  $B \in \mathcal{B}$ . By definition of B, B is on the unique path in T that connects two blocks  $C_1, C_2 \in \mathcal{C} \cup \{A\}$ . Since A is a leaf of  $T_{\mathcal{C}}$  by [\(4\)](#page-4-0) and we assumed that neither  $C_1$ nor  $C_2$  are embedded in  $A^*$ , B cannot be embedded in  $A^*$ . For every  $D \in \mathcal{D}$ , there is a cutvertex separating D from all  $C \in \{A\} \cup C$ . Therefore, B cannot be embedded in D. We conclude that B is embedded in  $\mathcal{B}^{\times} \cup \bigcup C^{\times}$ .

 $C \in \mathcal{C}$ To sum up,  $A \cup \bigcup$  $\bigcup_{B \in \mathcal{B}} B \cup \bigcup_{C \in \mathcal{C}}$  $\bigcup_{C \in \mathcal{C}} C$  is embedded in  $\mathcal{B}^{\times} \cup \bigcup_{C \in \mathcal{C}}$  $C \in \mathcal{C}$  $C^{\times}$ . However, the number of vertices v in  $\bigcup_{B \in \mathcal{B}} B \cup \bigcup_{C \in \mathcal{C}}$  $\bigcup_{C \in \mathcal{C}} C$  with  $d_H(v) \geq 3$  is the same as the number of vertices  $v'$  in  $\mathcal{B}^{\times} \cup \bigcup$  $C \in \mathcal{C}$  $C^{\times}$  with  $d_{H^*}(v') \geq 3$ .

By by Remark [2,](#page-1-1) A contains at least one vertex v with  $d_A(v) \geq 3$ . Since A is 2-connected, we conclude that it must contain at least two vertices  $v$  with  $d_A(v) \geq 3$ . Since A is a leaf of  $T_C$ , it shares exactly one vertex with  $\bigcup B \cup$ B∈B

U  $\bigcup_{C \in \mathcal{C}} C$ . Thus,  $A \setminus \left( \bigcup_{B \in \mathcal{C}}$  $\bigcup_{B \in \mathcal{B}} B \cup \bigcup_{C \in \mathcal{C}}$  $C \in \mathcal{C}$  $\left(C\right)$  contains at least one vertex v with  $d_H(v) \geq$  $d_A(v) \geq 3$ . But then it is impossible to embed  $A \cup \bigcup$ B∈B B∪ S  $C \in \mathcal{C}$  $C$  in  $\mathcal{B}^{\times} \cup$   $\bigcup$  $C \in \mathcal{C}$  $C^{\times}.$ Thus, Claim [\(2\)](#page-2-0) holds, proving the theorem.
