# Second order quantitative bounds for unadjusted generalized Hamiltonian Monte Carlo 

Evan Camrud, Alain Durmus, Pierre Monmarché, Gabriel Stoltz

May 14, 2024

#### Abstract

This paper provides a convergence analysis for generalized Hamiltonian Monte Carlo samplers, a family of Markov Chain Monte Carlo methods based on leapfrog integration of Hamiltonian dynamics and kinetic Langevin diffusion, that encompasses the unadjusted Hamiltonian Monte Carlo method. Assuming that the target distribution $\pi$ satisfies a log-Sobolev inequality and mild conditions on the corresponding potential function, we establish quantitative bounds on the relative entropy of the iterates defined by the algorithm, with respect to $\pi$. Our approach is based on a perturbative and discrete version of the modified entropy method developed to establish hypocoercivity for the continuous-time kinetic Langevin process. As a corollary of our main result, we are able to derive complexity bounds for the class of algorithms at hand. In particular, we show that the total number of iterations to achieve a target accuracy $\varepsilon>0$ is of order $d / \varepsilon^{1 / 4}$, where $d$ is the dimension of the problem. This result can be further improved in the case of weakly interacting mean field potentials, for which we find a total number of iterations of order $(d / \varepsilon)^{1 / 4}$.

## 1 Introduction

We consider in this paper the problem of sampling from a target distribution $\pi$. This problem is ubiquitous in various fields such as statistical physics [36], statistics [24], and machine learning [2]. However, in most applications, the distribution $\pi$ has a density with respect to a dominating measure known up to an intractable multiplicative constant. Markov chain Monte Carlo methods are now a family of popular algorithms for solving this problem. They consist in designing a Markov chain associated with a Markov kernel for which $\pi$ is an invariant distribution. One of the best known MCMC instances is the family of Metropolis-Hastings algorithms [40,31]. In the case where the target distribution has a smooth and positive density with respect to the Lebesgue measure on $\mathbb{R}^{d}$, denoted by $\pi$ still, another class of MCMC algorithms is based on discretizations of continuous-time stochastic dynamics [27, 26, 45]. Famous examples of such MCMC methods are the Unadjusted

Langevin Algorithm (ULA) [44] and Stochastic Gradient Langevin Dynamics [51], which are based on the overdamped Langevin diffusion.

Here we consider numerical schemes based on Hamiltonian-type dynamics, i.e., ideal Hamiltonian Monte Carlo and kinetic (or underdamped) Langevin diffusion. Although these two dynamics are different, they have many features in common. For example, both define an extended process on $\mathbb{R}^{2 d}$ that has the product of $\pi$ and the standard Gaussian distribution as invariant measure, denoted hereafter by $\mu$. Also, the infinitesimal generators of these extended processes differ only in their symmetric parts, while their antisymmetric parts are the same and correspond to the Hamiltonian dynamics associated with the potential $U$ associated with $\pi$, i.e., $\pi \propto \exp (-U)$. From this observation it follows that common discretization strategies have been employed for both dynamics. Among these methods, those based on splitting techniques [9, 34] are particularly attractive since they come with valuable properties and important convergence guarantees.

In this paper, we are particularly interested in the family of splitting methods known as generalized Hamiltonian Monte Carlo (gHMC). This method has been shown to yield weak second order errors. More precisely, denoting by $\mathrm{P}_{\omega}$ the Markov kernel associated with gHMC, where $\boldsymbol{\omega}$ are the hyperparameters of the algorithm including the step size $\delta>0$, the refreshment rate $\eta$ and the integration time $\mathrm{T}>0$, the following convergence bound holds under suitable conditions (see e.g. [1] for the Langevin case $\mathrm{T}=\delta$ ): for any sufficiently regular function $f: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$ and initial distribution $\nu_{0}$, there exist $C_{f} \geqslant 0$ and $c_{1}>0$ depending on the parameters $\boldsymbol{\omega}$ only through the friction $\gamma=(1-\eta) / \mathrm{T}\left(c_{1}\right.$ being independent of $\left.f, \nu_{0}\right)$ such that for any number of iterations $k \in \mathbb{N},\left|\nu_{0} \mathrm{P}_{\omega}^{k} f-\pi(f)\right| \leqslant C_{f}\left(\mathrm{e}^{-c_{1} \top k}+\delta^{2}\right)$. This result illustrates the advantages of using well-chosen splitting strategies compared to traditional Euler schemes, for which similar conclusions can be drawn but with a larger second term on the right hand side of the previous inequality, typically of order $\delta$ instead of $\delta^{2}$. While weak error bounds already provide significant convergence guarantees, another line of research is concerned with establishing quantitative bounds for MCMC algorithms, paying particular attention to the dimension dependence [15, 20].

Regarding the kinetic Langevin algorithm, existing works [37, 13, 52, 16] analyze for most of them a modification of the Euler scheme. For this particular algorithm, [37] shows that, when $\pi$ satisfies a $\log$-Sobolev inequality and under additional conditions on $U$, and denoting by $\nu_{k}$ the distribution of the $k$-th iterate of the algorithm starting from $\nu_{0}$ with step size $\delta>0$, there are constants $C_{\nu_{0}} \geqslant 0$ and $c_{1}>0$, independent of $\delta$, such that for any $k \in \mathbb{N}, \mathcal{H}\left(\nu_{k} \mid \pi\right) \leqslant C_{\nu_{0}}\left(\mathrm{e}^{-c_{1} \delta k}+\delta^{2}\right)$. where $\mathcal{H}$ denotes the relative entropy or KullbackLeibler divergence. Note that the Pinsker inequality then implies the same type of bounds for the total variation distance, but with a second term of order $\delta$.

Quantitative bounds for splitting schemes of the kinetic Langevin diffusion are scarcer up to our knowledge. Higher order quantitative bounds are established in [42] in this context for the case when the potential $U$ is convex. On the other hand, regarding unadjusted HMC, combining results from [6] and [18] implies that, for a fixed integration time $T>0$, there exists $c_{1}>0$ (depending on the parameters of the dynamics only through T ) such
that, for any initial distribution $\nu_{0}, k \in \mathbb{N}, \mathbf{W}_{1}\left(\tilde{\nu}_{k}, \pi\right) \leqslant C_{\nu_{0}}\left(\mathrm{e}^{-c_{1} k}+\delta^{2}\right)$, where $C_{\nu_{0}} \geqslant 0$ is a constant, $\tilde{\nu}_{k}$ is the distribution of the $k$-th iterates of unadjusted HMC starting from $\nu_{0}$, and $\mathbf{W}_{1}$ denotes the Wasserstein distance of order 1. This result once again highlights the improved accuracy of the leapfrog integrator. Finally, the analysis of gHMC in the Wasserstein distance has been conducted in [25], but only for the strongly convex scenario.

The main contribution of this paper is to extend and generalize to the non-convex scenario the results we just mentioned and to analyze gHMC. In particular, we show that gHMC achieves a higher order accuracy than traditional Euler schemes in relative entropy, under the condition that $\pi$ satisfies a log-Sobolev inequality, and additional relatively mild assumptions on the potential energy function $U$. Roughly speaking, we establish a bound of the form $\mathcal{H}\left(\nu_{0} \mathrm{P}^{k} \mid \mu\right) \leqslant C_{\nu_{0}} \mathrm{e}^{-c_{1} k}+C_{2} \delta^{4}$ for some explicit constants $C_{\nu_{0}}, C_{2} \geqslant 0$ and $c_{1}>0$. Our approach is based on a perturbative argument of the modified entropy approach initiated in [49], and more precisely to its recent discrete-time variation in [41] for idealized gHMC. From our main result, we derive bounds on the total number of iterations $k$ and a step size $\delta$ to achieve $\mathcal{H}\left(\nu_{0} \mathrm{P}^{k} \mid \mu\right) \leqslant \varepsilon$ for some $\varepsilon>0$, where two cases can be distinguished: in the general case, we obtain a bound on the number of gradient computations of order $\mathcal{O}\left(d / \varepsilon^{1 / 4}\right)$; while in a weakly interacting mean-field regime, an improved bound of order $\mathcal{O}\left((d / \varepsilon)^{1 / 4}\right)$ can be achieved.

The paper is organized as follows. The family of (unadjusted) generalized Hamiltonian Monte Carlo samplers is introduced in Section 2.1. Our main assumptions and results are stated in Section 2.2. They are discussed and compared to previous works in Section 2.3. Section 3 is devoted to the proof of Theorem 1. Other more technical proofs are postponed to Appendices.

Notation. We denote by $|x|$ the Euclidean norm of $x \in \mathbb{R}^{d}$. We denote by $\mathrm{C}^{k}\left(\mathbb{R}^{d}\right)$ the set of functions from $\mathbb{R}^{d}$ to $\mathbb{R}$ with continuous derivatives up to order $k$. For $f \in \mathrm{C}^{k}\left(\mathbb{R}^{d}\right)$, $\nabla f$ stands for the gradient of $f$ and $\mathrm{D}^{k} f$ for the $k$-th derivative of $f$. In addition, $\left|\mathrm{D}^{k} f(x)\right|$ is the multilinear operator norm of $\mathrm{D}^{k} f(x)$ with respect to the Euclidean norm on $\mathbb{R}^{d}$ and $\left\|\mathrm{D}^{k} f\right\|_{\infty}=\sup _{x \in \mathbb{R}^{d}}\left|\mathrm{D}^{k} f(x)\right|$. For a $d \times d$ matrix $\mathbf{A},|\mathbf{A}|$ stands for the operator norm on $\mathbb{R}^{d}$ with respect to the Euclidean norm. For a differentiable map $\Phi: \mathbb{R}^{d} \rightarrow \mathbb{R}^{p}$ and $x \in \mathbb{R}^{d}$ we write $\nabla \Phi(x)=\left(\partial_{x_{i}} \Phi_{j}(x)\right)_{i \in \llbracket 1, d \rrbracket, j \in \llbracket 1, p \rrbracket}$ (where $i$ stands for the line and $j$ for the column). This notation is such that $\nabla(\Phi \circ \Psi)=\nabla \Psi \nabla \Phi \circ \Psi$ and is consistent in the case $p=1$ (since $\nabla \Phi$ is in that case the gradient of $\Phi$ ). Notice that $\nabla \Phi$ is the transpose of what is most commonly named the Jacobian matrix of $\Phi$.

Leb stands for the Lebesgue measure, $\mathrm{N}\left(0, \mathrm{I}_{d}\right)$ for the $d$-dimensional standard Gaussian distribution and $\mathcal{P}\left(\mathbb{R}^{d}\right)$ for the set of distribution of $\mathbb{R}^{d}$ endowed with its Borel $\sigma$-field denoted by $\mathcal{B}\left(\mathbb{R}^{d}\right)$. We write $\nu \ll \mu$ when $\nu$ is absolutely continuous with respect to $\mu$. We define the relative entropy (or Kullback-Leibler [KL-] divergence) and the Fisher
information of $\nu_{1} \in \mathcal{P}\left(\mathbb{R}^{d}\right)$ with respect to $\nu_{2} \in \mathcal{P}\left(\mathbb{R}^{d}\right)$ respectively as
$\mathcal{H}\left(\nu_{1} \mid \nu_{2}\right)=\left\{\begin{array}{ll}\int \ln \left(\frac{\mathrm{d} \nu_{1}}{\mathrm{~d} \nu_{2}}\right) \mathrm{d} \nu_{2} & \text { if } \nu_{1} \ll \nu_{2} \\ +\infty & \text { otherwise }\end{array}, \quad \mathcal{I}\left(\nu_{1} \mid \nu_{2}\right)=\left\{\begin{array}{ll}\int\left|\nabla \ln \left(\frac{\mathrm{d} \nu_{1}}{\mathrm{~d} \nu_{2}}\right)\right|^{2} \mathrm{~d} \nu_{1} & \text { if } \nu_{1} \ll \nu_{2} \\ +\infty & \text { otherwise }\end{array}\right.\right.$, where for a measurable function $f: \mathbb{R}^{d} \rightarrow \mathbb{R},|\nabla f|$ is defined for any $z \in \mathbb{R}^{d}$ as

$$
|\nabla f|(z)=\lim _{r \downarrow 0} \sup \left\{\frac{|f(z)-f(y)|}{|z-y|}: y \in \mathbb{R}^{d}, 0<|y-z| \leqslant r\right\}
$$

If $f$ is continuously differentiable, note that $|\nabla f|(z)$ is simply the norm of $\nabla f(z)$ and therefore our notation is consistent.

We write $\llbracket i, j \rrbracket$ the integer interval $\{i, \ldots, j\}$ for $i, j \in \mathbb{Z}$.

## 2 Non-asymptotic bounds for splitting schemes for Hamiltonian type dynamics

### 2.1 Splitting schemes for Hamiltonian type dynamics - gHMC

Recall that we assume that the target distribution $\pi$ admits a positive density with respect to the Lebesgue measure $\pi \propto \exp (-U)$. In addition, we suppose the following condition on $U$.

H1. The potential $U \in \mathrm{C}^{4}\left(\mathbb{R}^{d}\right)$ is such that $\mathrm{e}^{-U} \in \mathrm{~L}^{1}\left(\mathbb{R}^{d}\right)$, and there exists $L>0$ such that $\left|\nabla^{2} U(x)\right| \leqslant L$ for any $x \in \mathbb{R}^{d}$.

We now introduce more formally the two continuous dynamics that are considered in this work: Hamiltonian dynamics and kinetic (also referred to as underdamped) Langevin dynamics. As previously mentioned, these two dynamics leave the extended target distribution $\mu=\pi \otimes \mathrm{N}\left(0, \mathrm{I}_{d}\right)$ invariant.

Ideal Hamiltonian Monte Carlo. The Hamiltonian dynamics associated with the potential $U$ defines the differential flow $\left(\psi_{t}\right)_{t \geqslant 0}$ for any $t \in \mathbb{R}_{+}$and $x, v \in \mathbb{R}^{d}$ as $\psi_{t}(x, v)=$ $\left(x_{t}, v_{t}\right)$, where $\left(x_{t}, v_{t}\right)_{t \geqslant 0}$ is the solution of the Hamiltonian differential equation:

$$
\begin{equation*}
\partial_{t} x_{t}=v_{t}, \quad \partial_{t} v_{t}=-\nabla U\left(x_{t}\right), \quad \text { with }\left(x_{0}, v_{0}\right)=(x, v) . \tag{1}
\end{equation*}
$$

As discussed in [43] for instance, the flow $\left(\psi_{t}\right)_{t \geqslant 0}$ preserves $\mu$, i.e., if $\left(X_{0}, V_{0}\right)$ has distribution $\mu$ then so does $\psi_{t}\left(X_{0}, V_{0}\right)$ for all $t \geqslant 0$. However, the trajectory $\left(\psi_{t}\left(X_{0}, V_{0}\right)\right)_{t \geqslant 0}$ is of course not ergodic for $\mu$ as, starting from any fixed initial conditions $x_{0}, v_{0} \in \mathbb{R}^{d}$, it remains in the corresponding level set $\left\{(x, v) \in \mathbb{R}^{2 d}: H(x, v)=H\left(x_{0}, v_{0}\right)\right\}$ of the Hamiltonian function $H$ defined by

$$
H(x, v)=U(x)+\frac{1}{2}|v|^{2} .
$$

To address this issue, one can add a velocity randomization (or refreshment) at deterministic times multiple of $\mathrm{T}>0$. To formalize this procedure, consider the Markov operator $\mathrm{D}_{\eta}$ given, for $\eta \in[0,1)$ and any measurable and bounded function $f: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$, by

$$
\mathrm{D}_{\eta} f(x, v)=\int_{\mathbb{R}^{d}} f\left(x, \eta v+\sqrt{1-\eta^{2}} g\right) \boldsymbol{\varphi}(g) \mathrm{d} g,
$$

where $\boldsymbol{\varphi}$ stands for the density with respect to Leb of $\mathrm{N}\left(0, \mathrm{I}_{d}\right)$. Then, under mild assumptions, the resulting kernel

$$
\begin{equation*}
\mathrm{K}_{\eta, \mathrm{T}} f(x, v)=\mathrm{D}_{\eta}\left[f \circ \psi_{\mathrm{T}}\right](x, v), \tag{2}
\end{equation*}
$$

is ergodic with respect to $\mu$. Recently, [41] used hypocoercivity techniques from [49] to show exponential convergence of $\mathrm{K}_{\eta, \mathrm{T}}$ in a modified entropy with respect to $\mu$.

Underdamped Langevin dynamics. The second process which shares some important features with Hamiltonian dynamics is the underdamped Langevin diffusion:

$$
\begin{equation*}
\mathrm{d} \mathbf{X}_{s}=\mathbf{V}_{s} \mathrm{~d} s, \quad \mathrm{~d} \mathbf{V}_{s}=-\nabla U\left(\mathbf{X}_{s}\right) \mathrm{d} s-\gamma \mathbf{V}_{s} \mathrm{~d} s+\sqrt{2 \gamma} \mathrm{~d} B_{s}, \tag{3}
\end{equation*}
$$

where $\left(B_{s}\right)_{s \geqslant 0}$ is a $d$-dimensional Brownian motion and $\gamma>0$ is a damping parameter. It can easily be shown that under mild assumptions on $U$, the Hamiltonian dynamics with a suitably scaled refreshment weakly converges to (3): for any $s \geqslant 0, x, v \in \mathbb{R}^{d}$ and smooth and bounded function $f: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$, it holds $\lim _{\delta \rightarrow 0} \mathrm{~K}_{\eta_{\delta}, \delta}^{[s / \delta]} f(x, v)=\mathbf{P}_{s} f(x, v)$ where

$$
\begin{equation*}
\eta_{\delta}=\mathrm{e}^{-\delta \gamma}, \tag{4}
\end{equation*}
$$

and $\left(\mathbf{P}_{s}\right)_{s \geqslant 0}$ is the Markov semigroup associated with (3).
Discretizations of underdamped Langevin and ideal HMC. We now present a family of splitting schemes which encompasses discretizations for both Hamiltonian and underdamped Langevin dynamics. This family of algorithms will be referred to as generalized Hamiltonian Monte Carlo (gHMC). It is based on the Verlet discretization of (1) defined at time $k \delta$, for $k \in \mathbb{N}$ and a given stepsize $\delta>0$, by $\left(x_{k}, v_{k}\right)=\Phi_{\delta}^{k}\left(x_{0}, v_{0}\right)$ where $\Phi_{\delta}^{k}=\Phi_{\delta}^{k-1} \circ \Phi_{\delta}$, with $\Phi_{\delta}^{0}$ is the identity function and

$$
\Phi_{\delta}=\Phi_{\delta / 2}^{(v)} \circ \Phi_{\delta}^{(x)} \circ \Phi_{\delta / 2}^{(v)}, \quad \Phi_{\delta / 2}^{(v)}(x, v)=(x, v-(\delta / 2) \nabla U(x)), \quad \Phi_{\delta}^{(x)}(x, v)=(x+\delta v, v) .
$$

It is well-known that the integrator $\Phi_{\delta}$ is symplectic and reversible (see [30]). Its inverse reads

$$
\begin{equation*}
\Phi_{\delta}^{-1}=\mathrm{R} \circ \Phi_{\delta} \circ \mathrm{R}, \quad \mathrm{R}(x, v)=(x,-v) . \tag{5}
\end{equation*}
$$

The gHMC algorithm then consists in the composition of a (possibly partial) velocity refreshment with a $K$-step Verlet scheme. Setting $\boldsymbol{\omega}=(K, \delta, \eta)$, this corresponds to the inexact Markov chain Monte Carlo (MCMC) method with Markov kernel specified by

$$
\mathrm{P}_{\omega}=\mathrm{D}_{\eta} \mathrm{V}_{\delta}^{K},
$$

where $\mathrm{V}_{\delta}$ corresponds to the deterministic kernel

$$
\mathrm{V}_{\delta}((x, v), \cdot)=\delta_{\Phi_{\delta}(x, v)}(\cdot), \quad \text { for } x, v \in \mathbb{R}^{d}
$$

For $\eta=0$ and $K \delta=\mathrm{T}$ for an integration time $\mathrm{T}>0$, the kernel $\mathrm{P}_{\boldsymbol{\omega}}$ corresponds to the usual unadjusted Hamiltonian Monte Carlo algorithm, which is a discretized version of the ideal Hamiltonian dynamics $\mathrm{K}_{\mathrm{T}, \eta}$ defined by (2). On the other hand, with $K=1$ and the damping parameter $\eta_{\delta}$ defined in (4), the kernel $\mathrm{P}_{\boldsymbol{\omega}}$ corresponds to a splitting scheme whose invariant probability measure is correct at second order in $\delta$ (this corresponds in fact to the so-called GLA scheme [7]; see also [34, 36] for other splitting schemes). Alternatively, taking $\eta=0$ and $K=1$ leads to the Euler-Maruyama scheme with step size $\delta^{2} / 2$ for the overdamped Langevin process.

Normalization and rescaling. When $\mathbf{H} 1$ is satisfied, we introduce

$$
\begin{equation*}
\mathrm{T}=\delta K \sqrt{L}, \quad \gamma=(1-\eta) / \mathrm{T}, \tag{6}
\end{equation*}
$$

which are respectively, up to a suitable rescaling, the physical time of integration of the Hamiltonian dynamics by the Verlet integrator, and the strength of the damping. As discussed in [25], upon rescaling the process so that $L=1$ (see the discussion in Section 2.2.1), the time needed for the process to forget its initial velocity is of order $1 / \gamma$, so that this quantity is also the typical distance covered by one of the coordinates of the process in a single ballistic run in flat parts of the space.

### 2.2 Main result

We present in this section our main result, under additional assumptions regarding $\pi$ and $U$ (see Section 2.2.1). We next provide in Section 2.2 .2 sufficient conditions under which these additional assumptions are satisfied.

### 2.2.1 Uniform convergence in time

Additional assumptions. Our first assumption is that $\pi$ satisfies a log-Sobolev inequality with constant $C_{\mathrm{LS}} \geqslant 0$, i.e.

$$
\begin{equation*}
\forall \nu \in \mathcal{P}\left(\mathbb{R}^{d}\right), \quad \mathcal{H}(\nu \mid \pi) \leqslant C_{\mathrm{LS}} \mathcal{I}(\nu \mid \pi) . \tag{7}
\end{equation*}
$$

Various sufficient conditions for this inequality to hold have been derived, see [4]. It holds for instance when $U$ is uniformly convex outside some compact set. Various estimates are available for $C_{\mathrm{LS}}$, e.g. in mean-field, convex or low-temperature cases, which can capture more specific information on the target $\pi$ than uniform bounds on the curvature $\langle x-y, \nabla U(x)-\nabla U(y)\rangle /|x-y|^{2}$ that are used in direct coupling methods. Notably, in non-convex cases, for a fixed dimension $d$, up to polynomial terms in the other parameters, the $\log$-Sobolev constant is of order $\mathrm{e}^{c_{*}}$ where $c_{*}$ is the so-called critical height of $U$ (see [41, Section 5] and references within).

Part of our analysis consists in controlling some numerical errors of the leapfrog integrator, i.e., for example differences of the Hamiltonian function evaluated at the dynamics at times 0 and $s>0$ starting from the $k$-th iterates of the gHMC chain. To this end, we need additional regularity conditions on $U$. More specifically, we require uniform bounds on the third and fourth derivatives of $U$, as made precise in the following condition.
H2. There exist two norms $\mathrm{N}_{3}$ and $\mathrm{N}_{4}$ on $\mathbb{R}^{d}$ such that, for all $x, y, z \in \mathbb{R}^{d}$,

$$
\begin{align*}
\left|\left(\nabla^{2} U(x+y)-\nabla^{2} U(x)\right) z\right| & \leqslant \mathrm{N}_{3}(y) \mathrm{N}_{3}(z),  \tag{8}\\
\left|\nabla U(x+y)-\nabla U(x)-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U(x+y)\right) y\right| & \leqslant \mathrm{N}_{4}^{3}(y) . \tag{9}
\end{align*}
$$

Using a third order Taylor expansion of $\nabla U$, it can be shown that (9) follows from a uniform bound on the third and fourth derivatives of $U$ (see Proposition 2 below). H2 may be relaxed, i.e, if one assumes only bounded third derivatives for $U$, our main result still holds but with worse dependencies with respect to the step size, see Remark 15 below.

Bounding the left-hand sides in (8) and (9) with respect to the Euclidean distance on $\mathbb{R}^{d}$ may lead to sub-optimal dependencies with respect to the dimension $d$ in Theorem 1 below (for instance when $U$ is separable, see Theorem 3 below), which is why we allow in $\mathbf{H} 2$ some flexibility in the choice of the norms. A specific choice of norms is given in Proposition 2, and the relevance of this choice for the dimensionality dependence is discussed in Remark 4.

As made precise in Section 3.4, the numerical errors that need to be controlled at a point $(x, v) \in \mathbb{R}^{2 d}$ can be bounded by the function

$$
\begin{equation*}
\mathbf{M}(x, v)=L^{2}|v|^{2}+L^{2}|\nabla U(x)|^{2}+\mathrm{N}_{3}^{4}(v)+\mathrm{N}_{3}^{4}(\nabla U(x))+\mathrm{N}_{4}^{6}(v)+\mathrm{N}_{4}^{6}(\nabla U(x)) . \tag{10}
\end{equation*}
$$

In order to control the expectation of these errors, one needs uniform moment bounds for the Markov kernel $P_{\omega}$. These estimates typically follow from a Lyapunov condition, but for clarity we postpone this analysis to Theorem 3 below and, for the time being, state it as the next assumption.
H 3. There exist $\rho, C_{1}, C_{2}>0$ and $\mathfrak{W}: \mathbb{R}^{2 d} \rightarrow \mathbb{R}_{+}$such that, for all $(x, v) \in \mathbb{R}^{2 d}, k \in$ $\{0, \ldots, K\}$ and $n \in \mathbb{N}$,

$$
\mathrm{P}_{\omega}^{n} \mathrm{D}_{\eta} \mathrm{V}_{\delta}^{k} \mathrm{M}(x, v) \leqslant C_{1} \mathrm{e}^{-\rho n \mathrm{~T}} \mathfrak{W}(x, v)+C_{2},
$$

where T is defined in (6).

In practice, this can be established by designing a suitable Lyapunov function $\mathfrak{W}$ such that $\mathbf{M} \leqslant C_{1} \mathfrak{W}$ and

$$
\begin{equation*}
\mathrm{P}_{\omega} \mathfrak{W} \leqslant \mathrm{e}^{-\rho \mathrm{T}} \mathfrak{W}+C_{2}^{\prime} \mathrm{T}, \tag{11}
\end{equation*}
$$

for some constants $C_{1}, C_{2}^{\prime}, \rho>0$. As we will see in Theorem 3, the constants $C_{1}, C_{2}, \rho$ typically only depend on the parameters $\boldsymbol{\omega}$ through $\gamma$ defined in (6). In particular, they are uniform over all sufficiently small step-sizes $\delta$. For the continuous-time kinetic Langevin diffusion and its discretizations, such Lyapunov functions have been designed in [39, 47, 19] under coercitivity conditions on $U$. We show in Appendix B that appropriate modifications of these Lyapunov functions can be used to establish a drift condition (11) for $\mathrm{P}_{\boldsymbol{\omega}}$.

Main convergence result. We are now in position to state our main result. For the sake of clarity, we only consider the case where $L=1$ in $\mathbf{H} 1$, the general case being obtained by rescaling, as discussed at the end of this section.

Theorem 1. Assume that $\boldsymbol{H} 1-\boldsymbol{H}_{2}$ hold with $L=1$, and consider $\boldsymbol{\omega}=(K, \delta, \eta)$ with $K \in$ $\mathbb{N}^{*}, \delta>0$ and $\eta \in[0,1)$ such that $\boldsymbol{H} 3$ holds and $\mathrm{T}=K \delta \leqslant 1 / 10$. Furthermore, assume that $\pi$ satisfies the log-Sobolev inequality (7). Consider an initial condition $\nu_{0}$ such that $\mathcal{I}\left(\nu_{0} \mid \mu\right)<+\infty$ and $\int_{\mathbb{R}^{2 d}}|z|^{p} \mathrm{~d} \nu_{0}(z)<+\infty$ for any $p>0$. Then, for any $n \in \mathbb{N}$,

$$
\begin{align*}
\mathcal{H}\left(\nu_{0} \mathrm{P}_{\boldsymbol{\omega}}^{n} \mid \mu\right) \leqslant & (1+\kappa \mathrm{T})^{-n}\left[\mathcal{H}\left(\nu_{0} \mid \mu\right)+2 a \mathcal{I}\left(\nu_{0} \mid \mu\right)\right] \\
& +\delta^{4} M\left[n \mathrm{~T} \theta^{n \mathrm{~T}} C_{1} \nu_{0}(\mathfrak{W})+C_{2}\left(\kappa^{-1}+\mathrm{T}\right)\right] \tag{12}
\end{align*}
$$

where $\theta=\max \left(\mathrm{e}^{-\rho},(1+\kappa \mathrm{T})^{-1 / \mathrm{T}}\right)$ and

$$
\begin{equation*}
a=\frac{\gamma}{7+3(\gamma+3)^{2}}, \quad \kappa=\frac{a}{3 \max \left(C_{\mathrm{LS}}, 1\right)+6 a}, \quad M=9+\frac{1}{a} . \tag{13}
\end{equation*}
$$

The first term on the right hand side of (12) encodes the long-time convergence of the idealized HMC chain [41] (and goes to 0 as $n \rightarrow \infty$ ). The Fisher term $\mathcal{I}\left(\nu_{0} \mid \mu\right)$ appearing there is due to the fact Theorem 1 is proven using a modified entropy (defined in (21)) instead of $\mathcal{H}$. The second line of (12), of order $\delta^{4}$, corresponds to the numerical error due to the Verlet integration, which is decomposed into two terms. The first one comes from the fact that the initial condition is not invariant under $\mathrm{P}_{\boldsymbol{\omega}}$ and highlights the exponential forgetting of this initial condition since $\theta<1$. The second term involving $C_{2}$ accounts for the numerical error at stationarity, i.e. the bias between the invariant probability measure of the discrete process and the reference probability measure $\mu$.

Since, in the case $L=1$, the physical integration time of the Hamiltonian dynamics is T , the total physical time of the simulation after $n$ iterations is $n$ T. The constant $\kappa$ is therefore the convergence rate per unit physical time. In view of (13), $\kappa$ depends on the parameters $\boldsymbol{\omega}$ only through the friction $\gamma$, with a dependency of order $\min \left(\gamma, \gamma^{-1}\right)$ similarly to what is obtained for the continuous-time Langevin diffusion (see for instance [17, 28, 33]). From this observation, it follows that the convergence per gradient computation is $\kappa \mathrm{T} / K=\kappa \delta$.

At the expense of more involved expressions, we provide an improved version of Theorem 1 in Theorem 5 below. In particular, we provide a slightly sharper value of $\kappa$, which is optimal in the overdamped case since, in the continuous time limit $\delta \rightarrow 0$, one obtains (see Remark 6)

$$
\begin{equation*}
\mathcal{H}\left(\hat{\nu}_{0} \mathrm{Q}_{s} \mid \pi\right) \leqslant \mathrm{e}^{-s / C_{\mathrm{LS}}} \mathcal{H}\left(\hat{\nu}_{0} \mid \pi\right), \tag{14}
\end{equation*}
$$

where $\left(\mathrm{Q}_{t}\right)_{t \geqslant 0}$ is the semi-group associated to the overdamped Langevin diffusion. This shows that our result is sharp since it implies that $\pi$ satistifes a log-Sobolev inequality with constant $C_{\mathrm{LS}}$ (see e.g., [4, Theorem 5.2.1]).

Rescaling. As mentioned above, following [41, Section 1.3], it is not restrictive to assume that $L=1$ in $\mathbf{H} 1$. Indeed, if $Z_{n}=\left(X_{n}, V_{n}\right)$ is an unadjusted gHMC chain with potential energy function $U$ and parameters $K, \delta, \eta$, then $\left(\sqrt{L} X_{n}, V_{n}\right)$ is an unadjusted gHMC chain associated with the potential energy function $\tilde{U}(x)=U(x / \sqrt{L})$ (so that $\nabla \tilde{U}$ is 1-Lipschitz under H1) and parameters $K, \delta \sqrt{L}, \eta$. Moreover, if $\pi$ satisfies a log-Sobolev inequality with constant $C_{\mathrm{LS}}$, then the change of variable $x \mapsto x / \sqrt{L}$ implies that the rescaled target measure $\tilde{\pi} \propto \mathrm{e}^{-\tilde{U}}$ satisfies a log-Sobolev inequality with constant $L C_{\text {LSS }}$. Similarly, using the same change of variable, the relative entropy is invariant by scaling, namely, if ( $X, V$ ) has distribution $\nu \in \mathcal{P}\left(\mathbb{R}^{2 d}\right)$ and $\tilde{\nu}$ stands for the law of $(\sqrt{L} X, V)$, then $\mathcal{H}(\nu \mid \mu)=\mathcal{H}(\tilde{\nu} \mid \tilde{\mu})$, where $\tilde{\mu}=\tilde{\pi} \otimes \mathrm{N}\left(0, \mathrm{I}_{d}\right)$; while the Fisher information satisfies

$$
\mathcal{I}(\tilde{\nu} \mid \tilde{\mu})=\int_{\mathbb{R}^{2 d}} \frac{L^{-1}\left|\nabla_{x} h\right|^{2}+\left|\nabla_{v} h\right|^{2}}{h} \mathrm{~d} \mu, \text { where } h=\mathrm{d} \nu / \mathrm{d} \mu .
$$

### 2.2.2 Sufficient conditions for H2 and H3

We now provide practical conditions on $U$ to establish $\mathbf{H} 2$ and $\mathbf{H} 3$. We assume that $d=d_{0} q$ for some $d_{0}, q \geqslant 1$ and, decomposing $x=\left(x_{1}, \ldots, x_{d_{0}}\right) \in \mathbb{R}^{d}=\left(\mathbb{R}^{q}\right)^{d_{0}}$, that $U$ is of the following form:

$$
\begin{equation*}
U(x)=\sum_{i=1}^{d_{0}} U^{(q)}\left(x_{i}\right)+\frac{\epsilon}{d_{0}} \sum_{i, j=1}^{d_{0}} W^{(q)}\left(x_{i}-x_{j}\right), \tag{15}
\end{equation*}
$$

where $U^{(q)}$ and $W^{(q)}$ are potentials defined on $\mathbb{R}^{q}$, and $\epsilon>0$. Such mean field potentials are commonly encountered in various applications (see e.g., [10]). Furthermore, in line with the approach taken in [8], we consider this formulation as a representative example to demonstrate the dimension dependence in weakly correlated cases. Let us however emphasize that (15) is not a restrictive setting since it always holds with the choice $d_{0}=1$, $U^{(q)}=U$, and $W^{(q)}=0$. However, as discussed below, this mean-field formulation allows us to precisely determine the dependence of $C_{1}$ and $C_{2}$ in $\mathbf{H} 3$ on the dimension $d$, in particular by distinguishing the roles of $d_{0}$ and $q$. For conditions under which $\pi$ satisfies a log-Sobolev inequality with a constant $C_{\mathrm{LS}}$ independent of $d_{0}$ for $U$ given by (15) (provided $\epsilon$ is sufficiently small), see [29, Theorem 8].

First, as proved in Appendix A, we can readily obtain the following.
Proposition 2. Assume that $d=d_{0} q$ for some $d_{0}, q \geqslant 1$ and that $U$ is of the form (15) where $U^{(q)}, W^{(q)} \in \mathrm{C}^{4}\left(\mathbb{R}^{q}\right)$ have uniformly bounded third and fourth derivatives. Then $\mathbf{H}^{2}$ holds with

$$
N_{3}(x)=L_{3}\left(\sum_{i=1}^{d_{0}}\left|x_{i}\right|^{4}\right)^{1 / 4}, \quad N_{4}(x)=L_{4}\left(\sum_{i=1}^{d_{0}}\left|x_{i}\right|^{6}\right)^{1 / 6},
$$

where

$$
\begin{aligned}
& L_{3}^{4}=(1+\epsilon)\left\|\mathrm{D}^{3} U^{(q)}\right\|_{\infty}^{2}+16 \epsilon(1+\epsilon)\left\|\mathrm{D}^{3} W^{(q)}\right\|_{\infty}^{2} \\
& L_{4}^{6}=\left(\frac{1+\epsilon}{144}\left\|\mathrm{D}^{4} U^{(q)}\right\|_{\infty}^{2}+\frac{4 \epsilon(1+\epsilon)}{9}\left\|\mathrm{D}^{4} W^{(q)}\right\|_{\infty}^{2}\right) q .
\end{aligned}
$$

As a consequence, assuming furthermore that $\nabla U^{(q)}(0)=0=\nabla W^{(q)}(0)$, the function $\mathbf{M}(x, v)$ defined in (10) is bounded as

$$
\mathbf{M}(x, v) \leqslant \sum_{i=1}^{d_{0}} \sum_{\ell \in\{2,4,6\}} L_{\ell}^{\ell}\left(r_{\ell}\left|x_{i}\right|^{\ell}+\left|v_{i}\right|^{\ell}\right),
$$

with $r_{2}=1, r_{\ell}=2^{\ell-1}\left\|\nabla^{2} U^{(q)}\right\|_{\infty}^{\ell}+2^{3 \ell} \epsilon^{\ell}\left\|\nabla^{2} W^{(q)}\right\|_{\infty}^{\ell}$ for $\ell \in\{4,6\}$ and $L_{2}=L$.
To establish moment bounds, we consider the following assumption.
H 4. The dimension is $d=d_{0} q$ for some $d_{0}, q \geqslant 1$ and $U$ is of the form (15) where $U^{(q)}, W^{(q)} \in \mathrm{C}^{2}\left(\mathbb{R}^{q}\right)$ have uniformly bounded second derivatives and are such that $\nabla U^{(q)}(0)=$ $\nabla W^{(q)}(0)=0$. In addition, there exist $\mathrm{m}>0$ and $\mathrm{M} \geqslant 0$ such that for any $x_{1} \in \mathbb{R}^{q}$,

$$
\begin{equation*}
\left\langle x_{1}, \nabla U^{(q)}\left(x_{1}\right)\right\rangle \geqslant \mathrm{m}\left|x_{1}\right|^{2}-\mathrm{M} \tag{16}
\end{equation*}
$$

Note that this assumption is more general than assuming that $U^{(q)}$ is strongly convex outside a compact set. For instance, a potential such as $\left|x_{1}\right|^{2}+C \cos \left|x_{1}\right|$ satisfies (16) for any $C \in \mathbb{R}$, but is not strongly convex when $|C| \geqslant 2$.

Theorem 3. Suppose that $\boldsymbol{H}_{4}$ is satisfied, and define

$$
\begin{equation*}
\mathfrak{W}(x, v)=\sum_{\ell \in\{2,4,6\}} \sum_{i=1}^{d_{0}}\left(\left|x_{i}\right|^{\ell}+\left|v_{i}\right|^{\ell}\right) . \tag{17}
\end{equation*}
$$

For any $\gamma_{0}>0$, there exist $\overline{\mathrm{T}}, \bar{\delta}, \bar{C}_{1}, \bar{C}_{2}, \bar{\epsilon}, \rho>0$, which depend on $\left\|\nabla^{2} U^{(q)}\right\|_{\infty},\left\|\nabla^{2} W^{(q)}\right\|_{\infty}$, $\mathrm{m}, \mathrm{M}, \gamma_{0}$ (but not on $q, d_{0}$ ), such that the following holds: for any $\epsilon \in(0, \bar{\epsilon}]$ and $\boldsymbol{\omega}=(K, \delta, \eta)$ with $\delta \in(0, \bar{\delta}], \eta \in[0,1)$ such that $(1-\eta) /(K \delta)=\gamma_{0}$ and $\delta K \leqslant \overline{\mathrm{~T}}$, it holds, for any $(x, v) \in$ $\mathbb{R}^{2 d}, k \in\{0, \ldots, K\}$ and $n \in \mathbb{N}$,

$$
\mathrm{P}_{\omega}^{n} \mathrm{D}_{\eta} \mathrm{V}_{\delta}^{k} \mathfrak{W}(x, v) \leqslant \bar{C}_{1} \mathrm{e}^{-\rho n K \delta} \mathfrak{W}(x, v)+\bar{C}_{2} d_{0} q^{3} .
$$

Explicit expressions for $\bar{C}_{1}, \bar{C}_{2}, \bar{\epsilon}, \rho$ are given in Appendix B, where a more detailed result, Theorem 18, is stated and proven. As explained in Appendix B, Theorem 3 is a straightforward corollary of Theorem 18.

Remark 4. In order to determine more precisely the dimension dependence of $C_{1}, C_{2}$ in $\boldsymbol{H}$ 3, obtained for $\mathfrak{W}$ given by (17) by combining Proposition 2 with Theorem 3, we treat $\left\|\mathrm{D}^{k} U^{(q)}\right\|_{\infty}$ and $\left\|\mathrm{D}^{k} W^{(q)}\right\|_{\infty}$ for $k \in\{2,3,4\}$ as constants independent from $q$. This motivates defining $R=q^{-1} \max \left\{L_{\ell}^{\ell} \max \left(r_{\ell}, 1\right): \ell \in\{2,4,6\}\right\}$, which can be considered to be uniform in $d_{0}$ and $q$ in this context, so that the expressions $C_{1}=R \bar{C}_{1} q, C_{2}=R \bar{C}_{2} d_{0} q^{4}$ capture the dimension dependence of $C_{1}, C_{2}$ in terms of $q, d_{0}$.

### 2.3 Discussion and related works

Complexity bounds. Regarding the dependence in the dimension of the constants appearing in $\mathbf{H} 3$, we distinguish two cases in view of Remark 4. In the first one, which we call the weakly interacting case, we consider that $C_{2}$ and $\nu_{0}(\mathfrak{W})$ in (12) are $\mathcal{O}(d)$. This corresponds in Remark 4 to the case where $q$ is fixed, so that $d$ is proportional to $d_{0}$. In the second case, which we call the general case, we consider that $C_{2}$ and $\nu_{0}(\mathfrak{W})$ are $\mathcal{O}\left(d^{4}\right)$. This corresponds in Remark 4 to the case $d_{0}=1$ and $d=q$. In both settings, we consider that $L, C_{1}$ and $\gamma$ are constants independent of the dimension, and that $\mathcal{H}\left(\nu_{0} \mid \mu\right)$ and $\mathcal{I}\left(\nu_{0} \mid \mu\right)$ are $\mathcal{O}(d)$ (see e.g. [48, Lemma 1]). Moreover, the convergence rate $\kappa$ is of order $1 / C_{\mathrm{LS}}$, with $C_{\mathrm{LS}}$ large, so that $(1+\kappa \mathrm{T})^{-n}$ is of order $\mathrm{e}^{-\alpha n K \delta / C_{\mathrm{LS}}}$ for some constant $\alpha>0$. In this context, Theorem 1 gives the following complexity bounds for a given error tolerance $\varepsilon>0$ (in relative entropy):

- in the general case, upon choosing $\delta=\mathcal{O}\left(\varepsilon^{1 / 4} d^{-1}\right)$ (so that the second term on the right hand side of (12) is of order $\varepsilon$ ), we get that $\mathcal{H}\left(\nu_{0} \mathrm{P}_{\omega}^{n} \mid \mu\right) \leqslant \varepsilon$ after a number $n K=\mathcal{O}\left(C_{\mathrm{LS}} d \varepsilon^{-1 / 4} \ln \left(d \varepsilon^{-1}\right)\right)$ of computations of the gradient $\nabla U$.
- in the weakly interacting case, a similar reasoning suggests choosing $\delta=\mathcal{O}\left(\varepsilon^{1 / 4} d^{-1 / 4}\right)$, in which cas $\mathcal{H}\left(\nu_{0} \mathrm{P}_{\boldsymbol{\omega}}^{n} \mid \mu\right) \leqslant \varepsilon$ after a number $n K=\mathcal{O}\left(C_{\mathrm{LS}}(d / \varepsilon)^{1 / 4} \ln \left(d \varepsilon^{-1}\right)\right)$ of computations of the gradient $\nabla U$.

Note that, in both cases, the Pinsker and Talagrand inequalities respectively imply that $\| \mu-$ $\nu_{0} \mathrm{P}_{\omega}^{n} \|_{\mathrm{TV}}$ and $\mathbf{W}_{2}\left(\mu, \nu_{0} \mathrm{P}_{\omega}^{n}\right)$ are of order $\mathcal{O}\left(\varepsilon^{1 / 2}\right)$, where $\|\cdot\|_{\text {TV }}$ and $\mathbf{W}_{2}$ respectively denote the total variation distance and Wasserstein distance of order 2 . In view of this, the dependence of the number of gradient evaluation on $\varepsilon^{1 / 2}$, namely $n K=\mathcal{O}\left(\varepsilon^{-1 / 4}\right)$ (omitting the logarithmic term), highlights that gMHC is a second-order splitting scheme. This is consistent with existing weak error estimates; see [1] and references therein.

Error estimates on the invariant probability measure. For a fixed set of parameters $\boldsymbol{\omega}$, if $\nu_{0} \mathrm{P}_{\omega}^{n}$ converges weakly to a stationary distribution $\mu_{\boldsymbol{\omega}}$, Theorem 1 implies that $\left\|\mu-\mu_{\omega}\right\|_{\mathrm{TV}}$ and $\mathbf{W}_{2}\left(\mu, \mu_{\omega}\right)$ are both of order $\mathcal{O}\left(\delta^{2}\right)$ (using the lower semicontinuity
of the entropy function, see [50, Theorem 29.1]). This is indeed the expected scaling of the bias on the invariant probability measure of the Markov chain, since the latter one is a composition of two evolution operators, namely $\mathrm{D}_{\eta}$ which exactly preserves $\mu$, and $\mathrm{V}_{\delta}$ which is a second order approximation of the Hamiltonian evolution operator exactly preserving $\mu$.

Comparison with previous works. There is an abundant literature on the convergence of Markov chain Monte Carlo algorithms based on discretization of continuous-time dynamics, see for instance $[39,47,16,12,42,3,38]$. Making a complete survey and a detailed description of these works is beyond the scope of the paper. Here, we focus on works establishing quantitative bounds for gHMC or some of its particular instances, and convergence in the entropic sense for discretizations of the kinetic Langevin diffusion.

- Entropy methods for discretization of the kinetic Langevin diffusion. An adaptation of the modified entropy strategy from [49] for continuous-time processes has been conducted by [37] for a slight modification of the Euler-Maruyama scheme for the kinetic Langevin process. More precisely, the scheme considered in [37] (introduced in [13] in the machine learning community, and referred to as the Stochastic exponential Euler scheme in [19], where earlier apparitions in the physics literature are mentioned [11, 23, 46]) is given by the solution of

$$
\begin{equation*}
\mathrm{d} \mathbf{X}_{t}^{\delta}=\mathbf{V}_{t}^{\delta} \mathrm{d} t, \quad \mathrm{~d} \mathbf{V}_{t}^{\delta}=-\nabla U\left(\mathbf{X}_{\delta[t / \delta\rceil}^{\delta}\right) \mathrm{d} t-\gamma \mathbf{V}_{t}^{\delta} \mathrm{d} t+\sqrt{2 \gamma} \mathrm{~d} B_{t} \tag{18}
\end{equation*}
$$

which is similar to (3), except that the force $-\nabla U$ is constant within time intervals $[k \delta,(k+1) \delta)$ for $k \in \mathbb{N}$. Hence, in [37], the approximate entropy dissipation is established through a continuous-time derivation. In contrast, we follow the discrete time computations of [41], which focuses on idealized gHMC, where the exact Hamiltonian dynamics is followed instead of the Verlet integration. In particular, we are not considering in this work the underdamped Langevin diffusion process as a continuous-time reference, since we also cover unadjusted HMC. Moreover, in terms of dependence with respect to the stepsize $\delta$, the schemes of [37] are only of first order (see the discussion in [37, Section 3.3], in particular Equation (14)), and we obtain an improvement from $\sqrt{\varepsilon}$ to $\varepsilon^{1 / 4}$ in the complexity. Concerning the dimension $d$, the stepsize in [37] scales as $d^{-1 / 2} L_{H}^{-1}$, where $L_{H}$ is the Lipschitz constant of $\nabla^{2} U$ in the Frobenius norm, i.e., $U$ is supposed to satisfy $\left\|\nabla^{2} U(x)-\nabla^{2} U(y)\right\|_{F} \leqslant L_{H}|x-y|$ for all $x, y \in \mathbb{R}^{d}$. Assuming that $L_{H}$ is independent of $d$ thus corresponds to the weakly interacting case, while the assumption that the derivatives of $U$ are bounded uniformy in $d$ (in terms of the Euclidean norm) leads to $L_{H}$ of order $\sqrt{d}$. We get an improvement from $d^{-1 / 2}$ to $d^{-1 / 4}$ in the first case, and the same dependence $d^{-1}$ in the second. Notice that, in order to take advantage of an higher order numerical scheme, we have to assume that $U$ has bounded first four derivatives, in contrast to [37] which only assumes that $U$ has bounded first three derivatives. As discussed in Remark 15, if we consider this second condition on $U$, a result similar to [37] and
with the same dependence on $\varepsilon$ and $d$ can be derived. The main takeaway of this observation is that gHMC can achieve better accuracy when $U$ is sufficiently smooth, and does not yield a worst complexity than the discretization (18) considered in [37] under the same conditions. Finally, up to our knowledge, our result is the first one based on entropy methods for unadjusted HMC, and for splitting discretization schemes of the underdamped Langevin diffusion.

- HMC. Analyses of HMC for strongly convex potentials $U$ have been conducted in $[38,6]$. For non-convex potentials, the works $[6,18,5,8]$ have established several non-asymptotic convergence bounds for position HMC (i.e., $\eta=0$ ), both in Wasserstein 1 distance and total variation norm. In the mean-field case in particular, [8, Theorem 10] shows that, after $\mathcal{O}\left(\sqrt{d_{0} / \varepsilon^{\prime}}\right)$ gradient evaluations, the law of the chain is at distance at most $\varepsilon^{\prime}$ to $\pi$ in terms of the $\mathbf{W}_{\ell_{1}}$ Wasserstein distance associated to the $\ell_{1}$ norm $\|x-y\|_{\ell_{1}}=\sum_{i=1}^{d_{0}}\left|x_{i}-y_{i}\right|$. To compare this result with ours, we can bound this distance by $\sqrt{d_{0}}$ times the standard $\mathbf{W}_{2}$ Wasserstein distance (associated with the Euclidean distance), whose square is bounded by the relative entropy times the log-Sobolev constant of $\pi$ (which, from the results of [29], is independent of $d_{0}$ in the weakly interacting case where $\epsilon$ is small enough, which is the regime where this complexity is obtained in [8]). In other words, we should take $\varepsilon^{\prime}=\sqrt{d_{0} \varepsilon}$ in the results of [8] for a fair comparison. In that case, the number of gradient computations required in $[8$, Theorem 10$]$ is $\mathcal{O}\left(\left(d_{0} / \varepsilon\right)^{1 / 4}\right)$ in the weakly interacting case, which is the same as our results. The approach in $[5,6,8]$ is based on reflection couplings and concave modifications of the distance (building upon the method developed for continuous-time diffusion processes, in particular [21] for the overdamped Langevin process and [22] for the underdamped one). In particular, it does not provide a result for the relative entropy or the $\mathbf{W}_{2}$ Wasserstein distance, and the bound on the convergence rate is expressed in terms of global bounds on $\langle x-y, \nabla U(x)-\nabla U(y)\rangle /|x-y|^{2}$.
- Splitting schemes for kinetic Langevin diffusion for strongly convex potential $U$. Splitting schemes for Langevin diffusion with strongly convex potential energy functions have been investigated in [42, 35]. Their conclusions on the complexity for the corresponding gHMC method are similar to ours. Finally, the analysis of the general gHMC methodology have been conducted in [25] under the same strong convexity condition. Once again, the same conclusions can be drawn.

As a conclusion, up to our knowledge, none of the existing works cover our results, which give simple second order explicit estimates in relative entropy uniformly over a class of unadjusted gHMC samplers and for non-convex potential energy functions $U$.

## 3 Proof of Theorem 1

The proof of Theorem 1 is an easy consequence of a more detailed result given in Section 3.1, stated for a modified entropy function mixing a relative entropy and some Fisher information similar to the one considered for the time continuous Langevin dynamics. Instead of time derivatives, we have to estimate the discrete-time evolution of the two parts of the modified entropy along the two steps $\mathrm{V}_{\delta}$ and $\mathrm{D}_{\eta}$ of the chain. The technical details of this analysis are postponed to Section 3.2, where this evolution is shown to involve, on the one hand, the Jacobian matrix of the Verlet map and, on the other hand, some numerical error terms (due to the fact $\mu$ is not invariant by $\mathrm{V}_{\delta}$ ). The study of these terms is performed respectively in Sections 3.3 and 3.4.

### 3.1 A more detailed approximate decay result for a modified entropy

Relative density and modified entropy. In the remainder of the present Section 3, for an initial distribution $\nu_{0} \in \mathcal{P}\left(\mathbb{R}^{2 d}\right)$ which satisfies the conditions in Theorem 1, parameters $\boldsymbol{\omega}=(K, \delta, \eta)$ and $n \in \mathbb{N}$, we denote by

$$
h_{n}=\frac{\mathrm{d}\left(\nu_{0} \mathrm{P}_{\omega}^{n}\right)}{\mathrm{d} \mu}, \quad \mathcal{H}\left(h_{n}\right)=\mathcal{H}\left(\nu_{0} \mathrm{P}_{\omega}^{n} \mid \mu\right), \quad \mathcal{I}\left(h_{n}\right)=\mathcal{I}\left(\nu_{0} \mathrm{P}_{\omega}^{n} \mid \mu\right),
$$

where $\mathcal{H}$ and $\mathcal{I}$ denote (with some abuse of notation) the relative entropy and Fisher information with respect to $\mu$ respectively. More generally, we denote by $\mathcal{H}(h)=\mathcal{H}(\nu \mid \mu)$ and $\mathcal{I}(h)=\mathcal{I}(\nu \mid \mu)$ for any probability density $h: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$ with respect to $\mu$, so that $\nu=h \mu$ is a probability measure. In addition, for $\tilde{\mathbf{A}} \in \mathbb{R}^{2 d \times 2 d}$, or possibly a matrix field $z \mapsto \tilde{\mathbf{A}}(z)$ on $\mathbb{R}^{2 d}$, define

$$
\mathcal{I}_{\tilde{\mathbf{A}}}(\nu \mid \mu)= \begin{cases}\int_{\mathbb{R}^{2 d}}\left|\tilde{\mathbf{A}} \nabla \ln \left(\frac{\mathrm{~d} \nu}{\mathrm{~d} \mu}\right)\right|^{2} \mathrm{~d} \nu & \text { if } \nu \ll \mu, \\ +\infty & \text { otherwise } .\end{cases}
$$

Note that if $\nu \ll \mu$ and $h=\mathrm{d} \nu / \mathrm{d} \mu$,

$$
\begin{equation*}
\mathcal{I}_{\tilde{\mathbf{A}}}(\nu \mid \mu)=\int_{\mathbb{R}^{2 d}} \frac{|\tilde{\mathbf{A}} \nabla h|^{2}}{h} \mathrm{~d} \mu . \tag{19}
\end{equation*}
$$

Following the convention above, we write $\mathcal{I}_{\tilde{\mathbf{A}}}(h)=\mathcal{I}_{\tilde{\mathbf{A}}}(\nu \mid \mu)$, for any probability density $h: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$ with respect to $\mu$ with $\nu=h \mu$.

The main result of this section, from which we deduce Theorem 1, establishes the dissipation in time of a suitable modified entropy up to some numerical error. More precisely, we consider, for $\nu \in \mathcal{P}\left(\mathbb{R}^{2 d}\right)$ and $\tilde{a}>0$,

$$
\mathcal{L}_{\tilde{a}}(\nu \mid \mu)=\mathcal{H}(h)+\tilde{a} \mathcal{I}_{\mathbf{A}}(h), \quad \mathbf{A}=\frac{1}{\sqrt{2}}\left(\begin{array}{ll}
1 & 1  \tag{20}\\
1 & 1
\end{array}\right) .
$$

When $\nu \ll \mu$ with $h=\mathrm{d} \nu / \mathrm{d} \mu$,

$$
\begin{equation*}
\mathcal{L}_{\tilde{a}}(\nu \mid \mu)=\int_{\mathbb{R}^{2 d}} h \ln (h) \mathrm{d} \mu+\tilde{a} \int_{\mathbb{R}^{2 d}} \frac{\left|\nabla_{x} h+\nabla_{v} h\right|^{2}}{h} \mathrm{~d} \mu, \tag{21}
\end{equation*}
$$

and, following the same convention as previously, we write $\mathcal{L}_{\tilde{a}}(h)=\mathcal{L}_{\tilde{a}}(\nu \mid \mu)$, for any probability density $h: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$ with respect to $\mu$ with $\nu=h \mu$. With this choice, $\mathcal{L}_{\tilde{a}}$ involves a mixed derivative term $\left\langle\nabla_{x} h, \nabla_{v} h\right\rangle$ in the Fisher part, which has been crucially used in hypocoercive studies of the continuous-time kinetic Langevin process [47, 32, 49]. More specifically, (21) is exactly the modified entropy introduced in continuous-time settings in [49, Section 6].

Precise statement of the convergence result. We are now ready to state the main result of this section.

Theorem 5. Assume $\boldsymbol{H} 1-\boldsymbol{H}_{2}$ with $L=1$, and consider $\boldsymbol{\omega}=(K, \delta, \eta)$ with $K \in \mathbb{N}^{*}, \delta>0$ and $\eta \in(0,1)$ such that $\boldsymbol{H} 3$ holds and $\mathrm{T}=K \delta \leqslant 1 / 10$. Furthermore, assume that $\pi$ satisfies the log-Sobolev inequality (7). Consider an initial condition $\nu_{0}$ such that $\mathcal{I}\left(\nu_{0} \mid \mu\right)<+\infty$ and for all $p>0, \int_{\mathbb{R}^{2 d}}|z|^{p} \mathrm{~d} \nu_{0}(z)<+\infty$. Then, for any $n \in \mathbb{N}$,

$$
\begin{equation*}
(1+\kappa \mathrm{T}) \mathcal{L}_{a}\left(h_{n+1}\right) \leqslant \mathcal{L}_{a}\left(h_{n}\right)+\mathrm{T} \delta^{4} M\left(C_{1} \mathrm{e}^{-\rho n t} \nu_{0}(\mathfrak{W})+C_{2}\right), \tag{22}
\end{equation*}
$$

where $a, \kappa, M$ are given in (13).
Moreover, a refined estimate can be obtained as follows: define

$$
m_{1}=2-3 \mathrm{~T}, \quad m_{2}=\frac{\gamma}{\eta}+2+4 \mathrm{~T}, \quad m_{3}=\frac{\gamma(1+\eta)}{\eta^{2}}\left(\frac{1}{2 \tilde{a}}+1\right)-2-4 \mathrm{~T},
$$

and

$$
\begin{equation*}
\lambda=\frac{m_{1}+m_{3}}{2}-\sqrt{\left(\frac{m_{1}+m_{3}}{2}\right)^{2}-m_{1} m_{3}+m_{2}^{2}} \tag{23}
\end{equation*}
$$

Then, for any $\tilde{a}>0$ such that $\lambda>0$, for any $\varepsilon \in(0,1)$ and $n \in \mathbb{N}$,

$$
\begin{equation*}
(1+\tilde{\kappa} \mathrm{T}) \mathcal{L}_{\tilde{a}}\left(h_{n+1}\right) \leqslant \mathcal{L}_{\tilde{a}}\left(h_{n}\right)+\mathrm{T} \delta^{4} \tilde{M}\left(C_{1} \mathrm{e}^{-\rho n t} \nu_{0}(\mathfrak{W})+C_{2}\right), \tag{24}
\end{equation*}
$$

where

$$
\tilde{\kappa}=\frac{\tilde{a} \lambda(1-\varepsilon)(1-3 \mathrm{~T})}{\max \left(L C_{\mathrm{LS}}, 1\right)+2 \tilde{a}}, \quad \tilde{M}=\frac{1}{\varepsilon \lambda}\left(\frac{4}{15 \tilde{a}}+24 \tilde{a}\right)+\tilde{a}\left((33 \lambda+4) \mathrm{T}+\frac{\lambda \varepsilon}{240}\right) .
$$

Note that this result is only stated for $\eta>0$. As explained in the proof of Theorem 1 , the case $\eta=0$ is obtained by a limiting procedure. The expression for $\lambda$ in (23) admits a
limit when $\eta \rightarrow 0$; more precisely, this limit is $2-3 \mathrm{~T}-2 \tilde{a} /[\mathrm{T}(1+2 \tilde{a})]$ which can be obtained from

$$
\lambda=\frac{m_{1} m_{3}-m_{2}^{2}}{\frac{m_{1}+m_{3}}{2}+\sqrt{\left(\frac{m_{1}+m_{3}}{2}\right)^{2}-m_{1} m_{3}+m_{2}^{2}}}
$$

the numerator and denominator being respectively $\eta^{-2} \gamma(2-3 \mathrm{~T})(1+1 /(2 \tilde{a}))$ and $\eta^{-2} \gamma[(1+$ $1 /(2 \tilde{a}))-\gamma]$ at dominant order in $\eta$, with $\gamma=\mathrm{T}^{-1}$ when $\eta=0$ in view of (6).

Remark 6. We discuss in this remark how to obtain (14) from the refined convergence result (24). First, since $L$ is any upper bound of $\left\|\nabla^{2} U\right\|_{\infty}$, we can assume without loss of generality that $L C_{\mathrm{LS}} \geqslant 1$. Upon rescaling, it can therefore be assumed that $L=1$ and $C_{\mathrm{LS}} \geqslant$ 1 (see the discussion at the end of Section 2.2.1). We consider an initial condition of the form $\nu_{0}=\hat{\nu}_{0} \otimes \mathrm{~N}\left(0, \mathrm{I}_{d}\right)$. Having in mind that the Euler-Maruyama discretization of overdamped Langevin dynamics corresponds to one-step HMC with full resampling of the momenta at each step with effective step-size $\delta^{2} / 2$, we set $K=1$ and $\eta=0$, and therefore consider $n=2 s / \delta^{2}$ for some time $s>0$. It follows from (6) that $\mathrm{T}=\delta$. Choosing for instance $\varepsilon=\delta$ (or any other choice ensuring that $\varepsilon$ vanishes as $\delta \rightarrow 0$ ) and $\tilde{a}=\alpha \delta$, it is then easily seen that $\lambda$ is at dominant order $2(1-\alpha)$, so that the convergence rate $\tilde{\kappa}$ is of order $2 \delta \alpha(1-\alpha) / C_{\mathrm{LS}}$. This suggests to choose $\alpha=1 / 2$ to maximize the convergence rate. Note that the factor $(1+\tilde{\kappa} \mathrm{T})^{-n}$ then converges to $s / C_{\mathrm{LS}}$ as $\delta \rightarrow 0$ with these choices, which leads to (14) as claimed.

Theorem 5 is proved below. First, let us deduce Theorem 1 from Theorem 5:
Proof of Theorem 1. In the case $\eta>0$, an easy induction based on (22) in Theorem 5 implies that, for any $n \geqslant 1$,

$$
\mathcal{L}_{a}\left(h_{n}\right) \leqslant(1+\kappa \mathrm{T})^{-n} \mathcal{L}_{a}\left(h_{0}\right)+\mathrm{T} \delta^{4} M \sum_{k=1}^{n}(1+\kappa \mathrm{T})^{-k}\left[C_{1} \mathrm{e}^{-\rho(n-k) \mathrm{T}} \nu_{0}(\mathfrak{W})+C_{2}\right]
$$

The proof then follows from the bounds

$$
\sum_{k=1}^{n}(1+\kappa \mathrm{T})^{-k} \leqslant \frac{1+\kappa \mathrm{T}}{\kappa \mathrm{~T}}, \quad \sum_{k=1}^{n}(1+\kappa \mathrm{T})^{-k} \mathrm{e}^{-\rho(n-k) \mathrm{T}} \leqslant n\left[\max \left((1+\kappa \mathrm{T})^{-1 / \mathrm{T}}, \mathrm{e}^{-\rho}\right)\right]^{n \mathrm{~T}}
$$

as well as $\mathcal{H}\left(h_{n}\right) \leqslant \mathcal{L}_{a}\left(h_{n}\right)$ and $\mathcal{L}_{a}\left(h_{0}\right) \leqslant \mathcal{H}\left(h_{0}\right)+2 a \mathcal{I}\left(h_{0}\right)$.
The case $\eta=0$ is obtained by letting $\eta$ go to 0 in the previous case. ${ }^{1}$ Indeed, it is clear that the right hand side of (12) converges. For the left hand side, we use the lower semi-continuity of the relative entropy (see [50, Theorem 29.1]) with respect to the weak convergence of probability measures. The convergence of $\nu_{0} \mathrm{P}_{\omega}^{n}$ in the Wasserstein sense

[^0](hence in the weak sense) as $\eta \rightarrow 0$ follows from the moment bounds of $\mathbf{H} 3$ together with a synchronous coupling argument, i.e. using the same Gaussian variables in the randomization steps of two chains, one with $\eta=0$ and one with $\eta^{\prime}>0$ (so that the expected distance between the chains goes to zero as $\eta^{\prime}$ goes to zero).

Proof of Theorem 5. Before providing the proof of Theorem 5, let us recall the key steps of the proof of the similar result established in [49] for the continuous-time kinetic Langevin process, as the structure of the proof is similar. Denoting by $\left(\hat{h}_{t}\right)_{t \geqslant 0}$ the analogue of $\left(h_{n}\right)_{n \in \mathbb{N}}$ in this continuous-time context, the first observation is that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \mathcal{H}\left(\hat{h}_{t}\right)=-\int_{\mathbb{R}^{2 d}} \frac{\left|\nabla_{v} \hat{h}_{t}\right|^{2}}{\hat{h}_{t}} \mathrm{~d} \mu \tag{25}
\end{equation*}
$$

This entropy dissipation is not sufficient to conclude to an exponential decay, as it can vanish for non-constant densities $\hat{h}_{t}$ (and thus in particular it cannot be upper bounded by $-\kappa \mathcal{H}\left(\hat{h}_{t}\right)$ for some $\left.\kappa>0\right)$. A key observation is then that, when $\nabla^{2} U$ is bounded,

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\mathbb{R}^{2 d}} \frac{\left|\nabla_{x} \hat{h}_{t}+\nabla_{v} \hat{h}_{t}\right|^{2}}{\hat{h}_{t}} \mathrm{~d} \mu\right) \leqslant-c \int_{\mathbb{R}^{2 d}} \frac{\left|\nabla_{x} \hat{h}_{t}\right|^{2}}{\hat{h}_{t}} \mathrm{~d} \mu+C \int_{\mathbb{R}^{2 d}} \frac{\left|\nabla_{v} \hat{h}_{t}\right|^{2}}{\hat{h}_{t}} \mathrm{~d} \mu \tag{26}
\end{equation*}
$$

for some constants $c, C>0$. The last term can be controlled thanks to the entropy dissipation (25). As a consequence, for $a$ small enough, considering $\mathcal{L}_{a}$ given by (21),

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \mathcal{L}_{a}\left(\hat{h}_{t}\right) \leqslant-a c \mathcal{I}\left(\hat{h}_{t}\right) \tag{27}
\end{equation*}
$$

and the conclusion follows from

$$
\mathcal{L}_{a}\left(\hat{h}_{t}\right) \leqslant\left(\max \left(C_{\mathrm{LS}}, 1\right)+2 a\right) \mathcal{I}\left(\hat{h}_{t}\right),
$$

where we used that $\mu$ satisfies a log-Sobolev inequality with constant $\max \left(C_{L S}, 1\right)$ as the tensor product of $\pi$ and $\mathrm{N}\left(0, \mathrm{I}_{d}\right)$.

The proof of Theorem 5 is fundamentally based on the same ingredients, but with discrete-time evolutions along the two steps $\mathrm{V}_{\delta}$ and $\mathrm{D}_{\eta}$ of the chain, instead of the time derivatives of (25) and (26). This requires various estimates given in Section 3.2.

Proof of Theorem 5. We start by general estimates, and then specify at the very end particular choices leading respectively to (22) and (24). Fix $\tilde{a}>0$ and $n \in \mathbb{N}$. In this proof, we consider the matrix $\mathbf{A}$ given in (20). We write the proof for $\eta>0$, the case $\eta=0$ being obtained by passing to the limit $\eta \rightarrow 0$ in the final expressions, as discussed after Theorem 5.

The estimates on the evolution of $h_{n}$ are based on a dual formulation where we consider the evolution of an arbitrary bounded measurable function $g$ :

$$
\int_{\mathbb{R}^{2 d}} h_{n+1} g \mathrm{~d} \mu=\int_{\mathbb{R}^{2 d}} h_{n} \mathrm{P}_{\omega} g \mathrm{~d} \mu
$$

in other words $h_{n+1}=\mathrm{P}_{\omega}^{*} h_{n}$ where we denote by $\mathrm{Q}^{*}$ the adjoint of a bounded linear operator Q on $\mathrm{L}^{2}(\mu)$. The first task is to identify the action of the adjoints of the operators constituting $\mathrm{P}_{\boldsymbol{\omega}}$. A simple calculation shows that the damping step is reversible in the probabilistic sense, namely $\mathrm{D}_{\eta}^{*}=\mathrm{D}_{\eta}$. Since the Verlet map $\Phi_{\delta}^{K}$ satisfies $\left|\operatorname{det} \nabla \Phi_{\delta}^{K}\right| \equiv 1$ (as a consequence of symplecticity [30]),

$$
\begin{aligned}
\int_{\mathbb{R}^{2 d}} h\left(\mathrm{~V}_{\delta}^{K} g\right) \mathrm{d} \mu & =\int_{\mathbb{R}^{2 d}} h(z) g\left(\Phi_{\delta}^{K}(z)\right) \mu(z) \mathrm{d} z=\int_{\mathbb{R}^{2 d}} h\left(\Phi_{\delta}^{-K}(z)\right) g(z) \mu\left(\Phi_{\delta}^{-K}(z)\right) \mathrm{d} z \\
& =\int_{\mathbb{R}^{2 d}} g\left[\left(\mathrm{~V}_{\delta}^{K}\right)^{*} h\right] \mathrm{d} \mu,
\end{aligned}
$$

which allows to identify the action of the adjoint operator as

$$
\begin{equation*}
\left(\mathrm{V}_{\delta}^{K}\right)^{*} h=\left(h \circ \Phi_{\delta}^{-K}\right) \mathrm{e}^{\square H}, \quad \square H=H-H \circ \Phi_{\delta}^{-K} \tag{28}
\end{equation*}
$$

In addition, using the reversibility property (5), we obtain that $\Phi_{\delta}^{-K}=\left(\Phi_{\delta}^{-1}\right)^{\circ K}$ with

$$
\begin{equation*}
\Phi_{\delta}^{-1}(x, v)=\left(x-\delta v-\frac{\delta^{2}}{2} \nabla U(x), v+\frac{\delta}{2}\left[\nabla U(x)+\nabla U\left(x-\delta v-\frac{\delta^{2}}{2} \nabla U(x)\right)\right]\right) . \tag{29}
\end{equation*}
$$

From these observations and since $\mathrm{P}_{\omega}^{*}=\left(\mathrm{V}_{\delta}^{K}\right)^{*} \mathrm{D}_{\eta}^{*}$, we consider the decomposition

$$
\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right)=\mathcal{L}_{\tilde{a}}\left(\mathrm{P}_{\omega}^{*} h_{n}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right)=\boldsymbol{\Delta}_{1}+\boldsymbol{\Delta}_{2}+\tilde{a} \boldsymbol{\Delta}_{3}+\tilde{a} \boldsymbol{\Delta}_{4},
$$

where

$$
\begin{aligned}
\boldsymbol{\Delta}_{1} & =\mathcal{H}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} \mathrm{D}_{\eta} h_{n}\right)-\mathcal{H}\left(\mathrm{D}_{\eta} h_{n}\right), & \boldsymbol{\Delta}_{2}=\mathcal{H}\left(\mathrm{D}_{\eta} h_{n}\right)-\mathcal{H}\left(h_{n}\right) \\
\boldsymbol{\Delta}_{3} & =\mathcal{I}_{\mathbf{A}}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} \mathrm{D}_{\eta} h_{n}\right), & \boldsymbol{\Delta}_{4}=-\mathcal{I}_{\mathbf{A}}\left(h_{n}\right) .
\end{aligned}
$$

We bound these four terms as follows. By Corollary 12 , for any $\varepsilon_{1}>0$,

$$
\Delta_{1} \leqslant 4 \varepsilon_{1} K \delta \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right)+E_{\varepsilon_{1}} W_{n},
$$

where for conciseness we write $W_{n}=C_{1} \mathrm{e}^{-\rho n \mathrm{~T}} \nu_{0}(\mathfrak{W})+C_{2}$ (recall the notation from $\mathbf{H} 3$ ), and, by Corollaries 14 and 17,

$$
\begin{aligned}
E_{\varepsilon_{1}} & =\sum_{j=0}^{K-1}\left[6 \delta^{7} j^{2} \varepsilon_{1}+\varepsilon_{1} \int_{0}^{\delta} 2 s^{6} \mathrm{~d} s+\frac{1}{30 \varepsilon_{1}} \delta^{5}\right] \\
& \leqslant 2 \varepsilon_{1} \delta^{7} K^{3}+\frac{2}{7} \varepsilon_{1} K \delta^{7}+\frac{1}{30 \varepsilon_{1}} K \delta^{5} \leqslant \frac{1}{30}\left(\varepsilon_{1}+\frac{1}{\varepsilon_{1}}\right) K \delta^{5},
\end{aligned}
$$

where we used that $K \delta \leqslant 1 / 10$.

By Lemma 7,

$$
\boldsymbol{\Delta}_{2} \leqslant-\frac{1}{2}\left(\eta^{-2}-1\right) \mathcal{I}_{\mathbf{B}_{v}}\left(\mathrm{D}_{\eta} h_{n}\right), \quad \boldsymbol{\Delta}_{4} \leqslant-\mathcal{I}_{\mathbf{A B}_{\eta}^{-1}}\left(\mathrm{D}_{\eta} h_{n}\right)
$$

where

$$
\mathbf{B}_{v}=\left(\begin{array}{cc}
0 & 0  \tag{30}\\
0 & 1
\end{array}\right), \quad \mathbf{B}_{\eta}^{-1}=\left(\begin{array}{cc}
1 & 0 \\
0 & 1 / \eta
\end{array}\right)
$$

Finally, using Lemma 8 and Corollary 14 and setting

$$
\begin{equation*}
\Psi=\left(\nabla \Phi_{\delta}^{-K}\right) \circ \Phi_{\delta}^{K} \tag{31}
\end{equation*}
$$

it holds, for any $\varepsilon_{2}>0$,

$$
\begin{aligned}
\boldsymbol{\Delta}_{3} & \leqslant\left(1+\varepsilon_{2}\right) \mathcal{I}_{\mathbf{A} \Psi}\left(\mathrm{D}_{\eta} h_{n}\right)+2\left(1+\varepsilon_{2}^{-1}\right)|\mathbf{A}|^{2} K^{2} \delta^{6} W_{n} \\
& \leqslant \mathcal{I}_{\mathbf{A} \Psi}\left(\mathrm{D}_{\eta} h_{n}\right)+\varepsilon_{2}|\mathbf{A}|^{2}\|\Psi\|_{\infty}^{2} \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right)+2\left(1+\varepsilon_{2}^{-1}\right)|\mathbf{A}|^{2} K^{2} \delta^{6} W_{n} \\
& \leqslant \mathcal{I}_{\mathbf{A} \Psi}\left(\mathrm{D}_{\eta} h_{n}\right)+3 \varepsilon_{2} \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right)+4\left(1+\varepsilon_{2}^{-1}\right) K^{2} \delta^{6} W_{n}
\end{aligned}
$$

where we used $|\mathbf{A}|=\sqrt{2}$ and $\|\Psi\|_{\infty} \|^{2} \leqslant 3 / 2$, the latter bound following from Equation (40) in Lemma 11 and $\mathrm{T}=K \delta \leqslant 1 / 10$.

Therefore, by combining the inequalities above, we get

$$
\begin{align*}
& \mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right) \leqslant-\frac{\eta^{-2}-1}{2} \mathcal{I}_{\mathbf{B}_{v}}\left(\mathrm{D}_{\eta} h_{n}\right)+\tilde{a} \mathcal{I}_{\mathbf{A} \Psi}\left(\mathrm{D}_{\eta} h_{n}\right)-\tilde{a} \mathcal{I}_{\mathbf{A B}}^{\eta} \\
& \quad+\left(4 \varepsilon_{1} K \delta+3 \tilde{a} \varepsilon_{2}\right) \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right)+\left[\frac{\varepsilon_{1}+\varepsilon_{1}^{-1}}{30} K \delta^{5}+4 \tilde{a}\left(1+\varepsilon_{2}^{-1}\right) K^{2} \delta^{6}\right] W_{n} \tag{32}
\end{align*}
$$

The sum of the terms in the first line of the right hand side is equal to

$$
\begin{equation*}
-\tilde{a} \mathcal{I}_{\mathbf{S}^{1 / 2}}\left(\mathrm{D}_{\eta} h_{n}\right)=-\tilde{a} \int_{\mathbb{R}^{2 d}} \frac{\left\langle\nabla\left(\mathrm{D}_{\eta} h_{n}\right), \mathbf{S} \nabla\left(\mathrm{D}_{\eta} h_{n}\right)\right\rangle}{\mathrm{D}_{\eta} h_{n}} \mathrm{~d} \mu \tag{33}
\end{equation*}
$$

with, for $z \in \mathbb{R}^{2 d}$,

$$
\mathbf{S}(z)=(2 \tilde{a})^{-1}\left(\eta^{-2}-1\right) \mathbf{B}_{v}^{\top} \mathbf{B}_{v}-(\mathbf{A} \Psi(z))^{\top} \mathbf{A} \Psi(z)+\left(\mathbf{A} \mathbf{B}_{\eta}^{-1}\right)^{\top} \mathbf{A} \mathbf{B}_{\eta}^{-1}
$$

where $\Psi$ is defined in (31).
A key step of the proof is now to establish a positive lower bound on $\mathbf{S}$ uniformly in $z$, for $\tilde{a}$ small enough, which is the analogue in our context of (27). We introduce the $d \times d$ block decompositions

$$
\Psi(z)=\left(\begin{array}{cc}
\psi_{11}(z) & \psi_{12}(z) \\
\psi_{21}(z) & \psi_{22}(z)
\end{array}\right), \quad \mathbf{S}(z)=\left(\begin{array}{ll}
s_{11}(z) & s_{12}(z) \\
s_{21}(z) & s_{22}(z)
\end{array}\right)
$$

so that

$$
\begin{aligned}
& s_{11}=\mathrm{I}_{d}-\left(\psi_{11}+\psi_{21}\right)^{\top}\left(\psi_{11}+\psi_{21}\right), \quad s_{12}=s_{21}=\eta^{-1} \mathrm{I}_{d}-\left(\psi_{11}+\psi_{21}\right)^{\top}\left(\psi_{12}+\psi_{22}\right), \\
& s_{22}=\left(\frac{\eta^{-2}-1}{2 \tilde{a}}+\eta^{-2}\right) \mathrm{I}_{d}-\left(\psi_{22}+\psi_{12}\right)^{\top}\left(\psi_{22}+\psi_{12}\right) .
\end{aligned}
$$

Using Lemma 11 and $\mathrm{T} \leqslant 1 / 10$, it holds, for any $x \in \mathbb{R}^{d}$,

$$
\begin{aligned}
& \left|\left(\psi_{11}+\psi_{21}\right) x\right| \leqslant\left|\left((1-\mathrm{T}) \mathrm{I}_{d}-\frac{\mathrm{T}^{2}}{2} \alpha\right) x\right|+\frac{2 \mathrm{~T}^{3}}{3}|x| \leqslant\left(1-\mathrm{T}+\mathrm{T}^{2}\right)|x| \\
& \left|\left(\psi_{22}+\psi_{12}\right) x\right| \leqslant\left|\left(\mathrm{I}_{d}+\mathrm{T} \beta-\frac{\mathrm{T}^{2}}{2} \zeta\right) x\right|+\frac{2 \mathrm{~T}^{3}}{3}|x| \leqslant\left(1+\mathrm{T}+\mathrm{T}^{2}\right)|x|,
\end{aligned}
$$

and similarly

$$
\left|\left(\psi_{11}+\psi_{21}\right) x-x\right| \leqslant\left(\mathrm{T}+\mathrm{T}^{2}\right)|x|, \quad\left|\left(\psi_{22}+\psi_{12}\right) x-x\right| \leqslant\left(\mathrm{T}+\mathrm{T}^{2}\right)|x|,
$$

so that, for any $x, y \in \mathbb{R}^{d}$,

$$
\begin{aligned}
\left\langle x, s_{11} x\right\rangle & \geqslant\left[1-\left(1-\mathrm{T}+\mathrm{T}^{2}\right)^{2}\right]|x|^{2} \geqslant\left(2 \mathrm{~T}-3 \mathrm{~T}^{2}\right)|x|^{2}, \\
\left\langle y, s_{22} y\right\rangle & \geqslant\left[\frac{\eta^{-2}-1}{2 \tilde{a}}+\eta^{-2}-\left(1+\mathrm{T}+\mathrm{T}^{2}\right)^{2}\right]|y|^{2} \geqslant\left(\frac{\eta^{-2}-1}{2 \tilde{a}}+\eta^{-2}-1-2 \mathrm{~T}-4 \mathrm{~T}^{2}\right)|y|^{2}, \\
\left\langle x, s_{12} y\right\rangle & =\left(\eta^{-1}-1\right) x \cdot y+x\left(\mathrm{I}_{d}-\left(\psi_{11}+\psi_{21}\right)^{\top}\left(\psi_{12}+\psi_{22}\right)\right) y \\
& =\left(\eta^{-1}-1\right) x \cdot y+\left\langle\left(\mathrm{I}_{d}-\left(\psi_{11}+\psi_{21}\right)\right) x,\left(\psi_{12}+\psi_{22}\right) y\right\rangle+\left\langle x,\left(\mathrm{I}_{d}-\left(\psi_{12}+\psi_{22}\right)\right) y\right\rangle \\
& \geqslant-\left(\eta^{-1}-1+\left(2+\mathrm{T}+\mathrm{T}^{2}\right)\left(\mathrm{T}+\mathrm{T}^{2}\right)\right)|x||y| \\
& \geqslant-\left(\eta^{-1}-1+2 \mathrm{~T}+4 \mathrm{~T}^{2}\right)|x||y| .
\end{aligned}
$$

Note that the last right hand sides in the previous three inequalities are of order T at dominant order in T (using (6) to write $\eta=1-\gamma \mathrm{T}$ ). This motivates factoring out T , and writing, for any $x, y \in \mathbb{R}^{d}$ and $z \in \mathbb{R}^{2 d}$,

$$
\begin{equation*}
\binom{x}{y}^{\top} \mathbf{S}(z)\binom{x}{y} \geqslant \mathrm{~T} \lambda\left(|x|^{2}+|y|^{2}\right) \tag{34}
\end{equation*}
$$

where $\lambda$ is the smallest eigenvalue of the symmetric $2 \times 2$ matrix

$$
\left(\begin{array}{ll}
m_{1} & m_{2} \\
m_{2} & m_{3}
\end{array}\right):=\frac{1}{\mathrm{~T}}\left(\begin{array}{cc}
2 \mathrm{~T}-3 \mathrm{~T}^{2} & -\left(\eta^{-1}-1+2 \mathrm{~T}+4 \mathrm{~T}^{2}\right) \\
-\left(\eta^{-1}-1+2 \mathrm{~T}+4 \mathrm{~T}^{2}\right) & \frac{\eta^{-2}-1}{2 \tilde{a}}+\eta^{-2}-1-2 \mathrm{~T}-4 \mathrm{~T}^{2}
\end{array}\right)
$$

$$
=\mathbf{B}_{\eta}^{-1}\left(\begin{array}{cc}
2-3 \mathrm{~T} & -(\gamma+\eta(2+4 \mathrm{~T})) \\
-(\gamma+\eta(2+4 \mathrm{~T})) & \gamma(1+\eta)\left(\frac{1}{2 \tilde{a}}+1\right)-\eta^{2}(2+4 \mathrm{~T})
\end{array}\right) \mathbf{B}_{\eta}^{-1}
$$

recalling the notation $\gamma=(1-\eta) /$. This provides the definitions given in (35). The expression (23) for $\lambda$ then follows from

$$
\lambda=\frac{m_{1}+m_{3}}{2}-\sqrt{\left(\frac{m_{1}+m_{3}}{2}\right)^{2}-m_{1} m_{3}+m_{2}^{2}}
$$

which is positive provided $\tilde{a}$ is small enough. Alternatively, to get the simpler expressions (13), we proceed as follows: using that $\eta \leqslant 1$ and $\mathrm{T} \leqslant 1 / 10$, we bound

$$
\begin{equation*}
m_{1} \geqslant \frac{17}{10}, \quad\left|m_{2}\right| \leqslant \frac{1}{\eta}\left(\gamma+\frac{12}{5}\right), \quad m_{3} \geqslant \frac{1}{\eta^{2}}\left(\frac{\gamma}{2 \tilde{a}}-\frac{12}{5}\right), \tag{35}
\end{equation*}
$$

to get that

$$
\begin{aligned}
\binom{x}{y}^{\top}\left(\begin{array}{ll}
m_{1} & m_{2} \\
m_{2} & m_{3}
\end{array}\right)\binom{x}{y} & =m_{1}|x|^{2}+2 m_{2}|x||y|+m_{3}|y|^{2} \\
& \geqslant \frac{1}{2} m_{1}|x|^{2}+\left(m_{3}-\frac{2 m_{2}^{2}}{m_{1}}\right)|y|^{2} \geqslant \frac{17}{20}\left(|x|^{2}+|y|^{2}\right),
\end{aligned}
$$

i.e., $\lambda \geqslant 17 / 20$ if we choose $\tilde{a}$ such that $m_{3} \geqslant m_{1} / 2+2 m_{2}^{2} / m_{1}$. This condition is satisfied for any $\eta \in(0,1]$ when it is satisfied for $\eta=1$, in which case it reads

$$
\frac{\gamma}{2 \tilde{a}} \geqslant \frac{17}{20}+\frac{12}{5}+\frac{20}{17}\left(\gamma+\frac{12}{5}\right)^{2} .
$$

This holds in particular with the choice of $\tilde{a}=a$ in (13).
In both cases, at this point, plugging the lower bound (34) in (33), we have determined $\lambda>0$ such that

$$
\tilde{a} \mathcal{I}_{\mathbf{S}^{1 / 2}}\left(\mathrm{D}_{\eta} h_{n}\right) \leqslant-\tilde{a} \lambda \mathrm{~T} \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right) .
$$

Combining this result with (32) yields

$$
\begin{equation*}
\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right) \leqslant-\rho^{\prime} \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right)+\left[\frac{\varepsilon_{1}+\varepsilon_{1}^{-1}}{30} K \delta^{5}+4 \tilde{a}\left(1+\varepsilon_{2}^{-1}\right) K^{2} \delta^{6}\right] W_{n}, \tag{36}
\end{equation*}
$$

for

$$
\begin{equation*}
\rho^{\prime}=\tilde{a} \lambda \mathrm{~T}-4 \varepsilon_{1} \mathrm{~T}-3 \tilde{a} \varepsilon_{2} . \tag{37}
\end{equation*}
$$

Now, applying Lemma 8 with $\tilde{\mathbf{A}}=\Psi^{-1} \circ \Phi_{\delta}^{-K}$ and $h$ replaced by $\mathrm{D}_{\eta} h_{n}$ (see Remark 9), we obtain that, for any $\varepsilon_{3}>0$

$$
\left(1+\varepsilon_{3}\right) \mathcal{I}\left(\mathrm{D}_{\eta} h_{n}\right) \geqslant \mathcal{I}_{\Psi^{-1} \circ \Phi_{\delta}^{-K}}\left(\mathrm{P}_{\omega}^{*} h_{n}\right)-\left(1+\varepsilon_{3}^{-1}\right)\left\|\Psi^{-1} \circ \Phi_{\delta}^{-K}\right\|_{\infty}^{2} \operatorname{Er}_{1}^{\delta, K}\left(\mathrm{D}_{\eta} h_{n}\right)
$$

Thanks to Lemma 11, and more specifically to (40), for any $z, u \in \mathbb{R}^{2 d}$,

$$
\begin{aligned}
\left|\Psi^{-1}(z) u\right|^{2} & \geqslant\left(1+\mathrm{T}+\mathrm{T}^{2} / 2+\mathrm{T}^{3} / 3\right)^{-2}|u|^{2} \\
& \geqslant(1+5 \mathrm{~T} / 2)^{-1}|u|^{2} \\
& \geqslant(1-5 \mathrm{~T} / 2)|u|^{2},
\end{aligned}
$$

so that $\mathcal{I}_{\Psi^{-1} \mathrm{o}_{\delta}^{-K}}\left(\mathrm{P}_{\omega}^{*} h_{n}\right) \geqslant(1-5 \mathrm{~T} / 2) \mathcal{I}\left(\mathrm{P}_{\omega}^{*} h_{n}\right)$. Using Lemma 11 again, we have, for any $z, u \in \mathbb{R}^{2 d}$,

$$
|u| \leqslant|\Psi(z) u|+|\Psi(z) u-u| \leqslant|\Psi(z) u|+\left(\mathrm{T}+\mathrm{T}^{2} / 2+\mathrm{T}^{3} / 3\right)|u|,
$$

and thus

$$
\left|\Psi^{-1}(z) u\right| \leqslant|u|+\left(\mathrm{T}+\mathrm{T}^{2} / 2+\mathrm{T}^{3} / 3\right)\left|\Psi^{-1}(z) u\right| \leqslant|u|+\frac{1}{2}\left|\Psi^{-1}(z) u\right|,
$$

so that $\left\|\Psi^{-1} \circ \Phi_{\delta}^{-K}\right\|_{\infty} \leqslant 2$. Plugging these bounds in (36) yields

$$
\begin{aligned}
\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right) \leqslant- & \frac{\rho^{\prime}}{1+\varepsilon_{3}}\left[\left(1-\frac{5 \mathrm{~T}}{2}\right) \mathcal{I}\left(h_{n+1}\right)-4\left(1+\varepsilon_{3}^{-1}\right) \operatorname{Er}_{1}^{\delta, K}\left(\mathrm{D}_{\eta} h_{n}\right)\right] \\
& +\left[\frac{\varepsilon_{1}+\varepsilon_{1}^{-1}}{30} K \delta^{5}+4 \tilde{a}\left(1+\varepsilon_{2}^{-1}\right) K^{2} \delta^{6}\right] W_{n}
\end{aligned}
$$

We next use that $\mu$ satisfies a log-Sobolev inequality with constant $\max \left(1, C_{\mathrm{LS}}\right)$ (by tensorization from the log-Sobolev inequalities satisfied by $\pi$ and $\mathrm{N}\left(0, \mathrm{I}_{d}\right)$ ), and the equality $|\mathbf{A}|^{2}=2$, to write

$$
\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right) \leqslant\left(\max \left(1, C_{\mathrm{LS}}\right)+2 \tilde{a}\right) \mathcal{I}\left(h_{n+1}\right) .
$$

Choosing $\varepsilon_{3}=\mathrm{T} / 4$, using Corollary 14 to bound the remaining numerical error term, setting

$$
M=8 \rho^{\prime}\left(1+\frac{4}{\mathrm{~T}}\right) \mathrm{T}+\frac{\varepsilon_{1}+\varepsilon_{1}^{-1}}{30}+4 \tilde{a}\left(1+\varepsilon_{2}^{-1}\right) \mathrm{T}
$$

and noting that $(1-5 \mathrm{~T} / 2) /(1+\mathrm{T} / 4) \geqslant 1-3 \mathrm{~T}$ and $\rho^{\prime}(1-3 \mathrm{~T})>0$, we can conclude that

$$
\begin{aligned}
\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)-\mathcal{L}_{\tilde{a}}\left(h_{n}\right) & \leqslant-\rho^{\prime}(1-3 \mathrm{~T}) \mathcal{I}\left(h_{n+1}\right)+\mathrm{T} \delta^{4} M W_{n} \\
& \leqslant-\frac{\rho^{\prime}(1-3 \mathrm{~T})}{\max \left(1, C_{\mathrm{LS}}\right)+2 \tilde{a}} \mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)+\mathrm{T} \delta^{4} M W_{n} .
\end{aligned}
$$

Let us finally discuss how to obtain (22) and (24):

- to obtain (22) with the simpler expressions of $\kappa$ and $M$ in (13), we first note that $a$ in (13) is smaller than $1 / 10$, as can be seen for instance by distinguishing the case $\gamma \leqslant$ 3 , for which $a \leqslant \gamma / 34$, and the case $\gamma \geqslant 3$, for which $\left.a \leqslant(\gamma+3) /\left[3(\gamma+3)^{2}\right]\right)$. We next rely on the expression (37) for $\rho^{\prime}$, with the choices $\varepsilon_{1}=a / 20$ and $\varepsilon_{2}=\mathrm{T} / 20$, so that, replacing $\lambda$ by $17 / 20$,

$$
\rho^{\prime}=a \mathrm{~T}\left(\lambda-\frac{1}{5}-\frac{3}{20}\right)=\frac{a \mathrm{~T}}{2}
$$

The value of $\kappa$ is then obtained as

$$
\kappa=\frac{\rho^{\prime}(1-3 \mathrm{~T})}{\max \left(1, C_{\mathrm{LS}}\right)+2 a}=\frac{a(1-3 \mathrm{~T})}{2\left[\max \left(1, C_{\mathrm{LS}}\right)+2 a\right]} \geqslant \frac{a}{3\left[\max \left(1, C_{\mathrm{LS}}\right)+2 a\right]}
$$

In the expression of $M$, we simply bound $\rho^{\prime} \leqslant 1 / 200, a \leqslant 1 / 10, \mathrm{~T} \leqslant 1 / 10$.

- To get the sharper inequality (24), we keep a free parameter $\varepsilon \in(0,1)$ and choose $\varepsilon_{1}=\tilde{a} \varepsilon \lambda / 8, \varepsilon_{2}=\mathrm{T} \varepsilon \lambda / 6$ which implies that $\rho^{\prime}=\tilde{a} \lambda \mathrm{~T}(1-\varepsilon)$ (which immediately leads to the claimed value for $\kappa$ ) and

$$
M=8 \tilde{a} \lambda \mathrm{~T}(\mathrm{~T}+4)+\frac{\tilde{a} \lambda \varepsilon}{240}+\frac{4}{15 \tilde{a} \lambda \varepsilon}+4 \tilde{a}\left(\mathrm{~T}+\frac{6}{\varepsilon \lambda}\right)
$$

and using that $\mathrm{T} \leqslant 1 / 10$ gives the claimed result.
This allows to conclude the proof of Theorem 5.
In the next sections, we derive the technical results that we used in the proof of Theorem 5. In Section 3.2, we bound $\mathcal{L}_{\tilde{a}}\left(h_{n+1}\right)$ in terms of $h_{n}$, the Jacobian matrix of the (reverse) Verlet map $\Phi_{\delta}^{-K}$ and some numerical error terms. The latters are studied respectively in Sections 3.3 and 3.4.

### 3.2 Evolution of entropies under elementary steps

In this section, we compute the evolution of the relative entropy and Fisher-like terms (19) along the damping and Verlet steps. The velocity randomization step is the same as in [41, Section 4.1.1], where the following is established.

Lemma 7 (Dissipation from velocity randomization). Recalling from (30) the notation

$$
\mathbf{B}_{v}=\left(\begin{array}{cc}
0 & 0 \\
0 & 1
\end{array}\right), \quad \mathbf{B}_{\eta}=\left(\begin{array}{cc}
1 & 0 \\
0 & \eta
\end{array}\right)
$$

then, for all $\eta \in(0,1)$ and all measurable $h$ with $\mathcal{H}(h)<+\infty$,

$$
\mathcal{H}\left(\mathrm{D}_{\eta} h\right)-\mathcal{H}(h) \leqslant-\left(\frac{\eta^{-2}-1}{2}\right) \mathcal{I}_{\mathbf{B}_{v}}\left(\mathrm{D}_{\eta} h\right)
$$

and, for any matrix $\tilde{\mathbf{A}}$,

$$
\mathcal{I}_{\tilde{\mathbf{A}} \mathbf{B}_{\eta}^{-1}}\left(\mathrm{D}_{\eta} h\right) \leqslant \mathcal{I}_{\tilde{\mathbf{A}}}(h) .
$$

Proof. The first inequality is equivalent to

$$
0 \leqslant \mathcal{H}\left(\mathrm{D}_{\eta} h\right)+\left(\frac{\eta^{-2}-1}{2}\right) \mathcal{I}_{\mathbf{B}_{v}}\left(\mathrm{D}_{\eta} h\right) \leqslant \mathcal{H}(h)<+\infty
$$

which is established in [41, Equation (45)] (it is sufficient to prove the bound for a smooth positive $h$ with compact support and pass to the limit).

The second point follows from Jensen's inequality and the convexity of $(t, x) \mapsto|x|^{2} / t$ on $\mathbb{R}_{+}^{*} \times \mathbb{R}^{d}$ (using [14, Proposition 2.3 (ii)]) which imply

$$
\int_{\mathbb{R}^{2 d}} \frac{|\tilde{\mathbf{A}} \nabla h|^{2}}{h} \mathrm{~d} \mu=\int_{\mathbb{R}^{2 d}} \mathrm{D}_{\eta}\left(\frac{|\tilde{\mathbf{A}} \nabla h|^{2}}{h}\right) \mathrm{d} \mu \geqslant \int_{\mathbb{R}^{2 d}} \frac{\left|\mathrm{D}_{\eta} \tilde{\mathbf{A}} \nabla h\right|^{2}}{\mathrm{D}_{\eta} h} \mathrm{~d} \mu=\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}} \mathbf{B}_{\eta}^{-1} \nabla \mathrm{D}_{\eta} h\right|^{2}}{\mathrm{D}_{\eta} h} \mathrm{~d} \mu
$$

where the last equality comes from $\nabla_{v}\left(\mathrm{D}_{\eta} h\right)=\eta \mathrm{D}_{\eta}\left(\nabla_{v} h\right)$ and $\mathrm{D}_{\eta}\left(\nabla_{x} h\right)=\nabla_{x}\left(\mathrm{D}_{\eta} h\right)$.
Lemma 8 (Fisher inequality on Verlet step). For all matrices $\tilde{\mathbf{A}}$, all smooth $h$ with $\mathcal{I}(h)<$ $+\infty$, and all $\varepsilon>0$,

$$
\mathcal{I}_{\tilde{\mathbf{A}}}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} h\right) \leqslant(1+\varepsilon) \mathcal{I}_{\tilde{\mathbf{A}} \Psi}(h)+\left(1+\varepsilon^{-1}\right)|\tilde{\mathbf{A}}|^{2} \operatorname{Er}_{1}^{\delta, K}(h)
$$

with $\Psi=\left(\nabla \Phi_{\delta}^{-K}\right) \circ \Phi_{\delta}^{K}$ and the error term

$$
\operatorname{Er}_{1}^{\delta, K}(h)=\int_{\mathbb{R}^{2 d}}\left|(\nabla \square H) \circ \Phi_{\delta}^{K}\right|^{2} h \mathrm{~d} \mu .
$$

Proof. By an approximation argument, it can be assumed that $h$ is bounded below by a positive constant and globally Lipschitz. Recalling the action of $\left(\mathrm{V}_{\delta}^{K}\right)^{*}$ from (28),

$$
\begin{aligned}
& \int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}} \nabla\left(\mathrm{~V}_{\delta}^{K}\right)^{*} h\right|^{2}}{\left(\mathrm{~V}_{\delta}^{K}\right)^{*} h} \mathrm{~d} \mu=\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}} \nabla\left(\left(h \circ \Phi_{\delta}^{-K}\right) \mathrm{e}^{\square H}\right)\right|^{2}}{\left(h \circ \Phi_{\delta}^{-K}\right) \mathrm{e}^{\square H}} \mathrm{~d} \mu \\
&=\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}}\left[\nabla\left(\Phi_{\delta}^{-K}\right)(\nabla h) \circ \Phi_{\delta}^{-K}-\left(h \circ \Phi_{\delta}^{-K}\right) \nabla \square H\right] \mathrm{e}^{\square H}\right|^{2}}{\left(h \circ \Phi_{\delta}^{-K}\right) \mathrm{e}^{\square H}} \mathrm{~d} \mu \\
&=\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}}\left[\nabla\left(\Phi_{\delta}^{-K}\right)(\nabla h) \circ \Phi_{\delta}^{-K}-\left(h \circ \Phi_{\delta}^{-K}\right) \nabla \square H\right]\right|^{2}}{h \circ \Phi_{\delta}^{-K}} \mathrm{e}^{\square H} \mathrm{~d} \mu \\
&=\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}}\left[\left(\nabla\left(\Phi_{\delta}^{-K}\right) \circ \Phi_{\delta}^{K}\right) \nabla h-h(\nabla \square H) \circ \Phi_{\delta}^{K}\right]\right|^{2}}{h} \mathrm{~d} \mu,
\end{aligned}
$$

where we used the change of variable $\Phi_{\delta}^{-K}$ in the last line. Introducing $\Psi=\nabla\left(\Phi_{\delta}^{-K}\right) \circ \Phi_{\delta}^{K}$, we therefore obtain, with a discrete Cauchy-Schwarz inequality: for any $\varepsilon>0$,
$\int_{\mathbb{R}^{2 d}} \frac{\left|\tilde{\mathbf{A}} \nabla\left(\mathrm{~V}_{\delta}^{K}\right)^{*} h\right|^{2}}{\left(\mathrm{~V}_{\delta}^{K}\right)^{*} h} \mathrm{~d} \mu \leqslant(1+\varepsilon) \int_{\mathbb{R}^{2 d}} \frac{|\tilde{\mathbf{A}} \Psi \nabla h|^{2}}{h} \mathrm{~d} \mu+\left(1+\frac{1}{\varepsilon}\right)|\tilde{\mathbf{A}}|^{2} \int_{\mathbb{R}^{2 d}}\left|\nabla \square H \circ \Phi_{\delta}^{K}\right|^{2} h \mathrm{~d} \mu$,
which is indeed the claimed estimate.
Remark 9. If the constant matrix $\tilde{\mathbf{A}}$ is replaced by a matrix field $z \mapsto \tilde{\mathbf{A}}(z)$, a straightforward adapation of the proof yields

$$
\mathcal{I}_{\tilde{\mathbf{A}}}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} h\right) \leqslant(1+\varepsilon) \mathcal{I}_{\left(\tilde{\mathbf{A}} \circ \Phi_{\delta}^{K}\right) \Psi}(h)+\left(1+\varepsilon^{-1}\right)\|\tilde{\mathbf{A}}\|_{\infty}^{2} \operatorname{Er}_{1}^{\delta, K}(h)
$$

with $\|\tilde{\mathbf{A}}\|_{\infty}=\sup _{z \in \mathbb{R}^{2 d}}|\tilde{\mathbf{A}}(z)|$.
Lemma 10 (Entropy inequality on Verlet step). For all smooth $h$ with $\mathcal{I}(h)<+\infty$ and all $\varepsilon>0$,

$$
\mathcal{H}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} h\right)-\mathcal{H}(h) \leqslant \sum_{j=0}^{K-1}\left[\frac{\varepsilon}{2} \int_{0}^{\delta} \mathcal{I}\left(\left(\mathrm{V}_{\delta}^{j} \mathrm{~V}_{s}^{1}\right)^{*} h\right) d s+\frac{1}{2 \varepsilon} \operatorname{Er}_{2}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right)\right]
$$

with the error term

$$
\operatorname{Er}_{2}(h)=\int_{0}^{\delta}\left(\int_{\mathbb{R}^{2 d}}\left|\partial_{s} \Phi_{s}-F_{H} \circ \Phi_{s}\right|^{2} h d \mu\right) \mathrm{d} s
$$

where

$$
\begin{equation*}
F_{H}(x, v)=\binom{v}{-\nabla U(x)} . \tag{38}
\end{equation*}
$$

Proof. In view of the decomposition

$$
\mathcal{H}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} h\right)-\mathcal{H}(h)=\sum_{j=0}^{K-1}\left[\mathcal{H}\left(\left(\mathrm{~V}_{\delta}^{j+1}\right)^{*} h\right)-\mathcal{H}\left(\left(\mathrm{V}_{\delta}^{j}\right)^{*} h\right)\right]
$$

we simply have to establish the result for $K=1$.
For $z \in \mathbb{R}^{2 d}$ and $t \in[0, \delta]$, let $z_{t}=\Phi_{t}(z)$. For $f_{0}$ an initial (smooth positive) distribution, denote by $f_{t}$ the law of $z_{t}$ when $z \sim f_{0}$ and $h_{t}=f_{t} / \mu$. By a change a variable we see that, for any smooth function $g$ on $\mathbb{R}^{2 d}$,

$$
\int_{\mathbb{R}^{2 d}} g(z) f_{t}(z) \mathrm{d} z=\int_{\mathbb{R}^{2 d}} g\left(z_{t}\right) f_{0}(z) \mathrm{d} z=\int_{\mathbb{R}^{2 d}} g(z) f_{0}\left(\Phi_{t}^{-1}(z)\right) \mathrm{d} z,
$$

i.e. $f_{t}(z)=f_{0}\left(\Phi_{t}^{-1}(z)\right)$, and

$$
\begin{align*}
\int_{\mathbb{R}^{2 d}} g(z) \partial_{t} f_{t}(z) \mathrm{d} z=\frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\mathbb{R}^{2 d}} g\left(z_{t}\right) f_{0}(z) \mathrm{d} z\right) & =\int_{\mathbb{R}^{2 d}} \partial_{t} \Phi_{t}(z) \cdot \nabla g\left(\Phi_{t}(z)\right) f_{0}(z) \mathrm{d} z \\
& =\int_{\mathbb{R}^{2 d}} j_{t}(z) \cdot \nabla g(z) f_{t}(z) \mathrm{d} z \tag{39}
\end{align*}
$$

with $j_{t}=\partial_{t} \Phi_{t} \circ \Phi_{t}^{-1}$. Then,

$$
\int_{\mathbb{R}^{2 d}} f_{\delta} \ln h_{\delta}-\int_{\mathbb{R}^{2 d}} f_{0} \ln h_{0}=\int_{0}^{\delta} \frac{\mathrm{d}}{\mathrm{~d} s}\left(\int_{\mathbb{R}^{2 d}} f_{s} \ln h_{s} \mathrm{~d} s\right),
$$

and

$$
\frac{\mathrm{d}}{\mathrm{~d} s}\left(\int_{\mathbb{R}^{2 d}} f_{s} \ln h_{s}\right)=\int_{\mathbb{R}^{2 d}} \partial_{s} h_{s} \mathrm{~d} \mu+\int_{\mathbb{R}^{2 d}}\left(\ln h_{s}\right) \partial_{s} f_{s}
$$

The first term of the right hand side vanishes as it is the time derivative of the integral of $h_{s}$, which is 1 for any $s \geqslant 0$. Combining the latter equality with (39) then gives

$$
\frac{\mathrm{d}}{\mathrm{~d} s}\left(\int_{\mathbb{R}^{2 d}} f_{s} \ln h_{s}\right)=\int_{\mathbb{R}^{2 d}} j_{s} \cdot \nabla\left(\ln h_{s}\right) f_{s} .
$$

Since $F_{H} \cdot \nabla \mu=0$ and $F_{H}$ is divergence free,

$$
\int_{\mathbb{R}^{2 d}} F_{H} \cdot \nabla\left(\ln h_{s}\right) f_{s}=\int_{\mathbb{R}^{2 d}} F_{H} \cdot \nabla h_{s} \mathrm{~d} \mu=-\int_{\mathbb{R}^{2 d}} h_{s}\left(F_{H} \cdot \nabla \mu+\mu \operatorname{div} F_{H}\right)=0
$$

Thus, we can add this term to the previous equality to get, for any $\varepsilon>0$,

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} s}\left(\int_{\mathbb{R}^{2 d}} f_{s} \ln h_{s}\right) & =\int_{\mathbb{R}^{2 d}}\left(j_{s}(z)-F_{H}(z)\right) \cdot \nabla \ln h_{s}(z) f_{s}(z) \mathrm{d} z \\
& \leqslant \frac{1}{2 \varepsilon} \int_{\mathbb{R}^{2 d}}\left|j_{s}(z)-F_{H}(z)\right|^{2} f_{s}(z) \mathrm{d} z+\frac{\varepsilon}{2} \int_{\mathbb{R}^{2 d}}\left|\nabla \ln h_{s}(z)\right|^{2} f_{s}(z) \mathrm{d} z \\
& =\frac{1}{2 \varepsilon} \int_{\mathbb{R}^{2 d}}\left|\partial_{s} \Phi_{s}-F_{H} \circ \Phi_{s}\right|^{2} h_{s} \mathrm{~d} \mu+\frac{\varepsilon}{2} \int_{\mathbb{R}^{2 d}}\left|\nabla \ln h_{s}(z)\right|^{2} f_{s}(z) \mathrm{d} z
\end{aligned}
$$

which gives the announced result once integrated over $s \in[0, \delta]$.
At this stage, gathering Lemmas 7, 8 and 10 yields a bound on $\mathcal{L}_{a}\left(h_{n+1}\right)$ involving $h_{n}$, the matrix field $\Psi$ of Lemma 8 and the numerical error terms of Lemmas 8 and 10. It remains to understand these parts. We give some estimates on $\Psi$ in Section 3.3 and analyse the numerical errors in Section 3.4.

### 3.3 Jacobian matrix of the Verlet integrator

As mentioned above, this section focuses on the matrix field $\Psi=\left(\nabla \Phi_{\delta}^{-K}\right) \circ \Phi_{\delta}^{K}$ appearing in Lemma 8. The following result is the analogue for the Verlet scheme of the first part of [41, Lemma 1] for the Hamiltonian dynamics.
Lemma 11. Under $\boldsymbol{H} 1$ with $L=1$, for all $z \in \mathbb{R}^{2 d}$, there exist $d \times d$ matrices $\alpha, \beta$, $\zeta$ with norms less than 1 such that, recalling the notation $\mathrm{T}=K \delta$,

$$
\left|\Psi(z)-\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{\mathrm{T}^{2}}{2} \alpha & \mathrm{~T} \beta \\
-\mathrm{T} & \mathrm{I}_{d}-\frac{\mathrm{T}^{2}}{2} \zeta
\end{array}\right)\right| \leqslant \frac{1}{3} \mathrm{~T}^{3} .
$$

In particular,

$$
\begin{equation*}
|\Psi(z)| \leqslant 1+\mathrm{T}+\frac{1}{2} \mathrm{~T}^{2}+\frac{1}{3} \mathrm{~T}^{3} . \tag{40}
\end{equation*}
$$

Proof. Denote by $\mathcal{M}_{1}$ the set of $d \times d$ matrices with operator norm bounded by 1 . Note that the product of two elements in $\mathcal{M}_{1}$ is still in $\mathcal{M}_{1}$. Fix $z \in \mathbb{R}^{2 d}$. For $k \geqslant 1$, set $z_{k}=\Phi_{\delta}^{-1}\left(z_{k-1}\right)$, with $z_{0}=\Phi_{\delta}^{K}(z)$. For $k \geqslant 0$, set $Q_{k}=\nabla^{2} U\left(x_{k}\right)$, where $z_{k}=\left(x_{k}, v_{k}\right)$. By assumption, $Q_{k} \in \mathcal{M}_{1}$ for all $k \geqslant 0$.

Recall that, for $F: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}$, we use the convention $\nabla F=\left(\partial_{i} F_{j}\right)_{1 \leqslant i, j \leqslant d}$ where $i$ stands for the row and $j$ for the column. Hence, from (29), for all $k \geqslant 0$,

$$
\nabla\left(\Phi_{\delta}^{-1}\right)\left(z_{k}\right)=\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k} & \left.\frac{\delta}{2}\left[Q_{k}+\left(\mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k}\right)\right) Q_{k+1}\right] \\
-\delta & \mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k+1}
\end{array}\right)
$$

In particular,

$$
\left|\nabla\left(\Phi_{\delta}^{-1}\right)\left(z_{k}\right)-\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k} & \frac{\delta}{2}\left[Q_{k}+Q_{k+1}\right]  \tag{41}\\
-\delta & \mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k+1}
\end{array}\right)\right| \leqslant \frac{\delta^{3}}{4} .
$$

For all $k \in \llbracket 1, K \rrbracket$, let us determine by induction a constant $C_{k} \geqslant 0$ and matrices $\alpha_{k}, \beta_{k}, \zeta_{k} \in$ $\mathcal{M}_{1}$ such that

$$
\left|\nabla\left(\Phi_{\delta}^{-k}\right)\left(z_{0}\right)-\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \alpha_{k} & \delta k \beta_{k}  \tag{42}\\
-\delta k & \mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \zeta_{k}
\end{array}\right)\right| \leqslant C_{k}
$$

For $k=1$, this is given by (41) (applied at $k=0$ ) with $C_{1}=\delta^{3} / 4$. Suppose that the result is true for some $k \geqslant 1$. In particular, using that $\delta k \leqslant 1 / 10$,

$$
\left|\nabla\left(\Phi_{\delta}^{-k}\right)\left(z_{0}\right)\right| \leqslant\left|\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \alpha_{k} & 0 \\
0 & \mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \zeta_{k}
\end{array}\right)\right|+\left|\left(\begin{array}{cc}
0 & \delta k \beta_{k} \\
-\delta k & 0
\end{array}\right)\right|+C_{k}
$$

$$
\begin{equation*}
\leqslant 1+\frac{21}{20} \delta k+C_{k} \tag{43}
\end{equation*}
$$

We next use $\nabla \Phi_{\delta}^{-k-1}\left(z_{0}\right)=\nabla \Phi_{\delta}^{-1}\left(z_{k}\right) \nabla \Phi_{\delta}^{-k}\left(z_{0}\right)$. At dominant order, the product of the terms on the right hand side of the previous equality is

$$
\begin{gathered}
\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k} & \frac{\delta}{2}\left[Q_{k}+Q_{k+1}\right] \\
-\delta & \mathrm{I}_{d}-\frac{\delta^{2}}{2} Q_{k+1}
\end{array}\right)\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \alpha_{k} & \delta k \beta_{k} \\
-\delta k & \mathrm{I}_{d}-\frac{(\delta k)^{2}}{2} \zeta_{k}
\end{array}\right) \\
=\left(\begin{array}{cc}
\mathrm{I}_{d}-\frac{\delta^{2}(k+1)^{2}}{2} \alpha_{k+1} & \delta(k+1) \beta_{k+1} \\
-\delta(k+1) & \mathrm{I}_{d}-\frac{\delta^{2}(k+1)^{2}}{2} \zeta_{k+1}
\end{array}\right)+\mathfrak{R}
\end{gathered}
$$

with

$$
\begin{gathered}
\alpha_{k+1}=\frac{1}{(k+1)^{2}}\left(Q_{k}+k^{2} \alpha_{k}+k\left(Q_{k}+Q_{k+1}\right)\right), \quad \beta_{k+1}=\frac{1}{2(k+1)}\left(Q_{k}+Q_{k+1}+2 k \beta_{k}\right) \\
\zeta_{k+1}=\frac{1}{(k+1)^{2}}\left(2 k \beta_{k}+Q_{k+1}+k^{2} \zeta_{k}\right)
\end{gathered}
$$

which are all three in $\mathcal{M}_{1}$, and a remainder term

$$
\mathfrak{R}=\left(\begin{array}{cc}
\frac{\delta^{4} k^{2}}{4} Q_{k} \alpha_{k} & -\frac{\delta^{3} k}{4}\left(2 Q_{k} \beta_{k}+k\left(Q_{k}+Q_{k+1}\right) \zeta_{k}\right) \\
\frac{\delta^{3} k}{2}\left(Q_{k+1}+k \alpha_{k}\right) & \frac{\delta^{4} k^{2}}{4} Q_{k+1} \zeta_{k}
\end{array}\right)
$$

Using that $\delta \leqslant 1 / 10$,

$$
\begin{align*}
|\mathfrak{R}| & =\frac{\delta^{4} k^{2}}{4}\left|\left(\begin{array}{cc}
Q_{k} \alpha_{k} & 0 \\
0 & Q_{k+1} \zeta_{k}
\end{array}\right)\right|+\frac{\delta^{3} k}{2}\left|\left(\begin{array}{cc}
0 & -Q_{k} \beta_{k}-k\left(Q_{k}+Q_{k+1}\right) / 2 \zeta_{k} \\
Q_{k+1}+k \alpha_{k} & 0
\end{array}\right)\right| \\
& \leqslant \frac{\delta^{4} k^{2}}{4}+\frac{\delta^{3} k}{2}(k+1) \leqslant \frac{21}{40} \delta^{3} k(k+1) . \tag{44}
\end{align*}
$$

Then,

$$
\begin{aligned}
& (\star):=\left|\nabla \Phi_{\delta}^{-k-1}\left(z_{0}\right)-\left(\begin{array}{cc}
\mathrm{I}_{d}-\delta^{2}(k+1)^{2} \alpha_{k+1} / 2 & \delta(k+1) \beta_{k+1} \\
-\delta(k+1) & \mathrm{I}_{d}-\delta^{2}(k+1)^{2} \zeta_{k+1} / 2
\end{array}\right)\right| \\
& \leqslant|\mathfrak{R}|+\left|\left[\nabla\left(\Phi_{\delta}^{-1}\right)\left(z_{k}\right)-\left(\begin{array}{cc}
\mathrm{I}_{d}-\delta^{2} Q_{k} / 2 & \delta\left[Q_{k}+Q_{k+1}\right] / 2 \\
-\delta & \mathrm{I}_{d}-\delta^{2} Q_{k+1} / 2
\end{array}\right)\right] \nabla \Phi_{\delta}^{-k}\left(z_{0}\right)\right| \\
& +\left|\left(\begin{array}{cc}
\mathrm{I}_{d}-\delta^{2} Q_{k} / 2 & \delta\left[Q_{k}+Q_{k+1}\right] / 2 \\
-\delta & \mathrm{I}_{d}-\delta^{2} Q_{k+1} / 2
\end{array}\right)\left[\nabla \Phi_{\delta}^{-k}\left(z_{0}\right)-\left(\begin{array}{cc}
\mathrm{I}_{d}-(\delta k)^{2} \alpha_{k} / 2 & \delta k \beta_{k} \\
-\delta k & \mathrm{I}_{d}-(\delta k)^{2} \zeta_{k} / 2
\end{array}\right)\right]\right|
\end{aligned}
$$

$$
\leqslant \frac{21}{40} \delta^{3} k(k+1)+\frac{\delta^{3}}{4}\left|\nabla \Phi_{\delta}^{-k}(z)\right|+\left(1+\frac{21}{20} \delta\right) C_{k},
$$

where we used (44) to bound $|\mathfrak{\Re}|$, (41) for the second term and the induction hypothesis (42) for the third one (with the same computation as in (43) for the factor $1+\frac{21}{20} \delta$ ). In view of (43), we finally obtain

$$
\begin{aligned}
(\star) \leqslant C_{k+1} & :=\frac{21}{40} \delta^{3} k(k+1)+\frac{\delta^{3}}{4}\left(1+\frac{21}{20} \delta k+C_{k}\right)+\left(1+\frac{21}{20} \delta\right) C_{k} \\
& \leqslant \frac{21}{40} \delta^{3}(k+1)^{2}+\left(1+\frac{11}{10} \delta\right) C_{k} .
\end{aligned}
$$

which allows to obtain the induction hypothesis (42) at the next step. From this, since $C_{1} \leqslant$ $21 \delta^{3} / 40$,

$$
C_{K} \leqslant \frac{21}{40} \delta^{3} \sum_{k=0}^{K-1}(k+1)^{2}\left(1+\frac{11}{10} \delta\right)^{K-1-k} \leqslant \frac{21}{40 \times 3}(\delta K)^{3} \mathrm{e}^{11 \delta K / 10} \leqslant \frac{1}{3}(\delta K)^{3} .
$$

which gives the desired estimate.

In particular, thanks to the estimate on $|\Psi|$ of Lemma 11 and to Lemma 8 we can bound the Fisher term appearing in Lemma 10 to get the following somewhat more explicit estimate.
Corollary 12 (Improved entropy inequality on Verlet step). For any $\varepsilon>0$,

$$
\begin{aligned}
\mathcal{H}\left(\left(\mathrm{V}_{\delta}^{K}\right)^{*} h\right)-\mathcal{H}(h) & \leqslant 4 \varepsilon K \delta \mathcal{I}(h) \\
& +\sum_{j=0}^{K-1}\left[3 \delta \varepsilon \operatorname{Er}_{1}^{\delta, j}(h)+\varepsilon \int_{0}^{\delta} \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) \mathrm{d} s+\frac{1}{2 \varepsilon} \operatorname{Er}_{2}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right)\right] .
\end{aligned}
$$

Proof. For $j \in \llbracket 0, K-1 \rrbracket$ and $s \in[0, \delta]$, writing $\Psi_{s}=\nabla \Phi_{s}^{-1} \circ \Phi_{s}$ and $\Psi_{j}=\nabla \Phi_{\delta}^{-j} \circ \Phi_{\delta}^{j}$, applying twice Lemma 8 (with $\tilde{\mathbf{A}}=I_{2 d}$ and $\varepsilon=1$ ) and using the bound (40) (with $s \leqslant K \delta \leqslant 1 / 10$ ) on $\left|\Psi_{s}\right|$ and $\left|\Psi_{j}\right|$, which implies that these quantities are smaller than 3/2 in sup norm,

$$
\begin{aligned}
\mathcal{I}\left(\left(\mathrm{V}_{\delta}^{j} \mathrm{~V}_{s}^{1}\right)^{*} h\right) & \leqslant 2 \mathcal{I}_{\Psi_{s}}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right)+2 \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) \\
& \leqslant 2\left\|\Psi_{s}\right\|_{\infty}^{2} \mathcal{I}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right)+2 \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) \\
& \leqslant 3 \mathcal{I}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right)+2 \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) \\
& \leqslant 6 \mathcal{I}_{\Psi_{j}}(h)+6 \operatorname{Er}_{1}^{\delta, j}(h)+2 \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) \\
& \leqslant 8 \mathcal{I}(h)+6 \operatorname{Er}_{1}^{\delta, j}(h)+2 \operatorname{Er}_{1}^{s, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} h\right) .
\end{aligned}
$$

Plugging this bound in the result of Lemma 10 gives the claimed estimate.

### 3.4 Numerical error

The goal of this section is to bound the numerical errors appearing in Lemmas 8 and 10 . At various places, we use the following inequality (obtained by convexity): for $\alpha \geqslant 1$ and nonnegative sequences $\left(a_{i}\right)_{1 \leqslant i \leqslant I}$ and $\left(w_{i}\right)_{1 \leqslant i \leqslant I}$, it holds

$$
\begin{equation*}
\left(\sum_{i=1}^{I} w_{i} a_{i}\right)^{\alpha} \leqslant\left(\sum_{i=1}^{I} w_{i}\right)^{\alpha-1} \sum_{i=1}^{I} w_{i} a_{i}^{\alpha} . \tag{45}
\end{equation*}
$$

### 3.4.1 Error in the Fisher term

Lemma 13. Under $\boldsymbol{H} 1$ with $L=1$ and $\boldsymbol{H} 2$, it holds, for any $z \in \mathbb{R}^{d}$,

$$
\begin{aligned}
&|\nabla \square H(z)|^{2} \leqslant 2 \delta^{6} K \sum_{k=0}^{K-1}\left[N_{4}^{6}\left(v_{k}\right)+N_{4}^{6}\left(\nabla U\left(x_{k}\right)\right)+N_{3}^{4}\left(v_{k}\right)+N_{3}^{4}\left(\nabla U\left(x_{k}\right)\right)\right. \\
&\left.+\left|v_{k}\right|^{2}+\left|\nabla U\left(x_{k}\right)\right|^{2}\right]
\end{aligned}
$$

where $\left(x_{k}, v_{k}\right)=\Phi_{\delta}^{-k}(z)$ for $k \in \llbracket 0, K \rrbracket$.
Proof. In view of the decomposition

$$
\square H=H-H \circ \Phi_{\delta}^{-K}=\sum_{k=1}^{K}\left(H \circ \Phi_{\delta}^{-k+1}-H \circ \Phi_{\delta}^{-k}\right),
$$

which leads to the upper bound

$$
|\nabla \square H|^{2} \leqslant K \sum_{k=1}^{K}\left|\nabla\left[H \circ \Phi_{\delta}^{-k+1}-H \circ \Phi_{\delta}^{-k}\right]\right|^{2} .
$$

it suffices to establish the estimate for $K=1$. Recall $H(x, v)=U(x)+|v|^{2} / 2$ and recall from (29) that

$$
\begin{aligned}
\left(x_{1}, v_{1}\right) & =\Phi_{\delta}^{-1}(x, v) \\
& =\left(x-\delta v-\frac{\delta^{2}}{2} \nabla U(x), v+\frac{\delta}{2}\left[\nabla U(x)+\nabla U\left(x-\delta v-\frac{\delta^{2}}{2} \nabla U(x)\right)\right]\right) .
\end{aligned}
$$

Hence, starting with the gradient with respect to the velocities,

$$
\begin{aligned}
& \nabla_{v}\left(H-H \circ \Phi_{\delta}^{-1}\right)(x, v) \\
& \quad=v-\left[-\delta \nabla U\left(x_{1}\right)+\left(I-\frac{\delta^{2}}{2} \nabla^{2} U\left(x_{1}\right)\right) v_{1}\right]
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{\delta}{2}\left(\nabla U\left(x_{1}\right)-\nabla U(x)\right)+\frac{\delta^{2}}{2} \nabla^{2} U\left(x_{1}\right) v+\frac{\delta^{3}}{4} \nabla^{2} U\left(x_{1}\right)\left(\nabla U(x)+\nabla U\left(x_{1}\right)\right) \\
& =\frac{\delta}{2}\left(\nabla U\left(x_{1}\right)-\nabla U(x)+\nabla^{2} U\left(x_{1}\right)\left(x-x_{1}\right)\right)+\frac{\delta^{3}}{4} \nabla^{2} U\left(x_{1}\right) \nabla U\left(x_{1}\right) .
\end{aligned}
$$

Notice that (8) implies that

$$
\begin{equation*}
\left|\nabla U(x+y)-\nabla U(x)-\nabla^{2} U(x) y\right|=\left|\int_{0}^{1}\left(\nabla^{2} U(x+s y)-\nabla^{2} U(x)\right) y \mathrm{~d} s\right| \leqslant \frac{1}{2} \mathrm{~N}_{3}^{2}(y) . \tag{46}
\end{equation*}
$$

Using this bound and the assumption $\left\|\nabla^{2} U\right\|_{\infty} \leqslant L=1$, we have thus obtained that

$$
\begin{aligned}
\left|\nabla_{v}\left(H-H \circ \Phi_{\delta}^{-1}\right)(x, v)\right| & \leqslant \frac{\delta}{4} \mathrm{~N}_{3}^{2}\left(x-x_{1}\right)+\frac{\delta^{3}}{4}\left|\nabla U\left(x_{1}\right)\right| \\
& \leqslant \frac{\delta^{3}}{2} \mathrm{~N}_{3}^{2}(v)+\frac{\delta^{5}}{8} \mathrm{~N}_{3}^{2}(\nabla U(x))+\frac{\delta^{3}}{4}\left(|\nabla U(x)|+\left|x_{1}-x\right|\right) \\
& \leqslant \frac{\delta^{3}}{2} \mathrm{~N}_{3}^{2}(v)+\frac{\delta^{5}}{8} \mathrm{~N}_{3}^{2}(\nabla U(x))+\frac{\delta^{4}}{4}|v|+\left(\frac{\delta^{3}}{4}+\frac{\delta^{5}}{8}\right)|\nabla U(x)| .
\end{aligned}
$$

With $\delta \leqslant 1 / 10$ and a Cauchy-Schwarz inequality,

$$
\begin{align*}
\left|\nabla_{v}\left(H-H \circ \Phi_{\delta}^{-1}\right)(x, v)\right|^{2} & \leqslant \delta^{6}\left(\frac{1}{2} \mathrm{~N}_{3}^{2}(v)+\frac{1}{800} \mathrm{~N}_{3}^{2}(\nabla U(x))+\frac{1}{40}|v|+\frac{201}{800}|\nabla U(x)|\right)^{2} \\
& \leqslant \frac{\delta^{6}}{3}\left(\mathrm{~N}_{3}^{4}(v)+\mathrm{N}_{3}^{4}(\nabla U(x))+|v|^{2}+|\nabla U(x)|^{2}\right) . \tag{47}
\end{align*}
$$

Turning to the gradient with respect to the positions,

$$
\begin{aligned}
& \nabla_{x}\left(H-H \circ \Phi_{\delta}^{-1}\right)(x, v) \\
& =\nabla U(x)-\left[\left(I-\frac{\delta^{2}}{2} \nabla^{2} U(x)\right) \nabla U\left(x_{1}\right)+\frac{\delta}{2}\left(\nabla^{2} U(x)+\left(I-\frac{\delta^{2}}{2} \nabla^{2} U(x)\right) \nabla^{2} U\left(x_{1}\right)\right) v_{1}\right] \\
& =(*)+(* *)+(* * *),
\end{aligned}
$$

with, organizing terms depending on their orders in $\delta$, and using $\delta v_{1}=x-x_{1}+\delta \nabla U\left(x_{1}\right) / 2$,

$$
\begin{aligned}
(*) & =\nabla U(x)-\nabla U\left(x_{1}\right)-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U\left(x_{1}\right)\right)\left(x-x_{1}\right), \\
(* *) & =\frac{\delta^{2}}{4}\left(\nabla^{2} U(x)-\nabla^{2} U\left(x_{1}\right)\right) \nabla U\left(x_{1}\right), \\
(* * *) & =\frac{\delta^{3}}{4} \nabla^{2} U(x) \nabla^{2} U\left(x_{1}\right) v_{1} .
\end{aligned}
$$

Using the bound (9) on the fourth derivative of $U$ and (45),

$$
|(*)| \leqslant N_{4}^{3}\left(x-x_{1}\right) \leqslant \delta^{3}\left(N_{4}(v)+\delta N_{4}(\nabla U(x))\right)^{3}
$$

$$
\leqslant \delta^{3}(1+\delta)^{2}\left(N_{4}^{3}(v)+\delta N_{4}^{3}(\nabla U(x))\right) .
$$

From the bound (8) on the third derivative of $U$ and that $\left\|\nabla^{2} U\right\|_{\infty} \leqslant L=1$

$$
\begin{aligned}
|(* *)| & \leqslant \frac{\delta^{2}}{4}\left|\left(\nabla^{2} U(x)-\nabla^{2} U\left(x_{1}\right)\right) \nabla U(x)\right|+\frac{\delta^{2}}{2}\left|\nabla U\left(x_{1}\right)-\nabla U(x)\right| \\
& \leqslant \frac{\delta^{2}}{4} N_{3}\left(x-x_{1}\right) N_{3}(\nabla U(x))+\frac{\delta^{2}}{2}\left|x_{1}-x\right| \\
& \leqslant \frac{\delta^{3}}{8} N_{3}^{2}(v)+\frac{\delta^{3}+\delta^{4}}{8} N_{3}^{2}(\nabla U(x))+\frac{\delta^{3}}{2}|v|+\frac{\delta^{4}}{4}|\nabla U(x)| .
\end{aligned}
$$

Finally,

$$
\begin{aligned}
|(* * *)| \leqslant \frac{\delta^{3}}{4}\left|v_{1}\right| & \leqslant \frac{\delta^{3}}{4}|v|+\frac{\delta^{4}}{4}|\nabla U(x)|+\frac{\delta^{4}}{8}\left|x_{1}-x\right| \\
& \leqslant \frac{2 \delta^{3}+\delta^{5}}{8}|v|+\frac{4 \delta^{4}+\delta^{6}}{16}|\nabla U(x)| .
\end{aligned}
$$

As a conclusion, using that $\delta \leqslant 1 / 10$ and Cauchy-Schwarz inequality,

$$
\begin{aligned}
& \left|\nabla_{x}\left(H-H \circ \Phi_{\delta}^{-1}\right)(x, v)\right|^{2} \\
& \leqslant \\
& \leqslant \delta^{6}\left[(1+\delta)^{2}\left(N_{4}^{3}(v)+\delta N_{4}^{3}(\nabla U(x))\right)+\frac{1}{8} N_{3}^{2}(v)\right. \\
& \left.\quad \quad+\frac{1+\delta}{8} N_{3}^{2}(\nabla U(x))+\left(\frac{3}{4}+\frac{\delta^{2}}{8}\right)|v|+\delta\left(\frac{1}{2}+\frac{\delta^{2}}{16}\right)|\nabla U(x)|\right]^{2} \\
& \leqslant
\end{aligned}
$$

which, combined with (47), gives the desired conclusion.
Integrating the bound of Lemma 13 with respect to $h \mu$ immediately yields the following (recall the definitions of the error in Lemma 8 and of the function $\mathbf{M}$ in (10)).

Corollary 14. Under $\boldsymbol{H} 1$ with $L=1$ and $\boldsymbol{H}_{2}$, for any smooth positive relative density $h$,

$$
\operatorname{Er}_{1}^{\delta, K}(h) \leqslant 2 \delta^{6} K \sum_{k=0}^{K-1} \int_{\mathbb{R}^{2 d}}\left(\mathbf{M} \circ \Phi_{\delta}^{k}\right) h \mathrm{~d} \mu .
$$

In particular, assuming moreover $\boldsymbol{H} 3$, and writing $h_{n}=\left(\mathrm{P}_{\omega}^{n}\right)^{*} h_{0}$ for $n \in \mathbb{N}$,

$$
\begin{aligned}
\operatorname{Er}_{1}^{\delta, K}\left(\mathrm{D}_{\eta} h_{n}\right) & \leqslant 2 \delta^{6} K^{2}\left(C_{1} \mathrm{e}^{-\rho n \mathrm{~T}} \nu_{0}(\mathfrak{W})+C_{2}\right), \\
\operatorname{Er}_{1}^{\delta, 1}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} \mathrm{D}_{\eta} h_{n}\right) & \leqslant 2 \delta^{6}\left(C_{1} \mathrm{e}^{-\rho n \mathrm{~T}} \nu_{0}(\mathfrak{W})+C_{2}\right),
\end{aligned}
$$

for all $j \in \llbracket 0, K \rrbracket$.

Remark 15. If in H2 we only assume (8) but not (9), from (8), using that $\nabla U(x+y)-$ $\nabla U(x)=\int_{0}^{1} \nabla^{2} U(x+s y) y \mathrm{~d} s$ (and distinguishing the integration on $[0,1 / 2]$ and on $[1 / 2,1]$ ), we deduce that for all $x, y \in \mathbb{R}^{d}$,

$$
\left|\nabla U(x+y)-\nabla U(x)-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U(x+y)\right) y\right| \leqslant \frac{1}{4} \mathrm{~N}_{3}^{2}(y) .
$$

We can thus use this inequality instead of (9) in Lemma 13 (which is the only place where (9) intervenes) and replace $\mathrm{N}_{4}^{6}$ by $\mathrm{N}_{3}^{4}$ in the definition (10) of M. Following then the rest of the proof, we see that Theorem 1 still holds in this case, but with $\delta^{4}$ replaced by $\delta^{2}$ as the error terms in Corollary 14 are of order $\delta^{4}$ instead of $\delta^{6}$.

### 3.4.2 Error on the entropy term

It suffices to consider the case $K=1$, as the general case is deduced from this one by summing up estimates. Recall that $F_{H}$ is defined in (38).

Lemma 16. Under $\boldsymbol{H} 1$ with $L=1$ and $\boldsymbol{H} 2$, for all $z \in \mathbb{R}^{d}$ and $s \in[0, \delta]$,

$$
\left|\partial_{s} \Phi_{s}(z)-F_{H}\left(\Phi_{s}(z)\right)\right|^{2} \leqslant s^{4}\left(\frac{1}{3}|v|^{2}+\frac{1}{7}|\nabla U(x)|^{2}+\frac{1}{7} N_{3}^{4}(v)+\frac{1}{140} N_{3}^{4}(\nabla U(x))\right) .
$$

Proof. Decomposing $z_{s}=\Phi_{s}(x, v)$ as

$$
z_{s}=\binom{x_{s}}{v_{s}}=\binom{x+s v-\frac{s^{2}}{2} \nabla U(x)}{v-\frac{s}{2}\left[\nabla U(x)+\nabla U\left(x+s v-\frac{s^{2}}{2} \nabla U(x)\right)\right]}
$$

we compute

$$
\begin{aligned}
\left(\partial_{s} \Phi_{s}\right)(z)-F_{H}\left(z_{s}\right) & =\binom{v-s \nabla U(x)}{-\frac{1}{2}\left(\nabla U(x)+\nabla U\left(x_{s}\right)\right)-\frac{s}{2} \nabla^{2} U\left(x_{s}\right) \frac{d x_{s}}{d s}}-\binom{v_{s}}{-\nabla U\left(x_{s}\right)} \\
& =\frac{1}{2}\binom{s\left(\nabla U\left(x_{s}\right)-\nabla U(x)\right)}{\nabla U\left(x_{s}\right)-\nabla U(x)-s \nabla^{2} U\left(x_{s}\right)(v-s \nabla U(x))} .
\end{aligned}
$$

As a consequence, using (46) and $\left\|\nabla^{2} U\right\|_{\infty} \leqslant 1$,

$$
\begin{aligned}
\left|\left(\partial_{s} \Phi_{s}\right)(z)-F_{H}\left(z_{s}\right)\right|^{2} \leqslant & \frac{s^{2}}{4}\left|x_{s}-x\right|^{2}+\frac{1}{2}\left|\nabla U\left(x_{s}\right)-\nabla U(x)-\nabla^{2} U\left(x_{s}\right)\left(x_{s}-x\right)\right|^{2} \\
& +\frac{1}{2}\left|x_{s}-x-s(v-s \nabla U(x))\right|^{2} \\
& \leqslant \frac{s^{2}}{4}\left|x_{s}-x\right|^{2}+\frac{1}{8} N_{3}^{4}\left(x_{s}-x\right)+\frac{s^{4}}{8}|\nabla U(x)|^{2}
\end{aligned}
$$

Using that $s \leqslant \delta \leqslant 1 / 10$, we bound

$$
N_{3}^{4}\left(x_{s}-x\right) \leqslant\left(s N_{3}(v)+\frac{s}{20} N_{3}(\nabla U(x))\right)^{4} \leqslant \frac{21^{3}}{20^{3}} s^{4}\left(N_{3}^{4}(v)+\frac{1}{20} N_{3}^{4}(\nabla U(x))\right),
$$

and similarly $\left|x_{s}-x\right|^{2} \leqslant 21 / 20 s^{2}\left(|v|^{2}+|\nabla U(x)|^{2} / 20\right)$, which allows to conclude.
Again, integrating the previous bound as

$$
\operatorname{Er}_{2}(\delta, h)=\int_{0}^{\delta}\left(\int_{\mathbb{R}^{2 d}}\left|\partial_{s} \Phi_{s}-F_{H} \circ \Phi_{s}\right|^{2} h d \mu\right) \mathrm{d} s \leqslant \frac{1}{3} \int_{0}^{\delta}\left(\int_{\mathbb{R}^{2 d}} s^{4} \mathbf{M} h d \mu\right) \mathrm{d} s
$$

immediately yields the following result (recall the definitions of the Error 2 in Lemma 10 and of the function $\mathbf{M}$ in (10)).

Corollary 17. Under $\boldsymbol{H} 1$ with $L=1$ and $\boldsymbol{H} 2$, for any smooth positive relative density $h$,

$$
\operatorname{Er}_{2}(h) \leqslant \frac{\delta^{5}}{15} \int_{\mathbb{R}^{2 d}} \mathbf{M} h d \mu
$$

In particular, assuming moreover $\boldsymbol{H}$ 3, and writing $h_{n}=\left(\mathrm{P}_{\omega}^{n}\right)^{*}$ for $n \in \mathbb{N}$ then, for any $j \in \llbracket 0, K-1 \rrbracket$,

$$
\operatorname{Er}_{2}\left(\left(\mathrm{~V}_{\delta}^{j}\right)^{*} \mathrm{D}_{\eta} h_{n}\right) \leqslant \frac{\delta^{5}}{15}\left(C_{1}(1-\rho K \delta)^{n} \nu_{0}(\mathfrak{W})+C_{2}\right) .
$$

## A Proof of Proposition 2

Note first that, for $j \neq i$ and defining $w\left(x_{i}, x_{j}\right)=W^{(q)}\left(x_{i}-x_{j}\right)$, it holds

$$
\nabla_{x_{i}, x_{j}}^{2} w\left(x_{i}, x_{j}\right)=-\frac{1}{d_{0}} \nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right)
$$

while

$$
\nabla_{x_{i}}^{2} w\left(x_{i}, x_{j}\right)=\frac{1}{d_{0}} \sum_{j=1}^{d_{0}} \nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right) .
$$

Therefore,

$$
\begin{aligned}
& \sum_{i=1}^{d_{0}}\left|\sum_{j=1}^{d_{0}}\left(\nabla_{x_{i}, x_{j}}^{2} w\left(x_{i}+y_{i}, x_{j}+y_{j}\right)-\nabla_{x_{i}, x_{j}}^{2} w\left(x_{i}, x_{j}\right)\right) z_{j}\right|^{2} \\
&=\frac{1}{d_{0}^{2}} \sum_{i=1}^{d_{0}}\left|\sum_{j \neq i}\left(\nabla^{2} W^{(q)}\left(x_{i}+y_{i}-x_{j}-y_{j}\right)-\nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right)\right)\left(z_{i}-z_{j}\right)\right|^{2} \\
&=\frac{1}{d_{0}^{2}} \sum_{i=1}^{d_{0}}\left|\sum_{j=1}^{d_{0}}\left(\nabla^{2} W^{(q)}\left(x_{i}+y_{i}-x_{j}-y_{j}\right)-\nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right)\right)\left(z_{i}-z_{j}\right)\right|^{2} .
\end{aligned}
$$

We can now compute

$$
\begin{aligned}
& \left|\left(\nabla^{2} U(x+y)-\nabla^{2} U(x)\right) z\right|^{2} \\
& \quad=\sum_{i=1}^{d_{0}}\left|\sum_{j=1}^{d_{0}}\left(\nabla_{x_{i}, x_{j}}^{2} U(x+y)-\nabla_{x_{i}, x_{j}}^{2} U(x)\right) z_{j}\right|^{2} \\
& \quad \leqslant(1+\epsilon) \sum_{i=1}^{d_{0}}\left|\left(\nabla^{2} U^{(q)}\left(x_{i}+y_{i}\right)-\nabla^{2} U^{(q)}\left(x_{i}\right)\right) z_{i}\right|^{2} \\
& \quad+\frac{\epsilon^{2}\left(1+\epsilon^{-1}\right)}{d_{0}^{2}} \sum_{i=1}^{d_{0}}\left|\sum_{j=1}^{d_{0}}\left(\nabla^{2} W^{(q)}\left(x_{i}+y_{i}-x_{j}-y_{j}\right)-\nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right)\right)\left(z_{i}-z_{j}\right)\right|^{2} \\
& \quad \leqslant(1+\epsilon)\left\|\mathrm{D}^{3} U^{(q)}\right\|_{\infty}^{2} \sum_{i=1}^{d_{0}}\left|y_{i}\right|^{2}\left|z_{i}\right|^{2}+\frac{\epsilon(1+\epsilon)}{d_{0}}\left\|\mathrm{D}^{3} W^{(q)}\right\|_{\infty}^{2} \sum_{i=1}^{d_{0}} \sum_{j=1}^{d_{0}}\left|y_{i}-y_{j}\right|^{2}\left|z_{i}-z_{j}\right|^{2} \\
& \quad \leqslant(1+\epsilon)\left(\left\|\mathrm{D}^{3} U^{(q)}\right\|_{\infty}^{2}+16 \epsilon\left\|\mathrm{D}^{3} W^{(q)}\right\|_{\infty}^{2}\right) \sqrt{\sum_{i=1}^{d_{0}}\left|y_{i}\right|^{4} \sum_{j=1}^{d_{0}}\left|z_{j}\right|^{4}},
\end{aligned}
$$

where we used

$$
\begin{aligned}
\frac{1}{d_{0}} \sum_{i=1}^{d_{0}} \sum_{j=1}^{d_{0}}\left|y_{i}-y_{j}\right|^{2}\left|z_{i}-z_{j}\right|^{2} & \leqslant \frac{4}{d_{0}} \sum_{i=1}^{d_{0}} \sum_{j=1}^{d_{0}}\left(\left|y_{i}\right|^{2}+\left|y_{j}\right|^{2}\right)\left(\left|z_{i}\right|^{2}+\left|z_{j}\right|^{2}\right) \\
& \leqslant 8 \sum_{i=1}^{d_{0}}\left|y_{i}\right|^{2}\left|z_{i}\right|^{2}+\frac{8}{d_{0}} \sum_{i=1}^{d_{0}}\left|y_{i}\right|^{2} \sum_{j=1}^{d_{0}}\left|z_{j}\right|^{2}
\end{aligned}
$$

$$
\leqslant 16 \sqrt{\sum_{i=1}^{d_{0}}\left|y_{i}\right|^{4} \sum_{j=1}^{d_{0}}\left|z_{j}\right|^{4}}
$$

to conclude the proof of (8). Following similar computations,

$$
\begin{aligned}
& \left|\nabla U(x+y)-\nabla U(x)-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U(x+y)\right) y\right|^{2} \\
& =\left|\left(\int_{0}^{1} \nabla^{2} U(x+s y) \mathrm{d} s-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U(x+y)\right)\right) y\right|^{2} \\
& =\sum_{i=1}^{d_{0}}\left|\sum_{j=1}^{d_{0}}\left(\int_{0}^{1} \nabla_{x_{i}, x_{j}}^{2} U(x+s y) \mathrm{d} s-\frac{1}{2}\left(\nabla_{x_{i}, x_{j}}^{2} U(x)+\nabla_{x_{i}, x_{j}}^{2} U(x+y)\right)\right) y_{j}\right|^{2} \\
& \leqslant \\
& \leqslant(1+\epsilon) \sum_{i=1}^{d_{0}}\left|\left(\int_{0}^{1} \nabla^{2} U^{(q)}\left(x_{i}+s y_{i}\right) \mathrm{d} s-\frac{1}{2}\left(\nabla^{2} U^{(q)}\left(x_{i}\right)+\nabla^{2} U^{(q)}\left(x_{i}+y_{i}\right)\right)\right) y_{i}\right|^{2} \\
& \left.\quad+\frac{\epsilon+\epsilon^{2}}{d_{0}} \sum_{i, j=1}^{d_{0}} \right\rvert\,\left(\int_{0}^{1} \nabla^{2} W^{(q)}\left(x_{i}-x_{j}+s\left(y_{i}-y_{j}\right)\right) \mathrm{d} s\right. \\
& \left.\quad-\frac{1}{2}\left(\nabla^{2} W^{(q)}\left(x_{i}-x_{j}\right)+\nabla^{2} W^{(q)}\left(x_{i}+y_{i}-x_{j}-y_{j}\right)\right)\right)\left.\left(y_{i}-y_{j}\right)\right|^{2}
\end{aligned}
$$

Using that, for all $f \in \mathrm{C}^{2}([0,1], \mathbb{R})$, integrating twice by parts,

$$
\int_{0}^{1} f(s) \mathrm{d} s-\frac{f(0)+f(1)}{2}=\frac{1}{2} \int_{0}^{1} s(1-s) f^{\prime \prime}(s) \mathrm{d} s
$$

fixing $i \in \llbracket 1, d_{0} \rrbracket, x_{i}, y_{i} \in \mathbb{R}^{q}$ and denoting by $\mathbf{e}_{\ell}$ the $\ell$-th canonical vector of $\mathbb{R}^{q}$,

$$
\begin{aligned}
\mid \mathbf{e}_{\ell} \cdot & \left.\left(\int_{0}^{1} \nabla^{2} U^{(q)}\left(x_{i}+s y_{i}\right) \mathrm{d} s-\frac{1}{2}\left(\nabla^{2} U^{(q)}\left(x_{i}\right)+\nabla^{2} U^{(q)}\left(x_{i}+y_{i}\right)\right)\right) y_{i} \right\rvert\, \\
& =\frac{1}{2}\left|\int_{0}^{1} s(1-s) \mathrm{D}^{4} U^{(q)}\left(x_{i}+s y_{i}\right)\left\{\mathbf{e}_{\ell}, y_{i}, y_{i}, y_{i}\right\} \mathrm{d} s\right| \\
& \leqslant \frac{1}{12}\left\|\mathrm{D}^{4} U^{(q)}\right\|_{\infty}\left|y_{i}\right|^{3} .
\end{aligned}
$$

The terms involving $W^{(q)}$ are treated in a similar manner and we get

$$
\begin{aligned}
& \left|\nabla U(x+y)-\nabla U(x)-\frac{1}{2}\left(\nabla^{2} U(x)+\nabla^{2} U(x+y)\right) y\right|^{2} \\
& \quad \leqslant(1+\epsilon) \sum_{i=1}^{d_{0}} \frac{q}{144}\left\|\mathrm{D}^{4} U^{(q)}\right\|_{\infty}^{2}\left|y_{i}\right|^{6}+\frac{\epsilon+\epsilon^{2}}{d_{0}} \sum_{i, j=1}^{d_{0}} \frac{q}{144}\left\|\mathrm{D}^{4} W^{(q)}\right\|_{\infty}^{2}\left|y_{i}-y_{j}\right|^{6}
\end{aligned}
$$

$$
\leqslant\left(\frac{1+\epsilon}{144}\left\|\mathrm{D}^{4} U^{(q)}\right\|_{\infty}^{2}+\frac{4\left(\epsilon+\epsilon^{2}\right)}{9}\left\|\mathrm{D}^{4} W^{(q)}\right\|_{\infty}^{2}\right) q \sum_{i=1}^{d_{0}}\left|y_{i}\right|^{6}
$$

which concludes the proof of (9).
Finally, to bound $\mathbf{M}$, for $\ell \in\{2,4,6\}$, using that $\nabla U^{(q)}(0)=0=\nabla W^{(q)}(0)$, we write

$$
\begin{aligned}
\left|\nabla_{x_{i}} U(x)\right|^{\ell}=\mid & \nabla U^{(q)}\left(x_{i}\right)+\left.\frac{2 \epsilon}{d_{0}} \sum_{j=1}^{d_{0}} \nabla W^{(q)}\left(x_{i}-x_{j}\right)\right|^{\ell} \\
& \leqslant 2^{\ell-1}\left|\nabla U^{(q)}\left(x_{i}\right)\right|^{\ell}+\frac{2^{2 \ell-1} \epsilon^{\ell}}{d_{0}} \sum_{j=1}^{d_{0}}\left|\nabla W^{(q)}\left(x_{i}-x_{j}\right)\right|^{\ell} \\
& \leqslant 2^{\ell-1}\left\|\nabla^{2} U^{(q)}\right\|_{\infty}^{\ell}\left|x_{i}\right|^{\ell}+\frac{2^{2 \ell-1} \epsilon^{\ell}}{d_{0}}\left\|\nabla^{2} W^{(q)}\right\|_{\infty}^{\ell} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{\ell} .
\end{aligned}
$$

Using $\left|x_{i}-x_{j}\right|^{\ell} \leqslant 2^{\ell-1}\left(\left|x_{i}\right|^{\ell}+\left|x_{j}\right|^{\ell}\right)$ in the last term, we end up with

$$
\sum_{i=1}^{d_{0}}\left|\nabla_{x_{i}} U(x)\right|^{\ell} \leqslant\left(2^{\ell-1}\left\|\nabla^{2} U^{(q)}\right\|_{\infty}^{\ell}+2^{3 \ell} \epsilon^{\ell}\left\|\nabla^{2} W^{(q)}\right\|_{\infty}^{\ell}\right) \sum_{i=1}^{d_{0}}\left|x_{i}\right|^{\ell}
$$

which leads to the claimed result.

## B Uniform-in-time moment bounds

In all this section, which is devoted to the proof of Theorem 3, assumption $\mathbf{H} 4$ is enforced. We denote by $L_{1}=\max \left(\left\|\nabla^{2} U^{(q)}\right\|_{\infty},\left\|\nabla^{2} W^{(q)}\right\|_{\infty}\right)$. In fact, using a rescaling as in Section 2.2.1, we assume without loss of generality that $L_{1} \leqslant 1$. The structure of the proof is the following. After providing some useful preliminary estimates, we describe the class of Lyapunov functions we consider, state the main result in Theorem 18, and discuss that it implies Theorem 3. The remainder of the section is then devoted to the proof of Theorem 18. We start by making precise in Lemma 19 how the Lyapunov function evolves over one Verlet step; and then over several steps in Lemma 21, relying on Lemma 20 which quantifies how much prefactors change when performing several steps. We can then consider the addition of the fluctuation-dissipation step, by first incorporating the momentum update in Lemma 22, then averaging over the momentum updates in Lemma 25, relying on some moment bounds provided by Lemma 24. The proof of Theorem 18 can then be concluded.

Let us emphasize that our proofs are written both for kinetic Langevin dynamics, for which $\eta>0$ (more precisely $1-\eta \geqslant 0$ is of order $\delta$ ), and for HMC, for which $\eta=0$. This second case requires more precise estimates.

Preliminary estimates. We state a few consequences of $\mathbf{H} 4$ which will be useful in the remainder of this section. We additionally assume without loss of generality that $U^{(q)}(0)=$ 0 . First, (16) and the inequality

$$
\left\langle x_{1}, \nabla U^{(q)}\left(x_{1}\right)\right\rangle \leqslant \frac{1}{2 \mathrm{~m}}\left|\nabla U^{(q)}\left(x_{1}\right)\right|^{2}+\frac{\mathrm{m}}{2}\left|x_{1}\right|^{2}
$$

imply that

$$
\begin{equation*}
\forall x_{1} \in \mathbb{R}^{q}, \quad\left|\nabla U^{(q)}\left(x_{1}\right)\right|^{2} \geqslant 2 \mathrm{~m}\left(\frac{\mathrm{~m}}{2}\left|x_{1}\right|^{2}-\mathrm{M}\right) \tag{48}
\end{equation*}
$$

In addition, since $\nabla U^{(q)}$ is $L_{1}$-Lipschitz and $\nabla U^{(q)}(0)=0$, the inequality $\left\langle x_{1}, \nabla U^{(q)}\left(x_{1}\right)\right\rangle \leqslant$ $L_{1}\left|x_{1}\right|^{2}$, and the drift condition (16) together imply, by taking the limit $\left|x_{1}\right| \rightarrow+\infty$, that

$$
\begin{equation*}
\mathrm{m} \leqslant L_{1} \leqslant 1 \tag{49}
\end{equation*}
$$

Finally, since $\nabla U^{(q)}(0)=\nabla W^{(q)}(0)=0$, we obtain that, for any $x_{1} \in \mathbb{R}^{q}$

$$
\begin{equation*}
\left|\nabla U^{(q)}\left(x_{1}\right)\right| \leqslant\left|x_{1}\right|, \quad\left|\nabla W^{(q)}\left(x_{1}\right)\right| \leqslant\left|x_{1}\right|, \quad U^{(q)}\left(x_{1}\right) \leqslant \frac{\left|x_{1}\right|^{2}}{2} \tag{50}
\end{equation*}
$$

Construction of Lyapunov functions. Our analysis is based on the following Lyapunov functions. Under $\mathbf{H} 4$, for $\boldsymbol{\omega}=(K, \delta, \eta) \in \mathbb{N}^{*} \times \mathbb{R}_{+}^{*} \times[0,1)$ and $\ell \in \mathbb{N}^{*}$, we define $\mathfrak{W}_{\omega}^{(\ell)}: \mathbb{R}^{2 d} \rightarrow \mathbb{R}$ as: for any $x=\left(x_{1}, \ldots, x_{d_{0}}\right)$ and $v=\left(v_{1}, \ldots, v_{d_{0}}\right) \in \mathbb{R}^{d}$,

$$
\mathfrak{W}_{\omega}^{(\ell)}(x, v)=\sum_{i=1}^{d_{0}}\left(\mathfrak{W}_{\omega, i}(x, v)\right)^{\ell}, \quad \mathfrak{W}_{\omega, i}(x, v)=\frac{\gamma_{0}^{2}}{2}\left|x_{i}\right|^{2}+\left|v_{i}\right|^{2}+\eta \gamma_{0}\left\langle x_{i}, v_{i}\right\rangle+U^{(q)}\left(x_{i}\right),
$$

where (recall (6)) $\gamma_{0}=\frac{1-\eta}{\delta K}$. Note that since $\eta \in[0,1)$, using Young's inequality $\langle\mathbf{a}, \mathbf{b}\rangle \leqslant$ $(\varepsilon / 2)|\mathbf{a}|^{2}+|\mathbf{b}|^{2} /(2 \varepsilon)$ with $\varepsilon=2 / 3$ for the left inequality and $\varepsilon=1$ for the right one, we get

$$
\begin{equation*}
\frac{1}{6}\left(\gamma_{0}^{2}|x|^{2}+|v|^{2}\right)+\sum_{i=1}^{d_{0}} U^{(q)}\left(x_{i}\right) \leqslant \mathfrak{W}_{\omega}^{(1)}(x, v) \leqslant \frac{3}{2}\left(\gamma_{0}^{2}|x|^{2}+|v|^{2}\right)+\sum_{i=1}^{d_{0}} U^{(q)}\left(x_{i}\right) . \tag{51}
\end{equation*}
$$

By (51) and the fact $0 \leqslant U^{(q)}\left(x_{1}\right) \leqslant\left|x_{1}\right|^{2} / 2$, the function $\mathfrak{W}$ defined in (17) is equivalent to $\mathfrak{W}_{\omega}^{(3)}$, more precisely there exists $A>0$ which depends only on $\gamma_{0}$ such that, for all $(x, v) \in \mathbb{R}^{2 d}$,

$$
\begin{equation*}
A^{-1}\left(d_{0}+\mathfrak{W}_{\omega}^{(3)}(x, v)\right) \leqslant d_{0}+\mathfrak{W}(x, v) \leqslant A\left(d_{0}+\mathfrak{W}_{\omega}^{(3)}(x, v)\right) \tag{52}
\end{equation*}
$$

Statement of the main result. The main result in this section is the following.
Theorem 18. Assume that $\boldsymbol{H}_{4}$ holds with $L_{1}=1$ and let $\bar{\delta}, \bar{T}, \bar{\eta}>0$. Then, for any $\ell \in \mathbb{N}$, $\epsilon>0, \boldsymbol{\omega}=(K, \delta, \eta), \delta>0, K \in \mathbb{N}^{*}, \eta \in[0, \bar{\eta})$ satisfying

$$
\epsilon \leqslant \epsilon_{1} \wedge \epsilon_{2}, \quad \delta \leqslant \delta_{1} \wedge \delta_{2} \wedge 1 /[7 \times 8] \wedge \bar{\delta}, \quad K \delta \leqslant T_{1} \wedge T_{2} \wedge T_{3} \wedge \bar{T}
$$

for any $x, v \in \mathbb{R}^{d}$ and $k \in\{0, \ldots, K\}$,

$$
\begin{align*}
& \mathrm{P}_{\omega}^{n} \mathrm{D}_{\eta} \mathrm{V}_{\delta}^{k} \mathfrak{W}_{\omega}^{(\ell)}(x, v) \leqslant C_{1, \ell}^{\ell}\left(1-\rho_{\omega} K \delta\right)^{\ell n} \mathfrak{W}_{\omega}^{(\ell)}(x, v) \\
&+d_{0}\left(C_{2, \ell q^{\ell}}+C_{3, \ell}\right) \sup _{s \in[0, \bar{T}]} \frac{s}{1-\left(1-\rho_{\omega} s / 8\right)^{\ell}}, \tag{53}
\end{align*}
$$

where $\epsilon_{1}, \epsilon_{2}, T_{1}, T_{2}, T_{3}, \delta_{1}, \delta_{2}$ are defined in (83)-(84)-(85)-(87)-(88),

$$
\begin{equation*}
\rho_{\boldsymbol{\omega}}=2^{5}\left[\gamma_{0} \wedge\left\{\eta \gamma_{0}+\gamma_{0}^{2} K \delta / 2\right\} \mathrm{m}\left(2^{6} 3\right)^{-1}\right], \tag{54}
\end{equation*}
$$

and $C_{1, \ell}, C_{2, \ell}, C_{3, \ell}$ are given in (89). These constants do not depend on $d_{0}, q$ and only depend on $\delta, K, \eta$ through $\gamma_{0}$ and $\rho_{\omega}$.

The remainder of Section B is devoted to the proof of this result. Before proceeding with this proof, let us notice that Theorem 18 implies Theorem 3 in view of (52) and, as can be checked on their expressions, the constants $\epsilon_{1}, \epsilon_{2}, T_{1}, T_{2}, T_{3}, \delta_{1}, \delta_{2}, C_{1, \ell}, C_{2, \ell}, C_{3, \ell}$ appearing in Theorem 18 depend only on $\mathrm{m}, \mathrm{M}, \bar{T}, \bar{\delta}, \gamma_{0}$ and not on $q, d_{0}, \epsilon$.

Evolution over one Verlet step. In order to prove Theorem 18, we will work with a Lyapunov function slightly more general than $\mathfrak{W}_{\omega, i}$. Consider, for any $\mathbf{o}=\left(a, b, c, b_{0}, e, f\right) \in$ $\mathbb{R}_{+}^{6}, i \in\left\{1, \ldots, d_{0}\right\}$, and $x=\left(x_{1}, \ldots, x_{q}\right), v=\left(v_{1}, \ldots, v_{q}\right) \in \mathbb{R}^{d}$, the function

$$
\begin{aligned}
\mathfrak{V}_{\mathbf{o}, i}(x, v)=a\left|x_{i}\right|^{2} & +b\left|v_{i}\right|^{2}+c\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right) \\
& +e \frac{\epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]+f .
\end{aligned}
$$

Notice that the structure of $\mathfrak{V}_{\mathbf{o}, i}$ is similar to the one of $\mathfrak{W}_{\boldsymbol{\omega}, i}$ except that we have added the parameters $\mathbf{o}$ to be more flexible. That way, we will bound the value of $\mathfrak{V}_{\mathbf{o}, i}$ after some Verlet steps in terms of $\mathfrak{V}_{\tilde{\mathbf{o}}, i}$ with different parameters $\tilde{\mathbf{o}}$, so that the general forms of the function is preserved and we only have to keep track of the evolution of the coefficients o.

Specifically, the following result makes precise how the Lyapunov function evolves over one Verlet step, by bounding it with a similar Lyapunov function with modified coefficients. Note that the coefficient $b_{0}$ in front of $U^{(q)}$ in the expression of $\mathfrak{V}_{\mathbf{o}, i}$ is fixed, so that this parameter of the Lyapunov function does not change over the iterations.

Lemma 19. Assume that $\boldsymbol{H}_{4}$ holds and that $\epsilon \leqslant \mathrm{m} / 4$. Then, for any $x, v \in \mathbb{R}^{2 d}, \delta \in$ $(0, \mathrm{~m} / 40], i \in\left\{1, \ldots, d_{0}\right\}$ and $\mathbf{o}=\left(a, b, c, b_{0}, e, f\right) \in \mathbb{R}_{+}^{6}$ with $b_{0} \leqslant b$, it holds

$$
\mathrm{V}_{\delta} \mathfrak{V}_{\mathbf{o}, i}(x, v) \leqslant \mathfrak{N}_{\tilde{\mathbf{o}}, i}(x, v),
$$

where $\tilde{\mathbf{o}}=\left(\tilde{a}, \tilde{b}, \tilde{c}, b_{0}, \tilde{e}, \tilde{f}\right)$ with

$$
\begin{aligned}
& \tilde{a}=a\left(1-\frac{\mathrm{m} \delta^{2}}{2}\right)+8 b \delta^{2}-b_{0} \frac{\delta^{2} \mathrm{~m}^{2}}{2}-\frac{\delta \mathrm{m} c}{2}+\delta\left(b-b_{0}\right), \\
& \tilde{b}=2 \delta^{2} a+\left(1+\epsilon \delta+31 \delta^{2}\right) b+2 b_{0} \delta^{2}+\delta(1+10 \delta) c+\delta\left(b-b_{0}\right), \\
& \tilde{c}=2 \delta a+c, \\
& \tilde{e}=e+\delta\left(2 a \delta+2 b+2 \delta b_{0}+2 c+7 e\right), \\
& \tilde{f}=f+a \delta^{2} \mathrm{M}+2 b_{0} \delta^{2} \mathrm{mM}+\delta \mathrm{M} c .
\end{aligned}
$$

Proof. Note first that the assumption $\epsilon \leqslant \mathrm{m} / 4$ and the bound $\mathrm{m} \leqslant 1$ from (49) imply that $\epsilon \leqslant 1 / 4$. Let $x, v \in \mathbb{R}^{d}, i \in\left\{1, \ldots, d_{0}\right\}, \delta \leqslant \mathrm{m} / 40$ and $\mathbf{o}=\left(a, b, c, b_{0}, e, f\right)$. To alleviate the notation, we introduce, for $j \in\left\{1, \ldots, d_{0}\right\}$, the partial derivative of $U$ with respect to the $j$-th variable, namely the function $\psi_{j}: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}$ defined for any $\tilde{x}=\left(\tilde{x}_{1}, \ldots, \tilde{x}_{d_{0}}\right) \in \mathbb{R}^{d}$ as

$$
\psi_{j}(\tilde{x})=\nabla U^{(q)}\left(\tilde{x}_{j}\right)+\frac{\epsilon}{d_{0}} \sum_{j^{\prime}=1}^{d_{0}} \nabla W^{(q)}\left(\tilde{x}_{j}-\tilde{x}_{j^{\prime}}\right) .
$$

With this notation, it holds by definition of $\mathrm{V}_{\delta}$ that

$$
\begin{equation*}
\mathrm{V}_{\delta} \mathfrak{V}_{\mathbf{o}, i}(x, v)=\mathfrak{V}_{\mathbf{o}, i}(y, p), \tag{55}
\end{equation*}
$$

where $y=\left(y_{1}, \ldots, y_{d_{0}}\right)$ and $p=\left(p_{1}, \ldots, p_{d_{0}}\right)$ with, for $j \in\left\{1, \ldots, d_{0}\right\}$,

$$
y_{j}=x_{j}+\delta v_{j}-\frac{\delta^{2}}{2} \psi_{j}(x), \quad p_{j}=v_{j}-\frac{\delta}{2}\left\{\psi_{j}(x)+\psi_{j}(y)\right\} .
$$

We start by giving some useful preliminary estimates. First, by a discrete CauchySchwarz inequality and (50),

$$
\begin{align*}
\left|\psi_{i}(x)-\psi_{j}(x)\right|^{2} \leqslant & 2\left|\nabla U^{(q)}\left(x_{i}\right)-\nabla U^{(q)}\left(x_{j}\right)\right|^{2} \\
& \quad+\frac{2 \epsilon^{2}}{d_{0}} \sum_{k=1}^{d_{0}}\left|\nabla W^{(q)}\left(x_{k}-x_{i}\right)-\nabla W^{(q)}\left(x_{k}-x_{j}\right)\right|^{2} \\
\leqslant & 2\left(1+\epsilon^{2}\right)\left|x_{i}-x_{j}\right|^{2} . \tag{56}
\end{align*}
$$

Next, by two successive discrete Cauchy-Schwarz inequalities and (50), we have, for any $j \in\left\{1, \ldots, d_{0}\right\}$,

$$
\left|y_{j}-x_{j}\right|^{2} \leqslant \frac{\delta^{4}}{2}\left|\psi_{j}(x)\right|^{2}+2 \delta^{2}\left|v_{j}\right|^{2}
$$

$$
\begin{align*}
& \leqslant 2\left(\delta^{4}\left|\nabla U^{(q)}\left(x_{j}\right)\right|^{2}+\frac{\delta^{4} \epsilon^{2}}{d_{0}} \sum_{j^{\prime}=1}^{d_{0}}\left|\nabla W^{(q)}\left(x_{j}-x_{j^{\prime}}\right)\right|^{2}+\delta^{2}\left|v_{j}\right|^{2}\right) \\
& \leqslant 2\left(\delta^{4}\left|x_{j}\right|^{2}+\frac{\delta^{4} \epsilon^{2}}{d_{0}} \sum_{j^{\prime}=1}^{d_{0}}\left|x_{j}-x_{j^{\prime}}\right|^{2}+\delta^{2}\left|v_{j}\right|^{2}\right) \tag{57}
\end{align*}
$$

In view of (50) and discrete Cauchy-Schwarz inequalities, it holds, for any $\tilde{x}=\left(\tilde{x}_{1}, \ldots, \tilde{x}_{d_{0}}\right), \tilde{y}=$ $\left(y_{1}, \ldots, y_{d_{0}}\right) \in \mathbb{R}^{d_{0}}$ and $i \in\left\{1, \ldots, d_{0}\right\}$,

$$
\begin{align*}
\left|\psi_{i}(\tilde{x})-\psi_{i}(\tilde{y})\right|^{2} & \leqslant 2\left|\tilde{x}_{i}-\tilde{y}_{i}\right|^{2}+\frac{2 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|\tilde{x}_{i}-\tilde{x}_{j}-\left(\tilde{y}_{i}-\tilde{y}_{j}\right)\right|^{2} \\
& \leqslant 2\left(1+2 \epsilon^{2}\right)\left|\tilde{x}_{i}-\tilde{y}_{i}\right|^{2}+\frac{4 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|\tilde{x}_{j}-\tilde{y}_{j}\right|^{2} \tag{58}
\end{align*}
$$

as well as

$$
\begin{equation*}
\left|\psi_{i}(\tilde{x})\right|^{2} \leqslant 2\left|\tilde{x}_{i}\right|^{2}+\frac{2 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|\tilde{x}_{i}-\tilde{x}_{j}\right|^{2} \tag{59}
\end{equation*}
$$

As a result, using (57) to bound all the terms on right hand side of (58), we obtain

$$
\begin{align*}
\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} \leqslant & 4\left(1+2 \epsilon^{2}\right)\left(\delta^{4}\left|x_{i}\right|^{2}+\delta^{4} \frac{\epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}\right) \\
& +\frac{8 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left(\delta^{4}\left|x_{j}\right|^{2}+\frac{\delta^{4} \epsilon^{2}}{d_{0}} \sum_{j^{\prime}=1}^{d_{0}}\left|x_{j}-x_{j^{\prime}}\right|^{2}+\delta^{2}\left|v_{j}\right|^{2}\right) \\
& \leqslant 4\left(1+2 \epsilon^{2}\right)\left(\delta^{4}\left|x_{i}\right|^{2}+\delta^{4} \frac{\epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}\right) \\
& +\frac{16 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left(\delta^{4}\left|x_{i}\right|^{2}+\left(1+2 \epsilon^{2}\right) \delta^{4}\left|x_{i}-x_{j}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}+\delta^{2}\left|v_{j}-v_{i}\right|^{2}\right) \\
& \leqslant 30\left(\delta^{4}\left|x_{i}\right|^{2}+\frac{\delta^{4} \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}+\frac{\epsilon^{2} \delta^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|v_{i}-v_{j}\right|^{2}\right) \tag{60}
\end{align*}
$$

where we used $20+40 \epsilon^{2} \leqslant 30$ in the last inequality, and the second inequality has been obtained by using

$$
\frac{1}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{j}\right|^{2} \leqslant 2\left|x_{i}\right|^{2}+\frac{2}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{j}-x_{i}\right|^{2}
$$

and a similar inequality for $v$, as well as the inequality $\left|x_{j}-x_{i}+x_{i}-x_{j^{\prime}}\right|^{2} \leqslant 2\left|x_{j}-x_{i}\right|^{2}+$ $2\left|x_{i}-x_{j^{\prime}}\right|^{2}$ to write

$$
\frac{1}{d_{0}^{2}} \sum_{j=1}^{d_{0}} \sum_{j^{\prime}=1}^{d_{0}}\left|x_{j}-x_{j^{\prime}}\right|^{2}=\frac{1}{d_{0}^{2}} \sum_{j=1}^{d_{0}} \sum_{j^{\prime}=1}^{d_{0}}\left|x_{j}-x_{i}+x_{i}-x_{j^{\prime}}\right|^{2} \leqslant \frac{4}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{j}-x_{i}\right|^{2}
$$

We can now turn to estimating the various terms in $\mathfrak{V}_{\tilde{\mathbf{o}}, i}(x, v)$. In view of (57),

$$
\begin{aligned}
\left|y_{i}\right|^{2}= & \left|x_{i}\right|^{2}+2\left\langle x_{i}, \delta v_{i}-\frac{\delta^{2}}{2} \psi_{i}(x)\right\rangle+\left|y_{i}-x_{i}\right|^{2} \\
\leqslant & \left|x_{i}\right|^{2}-\delta^{2}\left\langle x_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+\delta^{2} \epsilon\left|x_{i}\right|^{2}+\frac{\delta^{2} \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
& +2 \delta\left\langle x_{i}, v_{i}\right\rangle+2\left(\delta^{4}\left|x_{i}\right|^{2}+\frac{\delta^{4} \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}\right),
\end{aligned}
$$

where $\left\langle x_{i}, \nabla W^{(q)}\left(x_{i}-x_{j}\right)\right\rangle$ is bounded with a discrete Cauchy-Schwarz inequality and (50). Therefore, using first the drift condition (16) and the inequality $2 \delta^{2} \epsilon \leqslant 1$, and then $\max (\delta, \epsilon) \leqslant \mathrm{m} / 4 \leqslant 1 / 4$,

$$
\begin{align*}
\left|y_{i}\right|^{2} \leqslant & \left(1+\delta^{2} \epsilon+2 \delta^{4}\right)\left|x_{i}\right|^{2}+2 \delta\left\langle x_{i}, v_{i}\right\rangle+2 \delta^{2}\left|v_{i}\right|^{2} \\
& -\delta^{2}\left\langle x_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+\frac{\delta^{2} \epsilon\left(1+2 \delta^{2} \epsilon\right)}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
\leqslant & \left(1-\delta^{2} \mathrm{~m}+\delta^{2} \epsilon+2 \delta^{4}\right)\left|x_{i}\right|^{2}+2 \delta\left\langle x_{i}, v_{i}\right\rangle+2 \delta^{2}\left|v_{i}\right|^{2}+\delta^{2} \mathrm{M}+\frac{2 \delta^{2} \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
\leqslant & \left(1-\frac{\delta^{2} \mathrm{~m}}{2}\right)\left|x_{i}\right|^{2}+2 \delta\left\langle x_{i}, v_{i}\right\rangle+2 \delta^{2}\left|v_{i}\right|^{2}+\delta^{2} \mathrm{M}+\frac{2 \delta^{2} \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} . \tag{61}
\end{align*}
$$

Similarly, using a discrete Cauchy-Schwarz inequality to bound $\delta\left\langle v_{i}, \psi_{i}(x)-\psi_{i}(y)\right\rangle$,

$$
\begin{aligned}
\left|p_{i}\right|^{2}=\left|v_{i}\right|^{2}- & \delta\left\langle v_{i}, \psi_{i}(x)+\psi_{i}(y)\right\rangle+\frac{\delta^{2}}{4}\left|\psi_{i}(x)+\psi_{i}(y)\right|^{2} \\
\leqslant\left|v_{i}\right|^{2}- & 2 \delta\left\langle v_{i}, \psi_{i}(x)\right\rangle+\frac{\delta^{2}}{2}\left|v_{i}\right|^{2}+\frac{1}{2}\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} \\
& +\frac{\delta^{2}}{2}\left[4\left|\psi_{i}(x)\right|^{2}+\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2}\right] .
\end{aligned}
$$

Using

$$
2\left\langle v_{i}, \frac{1}{d_{0}} \sum_{j=1}^{d_{0}} \nabla W^{(q)}\left(x_{i}-x_{j}\right)\right\rangle \leqslant\left|v_{i}\right|^{2}+\frac{1}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2},
$$

as well as (59), it follows that

$$
\begin{align*}
&\left|p_{i}\right|^{2} \leqslant\left|v_{i}\right|^{2}- \\
& \quad 2 \delta\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+\left(\delta \epsilon+\frac{\delta^{2}}{2}\right)\left|v_{i}\right|^{2}+\frac{1+\delta^{2}}{2}\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} \\
&+4 \delta^{2}\left[\left|x_{i}\right|^{2}+\frac{\epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}\right]+\frac{\delta \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
& \leqslant\left(1+\delta \epsilon+\frac{\delta^{2}}{2}\right)\left|v_{i}\right|^{2}+4 \delta^{2}\left|x_{i}\right|^{2}-2 \delta\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+\frac{\delta \epsilon(1+4 \delta \epsilon)}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
& \quad+\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} \\
& \leqslant {\left[1+\delta \epsilon+\frac{\delta^{2}}{2}+30 \delta^{2}\right]\left|v_{i}\right|^{2}-2 \delta\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+4 \delta^{2}\left[1+8 \delta^{2}\right]\left|x_{i}\right|^{2} }  \tag{62}\\
&+\frac{\delta \epsilon\left(1+4 \delta \epsilon+30 \delta^{3} \epsilon\right)}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\frac{30 \epsilon^{2} \delta^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|v_{i}-v_{j}\right|^{2} \\
& \leqslant\left(1+\delta \epsilon+31 \delta^{2}\right)\left|v_{i}\right|^{2}-2 \delta\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle+8 \delta^{2}\left|x_{i}\right|^{2}  \tag{63}\\
&+\frac{2 \delta \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\frac{30 \epsilon^{2} \delta^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|v_{i}-v_{j}\right|^{2},
\end{align*}
$$

where we used (60) to obtain the third inequality and that $\delta \leqslant 1 / 40$ and $\epsilon \leqslant 1 / 4$ to simplify the bounds in the last inequality. Next,

$$
\begin{aligned}
\left\langle y_{i}, p_{i}\right\rangle= & \left\langle x_{i}+\delta v_{i}-\frac{\delta^{2}}{2} \psi_{i}(x), v_{i}-\frac{\delta}{2}\left(\psi_{i}(x)+\psi_{i}(y)\right)\right\rangle \\
= & \left\langle x_{i}, v_{i}\right\rangle-\frac{\delta}{2}\left\langle x_{i}, \psi_{i}(x)+\psi_{i}(y)\right\rangle+\delta\left|v_{i}\right|^{2}-\frac{\delta^{2}}{2}\left\langle v_{i}, \psi_{i}(x)\right\rangle \\
& -\frac{\delta^{2}}{2}\left\langle v_{i}, \psi_{i}(x)+\psi_{i}(y)\right\rangle+\frac{\delta^{3}}{4}\left\langle\psi_{i}(x), \psi_{i}(x)+\psi_{i}(y)\right\rangle \\
\leqslant & \left\langle x_{i}, v_{i}\right\rangle-\delta\left\langle x_{i}, \psi_{i}(x)\right\rangle+\frac{\delta}{2}\left|x_{i}\right|\left|\psi_{i}(x)-\psi_{i}(y)\right|+\delta\left|v_{i}\right|^{2}-\frac{3 \delta^{2}}{2}\left\langle v_{i}, \psi_{i}(x)\right\rangle \\
& +\frac{\delta^{2}}{2}\left|v_{i}\right|\left|\psi_{i}(x)-\psi_{i}(y)\right|+\frac{\delta^{3}}{2}\left|\psi_{i}(x)\right|^{2}+\frac{\delta^{3}}{4}\left|\psi_{i}(x)\right|\left|\psi_{i}(x)-\psi_{i}(y)\right| \\
\leqslant & \left\langle x_{i}, v_{i}\right\rangle-\delta\left\langle x_{i}, \psi_{i}(x)\right\rangle+\frac{1}{4}\left(\delta^{2}\left|x_{i}\right|^{2}+\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2}\right)-\frac{3 \delta^{2}}{2}\left\langle v_{i}, \psi_{i}(x)\right\rangle \\
& +\delta\left(1+\frac{\delta}{4}\right)\left|v_{i}\right|^{2}+\frac{5 \delta^{3}}{8}\left|\psi_{i}(x)\right|^{2}+\frac{\delta^{2}(2+\delta)}{8}\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} .
\end{aligned}
$$

Let us emphasize that the term $-\delta\left\langle x_{i}, \psi_{i}(x)\right\rangle$ is crucial to obtained a dissipation of order $\delta$ in the position variables. This motivates the inclusion of a cross term $\left\langle x_{i}, v_{i}\right\rangle$ in the

Lyapunov function. We next use (50), (59) and (60) and the drift condition (16) to write

$$
\begin{align*}
\left\langle y_{i}, p_{i}\right\rangle \leqslant & \left\langle x_{i}, v_{i}\right\rangle-\delta\left\langle x_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle-\frac{3 \delta^{2}}{2}\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle \\
& +\delta\left(\left|x_{i}\right|+\frac{3 \delta}{2}\left|v_{i}\right|\right) \frac{\epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|\nabla W^{(q)}\left(x_{i}-x_{j}\right)\right|+\delta\left(1+\frac{\delta}{4}\right)\left|v_{i}\right|^{2} \\
& +\frac{\delta^{2}}{4}\left|x_{i}\right|^{2}+\frac{7 \delta^{3}}{8}\left|\psi_{i}(x)\right|^{2}+\frac{2+\delta^{2}(2+\delta)}{8}\left|\psi_{i}(x)-\psi_{i}(y)\right|^{2} \\
\leqslant & \left\langle x_{i}, v_{i}\right\rangle-\delta \mathrm{m}\left|x_{i}\right|^{2}+\delta \mathrm{M}+\frac{3 \delta^{2}}{4}\left(\left|v_{i}\right|^{2}+\left|\nabla U^{(q)}\left(x_{i}\right)\right|^{2}\right)+\delta\left(1+\frac{\delta}{4}\right)\left|v_{i}\right|^{2} \\
& +\delta \epsilon\left(\frac{1}{2}\left|x_{i}\right|^{2}+\frac{9 \delta^{2}}{8}\left|v_{i}\right|^{2}+\frac{1}{d_{0}} \sum_{j=1}^{d_{0}}\left|\nabla W^{(q)}\left(x_{i}-x_{j}\right)\right|^{2}\right)+\frac{\delta^{2}}{4}\left|x_{i}\right|^{2} \\
& +\frac{7 \delta^{3}}{4}\left(\left|x_{i}\right|^{2}+\frac{\epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}\right) \\
& +\frac{30 \delta^{2}\left[2+\delta^{2}(2+\delta)\right]}{8}\left(\delta^{2}\left|x_{i}\right|^{2}+\frac{\delta^{2} \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}\right|^{2}+\frac{\epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|v_{i}-v_{j}\right|^{2}\right) \\
\leqslant & \left\langle x_{i}, v_{i}\right\rangle-\frac{\delta \mathrm{m}}{2}\left|x_{i}\right|^{2}+\delta \mathrm{M}+\delta(1+10 \delta)\left|v_{i}\right|^{2} \\
& +\frac{2 \delta \epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\frac{8 \delta^{2} \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|v_{i}-v_{j}\right|^{2}, \tag{64}
\end{align*}
$$

where we used in the last inequality that $\epsilon \leqslant \mathrm{m} / 4$ and $\delta \leqslant \mathrm{m} / 40 \leqslant 1 / 40$.
Using first a Taylor expansion and (recalling (50) and (59))

$$
\left\langle\nabla U^{(q)}\left(x_{i}\right), \psi_{i}(x)\right\rangle \leqslant \frac{1}{2}\left(\left|\nabla U^{(q)}\left(x_{i}\right)\right|^{2}+\left|\psi_{i}(x)\right|\right) \leqslant \frac{1}{2}\left(3\left|x_{i}\right|^{2}+\frac{2 \epsilon^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|\right)
$$

then (57) and (48), it follows

$$
\begin{aligned}
U^{(q)}\left(y_{i}\right) \leqslant & U^{(q)}\left(x_{i}\right)+\left\langle\nabla U^{(q)}\left(x_{i}\right), y_{i}-x_{i}\right\rangle+\frac{1}{2}\left|y_{i}-x_{i}\right|^{2} \\
\leqslant & U^{(q)}\left(x_{i}\right)+\left\langle\nabla U^{(q)}\left(x_{i}\right), \delta v_{i}-\frac{\delta^{2}}{2} \psi_{i}(x)\right\rangle+\frac{1}{2}\left|y_{i}-x_{i}\right|^{2} \\
\leqslant & U^{(q)}\left(x_{i}\right)-\frac{\delta^{2}}{2}\left|\nabla U^{(q)}\left(x_{i}\right)\right|^{2}+\delta\left\langle\nabla U^{(q)}\left(x_{i}\right), v_{i}\right\rangle \\
& \quad+\frac{\delta^{2} \epsilon}{2}\left(2\left|x_{i}\right|^{2}+\frac{2}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}\right)+\frac{1}{2}\left|y_{i}-x_{i}\right|^{2}
\end{aligned}
$$

$$
\begin{align*}
& \leqslant \\
& \leqslant U^{(q)}\left(x_{i}\right)-\frac{\delta^{2} \mathrm{~m}^{2}}{2}\left|x_{i}\right|^{2}+\delta^{2} \mathrm{mM}+\delta\left\langle\nabla U^{(q)}\left(x_{i}\right), v_{i}\right\rangle \\
& \quad+\delta^{2}\left(\epsilon+\delta^{2}\right)\left|x_{i}\right|^{2}+\delta^{2}\left|v_{i}\right|^{2}+\frac{\epsilon \delta^{2}\left(1+\delta^{2} \epsilon\right)}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} \\
& \leqslant
\end{aligned} \begin{aligned}
& U^{(q)}\left(x_{i}\right)-\frac{\delta^{2} \mathrm{~m}^{2}}{4}\left|x_{i}\right|^{2}+\delta^{2} \mathrm{mM}+\delta\left\langle\nabla U^{(q)}\left(x_{i}\right), v_{i}\right\rangle+\delta^{2}\left|v_{i}\right|^{2}  \tag{65}\\
& \quad+\frac{2 \epsilon \delta^{2}}{d_{0}} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2} .
\end{align*}
$$

,Using first $|\mathbf{a}+\mathbf{b}|^{2} \leqslant(1+\delta)|\mathbf{a}|^{2}+\left(1+\delta^{-1}\right)|\mathbf{b}|^{2}$, then (56) as well as $\delta \leqslant \mathrm{m} / 40 \leqslant 1 / 40$ and $\epsilon \leqslant \mathrm{m} / 4 \leqslant 1 / 4$, we obtain

$$
\begin{align*}
\left|y_{i}-y_{j}\right|^{2} & =\left|x_{i}-x_{j}-\frac{\delta^{2}}{2}\left(\psi_{i}(x)-\psi_{j}(x)\right)+\delta\left(v_{i}-v_{j}\right)\right|^{2} \\
& \leqslant(1+\delta)\left|x_{j}-x_{j}\right|^{2}+\delta^{2}\left(1+\delta^{-1}\right)\left|v_{i}-v_{j}-\frac{\delta}{2}\left(\psi_{i}(x)-\psi_{j}(x)\right)\right|^{2} \\
& \leqslant(1+\delta)\left|x_{i}-x_{j}\right|^{2}+2 \delta(1+\delta)\left|v_{i}-v_{j}\right|^{2}+\frac{\delta^{3}(1+\delta)}{2}\left|\psi_{i}(x)-\psi_{j}(x)\right|^{2} \\
& \leqslant\left[1+\delta+\delta^{3}(1+\delta)\left(1+\epsilon^{2}\right)\right]\left|x_{i}-x_{j}\right|^{2}+2 \delta(1+\delta)\left|v_{i}-v_{j}\right|^{2} \\
& \leqslant(1+2 \delta)\left|x_{i}-x_{j}\right|^{2}+4 \delta\left|v_{i}-v_{j}\right|^{2} . \tag{66}
\end{align*}
$$

Finally, using twice (56),

$$
\begin{aligned}
\left|p_{i}-p_{j}\right|^{2} \leqslant & (1+\delta)\left|v_{i}-v_{j}\right|^{2}+\frac{\delta^{2}\left(1+\delta^{-1}\right)}{4}\left|\psi_{i}(y)+\psi_{i}(x)-\psi_{j}(y)-\psi_{j}(x)\right|^{2} \\
\leqslant & (1+\delta)\left|v_{i}-v_{j}\right|^{2}+\frac{\delta(1+\delta)}{2}\left(\left|\psi_{i}(x)-\psi_{j}(x)\right|^{2}+\left|\psi_{i}(y)-\psi_{j}(y)\right|^{2}\right) \\
\leqslant & (1+\delta)\left|v_{i}-v_{j}\right|^{2}+\delta(1+\delta)\left(1+\epsilon^{2}\right)\left(\left|x_{i}-x_{j}\right|^{2}+\left|y_{i}-y_{j}\right|^{2}\right) \\
\leqslant & \delta(1+\delta)\left(1+\epsilon^{2}\right)\left(4\left|x_{i}-x_{j}\right|^{2}+3 \delta^{2}\left|v_{i}-v_{j}\right|^{2}+\frac{3 \delta^{4}}{4}\left|\psi_{i}(x)-\psi_{j}(x)\right|^{2}\right) \\
& \quad+(1+\delta)\left|v_{i}-v_{j}\right|^{2} \\
\leqslant & \delta(1+\delta)\left(1+\epsilon^{2}\right)\left(4+\frac{3 \delta^{2}}{2}\left(1+\epsilon^{2}\right)\right)\left|x_{i}-x_{j}\right|^{2}+(1+2 \delta)\left|v_{i}-v_{j}\right|^{2} \\
\leqslant & 5 \delta\left|x_{i}-x_{j}\right|^{2}+(1+2 \delta)\left|v_{i}-v_{j}\right|^{2} .
\end{aligned}
$$

Combining this last inequality with (61)-(63)-(64)-(65)-(66) in (55), and (recalling $b \geqslant b_{0}$ )

$$
-2 \delta\left(b-b_{0}\right)\left\langle v_{i}, \nabla U^{(q)}\left(x_{i}\right)\right\rangle \leqslant \delta\left(b-b_{0}\right)\left(\left|v_{i}\right|^{2}+\left|x_{i}\right|^{2}\right),
$$

completes the proof.

Quantifying how prefactors change over several steps. In view of Lemma 19, controlling the evolution of the Lyapunov function along several Verlet steps amounts to a discrete Grönwall-type result for the sequence of parameters defined recursively by the relation $\mathbf{0} \mapsto \tilde{\mathbf{o}}$ of Lemma 19. Notice that, among these parameters, $b_{0}$ is fixed and $f$ does not influence the other parameters, so that we focus first on the relations intertwining the parameters $a, b, c, e$. We state an abstract result, independent from the specific constants appearing in Lemma 19, except that it is crucial to keep track of the order of the various parts in terms of the step size $\delta$. More specifically, Lemma 19 reads $\tilde{\mathbf{o}}=\left(I+\delta A+\delta^{2} B\right) \mathbf{o}$ for some matrices $A, B$ and thus, iterating this $k$ times, as long as $k \delta$ is small enough, it is sufficient to keep the lowest order terms in $k \delta$ and $\delta$ in $\left(I+\delta A+\delta^{2} B\right)^{k}$. This is essentially the content of the next lemma.

Lemma 20. Consider the four real sequences $\left(a_{k}\right)_{k \in \mathbb{N}},\left(b_{k}\right)_{k \in \mathbb{N}},\left(c_{k}\right)_{k \in \mathbb{N}},\left(e_{k}\right)_{k \in \mathbb{N}}$ such as $a_{0}, b_{0}, c_{0}, e_{0}>0$ and defined by

$$
\begin{aligned}
a_{k+1} & =\left(1-\delta^{2} C_{a, 1}\right) a_{k}-\delta c_{k} C_{a, 2}+\delta^{2} b_{k} C_{a, 3}+\delta e_{k} C_{a, 4}+C_{a, 5} \delta\left(b_{k}-b_{0}\right) \\
b_{k+1} & =\left(1+C_{b, 1} \delta+C_{b, 2} \delta^{2}\right) b_{k}+\delta^{2} C_{b, 3} a_{k}+\delta c_{k} C_{b, 4}+\delta e_{k} C_{b, 5}+\delta\left(b_{k}-b_{0}\right) \\
c_{k+1} & =c_{k}+C_{c, 1} \delta a_{k}, \quad e_{k+1}=e_{k}+C_{e, 1} \delta\left(a_{k} \delta+b_{k}+c_{k}+e_{k}\right)
\end{aligned}
$$

for some non-negative real constants $\left\{C_{\square, \triangle}: \square \in\{a, b, c, e\}, \triangle \in\{1,2,3,4,5\}\right\}$ and $\delta>0$. Then, for any $\delta>0$ and $k \in \mathbb{N}$ satisfying

$$
\begin{equation*}
\delta \leqslant \tilde{\delta}_{1} \wedge \tilde{\delta}, \quad k \delta \leqslant \tilde{T}_{1} \wedge \tilde{T}_{2} \wedge \tilde{T} \tag{67}
\end{equation*}
$$

for $\tilde{T}, \tilde{\delta}>0$, with
$\tilde{\delta}_{1}=\left[C_{b, 2}\right]^{-1} \wedge\left[a_{0} C_{a, 2} C_{c, 1} /\left\{8\left(\tilde{C}_{e, 1} C_{a, 4}+\tilde{C}_{b, 3}\left(\tilde{\delta} C_{a, 3}+C_{a, 5}\right)\right)\right\}\right] \wedge\left[4 C_{a, 1}\right]^{-1} \wedge\left[4 C_{c, 1} C_{a, 2} \tilde{C}_{a, 3}\right]^{-1}$

& a_{k} \geqslant a_{0}\left(1-k \delta\left(C_{a, 2} c_{0} / a_{0}+\delta C_{a, 1}\right)-(k \delta)^{2} C_{a, 2} C_{c, 1}\left(1+\delta \tilde{T} \tilde{C}_{a, 3}\right)\right) \\
& c_{k} \geqslant c_{0}+C_{c, 1} k \delta a_{0}-(k \delta)^{2} C_{c, 1}\left(C_{a, 2} c_{0}+\delta C_{a, 1} a_{0}\right)-(k \delta)^{3} C_{c, 1}^{2} C_{a, 2} a_{0}\left(1+\delta \tilde{T} \tilde{C}_{a, 3}\right) \tag{69}
\end{align*}
$$

where

$$
\begin{aligned}
\tilde{C}_{a, 1} & =c_{0} C_{a, 2} /\left(2 a_{0}\right), \quad \tilde{C}_{a, 2}=a_{0}\left[C_{a, 1} \wedge C_{a, 2} C_{c, 1} / 16\right] \\
\tilde{C}_{a, 3} & =2 b_{0} C_{a, 3}+a_{0} C_{a, 1} \tilde{T}\left(\tilde{C}_{a, 1}+\tilde{T} \tilde{C}_{a, 2}\right), \\
\tilde{C}_{b, 1} & =C_{b, 1}+c_{0} C_{b, 4} / b_{0}+e_{0} C_{b, 5} / b_{0}, \\
\tilde{C}_{b, 2} & \left.=4\left[C_{b, 1} \tilde{C}_{b, 1}+\tilde{C}_{b, 1}+C_{b, 4}\left(C_{c, 1} a_{0}+\tilde{C}_{e, 1} C_{b, 5}\right)\right) / b_{0}\right], \\
\tilde{C}_{b, 3} & =3\left\{b_{0} C_{b, 2}+a_{0} C_{b, 3}+\tilde{T}\left(C_{b, 3} \tilde{C}_{a, 3}+b_{0} C_{b, 2} \tilde{C}_{b, 1}+C_{b, 5} \tilde{C}_{e, 2}+\tilde{T} \tilde{C}_{a, 3} C_{c, 1} C_{b, 4}\right)\right\} \\
\tilde{C}_{e, 1} & =2 C_{e, 1}\left(2 b_{0}+c_{0}+\tilde{T}\left(C_{e, 1} e_{0}+C_{c, 1} a_{0}+\delta \tilde{C}_{b, 3}\right)\right) \\
\tilde{C}_{e, 2} & \left.=2 C_{e, 1}\left(a_{0}+\tilde{T} \delta \tilde{C}_{a, 3}+\tilde{T}^{2} C_{c, 1} \tilde{C}_{a, 3}\right)\right) .
\end{aligned}
$$

Proof. The proof is by induction. Equation (69) is trivially true for $k=0$. Suppose that it is true for $k \in \mathbb{N}$ and suppose $\delta, k+1$ satisfy (67). Then by definition, the induction hypothesis implies that $c_{0}+(k+1) \delta a_{0} C_{c, 1} / 2 \leqslant c_{k+1} \leqslant c_{0}+(k+1) \delta a_{0} C_{c, 1}+(k+1)^{2} \delta^{3} C_{c, 1} \tilde{C}_{a, 3}$.

Similarly, it follows that

$$
\begin{aligned}
& b_{k+1} \leqslant\left[\left(1+k \delta \tilde{C}_{b, 1}+(k \delta)^{2} \tilde{C}_{b, 2}\right) b_{0}+\tilde{C}_{b, 3} \delta^{2} k\right]\left(1+C_{b, 1} \delta+C_{b, 2} \delta^{2}\right) \\
& \quad+\delta^{2} C_{b, 3}\left(a_{0}+\tilde{C}_{a, 3} \delta^{2} k\right)+\delta C_{b, 4}\left(c_{0}+\delta k C_{c, 1} a_{0}+(\delta k)^{2} \delta C_{c, 1} \tilde{C}_{a, 3}\right) \\
& \quad+\delta C_{b, 5}\left(2 e_{0}+\delta k \tilde{C}_{e, 1}+\delta^{2} k \tilde{C}_{e, 2}\right) \\
& \leqslant \\
& \leqslant b_{0}+\delta b_{0}\left(k \tilde{C}_{b, 1}+C_{b, 1}+c_{0} C_{b, 4} / b_{0}+2 C_{b, 5} e_{0} / b_{0}\right) \\
& \quad+\delta^{2} k b_{0}\left\{\tilde{C}_{b, 2} k+k \delta \tilde{C}_{b, 2} C_{b, 1}+C_{b, 1} \tilde{C}_{b, 1}+\tilde{C}_{b, 1}\right. \\
& \left.\quad \quad+\left(C_{b, 4} / b_{0}\right)\left(C_{c, 1} a_{0}+\tilde{C}_{e, 1} C_{b, 5}\right)+k \delta\left(\delta \tilde{C}_{b, 2} C_{b, 2}+\tilde{C}_{b, 2}\right)\right\} \\
& \quad+\delta^{2}\left(k \tilde{C}_{b, 3}+\tilde{C}_{b, 3}\left(k \delta C_{b, 1}+k \delta^{2} C_{b, 2}\right)+b_{0} C_{b, 2}+a_{0} C_{b, 3}\right. \\
& \left.\quad+\tilde{T}^{2} \tilde{C}_{a, 3} C_{c, 1} C_{b, 4}+\tilde{T} C_{b, 3} \tilde{C}_{a, 3}+\tilde{T} b_{0} C_{b, 2} \tilde{C}_{b, 1}+\tilde{T} C_{b, 5} \tilde{C}_{e, 2}\right) \\
& \leqslant \\
& \leqslant b_{0}\left(1+(k+1) \delta \tilde{C}_{b, 1}+k(k+2) \delta^{2} \tilde{C}_{b, 2}\right)+\tilde{C}_{b, 3}(k+1) \delta^{2}
\end{aligned}
$$

where we have used that $k \delta \leqslant 4^{-1}\left[C_{b, 1}^{-1} \wedge 1\right], \delta \leqslant C_{b, 2}^{-1}, \tilde{C}_{b, 1} \geqslant C_{b, 1}$ and $\tilde{C}_{b, 2} \geqslant C_{b, 2}$ by definition. In addition, $b_{0} \leqslant b_{k+1} \leqslant 2 b_{0}+\delta^{2} k \tilde{C}_{b, 3}$ since $\delta, k+1$ satisfy (67).

Similarly, using that $k \delta \leqslant\left(4 C_{e, 1}\right)^{-1}$, we have

$$
\begin{aligned}
& e_{k+1} \leqslant\left[\left(1+k \delta C_{e, 1}\right) e_{0}+\delta k \tilde{C}_{e, 1}+\delta^{2} k \tilde{C}_{e, 2}\right]\left(1+C_{e, 1} \delta\right) \\
& \quad+C_{e, 1} \delta^{2}\left(a_{0}+\tilde{C}_{a, 3} k \delta^{2}\right)+C_{e, 1} \delta\left(2 b_{0}+\delta^{2} k \tilde{C}_{b, 3}\right)+C_{e, 1} \delta\left(c_{0}+k \delta C_{c, 1} a_{0}+(k \delta)^{2} \delta C_{c, 1} \tilde{C}_{a, 3}\right) \\
& \leqslant \\
& \quad\left(1+(k+1) \delta C_{e, 1}\right) e_{0}+\delta\left(k \tilde{C}_{e, 1}+C_{e, 1}\left(2 b_{0}+c_{0}+\tilde{T} C_{e, 1} e_{0}+\tilde{T} \tilde{C}_{e, 1}+\tilde{T} C_{c, 1} a_{0}+\delta \tilde{T} \tilde{C}_{b, 3}\right)\right) \\
& \quad+\delta^{2}\left(k \tilde{C}_{e, 2}+C_{e, 1}\left(k \delta \tilde{C}_{e, 2}+a_{0}+k \delta^{2} \tilde{C}_{a, 3}+(k \delta)^{2} C_{c, 1} \tilde{C}_{a, 3}\right)\right),
\end{aligned}
$$

which concludes the proof of the upper bound for $e_{k+1}$ using $k \delta \leqslant 1 /\left(4 C_{e, 1}\right)$.
Using the induction hypothesis, in particular the lower bounds on $c_{k}$ and the definition of $\tilde{C}_{b, 1}$, we get

$$
a_{k+1} \leqslant a_{0}-\delta\left(a_{0} k \tilde{C}_{a, 1}+C_{a, 2} c_{0}-2 C_{a, 4} e_{0}\right)-\delta^{2} a_{0} C_{a, 1}
$$

$$
\begin{aligned}
& +\delta^{2}\left(k \tilde{C}_{a, 3}+2 b_{0} C_{a, 3}+a_{0} C_{a, 1} \tilde{T}\left(\tilde{C}_{a, 1}+\tilde{T} \tilde{C}_{a, 2}\right)\right) \\
& -\delta^{2} k\left[k \tilde{C}_{a, 2} a_{0}+a_{0} C_{c, 1} C_{a, 2} / 2-C_{a, 5} \tilde{C}_{b, 1} b_{0}-\tilde{C}_{e, 1} C_{a, 4}\right. \\
& \left.\quad-\delta k C_{a, 5} \tilde{C}_{b, 2} b_{0}-\delta^{2} C_{a, 3} \tilde{C}_{b, 3}-\delta C_{a, 4} \tilde{C}_{e, 1}-\delta C_{a, 5} \tilde{C}_{b, 3}\right] \\
\leqslant a_{0}- & \delta\left(a_{0} k \tilde{C}_{a, 1}+C_{a, 2} c_{0}-2 C_{a, 4} e_{0}-c_{0} C_{b, 4} C_{a, 5} \delta k\right)-\delta^{2} a_{0} C_{a, 1} \\
+ & \delta^{2}\left(k \tilde{C}_{a, 3}+2 b_{0} C_{a, 3}+a_{0} C_{a, 1} \tilde{T}\left(\tilde{C}_{a, 1}+\tilde{T} \tilde{C}_{a, 2}\right)\right) \\
- & \delta^{2} k\left[k \left[k \tilde{C}_{a, 2} a_{0}+a_{0} C_{c, 1} C_{a, 2} / 2-C_{a, 5}\left(C_{b, 1} b_{0}+C_{b, 5} e_{0}\right)-\tilde{C}_{e, 1} C_{a, 4}\right.\right. \\
& \left.\quad-\delta k C_{a, 5} \tilde{C}_{b, 2} b_{0}-\delta^{2} C_{a, 3} \tilde{C}_{b, 3}-\delta C_{a, 4} \tilde{C}_{e, 1}-\delta C_{a, 5} \tilde{C}_{b, 3}\right] .
\end{aligned}
$$

Using the condition (68), $\delta, k+1$ satisfy (67), we get that $a_{k+1} \leqslant a_{0}-a_{0}(k+1) \delta \tilde{C}_{a, 1}-$ $a_{0}(k+2) k \delta^{2} \tilde{C}_{a, 2}-a_{0} C_{a, 1} \delta^{2}+\delta^{2} k \tilde{C}_{a, 3} \leqslant a_{0}-a_{0}(k+1) \delta \tilde{C}_{a, 1}-a_{0}(k+1)^{2} \delta^{2} \tilde{C}_{a, 2}+\tilde{C}_{a, 3} \delta^{2}(k+1)$. The lower bound for $a_{k+1}$ proceeds similarly using the upper bound on $c_{k}$ given by the induction hypothesis. Finally, the conditions $(k+1) \delta \leqslant 8^{-1}\left\{\left[a_{0}\left(C_{a, 2} c_{0}\right)^{-1}\right] \wedge\left[C_{c, 1} C_{a, 2}\right]^{-1 / 2}\right\}$, $\delta \leqslant\left[4 C_{a, 1}\right]^{-1} \wedge\left[4 C_{c, 1} C_{a, 2} \tilde{C}_{a, 3}\right]^{-1}$ and $(k+1) \delta \leqslant 1 / 2$ imply that $a_{0} / 2 \leqslant a_{k+1} \leqslant a_{0}+\delta^{2} k \tilde{C}_{a, 3}$. The last inequality for $c_{k+1}$ in (69) uses the induction hypothesis $a_{k} \geqslant a_{0}\left(1-k \delta\left(C_{a, 2} c_{0} / a_{0}+\right.\right.$ $\left.\left.\delta C_{a, 1}\right)-(k \delta)^{2} C_{a, 2} C_{c, 1}\left(1+\delta \tilde{T} \tilde{C}_{a, 3}\right)\right)$ and $c_{k+1}=c_{k}+C_{c, 1} \delta a_{k}$.

Evolution over several Verlet steps. Combining Lemmas 19 and 20 leads to the following, which gives a control of the expected value of the Lyapunov function after a full trajectory of Verlet integrator.

Lemma 21. Assume that $\boldsymbol{H}_{4}$ holds. Let $\mathbf{o}=\left(a_{0}, b_{0}, c_{0}, 2 b_{0}, e_{0}, f_{0}\right) \in \mathbb{R}_{+}^{6}, \bar{T}, \bar{\delta}>0$ and denote

$$
\begin{aligned}
\bar{C}_{a, 1} & =\mathrm{m} /(3 \times 4), \quad \bar{C}_{a, 2}=\mathrm{m} /\left(3 \times 2^{3}\right), \bar{C}_{a, 3}=16 b_{0}+a_{0} \bar{T}(\mathrm{~m} / 2)^{2}(1+\bar{T}) \\
\bar{C}_{b, 1} & =\epsilon+\left(c_{0} / b_{0}\right)(1+10 \bar{\delta}), \quad \bar{C}_{b, 2,0}=4\left[(1+\epsilon) \bar{C}_{b, 1}+(1+10 \bar{\delta})\left(2 a_{0} / b_{0}\right)\right] \\
\bar{C}_{b, 3,0} & =3\left\{31 b_{0}+2 a_{0}+\bar{T}\left(2 \bar{C}_{a, 3}+31 b_{0} \bar{C}_{b, 1}+2 \bar{C}_{a, 3} \bar{T}(1+10 \bar{\delta})\right)\right\}, \\
\bar{C}_{b, 2} & =\bar{C}_{b, 2,0}+c_{0} \mathrm{~m}+a_{0} \mathrm{~m} \bar{T}, \quad \bar{C}_{b, 3}=\bar{C}_{b, 3,0}+\bar{C}_{a, 3}, \\
\bar{C}_{e, 1} & =14\left[2 b_{0}+c_{0}+\bar{T}\left(14 e_{0}+2 a_{0}+\bar{\delta} \bar{C}_{b, 3}\right)\right], \quad \bar{C}_{e, 2}=14\left(a_{0}+\bar{T} \bar{C}_{a, 3}(\bar{\delta}+2 \bar{T})\right), \\
\bar{C}_{f, 1} & =a_{0} \mathrm{M} \bar{\delta}+\bar{C}_{a, 3} \mathrm{M} \bar{\delta} \bar{T}+4 b_{0} \mathrm{mM} \bar{\delta}+\mathrm{M}\left(c_{0}+\bar{C}_{b, 3,0} \bar{T}^{2} \bar{\delta}+2 \bar{T} a_{0}+2 \bar{C}_{a, 3} \bar{T}^{2} \bar{\delta}\right) .
\end{aligned}
$$

Let $\epsilon \leqslant \mathrm{m} / 4$ and suppose that

$$
\begin{equation*}
\epsilon b_{0} \leqslant a_{0} \mathrm{~m} / 2^{3} \tag{70}
\end{equation*}
$$

Then, for any $\delta>0, \eta \in[0,1)$, and $K \in \mathbb{N}$ satisfying $\delta \leqslant \bar{\delta}_{1} \wedge \bar{\delta}$ and $K \delta \leqslant \bar{T}_{1} \wedge \bar{T}_{2} \wedge \bar{T}$, and

$$
\begin{equation*}
\delta \eta \bar{C}_{a, 3} \leqslant \frac{c_{0} \mathrm{~m}}{3 \times 2^{2}}, \quad 2 \delta \frac{(1-\eta)}{\delta K} \bar{C}_{a, 3} \leqslant \frac{a_{0} \mathrm{~m}}{3 \times 2^{3}}, \tag{71}
\end{equation*}
$$

where

$$
\begin{align*}
& \bar{\delta}_{1}=31^{-1} \wedge[\mathrm{~m} / 40] \wedge\left[a_{0} 2^{-3} /\left(\bar{C}_{b, 3}(1+8 \bar{\delta})\right)\right] \wedge[1 /(2 \mathrm{~m})] \wedge\left[1 /\left(8 \mathrm{~m} \bar{C}_{a, 3}\right)\right] \\
& \bar{T}_{1}=4^{-1}\left[31^{-1} \wedge \bar{C}_{b, 1}^{-1} \wedge \bar{C}_{b, 2}^{-1 / 2}\right]  \tag{72}\\
& \bar{T}_{2}=4^{-1}\left\{\left[2^{-3} \mathrm{~m} /(1+10 \bar{\delta})\right] \wedge\left[8^{-1} a_{0} /\left(\bar{C}_{b, 2} b_{0}\right)\right] \wedge a_{0} \mathrm{~m}\left(2 c_{0}\right)^{-1} \wedge 1 /(7 \mathrm{~m})^{1 / 2}\right\} .
\end{align*}
$$

it holds
(a) For any $i \in\left\{1, \ldots, d_{0}\right\}, x, v \in \mathbb{R}^{d}$, $\mathrm{V}_{\delta}^{K} \mathfrak{V}_{\mathbf{o}, i}(x, v) \leqslant \mathfrak{V}_{\mathbf{o}_{K}, i}(x, v)$, where $\mathbf{o}_{K}=$ $\left(a_{K}, b_{K}, c_{K}, 2 b_{0}, e_{K}, f_{K}\right)$

$$
\begin{aligned}
a_{K} & =a_{0}-K \delta \bar{C}_{a, 1} c_{0}-(K \delta)^{2} \bar{C}_{a, 2} a_{0}, \quad b_{K}=b_{0}\left(1+K \delta \bar{C}_{b, 1}+(K \delta)^{2} \bar{C}_{b, 2}\right)+\delta^{2} K \bar{C}_{b, 3}, \\
c_{K} & =c_{0}+2 K \delta a_{0}, \quad e_{K}=e_{0}(1+17 K \delta)+\bar{C}_{e, 1} K \delta+\bar{C}_{e, 2} K \delta^{2} \\

\end{aligned}
$$

(b) In addition for any $k \in\{0, \ldots, K\}, i \in\left\{1, \ldots, d_{0}\right\}, x, v \in \mathbb{R}^{d}, \mathrm{~V}_{\delta}^{k} \mathfrak{V}_{\mathbf{o}, i}(x, v) \leqslant$ $\mathfrak{V}_{\mathbf{o}_{k}, i}(x, v)$, where $\mathbf{o}_{k}=\left(a_{k}, b_{k}, c_{k}, 2 b_{0}, e_{k}, f_{k}\right)$

$$
\begin{aligned}
& a_{k}=a_{0}+2 \bar{C}_{a, 3} \delta^{2} k, \quad b_{k}=2 b_{0}+\delta^{2} k \bar{C}_{b, 3} \\
& c_{k}=c_{0}+2 k \delta a_{0}, \quad e_{k}=2 e_{0}+\bar{C}_{e, 1} k \delta+\bar{C}_{e, 2} k \delta^{2}, \quad f_{k}=f_{0}+k \delta \bar{C}_{f, 1} .
\end{aligned}
$$

Proof. (a) Let $i \in\left\{1, \ldots, d_{0}\right\}, \delta \leqslant \bar{\delta}_{1}, K \in \mathbb{N}, K \delta \leqslant \bar{T} \wedge \bar{T}_{1} \wedge \bar{T}_{2}$ and $x, v \in$ $\mathbb{R}^{d}$. Let $\left(a_{0}, b_{0}, c_{0}, e_{0}, f_{0}\right) \in \mathbb{R}_{+}^{6}$. By Lemma 19 , we have starting from $\tilde{\mathbf{o}}_{0}=\mathbf{o}_{0}=$ $\left(a_{0}, b_{0}, c_{0}, 2 b_{0}, e_{0}, f_{0}\right)$, for any $k \in \mathbb{N}$,

$$
\mathrm{V}_{\delta}^{k+1} \mathfrak{V}_{\tilde{\mathbf{o}}_{0}, i}(x, v) \leqslant \mathrm{V}_{\delta} \mathfrak{V}_{\tilde{\boldsymbol{o}}_{k}, i}(x, v) \leqslant \mathfrak{V}_{\tilde{\mathbf{o}}_{k+1}, i}(x, v),
$$

where $\tilde{\mathbf{o}}_{k+1}=\left(\tilde{a}_{k+1}, \tilde{b}_{k+1}, \tilde{c}_{k+1}, b_{0}, \tilde{e}_{k+1}, \tilde{f}_{k+1}\right)$ are defined by the recursion

$$
\begin{aligned}
\tilde{a}_{k+1} & =\tilde{a}_{k}\left(1-\mathrm{m} \delta^{2} / 2\right)+8 \tilde{b}_{k} \delta^{2}-\delta \mathrm{m} \tilde{c}_{k} / 2+\delta\left|\tilde{b}_{k}-b_{0}\right| \\
\tilde{b}_{k+1} & =2 \delta^{2} \tilde{a}_{k}+\left(1+\epsilon \delta+31 \delta^{2}\right) \tilde{b}_{k}+\delta(1+10 \delta) \tilde{c}_{k}+\delta\left|\tilde{b}_{k}-b_{0}\right| \\
\tilde{c}_{k+1} & =2 \delta \tilde{a}_{k}+\tilde{c}_{k}, \quad \tilde{e}_{k+1}=\tilde{e}_{k}+7 \delta\left(\tilde{a}_{k} \delta+\delta b_{0}+\tilde{b}_{k}+\tilde{c}_{k}+\tilde{e}_{k}\right) \\
\tilde{f}_{k+1} & =\tilde{f}_{k}+\tilde{a}_{k} \delta^{2} \mathrm{M}+2 \tilde{b}_{k} \mathrm{mM} \delta^{2}+\delta \mathrm{M} \tilde{c}_{k} .
\end{aligned}
$$

Applying Lemma 20, we get that for any $k \in\{0, \ldots, K\}$,

$$
\begin{aligned}
\tilde{a}_{k} & \leqslant a_{0}\left(1-\mathrm{m} k \delta c_{0} /\left(4 a_{0}\right)-\mathrm{m}(k \delta)^{2} / 2^{3}\right)+\left(16 b_{0}+a_{0}(\mathrm{~m} / 2)^{2} \bar{T}(1+\bar{T})\right) \delta^{2} k \\
\tilde{b}_{k} & \leqslant b_{0}\left(1+k \delta \bar{C}_{b, 1}+(k \delta)^{2} \bar{C}_{b, 2,0}\right)+\bar{C}_{b, 3,0} k \delta^{2} \\
\left|\tilde{c}_{k}-c_{0}-2 k \delta a_{0}\right| & \leqslant(k \delta)^{2} c_{0} \mathrm{~m}+a_{0} \mathrm{~m}(k \delta)^{3}+2 \bar{C}_{a, 3} \delta^{2} k \\
\tilde{e}_{k} & \leqslant e_{0}(1+7 k \delta)+k \delta \bar{C}_{e, 1}+k \delta^{2} \bar{C}_{e, 2}, \quad \tilde{f}_{k} \leqslant f_{0}+\delta k \bar{C}_{f, 1}
\end{aligned}
$$

Using that $\left|\left[c_{k}-c_{0}-2 \delta k a_{0}\right]\langle v, x\rangle\right| \leqslant 2^{-1}\left|c_{k}-c_{0}-2 \delta k a_{0}\right|\left[|x|^{2}+|v|^{2}\right],(71)$ and $K \delta \leqslant$ $3 \times 2^{-3}$ completes the proof.
(b) The proof of the second statement follows the same lines and is omitted.

Introducing momentum updates. In the next lemma, we state pointwise estimates that control the effect on the Lyapunov function of a momentum update for a given realization $g$ of a Gaussian variable. After raising these estimates to some powers, the expectation with respect to the Gaussian distribution will be taken afterwards (Lemma 25 below).

Lemma 22. Assume that $\boldsymbol{H}_{4}$ holds and that $\epsilon \leqslant \mathrm{m} / 4$ and consider the notations introduced in Lemma 21. Then, for any $i \in\left\{1, \ldots, d_{0}\right\}, \boldsymbol{\omega}=(\delta, K, \eta), \delta>0, K \in \mathbb{N}, \eta \in(0,1)$, $\mathbf{o}=\left(a_{0}, b_{0}, c_{0}, 2 b_{0}, e_{0}, f_{0}\right) \in \mathbb{R}_{+}^{6}$, satisfying $\delta \leqslant \bar{\delta}_{1}, K \delta \leqslant \bar{T} \wedge \bar{T}_{1} \wedge \bar{T}_{2}$ with $\bar{T}>0$, (70)-(71),

$$
\begin{align*}
& c_{0}(\eta-1)+2 \eta a_{0} \delta K=0, \quad c_{0} \leqslant \sqrt{2 a_{0} b_{0}}, \quad c_{0} / b_{0} \leqslant \eta(1-\eta) /(\delta K), \\
& \bar{C}_{b, 1}-c_{0} / b_{0} \leqslant(1-\eta) /[4 \delta K], \quad \delta K \bar{C}_{b, 2}+\delta \bar{C}_{b, 3} / b_{0} \leqslant(1-\eta) /[4 \delta K], \tag{73}
\end{align*}
$$

it holds
(a) For any $x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right), g=\left(g_{1}, \ldots, g_{d_{0}}\right) \in \mathbb{R}^{d}$,

$$
\begin{aligned}
& \mathrm{V}_{\delta}^{K} \mathfrak{V}_{\mathbf{o}, i}(x, \eta v+\tilde{\eta} g) \leqslant\left(1-\bar{\rho}_{\omega} K \delta\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]+f_{K} \\
& +2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+c_{K} \tilde{\eta}\langle x, g\rangle+\tilde{\eta}^{2} b_{K}\left|g_{i}\right|^{2}+e_{K} \frac{\epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}+g_{i}-g_{j}\right|^{2}\right],
\end{aligned}
$$

where $b_{K} \leqslant 2 b_{0}+\delta^{2} K \bar{C}_{b, 3}, e_{K} \leqslant 2 e_{0}+(K \delta) \bar{C}_{e, 1}+K \delta^{2} \bar{C}_{e, 2}$,

$$
\begin{aligned}
& \tilde{\eta}^{2}=1-\eta^{2} \\
& \bar{\rho}_{\boldsymbol{\omega}}=\left[\left(c_{0}+K \delta a_{0}\right) \bar{C}_{a, 2} /\left(4 a_{0}\right)\right] \wedge[(1-\eta) /(4 K \delta)] \wedge\left[\left(c_{0}+K \delta a_{0}\right) \bar{C}_{a, 2} /\left(4 b_{0} a_{0}\right)\right]
\end{aligned}
$$

(b) In addition for any $k \in\{1, \ldots, K\}, x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right), g=$ $\left(g_{1}, \ldots, g_{d_{0}}\right) \in \mathbb{R}^{d}$,

$$
\begin{aligned}
& \mathrm{V}_{\delta}^{k} \mathfrak{V}_{\mathbf{o}, i}(x, \eta v+\tilde{\eta} g) \leqslant \bar{C}_{1}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]+f_{K} \\
& +2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+c_{K} \tilde{\eta}\langle x, g\rangle+\tilde{\eta}^{2} b_{K}\left|g_{i}\right|^{2}+e_{K} \frac{\epsilon}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}+g_{i}-g_{j}\right|^{2}\right],
\end{aligned}
$$

where
$\bar{C}_{1}=\left[\left\{a_{0}+2 c_{0}+\bar{T} a_{0}+\bar{T}^{2} c_{0} \mathrm{~m} / 8+a_{0} \mathrm{~m} \bar{T}^{3} / 4+2 \bar{C}_{a, 3} \bar{\delta} \bar{T}\right\} / a_{0}\right] \vee\left[\left\{2 b_{0}+2 c_{0}+\bar{T} a_{0}+\bar{\delta} \bar{T} \bar{C}_{b, 3}\right\} / b_{0}\right]$.
Remark 23. Note that the first line in (73) is in particular satisfied choosing $b_{0}=1$, $a_{0}=(1-\eta)^{2} /\left[2(\delta K)^{2}\right]$ and $c_{0}=\eta(1-\eta) /(\delta K)$.

Proof. (a) Let $\delta>0, K \in \mathbb{N}, \eta \in(0,1)$, $\mathbf{o}=\left(a_{0}, b_{0}, c_{0}, 2 b_{0}, e_{0}, f_{0}\right) \in \mathbb{R}_{+}^{6}$, satisfying $\delta \leqslant \bar{\delta}_{1} \wedge \bar{\delta}, K \delta \leqslant \bar{T} \wedge \bar{T}_{1} \wedge \bar{T}_{2},(70)-(71)-(73)$. For any $x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right), g=$ $\left(g_{1}, \ldots, g_{d_{0}}\right) \in \mathbb{R}^{d}$, using Lemma 21-(a), we get

$$
\begin{aligned}
& \mathrm{V}_{\delta}^{K} \mathfrak{V}_{\mathbf{o}, i}(x, \eta v+\tilde{\eta} g) \leqslant a_{K}\left|x_{i}\right|^{2}+b_{K} \eta^{2}\left|v_{i}\right|^{2}+c_{K} \eta\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)+f_{K} \\
& +2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+\tilde{\eta}^{2} b_{K}\left|g_{i}\right|^{2}+c_{K} \tilde{\eta}\left\langle x_{i}, g_{i}\right\rangle+\frac{\epsilon e_{K}}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}+g_{i}-g_{j}\right|^{2}\right] .
\end{aligned}
$$

Note that by the first line in (73) and using $c_{K}=c_{0}+2 K \delta a_{0}$,

$$
\begin{equation*}
\eta c_{K}\langle x, v\rangle=c_{0}\langle x, v\rangle . \tag{74}
\end{equation*}
$$

Second using the second line in (73), we have

$$
\begin{align*}
b_{K} \eta^{2} & =\left(1+\bar{C}_{b, 1} K \delta+\bar{C}_{b, 2}(K \delta)^{2}+\bar{C}_{b, 3} K \delta^{2} / b_{0}\right) b_{0}(1-(1+\eta)(1-\eta)) \\
& \leqslant b_{0}\left[1-(1-\eta)-\eta(1-\eta)+C_{1} \delta K+\delta K\left(\delta K \bar{C}_{2, b}+\delta \bar{C}_{3, b} / b_{0}\right)\right] \\
& \leqslant b_{0}\left[1-(1-\eta)-\eta(1-\eta)+c_{0} \delta K / b_{0}+(1-\eta) / 4+\delta K\left(\bar{C}_{2, b}+\delta \bar{C}_{3, b} / b_{0}\right)\right] \\
& \leqslant b_{0}(1-\delta K(1-\eta) /[2 \delta K]) . \tag{75}
\end{align*}
$$

Then using (74)-(75), $U(x) \leqslant|x|^{2}$ under $\mathbf{H} 4$ and since $U(0)=0$, we get setting $\bar{C}_{a, 4}=K \delta \bar{C}_{a, 2}\left(c_{0}+\delta K a_{0}\right) / a_{0}$,

$$
\begin{aligned}
& \mathrm{V}_{\delta}^{K} \mathfrak{V}_{\mathbf{o}, i}(x, \eta v+\tilde{\eta} g) \leqslant\left(1-\bar{C}_{a, 4} / 2\right) a_{0}\left|x_{i}\right|^{2}+\delta K(1-\eta)\left|v_{i}\right|^{2} /[2 K \delta]+c_{0}\left\langle x_{i}, v_{i}\right\rangle \\
& \quad+\left(1-\bar{C}_{a, 4} /\left(4 b_{0}\right)\right) 2 b_{0} U^{(q)}\left(x_{i}\right)+f_{K}+2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+\tilde{\eta}^{2} b_{K}\left|g_{i}\right|^{2}+c_{K} \tilde{\eta}\left\langle x_{i}, g_{i}\right\rangle \\
& \quad+\frac{\epsilon e_{K}}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}+g_{i}-g_{j}\right|^{2}\right] \\
& \leqslant\left(1-\bar{C}_{a, 4} / 2\right) a_{0}\left|x_{i}\right|^{2}+\delta K(1-\eta)\left|v_{i}\right|^{2} /[2 K \delta]+c_{0}\left(1-\bar{\rho}_{\omega} K \delta\right)\left\langle x_{i}, v_{i}\right\rangle+\bar{\rho}_{\omega} K \delta c_{0}\langle x, v\rangle \\
& \quad+\left(1-\bar{C}_{a, 4} /\left(4 b_{0}\right)\right) 2 b_{0} U^{(q)}\left(x_{i}\right)+f_{K}+2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+\tilde{\eta}^{2} b_{K}\left|g_{i}\right|^{2}+c_{K} \tilde{\eta}\left\langle x_{i}, g_{i}\right\rangle \\
& \quad+\frac{\epsilon e_{K}}{d_{0}} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}+g_{i}-g_{j}\right|^{2}\right],
\end{aligned}
$$

which completes the proof using the Cauchy-Schwarz inequality and the condition $c_{0} \leqslant$ $2 \sqrt{a_{0} b_{0}}$.
(b) The proof of the second statement follows the same lines using Lemma 21-(b) instead of Lemma 21-(a).

Averaging over momentum updates. We first give a technical result on certain Gaussian moments.

Lemma 24. Let $a \in \mathbb{R}_{+}, \ell \in \mathbb{N}^{*}$ and $G$ be a d-dimensional zero-mean Gaussian random variable with covariance matrix identity. Then, for any $x \in \mathbb{R}^{d}$,

$$
\begin{equation*}
\mathbb{E}\left[(a+\langle G, x\rangle)^{\ell}\right] \leqslant a^{\ell-2\lfloor\ell / 2\rfloor}\left(a^{2}+\tilde{\mathbf{m}}_{\ell}|x|^{2}\right)^{\lfloor\ell / 2\rfloor}, \text { where } \tilde{\mathbf{m}}_{\ell}=\mathrm{e}^{2}(\ell / 2)^{2}\lfloor\ell / 2\rfloor^{-1} \mathbf{m}_{2\lfloor\ell / 2\rfloor}^{1 /\lfloor/ 2\rfloor} \tag{76}
\end{equation*}
$$

and $\mathbf{m}_{\ell^{\prime}}$ is the $\ell^{\prime}$-th moment of the zero-mean one-dimensional Gaussian distribution with variance 1 .

Proof. Expanding $(a+\langle G, x\rangle)^{\ell}$ and using that $\langle G, x\rangle$ is a zero-mean Gaussian random variable with variance $|x|^{2}$, we get

$$
\begin{aligned}
\mathbb{E}\left[(a+\langle G, x\rangle)^{\ell}\right] & =\sum_{k=0}^{\ell}\binom{\ell}{k} a^{\ell-k} \mathbb{E}\left[\langle G, x\rangle^{k}\right]=\sum_{k=0}^{\lfloor\ell / 2\rfloor}\binom{\ell}{2 k}|x|^{2 k} a^{\ell-2 k} \mathbf{m}_{2 k}^{2 k / 2 k} \\
& \leqslant a^{\ell-2\lfloor\ell / 2\rfloor} \sum_{k=0}^{\lfloor\ell / 2\rfloor}\binom{\ell}{2 k}|x|^{2 k} a^{2(\lfloor/ 2\rfloor-k)} \mathbf{m}_{2\lfloor\ell / 2\rfloor}^{2 k / 2\rfloor / 2\rfloor},
\end{aligned}
$$

where we apply Jensen inequality for the last step. Using that $\binom{\ell}{2 k} \leqslant(e \ell /(2 k))^{2 k} \leqslant$ $\left(\mathrm{e}^{2} \ell / 2\right)^{k}(\ell /(2 k))^{k} \leqslant\left(\mathrm{e}^{2}(\ell / 2)^{2}\lfloor\ell / 2\rfloor^{-1}\right)^{k}\binom{\lfloor\ell / 2\rfloor}{ k}$, we get

$$
\begin{aligned}
\mathbb{E}\left[(a+\langle G, x\rangle)^{\ell}\right] & \leqslant a^{\ell-2\lfloor\ell / 2\rfloor} \sum_{k=0}^{\lfloor\ell / 2\rfloor}\left(\mathrm{e}^{2}(\ell / 2)^{2}\lfloor\ell / 2\rfloor^{-1}\right)^{k}\binom{\lfloor\ell / 2\rfloor}{ k}|x|^{2 k} a^{2(\lfloor\ell / 2\rfloor-k)} \mathbf{m}_{2\lfloor\ell / 2\rfloor}^{2 k / 2\lfloor/ 2\rfloor} \\
& \leqslant a^{\ell-2\lfloor\ell / 2\rfloor}\left(a^{2}+\mathrm{e}^{2}(\ell / 2)^{2}\lfloor\ell / 2\rfloor^{-1}|x|^{2} \mathbf{m}_{2\lfloor\ell / 2\rfloor}^{1 /\lfloor\ell / 2\rfloor}\right)^{\lfloor\ell / 2\rfloor},
\end{aligned}
$$

which completes the proof.
Define for any $x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right) \in \mathbb{R}^{d}$ and $\ell \in \mathbb{N}^{*}$,

$$
\mathfrak{V}_{\mathbf{o}}^{(\ell)}(x, v)=\sum_{i=1}^{d_{0}} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, v) .
$$

We are now ready to control the evolution of the Lyapunov function $\mathfrak{V}_{\mathbf{o}, i}^{\ell}$ for any $\ell \in \mathbb{N}^{*}$ over one full transition of the gHMC chain (notice that we are essentially interested in $\ell=3$, since this is the dominant order in (52)).

Lemma 25. Assume that $\boldsymbol{H}_{4}$ holds and that $\epsilon \leqslant \mathrm{m} / 4$. Then, for any $\boldsymbol{\omega}=(K, \delta, \eta), K \in \mathbb{N}$, $\delta>0, \eta \in(0,1)$, $\mathbf{o}=\left(a_{0}, b_{0}, c_{0}, 2 b_{0}, e_{0}, f_{0}\right) \in \mathbb{R}_{+}^{6}$, satisfying $\delta \leqslant \bar{\delta}_{1} \wedge \bar{\delta}, K \delta \leqslant \bar{T} \wedge \bar{T}_{1} \wedge \bar{T}_{2}$ with $\bar{T}, \bar{\delta}>0,(70)-(71)-(73)$, it holds:
(a) For any $x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right) \in \mathbb{R}^{d}$ and $\ell \in \mathbb{N}^{*}$,

$$
\mathrm{P}_{\omega} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, v) \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell}
$$

$$
\begin{aligned}
& +2^{\ell}\lfloor\ell / 2\rfloor \bar{E}_{\ell}\left[\left(a_{0} \bar{D}_{2}^{x}+b_{0}\left(\bar{D}_{2}^{v}+2 \bar{D}_{2}^{x}\right)+c_{0}\left(\bar{D}_{2}^{x}\right)^{1 / 2}\left(\bar{D}_{2}^{v}\right)^{1 / 2}\right)^{2}+\bar{E}_{\ell}\right]^{\lfloor\ell / 2\rfloor-1} \\
& +12^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right] \\
& +12^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell}\left[d_{0}^{-1} \sum_{j=1}^{d_{0}}\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]^{\ell}
\end{aligned}
$$

where

$$
\begin{align*}
\bar{D}_{1}^{x} & =\frac{2^{3 / 2}\left(c_{K} \tilde{\eta}\right)^{2} \tilde{\mathbf{m}}_{\ell}}{a_{0}^{2} \bar{\rho}_{\boldsymbol{\omega}} K \delta(\sqrt{2}-1)}, \quad \bar{D}_{1}^{v}=\frac{8 \sqrt{2}\left(\tilde{\eta} \eta b_{K}\right)^{2} \tilde{\mathbf{m}}_{\ell}}{\bar{\rho}_{\boldsymbol{\omega}} K \delta(\sqrt{2}-1)},  \tag{77}\\
\bar{D}_{2}^{x} & =\left[2 \bar{D}_{1}^{x}\right] \vee 4 \sqrt{\frac{\bar{D}_{1}^{v} \tilde{\mathbf{m}}_{\ell}\left(\eta \tilde{\eta} b_{K}\right)^{2} \sqrt{2}}{\bar{\rho}_{\boldsymbol{\omega}} K \delta a_{0}^{2}(\sqrt{2}-1)}}, \quad \bar{D}_{2}^{v}=\left[2 \bar{D}_{1}^{v}\right] \vee 2 \sqrt{\frac{\bar{D}_{1}^{x} \tilde{\mathbf{m}}_{\ell}\left(\tilde{\eta} c_{K}\right)^{2} \sqrt{2}}{\bar{\rho}_{\omega} K \delta b_{0}^{2}(\sqrt{2}-1)}} \\
\bar{E}_{\ell} & =\left[4\left(\tilde{\eta} \eta b_{K}\right)^{2} \bar{D}_{2}^{v}+2\left(c_{K} \tilde{\eta}\right)^{2} \bar{D}_{2}^{x}\right] \tilde{\mathbf{m}}_{\ell}
\end{align*}
$$

where $\tilde{\mathbf{m}}_{\ell}$ is defined in (76) and $\tilde{\eta}^{2}=1-\eta^{2}$.
(b) In addition, if for $\ell \in \mathbb{N}^{*}$

$$
\begin{equation*}
\epsilon \leqslant \ell^{1 /(\ell-1)}\left(1-\bar{\rho}_{\omega} K \delta / 4\right), \quad 24 e_{K} \epsilon\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{(\ell-1) / \ell} \leqslant \bar{\rho}_{\omega} K \delta / 8 \tag{78}
\end{equation*}
$$

for any $x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right) \in \mathbb{R}^{d}$,

$$
\begin{aligned}
\mathrm{P}_{\omega} \mathfrak{V}_{\mathbf{o}}^{(\ell)}(x, v) \leqslant(1 & \left.-\bar{\rho}_{\omega} K \delta / 8\right)^{\ell} \sum_{i=1}^{d_{0}}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell} \\
& +4^{\ell}\lfloor\ell / 2\rfloor \bar{E}_{\ell}\left[\left(a_{0} \bar{D}_{1}^{x}+b_{0}\left(\bar{D}_{1}^{v}+2 \bar{D}_{1}^{x}\right)+c_{0}\left(\bar{D}_{1}^{x}\right)^{1 / 2}\left(\bar{D}_{1}^{v}\right)^{1 / 2}\right)^{2}+\bar{E}_{\ell}\right]^{\lfloor\ell / 2\rfloor-1} \\
& +12^{\ell-1} d_{0}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right]
\end{aligned}
$$

(c) Finally, for any $k \in\{0, \ldots, K\}, x=\left(x_{1}, \ldots, x_{d_{0}}\right), v=\left(v_{1}, \ldots, v_{d_{0}}\right) \in \mathbb{R}^{d}$ and $\ell \in \mathbb{N}^{*}$,

$$
\begin{aligned}
\mathrm{D}_{\eta} \mathrm{V}_{\delta}^{k} \mathfrak{V}_{\mathbf{o}}^{(\ell)}(x, v) \leqslant & \bar{C}_{2}^{\ell} \sum_{i=1}^{d_{0}}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell} \\
& +12^{\ell-1} d_{0}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right]
\end{aligned}
$$

where

$$
\begin{equation*}
\bar{C}_{2}=8\left(1+\bar{\rho}_{\omega} K \delta / 4\right)\left[\bar{C}_{1}+\left(\left[4\left(\eta \tilde{\eta} b_{K}\right)^{2} b_{0}^{-1}\right] \vee\left[\left(c_{K} \tilde{\eta}\right)^{2} a_{0}^{-1}\right]\right)\right]+24\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{(\ell-1) / \ell} \epsilon e_{K} \tag{79}
\end{equation*}
$$

Proof. Let $\delta \leqslant \bar{\delta}_{1} \wedge \bar{\delta}, K \delta \leqslant \bar{T} \wedge \bar{T}_{1} \wedge \bar{T}_{2}$ with $\bar{T}, \bar{\delta}>0$, satisfying (70)-(71)-(73).
(a) Consider $x, v \in \mathbb{R}^{d}$ and $\ell \in \mathbb{N}^{*}$. Using Lemma 22-(a) and Jensen inequality, we have, for any $g=\left(g_{1}, \ldots, g_{d_{0}}\right) \in \mathbb{R}^{d}$,

$$
\begin{aligned}
& \mathrm{V}_{\delta}^{K} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, \eta v+\tilde{\eta} g) \\
& \leqslant\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1}\left[A+2 \eta \tilde{\eta} b_{K}\left\langle v_{i}, g_{i}\right\rangle+c_{K} \tilde{\eta}\left\langle x_{i}, g_{i}\right\rangle\right]^{\ell}
\end{aligned}
$$

$$
\begin{aligned}
& +12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell}|g|^{2 \ell}+\epsilon^{\ell} e_{K}^{\ell} d_{0}^{-1} \sum_{j=1}^{d_{0}}\left|g_{i}-g_{j}\right|^{2 \ell}+f_{K}^{\ell}\right] \\
& +12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell}\left[d_{0}^{-1} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]^{\ell},\right.
\end{aligned}
$$

where we have set $A=\left(1-\bar{\rho}_{\omega} K \delta\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]$. Then, taking expectation and Lemma 24 imply that

$$
\begin{align*}
& \mathrm{P}_{\omega} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, v) \leqslant\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1} A^{\ell-2\lfloor\ell / 2\rfloor} B^{\lfloor\ell / 2\rfloor}  \tag{80}\\
& \quad+12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right] \\
& \quad+12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} d_{0}^{-1} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]^{\ell} .
\end{align*}
$$

with $B=A^{2}+\left[4\left(\eta \tilde{\eta} b_{K}\right)^{2}\left|v_{i}\right|^{2}+\left(c_{K} \tilde{\eta}\right)^{2}\left|x_{i}\right|^{2}\right] \tilde{\mathbf{m}}_{\ell}$. For $\left|x_{i}\right|^{2} \geqslant \bar{D}_{1}^{x}$ and $\left|v_{i}\right|^{2} \geqslant \bar{D}_{1}^{v}$, we get using $c_{0}\left\langle x_{i}, v_{i}\right\rangle \leqslant\left(a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}\right) / \sqrt{2}$ since $c_{0} \leqslant \sqrt{2 a_{0} b_{0}}$ by the first line in (73),

$$
\begin{aligned}
B \leqslant & \left(1-\bar{\rho}_{\omega} K \delta / 2\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{2} \\
& \quad-\bar{\rho}_{\omega} K \delta(\sqrt{2}-1) 2^{-1 / 2}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}\right]^{2}+\left[4\left(\eta \tilde{\eta} b_{K}\right)^{2}\left|v_{i}\right|^{2}+\left(c_{K} \tilde{\eta}\right)^{2}\left|x_{i}\right|^{2}\right] \tilde{\mathbf{m}}_{\ell} \\
& \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 2\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{2} .
\end{aligned}
$$

Similarly, for $\left|x_{i}\right|^{2} \geqslant \bar{D}_{2}^{x}$ and $\left|v_{i}\right|^{2} \leqslant \bar{D}_{1}^{v}$ or $\left|x_{i}\right|^{2} \leqslant \bar{D}_{1}^{x}$ and $\left|v_{i}\right|^{2} \geqslant \bar{D}_{2}^{v}$, we get

$$
B \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 2\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{2} .
$$

It yields for $\left|x_{1}\right|^{2} \geqslant \bar{D}_{2}^{x}$ or $\left|v_{i}\right|^{2} \geqslant \bar{D}_{2}^{v}$,

$$
\begin{aligned}
& \left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1} A^{\ell-2\lfloor\ell / 2\rfloor} B^{\lfloor\ell / 2\rfloor} \\
& \leqslant\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell} A^{\ell-2\lfloor\ell / 2\rfloor}\left(\left(1-\bar{\rho}_{\omega} K \delta / 2\right)\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{2}\right)^{\ell \ell / 2\rfloor} \\
& \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell} .
\end{aligned}
$$

Therefore, the proof is completed for $\left|x_{1}\right|^{2} \geqslant \bar{D}_{2}^{x}$ or $\left|v_{i}\right|^{2} \geqslant \bar{D}_{2}^{v}$. It remains to consider the case where $\left|x_{1}\right|^{2} \leqslant \bar{D}_{2}^{x}$ and $\left|v_{i}\right|^{2} \leqslant \bar{D}_{2}^{v}$.

Using that $(t+s)^{\ell^{\prime}}-t^{\ell^{\prime}} \leqslant \ell^{\prime} s(t+s)^{\ell^{\prime}-1}$, for $s, t \geqslant 0$ and $\ell^{\prime} \geqslant 1$, we get for $\left|x_{1}\right|^{2} \leqslant \bar{D}_{2}^{x}$ and $\left|v_{i}\right|^{2} \leqslant \bar{D}_{2}^{v}$,

$$
B^{\lfloor\ell / 2\rfloor}-A^{2\lfloor\ell / 2\rfloor} \leqslant\left(A^{2}+\bar{E}_{\ell}\right)^{\lfloor\ell / 2\rfloor}-A^{2\lfloor/ 2\rfloor} \leqslant\lfloor\ell / 2\rfloor \bar{E}_{\ell} B^{\lfloor\ell / 2\rfloor-1} .
$$

Combining this inequality and (81), we obtain

$$
\begin{align*}
\mathrm{P}_{\omega} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, v) \leqslant\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1} A^{\ell}+\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1}\lfloor\ell / 2\rfloor \bar{E}_{\ell} B^{\lfloor\ell / 2\rfloor}  \tag{81}\\
\quad+12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right] \\
\quad+12^{\ell-1}\left(1+4 / \bar{\rho}_{\omega} K \delta\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} d_{0}^{-1} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]^{\ell}
\end{align*}
$$

and the proof is completed using the definition of $A,\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1}\left(1-\bar{\rho}_{\omega} K \delta\right)^{\ell} \leqslant$ $\left(1-\bar{\rho}_{\omega} K \delta / 2\right)^{\ell}, B \leqslant\left(a_{0} \bar{D}_{2}^{x}+b_{0}\left(\bar{D}_{2}^{v}+2 \bar{D}_{2}^{x}\right)+c_{0}\left(\bar{D}_{2}^{x}\right)^{1 / 2}\left(\bar{D}_{2}^{v}\right)^{1 / 2}\right)^{2}+\bar{E}_{\ell}$ since $U(x) \leqslant|x|^{2}$ under $\mathbf{H} 4$ and $\left(1+\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1} \leqslant 2^{\ell}$.
(b) By Young's inequality, we have

$$
\begin{aligned}
\mathrm{P}_{\omega} \mathfrak{V}_{\mathbf{o}}^{(\ell)}(x, v) \leqslant & \left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell} \sum_{i=1}^{d_{0}}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell} \\
& +2^{\ell}\lfloor\ell / 2\rfloor d_{0} \bar{E}_{\ell}\left[\left(a_{0} \bar{D}_{2}^{x}+b_{0}\left(\bar{D}_{2}^{v}+2 \bar{D}_{2}^{x}\right)+c_{0}\left(\bar{D}_{2}^{x}\right)^{1 / 2}\left(\bar{D}_{2}^{v}\right)^{1 / 2}\right)^{\ell}+\bar{E}_{\ell}^{\ell}\right] \\
& +12^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1} d_{0}\left[\tilde{\eta}^{\ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right] \\
& +2 \times 24^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} \sum_{i=1}^{d_{0}}\left[\left|x_{i}\right|^{2}+\left|v_{i}\right|^{2}\right]^{\ell} .
\end{aligned}
$$

Then the proof is completed using
$a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2} \leqslant \sqrt{2} /(\sqrt{2}-1)\left\{a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle\right\} \leqslant 4\left\{a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle\right\}$,
the fact that by (78)

$$
\begin{aligned}
& \left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell}+2 \times 4 \times 24^{\ell-1}\left[a_{0}^{-1} \vee b_{0}^{-1}\right]^{\ell}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} \\
& \quad \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell}+\ell\left(1-\bar{\rho}_{\omega} K \delta / 4\right)^{\ell-1}\left[24 e_{K} \epsilon\left[a_{0}^{-1} \vee b_{0}^{-1}\right]\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{(\ell-1) / \ell}\right] \\
& \quad \leqslant\left(1-\bar{\rho}_{\omega} K \delta / 4+24 e_{K} \epsilon\left[a_{0}^{-1} \vee b_{0}^{-1}\right]\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{(\ell-1) / \ell}\right)^{\ell},
\end{aligned}
$$

and (78) again.
(c) Following the same lines as in the proof (a) using Lemma 22-(b) instead of Lemma 22(a) we have using (82)

$$
\begin{aligned}
\mathrm{D}_{\eta} \mathrm{V}_{\delta}^{k} \mathfrak{V}_{\mathbf{o}, i}^{\ell}(x, v) \leqslant & \bar{C}_{2,0}^{\ell}\left[a_{0}\left|x_{i}\right|^{2}+b_{0}\left|v_{i}\right|^{2}+c_{0}\left\langle x_{i}, v_{i}\right\rangle+2 b_{0} U^{(q)}\left(x_{i}\right)\right]^{\ell} \\
& +2^{\ell}\lfloor\ell / 2\rfloor \bar{E}_{\ell}\left[\left(a_{0} \bar{D}_{2}^{x}+b_{0}\left(\bar{D}_{2}^{v}+2 \bar{D}_{2}^{x}\right)+c_{0}\left(\bar{D}_{2}^{x}\right)^{1 / 2}\left(\bar{D}_{1}^{v}\right)^{1 / 2}\right)^{\ell}+\bar{E}_{\ell}^{\ell}\right] \\
& +12^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1}\left[\tilde{\eta}^{2 \ell} b_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} q^{\ell} \mathbf{m}_{2 \ell}+f_{K}^{\ell}\right] \\
& +12^{\ell-1}\left(1+4 /\left(\bar{\rho}_{\omega} K \delta\right)\right)^{\ell-1} \epsilon^{\ell} e_{K}^{\ell} d_{0}^{-1} \sum_{j=1}^{d_{0}}\left[\left|x_{i}-x_{j}\right|^{2}+\left|v_{i}-v_{j}\right|^{2}\right]^{\ell},
\end{aligned}
$$

with

$$
\bar{C}_{2,0}=8\left(1+\bar{\rho}_{\omega} K \delta / 4\right)\left[\bar{C}_{1}+\left(\left[4\left(\eta \tilde{\eta} b_{K}\right)^{2} \tilde{\mathbf{m}}_{\ell} b_{0}^{-1}\right] \vee\left[\left(c_{K} \tilde{\eta}\right)^{2} \tilde{\mathbf{m}}_{\ell} a_{0}^{-1}\right]\right)\right] .
$$

The proof is then easily completed.

Conclusion. We can finally conclude this section by providing the proof of Theorem 18. Indeed, it only remains to chose carefully the initial parameters o so that Lemma 25 reads $\mathrm{P}_{\omega} \mathfrak{V}_{o}^{(\ell)} \leqslant\left(1-\rho_{\omega} K \delta\right)^{\ell} \mathfrak{V}_{o}^{(\ell)}+C$ for some constant $C$ (with $\rho_{\omega}$ given by (54)), and then (53) will follow by induction on $n$ and the equivalence between $\mathfrak{W}_{\omega, i}$ and $\mathfrak{V}_{\mathbf{o}}^{(\ell)}$.

Proof of Theorem 18. Taking

$$
a_{0}=\gamma_{0}^{2} / 2, \quad b_{0}=1, \quad c_{0}=\eta \gamma_{0}, \quad \gamma_{0}=(1-\eta) /(\delta K), \quad f_{0}=0, \quad e_{0}=0 .
$$

As mentioned in Remark 23, the first condition in (73) is satisfied for this case. In addition, for this choice of parameter, the constants appearing in Lemma 21 become:

$$
\begin{aligned}
C_{a, 1} & =\mathrm{m} /\left(3 \times 2^{5}\right), \quad C_{a, 2}=\mathrm{m} /\left(3 \times 2^{6}\right), C_{a, 3}=20+\gamma_{0}^{2} \bar{T}\left(\mathrm{~m} /\left(3 \times 2^{5}\right)+\bar{T} \mathrm{~m} /\left(3 \times 2^{6}\right)\right) / 2, \\
C_{b, 1} & =\epsilon+\eta \gamma_{0}(1+10 \bar{\delta}), \quad C_{b, 2,0}=4\left[(1+\epsilon) C_{b, 1}+(1+10 \bar{\delta})\left(\gamma_{0}^{2}+C_{e, 1} \epsilon\right)\right] \\
C_{b, 3,0} & =17+\gamma_{0}^{2}+\bar{T}\left(2 C_{a, 3}+17 C_{b, 1}+\epsilon C_{e, 2}+20 \bar{T}(1+10 \bar{\delta})\right), \\
C_{b, 2} & =C_{b, 2,0}+\eta \gamma_{0} \mathrm{~m} / 8+a_{0} \mathrm{~m} \bar{T} / 4, \quad C_{b, 3}=C_{b, 3,0}+20+2 C_{a, 3}, \\
C_{e, 1} & =37\left[2+\eta \gamma_{0}+\bar{T}\left(17 \eta \gamma_{0}+\gamma_{0}^{2}+\bar{\delta} C_{b, 3}\right)\right], \quad C_{e, 2}=37\left(\gamma_{0}^{2}+\bar{T} C_{a, 3}\left(\bar{\delta} C_{a, 3}+2 \bar{T}\right)\right), \\
C_{f, 1} & =\gamma_{0}^{2} \mathrm{M} \bar{\delta} / 2+\bar{C}_{a, 3} \mathrm{M} \bar{\delta} \bar{T}+\mathrm{mM} \bar{\delta} / 2+\mathrm{M}\left(\eta \gamma_{0}+\bar{T} \gamma_{0}^{2} / 2\right) .
\end{aligned}
$$

Then, with these notations, $\delta_{1}, \bar{T}_{1}, \bar{T}_{2}$ in (72) can be written as

$$
\begin{align*}
\delta_{1} & =17^{-1} \wedge[\mathrm{~m} / 40] \wedge\left[\gamma_{0}^{2} 2^{-6} /\left(48 \epsilon C_{e, 1}+C_{b, 3}(1+10 \bar{\delta})\right)\right], \\
T_{1} & =4^{-1}\left[17^{-1} \wedge C_{b, 1}^{-1} \wedge C_{b, 2,0}^{-1 / 2}\right]  \tag{83}\\
T_{2} & =4^{-1}\left\{\left[2^{-5} /(1+10 \bar{\delta})\right] \wedge\left[2^{4} \gamma_{0}^{2} / C_{b, 2}\right] \wedge \gamma_{0} / 2^{4} \wedge 2\right\} .
\end{align*}
$$

and the condition (70)-(71) are equivalent to

$$
\begin{equation*}
\epsilon \leqslant \epsilon_{1}, \quad \epsilon_{1}=\gamma_{0}^{2} \mathrm{~m} 2^{-6} /\left[1+48 C_{e, 1}\right], \tag{84}
\end{equation*}
$$

and

$$
\begin{equation*}
\delta \leqslant \delta_{2}, \quad \delta_{2}=\gamma_{0} \mathrm{~m}\left(3 \times 2^{8}\right)^{-1} /\left[20+\gamma_{0}^{2} \bar{T}\left(C_{a, 1}+\bar{T} C_{a, 2}\right) / 2\right] . \tag{85}
\end{equation*}
$$

In addition,

$$
\begin{equation*}
b_{K} \leqslant \bar{b}, \quad \bar{b}=2+\bar{T} \bar{\delta} C_{b, 3}, \quad e_{K} \leqslant K \delta \bar{e}, \quad \bar{e}=\left(C_{e, 1}+\bar{\delta} C_{e, 2}\right) . \tag{86}
\end{equation*}
$$

Furthermore, the second line of (73) is equivalent to $\delta \leqslant 1 /(7 \times 8)$ and

$$
\begin{equation*}
K \delta \leqslant T_{3}, \quad T_{3}=4^{-1} \gamma_{0} /\left[\left(1-\eta^{2}\right)^{1 / 2} C_{b, 1}+C_{b, 2}\right] . \tag{87}
\end{equation*}
$$

Then, the proof is an easy consequence of Lemma 25 with $\rho_{\omega}$ given by (54). Condition (78) is equivalent using (86) to

$$
\begin{equation*}
\epsilon \leqslant \epsilon_{2}, \quad \epsilon_{2}=\left[\ell^{1 /(\ell-1)}\left(1-\bar{\rho}_{\omega} K \delta / 4\right)\right] \wedge\left[(8 \times 24)^{-1} \bar{\rho}_{\omega} /\left\{\bar{e}\left(1+4 /\left(\rho_{\omega} \bar{T}\right)\right)^{(\ell-1) / \ell}\right\}\right] . \tag{88}
\end{equation*}
$$

and (77)-(79) can be written using (86) and $1+\eta \leqslant 2$, as

$$
\begin{aligned}
D_{1} & =16 \gamma_{0} \rho_{\omega}^{-1}\left\{\bar{\eta}^{2}+\bar{T}^{2} \gamma_{0}^{2}\right\}, \quad D_{2}=32 \times 2 \bar{\eta}^{2} \gamma_{0} / \rho_{\omega} \\
E_{\ell} & =\delta K F_{\ell}, \quad F_{\ell}=8 \gamma_{0}\left[\bar{\eta}^{2}\left(2+C_{b, 3} \bar{\delta} \bar{T}\right) D_{2}+\left(\gamma_{0}^{2} \bar{\eta}^{2}+\gamma_{0}^{4} \bar{T}^{2}\right) D_{1}\right] \tilde{\mathbf{m}}_{\ell} \\
C_{2} & =\left(1+\rho_{\omega} \bar{T} / 4\right)\left[C_{1}+\left(\left[8 \gamma_{0} \bar{T} \bar{\eta}^{2}\left(2+C_{b, 3} \bar{\delta} \bar{T}\right)\right] \vee\left[16 \gamma_{0} \bar{T}\left(\bar{\eta}^{2}+\gamma_{0}^{2} \bar{T}^{2}\right)\right]\right)\right]
\end{aligned}
$$

$$
\begin{gathered}
+24 \bar{T}\left(C_{e, 1}+\bar{\delta} C_{e, 2}\right)\left(4+\rho_{\omega}\right)^{(\ell-1) / \ell} \\
C_{1}=\left[2\left\{\left(1+\bar{T}+\bar{T}^{3} \mathrm{~m} / 4\right) \gamma_{0}^{2} / 2+2 \bar{\eta}\left(1+\bar{T}^{2} \mathrm{~m} / 8\right) \gamma_{0}+2 C_{a, 3} \bar{\delta} \bar{T}\right\} / \gamma_{0}^{2}\right] \\
\vee\left[2+2 \gamma_{0} \bar{\eta}+\bar{T} \gamma_{0}^{2} / 2+\bar{\delta} \bar{T} C_{b, 3}\right]
\end{gathered}
$$

where $\tilde{\mathbf{m}}_{\ell}$ is defined in (76). It completes the proof of (53) with

$$
C_{1, \ell}=C_{2},
$$

$$
C_{2, \ell}=2^{\ell}\lfloor\ell / 2\rfloor F_{\ell}\left[\left(a_{0} D_{1}+b_{0}\left(D_{2}+2 D_{1}\right)+c_{0} D_{1}^{1 / 2} D_{2}^{1 / 2}\right)^{\ell}+\bar{T}^{\ell} F_{\ell}^{\ell}\right],
$$

$$
\begin{equation*}
C_{3, \ell}=2 \times 12^{\ell-1} \rho_{\omega}^{1-\ell}\left(4+\rho_{\omega} \bar{T}\right)^{\ell-1}\left[4^{\ell} \gamma_{0}^{\ell}\left(2+\bar{\delta} \bar{T} C_{b, 3}\right) \mathbf{m}_{2 \ell}+8^{\ell-1} \epsilon^{\ell}\left(C_{e, 1}+\bar{\delta} C_{e, 2}\right)^{\ell} \mathbf{m}_{2 \ell}+C_{f, 1}\right], \tag{89}
\end{equation*}
$$

where $\mathbf{m}_{\ell^{\prime}}$ is the $\ell^{\prime}$-th moment of the zero-mean one-dimensional Gaussian distribution with variance 1 .

[^0]:    ${ }^{1}$ We mention that the argument in the case $\eta=0$ in [41] is not correct, an inequality is used in the wrong sense.
