# THE $\tau_{N}$-CONFIGURATIONS AND POLYCONVEX GRADIENT FLOWS 

BAISHENG YAN

#### Abstract

We study a generalization of $T_{N}$-configurations, called the $\tau_{N}$-configurations, for constructing certain irregular solutions of some nonlinear diffusion systems by the method of convex integration. We construct some polyconvex functions that support a parametrized family of $\tau_{N}$-configurations satisfying a general openness condition; this will guarantee the existence of nowhere- $C^{1}$ Lipschitz weak solutions to the initial boundary value problems of the polyconvex gradient flows. We elaborate on such constructions and the subsequent verification of the openness condition when the dimension is at least 4 to avoid some complicated calculations that cannot be done by hand but would otherwise be needed for dimensions 2 and 3 .

## 1. Introduction

Let $m, n \geq 1$ and $\mathbb{R}^{m \times n}$ be the usual space of real $m \times n$ matrices with inner-product $\langle A, B\rangle=\operatorname{tr}\left(A^{T} B\right)$. Given a bounded domain $\Omega \subset \mathbb{R}^{n}$, a number $T>0$ and a continuous function $\sigma: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}^{m \times n}$, we study the time-dependent diffusion system:

$$
\begin{equation*}
\partial_{t} u=\operatorname{div} \sigma(D u) \quad \text { in } \Omega_{T}=\Omega \times(0, T), \tag{1.1}
\end{equation*}
$$

for the unknown $u=\left(u^{1}, \ldots, u^{m}\right): \Omega_{T} \rightarrow \mathbb{R}^{m}$, where $\partial_{t} u=\left(\partial_{t} u^{1}, \cdots, \partial_{t} u^{m}\right)$ and $D u=\left(\frac{\partial u^{i}}{\partial x_{j}}\right)$ are the time-derivative and space-gradient of $u$, respectively. We say that a function $u \in L_{l o c}^{1}\left(0, T ; W_{l o c}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)\right)$ is a (very) weak solution of (1.1) provided that $\sigma(D u) \in L_{l o c}^{1}\left(\Omega_{T} ; \mathbb{R}^{m \times n}\right)$ and

$$
\begin{equation*}
\int_{\Omega_{T}}\left(u \cdot \partial_{t} \varphi-\langle\sigma(D u), D \varphi\rangle\right) d x d t=0 \quad \forall \varphi \in C_{c}^{\infty}\left(\Omega_{T} ; \mathbb{R}^{m}\right) \tag{1.2}
\end{equation*}
$$

The system (1.1) is called (uniformly) parabolic if $\sigma$ satisfies a uniform rank-one monotonicity (also known as Legendre-Hadamard ellipticity) condition:

$$
\begin{equation*}
\langle\sigma(A+p \otimes a)-\sigma(A), p \otimes a\rangle \geq \nu|p|^{2}|a|^{2} \tag{1.3}
\end{equation*}
$$

[^0]for all $A \in \mathbb{R}^{m \times n}, p \in \mathbb{R}^{m}$ and $a \in \mathbb{R}^{n}$, where $\nu>0$ is a constant. However, it is known that condition (1.3) is not enough for any feasible theory of existence and regularity for system (1.1); further stronger structural conditions would be needed. For example, under a stronger condition known as quasimonotonicity, the best regularity result for weak solutions of (1.1) is the partial $C^{1, \alpha}$-regularity in space: $D u \in C_{l o c}^{\alpha, \alpha / 2}\left(U ; \mathbb{R}^{m \times n}\right)$ for some $0<\alpha<1$ and open set $U \subset \Omega_{T}$ with $\left|\Omega_{T} \backslash U\right|=0$ (see, e.g., [1]).

We address the issues on counterexamples to uniqueness and regularity for system (1.1). To construct such counterexamples, a general approach is to reformulate system (1.1) as a first-order partial differential relation:

$$
\begin{equation*}
u=\operatorname{div} v, \quad\left(D u, \partial_{t} v\right) \in \mathcal{K} \text { a.e. on } \Omega_{T} \tag{1.4}
\end{equation*}
$$

for functions $(u, v): \Omega_{T} \rightarrow \mathbb{R}^{m} \times \mathbb{R}^{m \times n}$, where

$$
\mathcal{K}=\left\{(A, \sigma(A)): A \in \mathbb{R}^{m \times n}\right\}
$$

is the graph of $\sigma$ in $\mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}$, and then apply the method of convex integration. Such an approach has been successful if $\sigma$ satisfies some non-monotonicity conditions in the scalar cases $(m=1)$ as studied in [10, 11, 12, 24, 25] or if $\sigma$ satisfies even some conditions much stronger than the rank-one monotonicity in the system cases $(m, n \geq 2)$ as studied in [22, 23]. Earlier work on the corresponding elliptic systems and certain timedependent solutions of parabolic systems has been pioneered in [16, 17, 19] using the convex integration method. We remark that the convex integration method has recently found remarkable success in studying many other important PDE problems, such as the incompressible Euler and Navier-Stokes equations [2, 5, 6, 7, the porous medium equations [4, the Monge-Ampère equations [15], the active scalar equations [18], and most recently, the wild solutions to elliptic equations including the $p$-Laplacian equation [3, 8], to just list a few.

In this paper, we focus on the systems given by $\sigma(A)=D F(A)$ with strongly polyconvex functions $F: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}$ in the sense that

$$
\begin{equation*}
F(A)=\frac{\nu}{2}|A|^{2}+G(\Gamma(A)), \tag{1.5}
\end{equation*}
$$

where $\nu>0, \Gamma(A) \in \mathbb{R}^{r}$ is an ordered $r$-tuple of certain subdeterminants of $A$, and $G: \mathbb{R}^{r} \rightarrow \mathbb{R}$ is a smooth convex function. For such a function $F$, condition (1.3) is automatically satisfied for $\sigma=D F$, and system (1.1) becomes the $L^{2}$-gradient flow of energy functional $I(u)=\int_{\Omega} F(D u(x)) d x$.

Some basic structures of the set $\mathcal{K}$ that are useful for the convex integration of (1.4) can be elucidated by the rank-one matrices in the full spacetime gradient space of $(u, v)$. However, condition (1.3) rules out nontrivial rank-one connections in a full gradient set that contains $\mathcal{K}$ as its diagonal projection, and thus other rank-one convex hull structures are needed. Indeed, as in [22], we consider the $T_{N}$-configurations in the full gradient space and then project them onto the diagonal to obtain the so-called $\tau_{N^{-}}$ configurations in the space of $\mathcal{K}$. We remark that the $T_{4}$-configuration was
discovered independently by several authors in different contexts and was used in [20] to study separately convex functions. The $T_{4}$-configuration and its generalization of $T_{N}$-configurations (see [13]) have been greatly explored and applied in constructing wild solutions for elliptic systems in [17, 19] and for parabolic systems in [16, 22].

Based on the work [22], we introduce a structural condition, called Condition $(O C)_{N}$ (see Definition [2.2), which requires that certain parametrized family of $\tau_{N}$-configurations be supported on the set $\mathcal{K}$ and satisfy some openness conditions. It turns out that this condition is sufficient for constructing nowhere- $C^{1}$ Lipschitz weak solutions of system (1.1); the proof of such a sufficiency will be published elsewhere [23]. For the counterexamples concerning polyconvex gradient flows, the question is reduced to a system with two equations; i.e., $m=2$. (See Section 3.) We present a general parametrization for some special $\tau_{N}$-configurations in $\mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$ and show that the graph of $D F$ for a polyconvex function $F$ can support such special $\tau_{N}$-configurations easily when $n \geq 4$. (See Section 4.) The result is also true when $n=2$ (see [22]), but for $n=3$ some more complicated calculations are necessary that cannot be done by hand. Finally we elaborate on the main steps toward the verification of Condition $(O C)_{N}$, including the dimension $n=2$. (See Section 5.) The only difficulties encountered would be the verification of several rational or analytic functions being not identically zero; these verifications may require some necessary calculations.

## 2. The $\tau_{N}$-Configurations and Condition $(O C)_{N}$

We first recall the definition of $\tau_{N}$-configurations introduced in [22, Definition 3.1].

Definition 2.1. Let $N>1$. An ordered $N$-tuple $\left(\xi_{1}, \xi_{2}, \ldots, \xi_{N}\right)$ in $\mathbb{R}^{m \times n} \times$ $\mathbb{R}^{m \times n}$ is called a $\tau_{N}$-configuration provided that there exist $\rho \in \mathbb{R}^{m \times n} \times$ $\mathbb{R}^{m \times n}, \kappa_{i}>1$ and $\gamma_{i}=\left(p_{i} \otimes a_{i}, s_{i} B_{i}\right)$, for $i=1, \cdots, N$, such that

$$
\left\{\begin{align*}
& \xi_{1}=\rho+\kappa_{1} \gamma_{1}  \tag{2.1}\\
& \xi_{2}=\rho+\gamma_{1}+\kappa_{2} \gamma_{2} \\
& \vdots \\
& \xi_{N}=\rho+\gamma_{1}+\cdots+\gamma_{N-1}+\kappa_{N} \gamma_{N}
\end{align*}\right.
$$

where $p_{i} \in \mathbb{R}^{m}, a_{i} \in \mathbb{R}^{n}, s_{i} \in \mathbb{R}$ and $B_{i} \in \mathbb{R}^{m \times n}$ satisfy

$$
\left\{\begin{array}{l}
B_{i} a_{i}=0, \quad\left(\left|p_{i}\right|+\left|B_{i}\right|\right)\left(\left|a_{i}\right|+\left|s_{i}\right|\right) \neq 0 \quad \forall i=1, \cdots, N,  \tag{2.2}\\
\sum_{i=1}^{N} p_{i} \otimes a_{i}=0, \quad \sum_{i=1}^{N} B_{i} \otimes a_{i}=0, \quad \sum_{i=1}^{N} s_{i} p_{i}=0, \quad \sum_{i=1}^{N} s_{i} B_{i}=0 .
\end{array}\right.
$$

Let $\pi_{1}=\rho, \pi_{i}=\rho+\gamma_{1}+\cdots+\gamma_{i-1}$ for $i=2, \cdots, N$, and $\chi_{i}=\frac{1}{\kappa_{i}} \in(0,1)$. Then, in terms of $\chi_{i}, \xi_{i}$ and $\pi_{i}$, the $\tau_{N}$-configuration (2.1) is equivalent to

$$
\left\{\begin{array}{l}
\pi_{i+1}-\pi_{i}=\gamma_{i}  \tag{2.3}\\
\pi_{i+1}=\chi_{i} \xi_{i}+\left(1-\chi_{i}\right) \pi_{i}
\end{array} \quad \forall i \bmod N\right.
$$

where $\gamma_{i}=\left(p_{i} \otimes a_{i}, s_{i} B_{i}\right)$ with $\left\{\left(p_{i}, a_{i}, s_{i}, B_{i}\right)\right\}_{i=1}^{N}$ satisfying (2.2).
(See Figure 1 for an illustration of a $\tau_{5}$-configuration.)

Figure 1. An illustration of a $\tau_{5}$-configuration $\left(\xi_{1}, \cdots, \xi_{5}\right)$
We now define the Condition $(O C)_{N}$ as a detailed refinement of Condition (OC) introduced in [22, Definition 3.2].
Definition 2.2. Let $\sigma: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}^{m \times n}$ and $\mathcal{K}=\left\{(A, \sigma(A)): A \in \mathbb{R}^{m \times n}\right\}$ be the graph of $\sigma$ in $\mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}$. Given $N>1$, we say that $\sigma$ satisfies Condition $(O C)_{N}$ provided that there exist smooth functions

$$
\chi_{i}: \overline{\mathbb{B}}_{r}(0) \rightarrow\left[\nu_{0}, \nu_{1}\right], \quad \xi_{i}: \overline{\mathbb{B}}_{r}(0) \rightarrow \mathcal{K}, \quad \pi_{i}: \overline{\mathbb{B}}_{r}(0) \rightarrow \mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}
$$

for $i=1, \cdots, N$, where $\overline{\mathbb{B}}_{r}(0)$ is a closed ball in $\mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}$ and $0<\nu_{0}<$ $\nu_{1}<1$ are some numbers, with the following properties:
(P1) $\pi_{1}(\rho)=\rho$ for all $\rho \in \overline{\mathbb{B}}_{r}(0), \pi_{i}\left(\mathbb{B}_{r}(0)\right)$ is open for $1 \leq i \leq N$, and $\xi_{i}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right) \cap \xi_{j}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right)=\pi_{i}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right) \cap \pi_{j}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right)=\emptyset \quad \forall i \neq j$, where $\eta^{1} \in \mathbb{R}^{m \times n}$ is the projection of $\eta=\left(\eta^{1}, \eta^{2}\right) \in \mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}$.
(P2) There exist smooth functions $p_{i}(\rho) \in \mathbb{R}^{m}, a_{i}(\rho) \in \mathbb{R}^{n}, s_{i}(\rho) \in \mathbb{R}$ and $B_{i}(\rho) \in \mathbb{R}^{m \times n}$ on $\rho \in \overline{\mathbb{B}}_{r}(0)$, for $i=1, \cdots, N$, such that condition (2.2) is satisfied point-wise on $\rho \in \overline{\mathbb{B}}_{r}(0)$ and, for $\gamma_{i}(\rho)=\left(p_{i}(\rho) \otimes\right.$ $\left.a_{i}(\rho), s_{i}(\rho) B_{i}(\rho)\right)$ and $\rho \in \overline{\mathbb{B}}(0)$, it follows that

$$
\left\{\begin{array}{l}
\pi_{i+1}(\rho)-\pi_{i}(\rho)=\gamma_{i}(\rho) \\
\pi_{i+1}(\rho)=\chi_{i}(\rho) \xi_{i}(\rho)+\left(1-\chi_{i}(\rho)\right) \pi_{i}(\rho)
\end{array} \quad \forall i \bmod N\right.
$$

(P3) For $0 \leq \lambda \leq 1$ and $1 \leq i \leq N$, define the subsets in $\mathbb{R}^{m \times n} \times \mathbb{R}^{m \times n}$ :

$$
\left\{\begin{array}{l}
S_{i}(\lambda)=\left\{\lambda \xi_{i}(\rho)+(1-\lambda) \pi_{i}(\rho): \rho \in \mathbb{B}_{r}(0)\right\} \\
K(\lambda)=\cup_{i=1}^{N} S_{i}(\lambda) \\
\Sigma(0)=K(0), \quad \Sigma(\lambda)=\cup_{0 \leq \lambda^{\prime}<\lambda} K\left(\lambda^{\prime}\right) \quad \forall 0<\lambda \leq 1
\end{array}\right.
$$

Then $\Sigma(\lambda)$ is open for all $\lambda \in[0,1]$; moreover, there is a number $\delta_{1} \in(0,1)$ such that $\left\{S_{i}(\lambda)\right\}_{i=1}^{N}$ is a family of disjoint open sets for each $\lambda \in\left[\delta_{1}, 1\right)$.
We state the following theorem, which guarantees the existence of nowhere$C^{1}$ Lipschitz weak solutions to the initial boundary value problem for system (1.1) under the assumption of Condition $(O C)_{N}$. The proof of this theorem will be given elsewhere; see [23] for the case $m=n=2$.

Theorem 2.1. Let $\sigma$ be locally Lipschitz and satisfy Condition $(O C)_{N}$ for some $N>1$. Then for any $(\bar{u}, \bar{v}) \in C^{1}\left(\bar{\Omega}_{T} ; \mathbb{R}^{m} \times \mathbb{R}^{m \times n}\right)$ satisfying

$$
\begin{equation*}
\bar{u}=\operatorname{div} \bar{v}, \quad\left(D \bar{u}, \partial_{t} \bar{v}\right) \in \Sigma(\bar{\lambda}) \quad \text { on } \bar{\Omega}_{T}, \tag{2.4}
\end{equation*}
$$

where $0<\bar{\lambda}<1$, and $\delta>0$, the full Dirichlet problem

$$
\left\{\begin{array}{l}
\partial_{t} u=\operatorname{div} \sigma(D u) \text { on } \Omega_{T},  \tag{2.5}\\
\left.u\right|_{\partial \Omega_{T}}=\bar{u}
\end{array}\right.
$$

possesses a Lipschitz weak solution $u$ with $\|u-\bar{u}\|_{L^{\infty}}+\left\|\partial_{t} u-\partial_{t} \bar{u}\right\|_{L^{\infty}}<\delta$ such that $D u$ is not essentially continuous at any point of $\Omega_{T}$.

## 3. Counterexamples for polyconvex gradient flows

We consider the following problem concerning nowhere- $C^{1}$ Lipschitz solutions to the initial boundary value problem of polyconvex gradient flows.

Problem 3.1. Given $m, n \geq 2$, find a function $F: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}$ of the form

$$
\begin{equation*}
F(A)=\frac{\nu}{2}|A|^{2}+G(\Gamma(A)) \tag{3.1}
\end{equation*}
$$

where $\nu>0, \Gamma(A) \in \mathbb{R}^{r}$ is an ordered $r$-tuple of certain subdeterminants of $A$, and $G: \mathbb{R}^{r} \rightarrow \mathbb{R}$ is a smooth convex function, such that the initial boundary value problem

$$
\left\{\begin{array}{l}
\partial_{t} u=\operatorname{div} D F(D u) \text { in } \Omega_{T},  \tag{3.2}\\
\left.u\right|_{\partial^{\prime} \Omega_{T}}=0
\end{array}\right.
$$

where $\partial^{\prime} \Omega_{T}=(\Omega \times\{0\}) \cup(\partial \Omega \times(0, T))$ is the parabolic boundary of $\Omega_{T}$, possesses infinitely many Lipschitz weak solutions for which $D u$ is nowhere essentially continuous in $\Omega_{T}$.

Problem 3.1 can be reduced to the case $m=2$ as follows. Let $m>2$. Consider

$$
F(A)=\frac{\nu}{2}|A|^{2}+G\left(A_{1}, J\left(A_{1}\right)\right) \quad \forall A \in \mathbb{R}^{m \times n}
$$

where $A_{1} \in \mathbb{R}^{2 \times n}$ is the submatrix of first two rows of $A$ and $J\left(A_{1}\right) \in \mathbb{R}^{r}$ is an ordered $r$-tuple of certain $2 \times 2$ subdeterminants of $A_{1}$. Then

$$
D F(A)=\nu A+\left[\begin{array}{c}
G_{A_{1}}\left(\tilde{A}_{1}\right) \\
O
\end{array}\right]+\left[\begin{array}{c}
G_{J}\left(\tilde{A}_{1}\right) D J\left(A_{1}\right) \\
O
\end{array}\right]
$$

where $\tilde{A}_{1}=\left(A_{1}, J\left(A_{1}\right)\right)$. Let

$$
\tilde{F}\left(A_{1}\right)=\frac{\nu}{2}\left|A_{1}\right|^{2}+G\left(A_{1}, J\left(A_{1}\right)\right) \quad \forall A_{1} \in \mathbb{R}^{2 \times n} .
$$

Consider functions $u=(\tilde{u}, 0, \cdots, 0)$, where $\tilde{u}=\left(u^{1}, u^{2}\right): \Omega_{T} \rightarrow \mathbb{R}^{2}$. We have

$$
\partial_{t} u=\left[\begin{array}{c}
\partial_{t} \tilde{u} \\
0
\end{array}\right], \quad D u=\left[\begin{array}{c}
D \tilde{u} \\
O
\end{array}\right], \quad D F(D u)=\left[\begin{array}{c}
D \tilde{F}(D \tilde{u}) \\
O
\end{array}\right] .
$$

For such functions, problem (3.2) is equivalent to the zero initial boundary value problem for system $\partial_{t} \tilde{u}=\operatorname{div} D \tilde{F}(D \tilde{u})$. This reduces the question to the case $m=2$. However, there seems no way to reduce the dimension $n$.

In what follows, we consider functions $F: \mathbb{R}^{2 \times n} \rightarrow \mathbb{R}$ of the form

$$
\begin{equation*}
F(A)=\frac{\epsilon}{2}|A|^{2}+G(A, J(A)) \quad \forall A \in \mathbb{R}^{2 \times n}, \tag{3.3}
\end{equation*}
$$

where $\epsilon>0, J(A) \in \mathbb{R}^{d}$ is an ordered $d$-tuple of all $2 \times 2$ subdeterminants of $A$, with $d=n(n-1) / 2$, and $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ is a smooth function. Thus

$$
D F(A)=\epsilon A+G_{A}(\tilde{A})+G_{J}(\tilde{A}) D J(A),
$$

where $\tilde{A}=(A, J(A))$.
By virtue of Theorem [2.1, the resolution of Problem 3.1 relies on constructing functions $F: \mathbb{R}^{2 \times n} \rightarrow \mathbb{R}$ of the form (3.3) with smooth convex $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that $\sigma=D F$ satisfies Condition $(O C)_{N}$.

## 4. Polyconvex functions supporting special $\tau_{N}$-Configurations

In this section, we construct a polyconvex function $F_{0}: \mathbb{R}^{2 \times n} \rightarrow \mathbb{R}$ of the form (3.3) with smooth convex $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that the graph $\mathcal{K}_{F_{0}}$ of $\sigma=D F_{0}$ contains a special $\tau_{N}$-configuration for some $N>1$.
4.1. Parametrizing some special $\tau_{N}$-configurations. We consider some special $\tau_{N}$-configurations in $\mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$.

First, we modify the second condition in the first line of condition (2.2) by considering the elements $\left\{\left(p_{i}, a_{i}, B_{i}, s_{i}\right)\right\}_{i=1}^{N}$ in $\mathbb{R}^{2} \times \mathbb{R}^{n} \times \mathbb{R}^{2 \times n} \times \mathbb{R}$ satisfying

$$
\left\{\begin{array}{l}
B_{i} a_{i}=0, \quad\left|p_{i}\right|\left|a_{i}\right| \neq 0 \quad \forall i=1, \cdots, N,  \tag{4.1}\\
\sum_{i=1}^{N} p_{i} \otimes a_{i}=0, \quad \sum_{i=1}^{N} B_{i} \otimes a_{i}=0, \\
\sum_{i=1}^{N} s_{i} p_{i}=0, \quad \sum_{i=1}^{N} s_{i} B_{i}=0 .
\end{array}\right.
$$

Second, we observe that if $s_{i}=a_{i} \cdot q$ for all $i=1, \cdots, N$, where $q \in \mathbb{R}^{n}$ is a fixed nonzero vector, then the third-lined conditions of (4.1) will follow
automatically from the second-lined conditions. So, we will focus on such special $\tau_{N}$-configurations.

To explicitly parametrize the first-lined and second-lined conditions of (4.1), we define for all $r=1,2, \cdots, n$ and $\mathbf{x}, \mathbf{y}, \mathbf{z} \in \mathbb{R}^{n-1}$,

$$
\left\{\begin{array}{l}
\alpha_{r}(\mathbf{x})=\left(x_{1}, \cdots, x_{r-1}, 1, x_{r}, \cdots, x_{n-1}\right)^{T} \in \mathbb{R}^{n},  \tag{4.2}\\
b_{r}(\mathbf{x}, \mathbf{y})=\left(y_{1}, \cdots, y_{r-1},-(\mathbf{x} \cdot \mathbf{y}), y_{r}, \cdots, y_{n-1}\right) \in\left(\mathbb{R}^{n}\right)^{T}, \\
\beta_{r}(\mathbf{x}, \mathbf{y}, \mathbf{z})=\left[\begin{array}{l}
b_{r}(\mathbf{x}, \mathbf{y}) \\
b_{r}(\mathbf{x}, \mathbf{z})
\end{array}\right]
\end{array}\right.
$$

where $\mathbf{x}=\left(x_{1}, \cdots, x_{n-1}\right)$, etc. Then

$$
\beta_{r}(\mathbf{x}, \mathbf{y}, \mathbf{z}) \alpha_{r}(\mathbf{x})=0 \quad \forall \mathbf{x}, \mathbf{y}, \mathbf{z} \in \mathbb{R}^{n-1}, \quad r=1, \cdots, n
$$

Assume $N \geq n+3$ and let $r_{1}, \cdots, r_{N} \in\{1, \cdots, n\}$ be such that

$$
r_{i}=i \bmod n \quad \forall i=1, \cdots, N .
$$

Given $\mathbf{x}_{i}, \mathbf{y}_{i}, \mathbf{z}_{i} \in \mathbb{R}^{n-1}$ and $p_{i} \in \mathbb{R}^{2}$ for $i=1, \cdots, N$, let

$$
a_{i}=\alpha_{r_{i}}\left(\mathbf{x}_{i}\right), \quad B_{i}=\beta_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}, \mathbf{z}_{i}\right)
$$

For such $a_{i}$ and $B_{i}$, we write the second-lined conditions of (4.1) as

$$
\begin{equation*}
\sum_{i=1}^{n} p_{i} \otimes a_{i}=-\sum_{j=n+1}^{N} p_{j} \otimes a_{j}, \quad \sum_{i=1}^{n+1} B_{i} \otimes a_{i}=-\sum_{j=n+2}^{N} B_{j} \otimes a_{j} . \tag{4.3}
\end{equation*}
$$

Define

$$
\begin{equation*}
\Delta\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)=\operatorname{det}\left[\alpha_{1}\left(\mathbf{x}_{1}\right) \alpha_{2}\left(\mathbf{x}_{2}\right) \cdots \alpha_{n}\left(\mathbf{x}_{n}\right)\right] \tag{4.4}
\end{equation*}
$$

which is a nonzero polynomial in $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)$. If $\Delta\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right) \neq 0$, then from the first equation of (4.3), we can solve for $p_{1}, \cdots, p_{n}$ to obtain

$$
\begin{equation*}
p_{i}=\sum_{j=n+1}^{N} \frac{S_{i j}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)}{\Delta\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right)} p_{j} \quad \forall i=1, \cdots, n \tag{4.5}
\end{equation*}
$$

where all the coefficients $S_{i j}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)$ are polynomials of $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)$.
Since $B_{i} \otimes a_{i}=\binom{b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)}{b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{z}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)}$ and $b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)=0$, we have

$$
\begin{equation*}
\left(b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)\right)_{11}=-\sum_{j=2}^{n}\left(b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)\right)_{j j} \tag{4.6}
\end{equation*}
$$

for all $i=1, \cdots, N$; the same holds for $\left(b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{z}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)\right)_{11}$. The second equation of (4.3) is equivalent to two sets of equations:

$$
\begin{equation*}
\sum_{i=1}^{n+1} b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)=-\sum_{j=n+2}^{N} b_{r_{j}}\left(\mathbf{x}_{j}, \mathbf{y}_{j}\right) \otimes \alpha_{r_{j}}\left(\mathbf{x}_{j}\right) \tag{4.7}
\end{equation*}
$$

$$
\begin{equation*}
\sum_{i=1}^{n+1} b_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{z}_{i}\right) \otimes \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)=-\sum_{j=n+2}^{N} b_{r_{j}}\left(\mathbf{x}_{j}, \mathbf{z}_{j}\right) \otimes \alpha_{r_{j}}\left(\mathbf{x}_{j}\right) . \tag{4.8}
\end{equation*}
$$

Because of (4.6), both (4.7) and (4.8) are the same linear system of $\left(n^{2}-\right.$ 1) equations for $(n+1)(n-1)=\left(n^{2}-1\right)$ variables $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{n+1}\right\}$ and $\left\{\mathbf{z}_{1}, \cdots, \mathbf{z}_{n+1}\right\}$, respectively. If we order $\left\{\mathbf{y}_{1}, \cdots, \mathbf{y}_{n+1}\right\}$ as

$$
\mathbf{y}^{\prime}=\left(y_{11}, \cdots, y_{1(n-1)} ; y_{21}, \cdots, y_{2(n-1)} ; \cdots ; y_{(n+1) 1}, \cdots, y_{(n+1)(n-1)}\right)
$$

as a vector in $\mathbb{R}^{n^{2}-1}$, then the coefficient matrix $A$ of system (4.7) is a square $\left(n^{2}-1\right) \times\left(n^{2}-1\right)$ matrix $A=A\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \cdots, \mathbf{x}_{n+1}\right)$ whose entries are all polynomials of $\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \cdots, \mathbf{x}_{n+1}\right)$ of degree at most 2 . Define

$$
\begin{equation*}
T\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right)=\operatorname{det} A\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right) \tag{4.9}
\end{equation*}
$$

which is a nonzero polynomial in $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right)$. If $T\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right) \neq 0$, then we can solve $\mathbf{y}^{\prime}=\left(\mathbf{y}_{1}, \cdots, \mathbf{y}_{n+1}\right)$ from (4.7) to obtain

$$
\begin{equation*}
\mathbf{y}^{\prime}=\frac{L\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)\left(\mathbf{y}_{n+2}, \cdots, \mathbf{y}_{N}\right)}{T\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right)} \tag{4.10}
\end{equation*}
$$

where $L\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)$ is a linear mapping on $\left(\mathbf{y}_{n+2}, \cdots, \mathbf{y}_{N}\right)$ with all coefficients being polynomials of $\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)$. In the same way, we have

$$
\begin{equation*}
\mathbf{z}^{\prime}=\frac{L\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)\left(\mathbf{z}_{n+2}, \cdots, \mathbf{z}_{N}\right)}{T\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right)} \tag{4.11}
\end{equation*}
$$

Let $\mathcal{V}$ be the set of elements $(P, X)$ with $P=\left(p_{n+1}, \cdots, p_{N}\right) \in\left(\mathbb{R}^{2}\right)^{N-n}$ and $X=\left(\mathrm{x}_{1}, \cdots, \mathrm{x}_{N}\right) \in\left(\mathbb{R}^{n-1}\right)^{N}$ satisfying

$$
\left\{\begin{array}{l}
\Delta\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n}\right) \neq 0  \tag{4.12}\\
T\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{n+1}\right) \neq 0 \\
p_{j} \neq 0 \quad \forall j=n+1, \cdots, N \\
\sum_{j=n+1}^{N} S_{i j}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right) p_{j} \neq 0 \quad \forall i=1, \cdots, n,
\end{array}\right.
$$

where $S_{i j}\left(\mathbf{x}_{1}, \cdots, \mathbf{x}_{N}\right)$ are the polynomials defined in (4.5). Since all $\Delta, T$, $p_{j}$ and $\sum_{j=n+1}^{N} S_{i j} p_{j}$ are nonzero polynomials in $(P, X)$, it follows that $\mathcal{V}$ is a nonempty open dense set in $\left(\mathbb{R}^{2}\right)^{N-n} \times\left(\mathbb{R}^{n-1}\right)^{N}$.

Define $\mathcal{U}$ to be the set of all elements

$$
\begin{equation*}
U=\left(P, X, Y, Z, b, \kappa_{1}, \cdots, \kappa_{N}\right), \tag{4.13}
\end{equation*}
$$

where $(P, X) \in \mathcal{V}, Y=\left(\mathbf{y}_{n+2}, \cdots, \mathbf{y}_{N}\right)$ and $Z=\left(\mathbf{z}_{n+2}, \cdots, \mathbf{z}_{N}\right)$ with $\mathbf{y}_{j}, \mathbf{z}_{j} \in \mathbb{R}^{n-1}$ for $n+2 \leq j \leq N, b \in \mathbb{R}^{n-2}$, and $\kappa_{i}>1$ for $1 \leq i \leq N$. Then $\mathcal{U}$ is an open set in $\mathbb{R}^{D}$, where the total dimension $D$ equals

$$
2(N-n)+N(n-1)+2(N-n-1)(n-1)+(n-2)+N=3 n N-2 n^{2}-n .
$$

For each $U \in \mathcal{U}$ given by (4.13), we define $p_{i}=p_{i}(U)=p_{i}(P, X)$ for $i=1, \cdots, n$ by formula (4.5) and define $\mathbf{y}^{\prime}=\mathbf{y}^{\prime}(U)=\mathbf{y}^{\prime}(X, Y)$ and $\mathbf{z}^{\prime}=$ $\mathbf{z}^{\prime}(U)=\mathbf{z}^{\prime}(X, Z)$ by formulas (4.10) and (4.11). In this way, we obtain

$$
\begin{equation*}
p_{i}=p_{i}(U) \in \mathbb{R}^{2} \backslash\{0\}, \quad \mathbf{y}_{i}=\mathbf{y}_{i}(U) \in \mathbb{R}^{n-1}, \quad \mathbf{z}_{i}=\mathbf{z}_{i}(U) \in \mathbb{R}^{n-1} \tag{4.14}
\end{equation*}
$$

for all $i=1, \cdots, N$. Also define $q(U)=q(b)=\left(1,1, b_{1}, \cdots, b_{n-2}\right)^{T} \in \mathbb{R}^{n}$ if $b=\left(b_{1}, \cdots, b_{n-2}\right)^{T} \in \mathbb{R}^{n-2}$. Finally we define

$$
\left\{\begin{array}{l}
a_{i}(U)=\alpha_{r_{i}}\left(\mathbf{x}_{i}\right)  \tag{4.15}\\
B_{i}(U)=\beta_{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U), \mathbf{z}_{i}(U)\right), \\
s_{i}(U)=a_{i}(U) \cdot q(b) \\
\gamma_{i}(U)=\left(p_{i}(U) \otimes a_{i}(U), s_{i}(U) B_{i}(U)\right),
\end{array} \quad \forall i=1, \cdots, N\right.
$$

Note that all these functions are independent of $\left(\kappa_{1}, \cdots, \kappa_{N}\right)$.
Let

$$
\left\{\begin{array}{l}
\eta_{1}(U)=\kappa_{1} \gamma_{1}(U)  \tag{4.16}\\
\eta_{2}(U)=\gamma_{1}(U)+\kappa_{2} \gamma_{2}(U) \\
\quad \vdots \\
\eta_{N}(U)
\end{array}\right)=\gamma_{1}(U)+\gamma_{2}(U)+\cdots+\gamma_{N-1}(U)+\kappa_{N} \gamma_{N}(U) \text {. }
$$

We summarize the constructions above in the following result.
Proposition 4.1. For each $U \in \mathcal{U}$, the $N$-tuple $\left(\eta_{1}(U), \eta_{2}(U), \cdots, \eta_{N}(U)\right)$
 $\eta_{i}^{1}(U)$ is linear in $P$ with coefficients rational functions of $\left(X, \kappa_{1}, \cdots, \kappa_{N}\right)$, and each $\eta_{i}^{2}(U)$ is linear in $(Y, Z)$ with coefficients rational functions of $\left(X, b, \kappa_{1}, \cdots, \kappa_{N}\right)$.

The following result will be useful later.
Lemma 4.2. $\operatorname{Let} \zeta_{i}(U)=\kappa_{i} \gamma_{i}(U)$ for $i=1, \cdots, N$. Then

$$
\operatorname{rank} D \zeta_{i}(U) \leq 3 n-1
$$

Proof. Write $\zeta_{i}(U) \in \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$ as a column vector in $\mathbb{R}^{4 n}$ :

$$
\zeta_{i}(U)=\left[\begin{array}{c}
f(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right) \\
g(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right) \\
h(U) b_{r_{i}}^{T}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U)\right) \\
h(U) b_{r_{i}}^{T}\left(\mathbf{x}_{i}, \mathbf{z}_{i}(U)\right)
\end{array}\right]
$$

where $f(U)=\kappa_{i} p_{i}^{1}(U), g(U)=\kappa_{i} p_{i}^{2}(U)$ and $h(U)=\kappa_{i} s_{i}(U)$. Since $p_{i}(U) \neq$ 0 , without loss of generality, we assume $f(U) \neq 0$. Note that

$$
\begin{aligned}
D\left(f(U) \alpha_{r_{i}}^{j}\left(\mathbf{x}_{i}\right)\right) & =f D \alpha_{r_{i}}^{j}+\alpha_{r_{i}}^{j} D f \quad \forall j \neq r_{i} \\
D\left(f(U) \alpha_{r_{i}}^{r_{i}}\left(\mathbf{x}_{i}\right)\right) & =D f \quad\left(\text { since } \alpha_{r_{i}}^{r_{i}}\left(\mathbf{x}_{i}\right)=1\right)
\end{aligned}
$$

After elementary row operations, we have the following row equivalence:

$$
D\left[f(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)\right] \sim\left[\begin{array}{c}
f(U) D \alpha_{r_{i}}^{\prime}\left(\mathbf{x}_{i}\right) \\
D f(U)
\end{array}\right] \sim\left[\begin{array}{c}
f(U) D \mathbf{x}_{i} \\
D f(U)
\end{array}\right],
$$

where $\alpha_{r_{i}}^{\prime}=\left(\alpha_{r_{i}}^{j}\right)_{j \neq r_{i}}$. Similarly,

$$
D\left[g(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)\right] \sim\left[\begin{array}{c}
g(U) D \mathbf{x}_{i} \\
D g(U)
\end{array}\right]
$$

and thus

$$
D\left[\begin{array}{l}
f(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right) \\
g(U) \alpha_{r_{i}}\left(\mathbf{x}_{i}\right)
\end{array}\right] \sim\left[\begin{array}{c}
f(U) D \mathbf{x}_{i} \\
D f(U) \\
g(U) D \mathbf{x}_{i} \\
D g(U)
\end{array}\right] \sim\left[\begin{array}{c}
f(U) D \mathbf{x}_{i} \\
D f(U) \\
D g(U)
\end{array}\right]
$$

Note that by interchanging rows, we have $b_{r_{i}}^{\prime}(\mathbf{x}, \mathbf{y}) \sim \mathbf{y}$, where $b_{r_{i}}^{\prime}=\left(b_{r_{i}}^{j}\right)_{j \neq r_{i}}$ and $b_{r_{i}}^{r_{i}}(\mathbf{x}, \mathbf{y})=-(\mathbf{x} \cdot \mathbf{y})$. Thus

$$
\begin{gathered}
D\left[h(U) b_{r_{i}}^{\prime}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U)\right)\right] \sim h(U) D \mathbf{y}_{i}(U)+\mathbf{y}_{i}(U) \otimes D h(U), \\
D\left[h(U) b_{r_{i}}^{r_{i}}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U)\right)\right]=-h(U) D\left(\mathbf{x}_{i} \cdot \mathbf{y}_{i}(U)\right)-\left(\mathbf{x}_{i} \cdot \mathbf{y}_{i}(U)\right) D h(U) .
\end{gathered}
$$

After elementary row operations and using $D\left(\mathbf{x}_{i} \cdot \mathbf{y}_{i}(U)\right)=\mathbf{x}_{i} \cdot D \mathbf{y}_{i}(U)+$ $\mathbf{y}_{i}(U) D \mathbf{x}_{i}$, we have

$$
D\left[h(U) b_{r_{i}}^{T}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U)\right)\right] \sim\left[\begin{array}{c}
h(U) D \mathbf{y}_{i}(U)+\mathbf{y}_{i}(U) \otimes D h(U) \\
h(U) \mathbf{y}_{i}(U) \cdot D \mathbf{x}_{i}
\end{array}\right] .
$$

(There is no row cancellation here!) Thus

$$
D\left[\begin{array}{c}
h(U) b_{r_{i}}^{T}\left(\mathbf{x}_{i}, \mathbf{y}_{i}(U)\right) \\
h(U) b_{r_{i}}^{T}\left(\mathbf{x}_{i}, \mathbf{z}_{i}(U)\right)
\end{array}\right] \sim\left[\begin{array}{c}
h(U) D \mathbf{y}_{i}(U)+\mathbf{y}_{i}(U) \otimes D h(U) \\
h(U) \mathbf{y}_{i}(U) \cdot D \mathbf{x}_{i} \\
h(U) D \mathbf{z}_{i}(U)+\mathbf{z}_{i}(U) \otimes D h(U) \\
h(U) \mathbf{z}_{i}(U) \cdot D \mathbf{x}_{i}
\end{array}\right] .
$$

Since both $h(U) \mathbf{y}_{i}(U) \cdot D \mathbf{x}_{i}$ and $h(U) \mathbf{z}_{i}(U) \cdot D \mathbf{x}_{i}$ can be cancelled by $f(U) D \mathbf{x}_{i}$, we finally have

$$
D \zeta_{i}(U) \sim\left[\begin{array}{c}
f(U) D \mathbf{x}_{i} \\
D f(U) \\
D g(U) \\
h(U) D \mathbf{y}_{i}(U)+\mathbf{y}_{i}(U) \otimes D h(U) \\
h(U) D \mathbf{z}_{i}(U)+\mathbf{z}_{i}(U) \otimes D h(U)
\end{array}\right],
$$

which has $(3 n-1)$ rows. This completes the proof.
4.2. Embedding $\tau_{N}$-configurations onto the graph of $D F$. Our goal is to embed a parameterized family of $\tau_{N}$-configurations of the form

$$
\left(\rho+\eta_{1}(U), \rho+\eta_{2}(U), \cdots, \rho+\eta_{N}(U)\right),
$$

where $\rho \in \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$ and $U \in \mathcal{U}$, onto the graph $\mathcal{K}_{F}$ of $D F$ for some function $F$ of the form (3.3) with a convex $G$. To this end, let $\Phi(A, B)=$ $D F(A)-B$ and we try to solve

$$
\Psi(\rho, U):=\left(\Phi\left(\rho+\eta_{1}(U)\right), \cdots, \Phi\left(\rho+\eta_{N}(U)\right)\right)=0 \in \mathbb{R}^{2 n N} .
$$

If we would like to apply the implicit function theorem to solve for $U$ in terms of $\rho$, then it is necessary that

$$
\begin{equation*}
D=\operatorname{dim} \mathcal{U}=2 n N ; \quad \text { thus, } N=2 n+1 \tag{4.17}
\end{equation*}
$$

In what follows, let $N=2 n+1$ and we first try to embed one $\tau_{N^{-}}$ configuration $\left(\eta_{1}(U), \eta_{2}(U), \cdots, \eta_{N}(U)\right)$ onto the graph $\mathcal{K}_{F}$ for some $U \in \mathcal{U}$; that is,

$$
\begin{equation*}
\Phi\left(\eta_{i}(U)\right)=0 \quad \forall i=1, \cdots, N . \tag{4.18}
\end{equation*}
$$

Since $\Phi(A, B)=\epsilon A+G_{A}(\tilde{A})+G_{J}(\tilde{A}) D J(A)-B$, where $\tilde{A}=(A, J(A)) \in$ $\mathbb{R}^{2 \times n} \times \mathbb{R}^{d}$, condition (4.18) is equivalent to that for all $i=1, \cdots, N$,

$$
\begin{equation*}
G_{A}\left(\tilde{\eta}_{i}^{1}(U)\right)=\eta_{i}^{2}(U)-\epsilon \eta_{i}^{1}(U)-G_{J}\left(\tilde{\eta}_{i}^{1}(U)\right) D J\left(\eta_{i}^{1}(U)\right), \tag{4.19}
\end{equation*}
$$

where $\tilde{\eta}_{i}^{1}(U)=\left(\eta_{i}^{1}(U), J\left(\eta_{i}^{1}(U)\right)\right)$.
As in [19, 22], we can construct a smooth convex function $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow$ $\mathbb{R}$ such that

$$
G\left(\tilde{\eta}_{i}^{1}(U)\right)=c_{i}, \quad G_{J}\left(\tilde{\eta}_{i}^{1}(U)\right)=d_{i}, \quad G_{A}\left(\tilde{\eta}_{i}^{1}(U)\right)=Q_{i} \quad \forall i=1, \cdots, N
$$

provided that the quantities $\left\{c_{i}, d_{i}, Q_{i}\right\}_{i=1}^{N}$ satisfy

$$
\begin{equation*}
c_{j}-c_{i}>\left\langle Q_{i}, \eta_{j}^{1}(U)-\eta_{i}^{1}(U)\right\rangle+d_{i} \cdot\left[J\left(\eta_{j}^{1}(U)\right)-J\left(\eta_{i}^{1}(U)\right)\right] \tag{4.20}
\end{equation*}
$$

for all $1 \leq i \neq j \leq N$.
If $Q_{i}=G_{A}\left(\tilde{\eta}_{i}^{1}(U)\right)$ is given by (4.19) with $G_{J}\left(\tilde{\eta}_{i}^{1}(U)\right)=d_{i}$, then condition (4.20) will be satisfied for all sufficiently small $\epsilon>0$ provided that the following condition is satisfied:

$$
\begin{equation*}
c_{j}-c_{i}>\left\langle\eta_{i}^{2}(U), \eta_{j}^{1}(U)-\eta_{i}^{1}(U)\right\rangle+d_{i} \cdot J\left(\eta_{j}^{1}(U)-\eta_{i}^{1}(U)\right) \quad \forall i \neq j, \tag{4.21}
\end{equation*}
$$

where we have used the identity: $J(A)-J(B)-D J(B)(A-B)=J(A-B)$.
From the specific dependence of $\eta_{i}^{1}(U)$ and $\eta_{i}^{2}(U)$ on $U$ as described in Proposition 4.1, we see that

$$
\left\langle\eta_{i}^{2}(U), \eta_{j}^{1}(U)-\eta_{i}^{1}(U)\right\rangle=(Y, Z) \cdot \mathcal{S}_{j i}\left(P, U^{\prime}\right),
$$

where $U^{\prime}=\left(X, b, \kappa_{1}, \cdots, \kappa_{N}\right)$ and $\mathcal{S}_{j i}\left(P, U^{\prime}\right) \in \mathbb{R}^{2[(N-n-1)(n-1)]}$ are linear in $P$ with coefficients being rational functions of $U^{\prime}$. Also write $J\left(\eta_{j}^{1}(U)-\right.$ $\left.\eta_{i}^{1}(U)\right)=J_{j i}\left(P, U^{\prime}\right)$ as a quadratic function in $P$ with coefficients being rational functions of $U^{\prime}$. In this way, condition (4.21) becomes

$$
\begin{equation*}
c_{i}-c_{j}+(Y, Z) \cdot \mathcal{S}_{j i}\left(P, U^{\prime}\right)+d_{i} \cdot J_{j i}\left(P, U^{\prime}\right)<0 \quad \forall i \neq j, \tag{4.22}
\end{equation*}
$$

which consists of $N(N-1)$ homogeneous linear inequalities on the variables $\left\{\left(c_{i}, d_{i}\right)\right\}_{i=1}^{N}$ and $(Y, Z)$. The total number of the variables is

$$
N(1+d)+2(N-n-1)(n-1) .
$$

For example, if $n=2$ then (4.22) is a $20 \times 14$ system of homogeneous linear inequalities, and if $n=3$ then (4.22) is a $42 \times 40$ system, both being overdetermined; however, when $n \geq 4$ the condition (4.22) becomes underdetermined. In fact, we have the following result.
Proposition 4.3. Let $n \geq 4$ and $N=2 n+1$. Given any $\left\{c_{i}\right\}_{i=1}^{N}$, there exist $d_{1}, \cdots, d_{N}$ in $\mathbb{R}^{d}$ such that condition (4.21) is satisfied at some point $U_{0} \in \mathcal{U}$. In this case, 4.21) is also satisfied for all $U$ in a neighborhood $\mathcal{N}\left(U_{0}\right)$ of $U_{0}$ in $\mathcal{U}$ by the same $\left\{c_{i}\right\}_{i=1}^{N}$ and $\left\{d_{i}\right\}_{i=1}^{N}$.
Proof. Given $\left\{c_{i}\right\}_{i=1}^{N}$, we solve the linear system:

$$
\begin{equation*}
(Y, Z) \cdot \mathcal{S}_{j i}\left(P, U^{\prime}\right)+d_{i} \cdot J_{j i}\left(P, U^{\prime}\right)=-1-c_{i}+c_{j} \quad \forall i \neq j \tag{4.23}
\end{equation*}
$$

for unknown variables $d_{1}, \cdots, d_{N}$ and $(Y, Z)$. The total number of the unknown variables is

$$
N d+2(N-n-1)(n-1),
$$

which is greater than the number $N(N-1)$ of equations if $n \geq 4$; thus system (4.23) is underdetermined. The coefficient matrix $\mathcal{M}\left(P, U^{\prime}\right)$ of (4.23) has all entries being polynomials in $P$ and rational functions in $U^{\prime}$, and its rows have some special forms which ensure that these rows cannot be linearly dependent for all $\left(P, U^{\prime}\right)$. Thus $\mathcal{M}\left(P, U^{\prime}\right)$ will be of the full rank $N(N-1)$ for some $\left(P_{0}, U_{0}^{\prime}\right)$ with $\left(P_{0}, X_{0}\right) \in \mathcal{V}$. Fix any such $\left(P_{0}, U_{0}^{\prime}\right)$ and the system (4.23) will have solutions $\left\{d_{i}\right\}_{i=1}^{N}$ and $\left(Y_{0}, Z_{0}\right)$ that are also rational functions of $\left(\left\{c_{i}\right\}_{i=1}^{N}, P_{0}, U_{0}^{\prime}\right)$. Hence (4.22) is satisfied by $\left\{c_{i}\right\}_{i=1}^{N},\left\{d_{i}\right\}_{i=1}^{N}$ and $\left(Y_{0}, Z_{0}\right)$ at $\left(P_{0}, U_{0}^{\prime}\right)$. With $\left(P_{0}, U_{0}^{\prime}, Y_{0}, Z_{0}\right)$ we obtain $U_{0} \in \mathcal{U}$ such that condition (4.21) is satisfied at $U_{0}$ by $\left\{c_{i}\right\}_{i=1}^{N}$ and $\left\{d_{i}\right\}_{i=1}^{N}$. Clearly, (4.21) is also satisfied at all $U$ in a neighborhood $\mathcal{N}\left(U_{0}\right) \subset \mathcal{U}$ by the same $\left\{c_{i}\right\}_{i=1}^{N}$ and $\left\{d_{i}\right\}_{i=1}^{N}$.
Remark 4.1. When $n=2$ and $N=5$, it has been proved in [22] that condition (4.21) is satisfied by some $\left\{\left(c_{i}, d_{j}\right)\right\}_{i=1}^{5}$ at some point $U_{0} \in \mathcal{U}$; however, the proof requires lots of complicated calculations using MATLAB. We believe that the condition (4.21) should be feasible for $n=3$ as well, but, like in the case $n=2$, a proof would involve a considerable number of necessary complicated calculations that cannot be done easily by hand.

We summarize the constructions above in the following result.
Proposition 4.4. Suppose that condition (4.21) is satisfied by $\left\{\left(c_{i}, d_{i}\right)\right\}_{i=1}^{N}$ at some $U_{0} \in \mathcal{U}$. Then for some $\epsilon_{0}>0$ and all $\epsilon \in\left(0, \epsilon_{0}\right)$ there exists a smooth convex function $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that $G\left(\tilde{\eta}_{i}^{1}\left(U_{0}\right)\right)=c_{i}$, $G_{J}\left(\tilde{\eta}_{i}^{1}\left(U_{0}\right)\right)=d_{i}$ and $G_{A}\left(\tilde{\eta}_{i}^{1}\left(U_{0}\right)\right)$ is given by (4.19) for $i=1, \cdots, N$. Let

$$
F_{0}(A)=\frac{\epsilon}{2}|A|^{2}+G(A, J(A)) .
$$

Then $\eta_{i}\left(U_{0}\right) \in \mathcal{K}_{F_{0}}$ and $\eta_{i}^{1}\left(U_{0}\right) \neq \eta_{j}^{1}\left(U_{0}\right)$ for all $1 \leq i \neq j \leq N$.

## 5. Compatibility of polyconvexity and Condition $(O C)_{N}$.

In this section, we elaborate on the construction of function $F: \mathbb{R}^{2 \times n} \rightarrow \mathbb{R}$ of the form (3.3) with smooth convex $G: \mathbb{R}^{2 \times n} \times \mathbb{R}^{d} \rightarrow \mathbb{R}$ such that $\sigma=D F$ satisfies Condition $(O C)_{N}$.

In what follows, let $F_{0}$ be the function defined in Proposition 4.4, Note that $F_{0}$ depends on $U_{0} \in \mathcal{U}$.
5.1. Perturbing the function $F_{0}$. Let $B_{1}(0)$ be the unit ball in $\mathbb{R}^{2 \times n}$ and $\zeta \in C_{c}^{\infty}\left(B_{1}(0) ;[0,1]\right)$ be such that $\zeta(0)=1$. Given $r>0$ and tensor $H=\left(H^{p q i j}\right)$ with $H^{p q i j}=H^{i j p q} \in \mathbb{R}$ for all $i, p=1,2$ and $j, q=1, \cdots, n$, we define the function

$$
V_{H, r}(A)=\frac{1}{2} \zeta(A / r) \sum_{i, p=1}^{2} \sum_{j, q=1}^{n} H^{i j p q} a_{i j} a_{p q} \quad \forall A=\left(a_{i j}\right) \in \mathbb{R}^{2 \times n}
$$

Then $V_{H, r} \in C_{c}^{\infty}\left(\mathbb{R}^{2 \times n}\right)$ has support in $B_{r}(0)$, and

$$
\left\{\begin{array}{l}
V_{H, r}(0)=0, \quad D V_{H, r}(0)=0, \quad D^{2} V_{H, r}(0)=H  \tag{5.1}\\
\left|D^{2} V_{H, r}(A)\right| \leq C_{0}|H| \quad \forall A \in \mathbb{R}^{2 \times n}
\end{array}\right.
$$

where $C_{0}>0$ is a constant independent of $H, r$. Let

$$
r_{0}=\min _{i \neq j}\left\{\left|\eta_{i}^{1}\left(U_{0}\right)-\eta_{j}^{1}\left(U_{0}\right)\right|\right\}>0
$$

and define

$$
\begin{equation*}
F(A)=F_{0}(A)+\sum_{j=1}^{N} V_{\tilde{H}_{j}, r_{0}}\left(A-\eta_{j}^{1}\left(U_{0}\right)\right) \quad \forall A \in \mathbb{R}^{2 \times n} \tag{5.2}
\end{equation*}
$$

where $\tilde{H}_{1}, \cdots, \tilde{H}_{N}$ are to be chosen later. Then

$$
\left\{\begin{array}{l}
D F\left(\eta_{j}^{1}\left(U_{0}\right)\right)=D F_{0}\left(\eta_{j}^{1}\left(U_{0}\right)\right),  \tag{5.3}\\
D^{2} F\left(\eta_{j}^{1}\left(U_{0}\right)\right)=D^{2} F_{0}\left(\eta_{j}^{1}\left(U_{0}\right)\right)+\tilde{H}_{j} \quad \forall 1 \leq j \leq N
\end{array}\right.
$$

Thus $\eta_{j}\left(U_{0}\right) \in \mathcal{K}_{F}$ for all $j=1, \cdots, N$.
Lemma 5.1. The function $g(A)=\frac{\epsilon}{4}|A|^{2}+\sum_{j=1}^{N} V_{\tilde{H}_{j}, r_{0}}\left(A-\eta_{j}^{1}\left(U_{0}\right)\right)$ is convex provided that

$$
\begin{equation*}
\sum_{j=1}^{N}\left|\tilde{H}_{j}\right|<\frac{\epsilon}{2 C_{0}}, \text { with } C_{0} \text { being the constant in (5.1), } \tag{5.4}
\end{equation*}
$$

In this case, the function $F$ defined by (5.2) is of the form

$$
F(A)=\frac{\epsilon}{4}|A|^{2}+\tilde{G}(A, J(A))
$$

where $\tilde{G}(A, J)=g(A)+G(A, J)$ is smooth and convex on $\mathbb{R}^{2 \times n} \times \mathbb{R}^{d}$.

Given any $\left(H_{1}^{0}, \cdots, H_{N}^{0}\right)$, let $F$ be the function defined by (5.2) with

$$
\begin{equation*}
\tilde{H}_{j}=H_{j}^{0}-D^{2} F_{0}\left(\eta_{j}^{1}\left(U_{0}\right)\right) \quad \forall j=1, \cdots, N, \tag{5.5}
\end{equation*}
$$

and define

$$
\Phi(\xi)=D F(A)-B \quad \forall \xi=(A, B) \in \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}
$$

Note that, in terms of the Jacobian matrix, we have

$$
\begin{equation*}
D \Phi(\xi)=E+\mathcal{L}\left(D^{2} F(A)\right) \quad \forall \xi=(A, B), \tag{5.6}
\end{equation*}
$$

where $E$ is a constant matrix and $\mathcal{L}(H)$ is a matrix that is linear in $H$ with constant coefficients. Let

$$
\Psi(\rho, U)=\left(\Phi\left(\rho+\eta_{1}(U)\right), \cdots, \Phi\left(\rho+\eta_{N}(U)\right)\right)
$$

for all $\rho \in \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$ and $U \in \mathcal{U}$. Then $\Psi\left(0, U_{0}\right)=0$.
The partial derivative $\frac{\partial \Psi}{\partial U}(\rho, U)$, viewed as a $2 n N \times 2 n N$ matrix, has all its entries being the set $\left\{D \Phi\left(\rho+\eta_{1}(U)\right) D \eta_{1}(U), \cdots, D \Phi\left(\rho+\eta_{N}(U)\right) D \eta_{N}(U)\right\}$. In particular, all entries of the matrix $\frac{\partial \Psi}{\partial U}\left(0, U_{0}\right)$ are affine in $\left(H_{1}^{0}, \cdots, H_{N}^{0}\right)$ with coefficients linear in $\left(D \eta_{1}\left(U_{0}\right), \cdots, D \eta_{N}\left(U_{0}\right)\right)$ that are independent of $F$. Therefore,

$$
J=\operatorname{det} \frac{\partial \Psi}{\partial U}\left(0, U_{0}\right)=J\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)
$$

is a polynomial in $\left(H_{1}^{0}, \cdots, H_{N}^{0}\right)$ with coefficients being polynomials in $\left(D \eta_{1}\left(U_{0}\right), \cdots, D \eta_{N}\left(U_{0}\right)\right)$ and thus rational functions of $U_{0}$ that are independent of $F$. If all these coefficient rational functions vanish at $U_{0}$, then some of them does not vanish at a point in any neighborhood of $U_{0}$, and thus $J\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$ is not identically zero. Hence we have the following:

Lemma 5.2. There exists $\left(H_{1}^{0}, \ldots, H_{N}^{0}, U_{0}\right)$ such that

$$
\left\{\begin{array}{l}
J\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right) \neq 0  \tag{5.7}\\
(5.4) \text { is satisfied by } \tilde{H}_{j}=H_{j}^{0}-D^{2} F_{0}\left(\eta_{j}^{1}\left(U_{0}\right)\right) .
\end{array}\right.
$$

We will further adjust $\left(H_{1}^{0}, \ldots, H_{N}^{0}, U_{0}\right)$ later, but for now we assume that $\left(H_{1}^{0}, \ldots, H_{N}^{0}, U_{0}\right)$ satisfies (5.7) and let $F$ be defined by (5.2). Then $F$ is of the form (3.3) with a smooth convex $G$. We also have the following result.
Proposition 5.3. There exists a ball $\overline{\mathbb{B}}_{r}(0) \subset \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$ and a smooth function $U: \overline{\mathbb{B}}_{r}(0) \rightarrow \mathcal{N}\left(U_{0}\right)$, a neighborhood of $U_{0}$ in $\mathcal{U}$, such that

$$
\begin{equation*}
U(0)=U_{0}, \quad \Psi(\rho, U(\rho))=0, \quad \operatorname{det} \frac{\partial \Psi}{\partial U}(\rho, U) \neq 0 \tag{5.8}
\end{equation*}
$$

for all $\rho \in \overline{\mathbb{B}}_{r}(0)$ and $U \in \mathcal{N}\left(U_{0}\right)$. Moreover,

$$
D U(\rho)=-\left[\frac{\partial \Psi}{\partial U}(\rho, U(\rho))\right]^{-1} \frac{\partial \Psi}{\partial \rho}(\rho, U(\rho)) \quad \forall \rho \in \overline{\mathbb{B}}_{r}(0) ;
$$

in particular,

$$
D U(0)=-\left[\frac{\partial \Psi}{\partial U}\left(0, U_{0}\right)\right]^{-1} \frac{\partial \Psi}{\partial \rho}\left(0, U_{0}\right)
$$

is a rational function of $\left(H_{1}^{0}, \ldots, H_{N}^{0}\right)$ with coefficients being rational functions of $U_{0}$ independent of $F$. Thus we can adjust $\left(H_{1}^{0}, \ldots, H_{N}^{0}, U_{0}\right)$ so that $D U(0)$ and thus all $D U(\rho)$ will have a full rank of $4 n$.

Proof. This follows from the implicit function theorem.
5.2. Toward the verification of Condition $(O C)_{N}$. Let $\gamma_{i}(U)$ and $\eta_{i}(U)$ be defined in (4.15) and (4.16) above, and let $\kappa_{i}(U)$ be simply the projection of $U \in \mathcal{U}$ to $\kappa_{i}$ for $i=1, \cdots, N$.

With the function $U=U(\rho)$ defined in Proposition 5.3, we define the following functions of $\rho \in \overline{\mathbb{B}}_{r}(0)$ :

$$
\left\{\begin{array}{l}
\chi_{i}(\rho)=\frac{1}{\kappa_{i}(U(\rho))},  \tag{5.9}\\
\xi_{i}(\rho)=\rho+\eta_{i}(U(\rho)), \\
\pi_{1}(\rho)=\rho, \\
\pi_{i+1}(\rho)=\pi_{i}(\rho)+\gamma_{i}(U(\rho))
\end{array} \quad \forall i \bmod N\right.
$$

Clearly, these functions verify Property (P2) of Definition 2.2 for $\sigma=D F$.
Since $\pi_{i}(\rho)=\rho+\gamma_{1}(U(\rho))+\cdots+\gamma_{i-1}(U(\rho))$, it follows that

$$
\operatorname{det} D \pi_{i}(0)=\operatorname{det}\left[I+D\left(\gamma_{1}+\cdots+\gamma_{i-1}\right)\left(U_{0}\right) D U(0)\right]
$$

is a polynomial in $\left(H_{1}^{0}, \cdots, H_{N}^{0}\right)$ with coefficients being rational functions of $U_{0}$ that are independent of $F$. Thus $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$ can be adjusted to satisfy

$$
\begin{equation*}
\operatorname{det} D \pi_{i}(0) \neq 0 \quad \forall i=1, \cdots, N \tag{5.10}
\end{equation*}
$$

We choose a further small $r>0$ such that

$$
\left\{\begin{array}{l}
\pi_{i}\left(\mathbb{B}_{r}(0)\right) \text { is open and } \operatorname{det} D \pi_{i}{\mid \overline{\mathbb{B}}_{r}(0)}^{=0}  \tag{5.11}\\
\xi_{i}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right) \cap \xi_{j}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right)=\pi_{i}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right) \cap \pi_{j}^{1}\left(\overline{\mathbb{B}}_{r}(0)\right)=\emptyset
\end{array}\right.
$$

for all $i \neq j \in\{1, \cdots, N\}$; this will verify Property (P1).
To verify Property (P3), we define, for each fixed $i=1, \cdots, N$,

$$
\left\{\begin{array}{l}
z_{i}(\rho)=\zeta_{i}(U(\rho))=\kappa_{i}(U(\rho)) \gamma_{i}(U(\rho)) \\
M_{i}(\rho)=\left(D \pi_{i}(\rho)\right)^{-1} D z_{i}(\rho)
\end{array}\right.
$$

Proposition 5.4. The matrix $M_{i}(\rho)$ has an eigenvalue 0 of multiplicity at least $(n+1)$ and an eigenvalue -1 of multiplicity at least $2 n$, and thus has at most $(n-1)$ eigenvalues not equal to 0 or -1 . We write the characteristic polynomial of $M_{i}(\rho)$ as

$$
\operatorname{det}\left[x I-M_{i}(\rho)\right]=x^{n+1}(x+1)^{2 n} Q(\rho)(x)
$$

where $Q(\rho)(x)=x^{n-1}+c_{1}(\rho) x^{n-2}+\cdots+c_{n-1}(\rho)$, with functions $c_{j}(\rho)$ being polynomials of $M_{i}(\rho)$.

Proof. Since $\Phi\left(\pi_{i}(\rho)+z_{i}(\rho)\right)=\Phi\left(\xi_{i}(\rho)\right)=0$ and $\operatorname{rank} D \Phi\left(\xi_{i}(\rho)\right)=2 n$ for all $\rho \in \mathbb{B}_{r}(0)$, we have $D \Phi\left(\xi_{i}(\rho)\right) D \xi_{i}(\rho)=0$, and thus

$$
\operatorname{dim} \operatorname{ker}\left(I+M_{i}(\rho)\right)=\operatorname{dim} \operatorname{ker} D \xi_{i}(\rho) \geq 2 n
$$

Thus $M_{i}(\rho)$ has an eigenvalue -1 of multiplicity at least $2 n$. By Lemma 4.2,

$$
\operatorname{rank} M_{i}(\rho)=\operatorname{rank} D z_{i}(\rho) \leq \operatorname{rank} D \zeta_{i}(U(\rho)) \leq 3 n-1
$$

Thus $\operatorname{dim} \operatorname{ker} M_{i}(\rho) \geq n+1$ and hence $M_{i}(\rho)$ has an eigenvalue 0 of multiplicity at least $(n+1)$. Therefore, the number (counted by multiplicity) of eigenvalues of $M_{i}(\rho)$ other than 0 and -1 is at most $4 n-(n+1)-2 n=n-1$. Long divisions show that the coefficients of $Q(\rho)$ are affine functions of the coefficients of polynomial $\operatorname{det}\left[x I-M_{i}(\rho)\right]$ and hence are polynomials of $M_{i}(\rho)$.

For $\rho \in \mathbb{B}_{r}(0)$, let $D(\rho)$ be the discriminant of polynomial

$$
Q(\rho)(x)=x^{n-1}+c_{1}(\rho) x^{n-2}+\cdots+c_{n-1}(\rho) .
$$

Then $D(\rho)$ is a polynomial of $\left(c_{1}(\rho), \cdots, c_{n-1}(\rho)\right)$ and thus a polynomial of $M_{i}(\rho)$. Furthermore,

$$
Q(\rho)(-1)=(-1)^{n-1}+c_{1}(\rho)(-1)^{n-2}+\cdots+c_{n-1}(\rho) .
$$

is a polynomial of $M_{i}(\rho)$. Thus both $D(0)$ and $Q(0)(-1)$ are polynomials of $M_{i}(0)$ and hence are rational functions of $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$. Some calculations can show that these rational functions are not identically zero; thus we adjust ( $H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}$ ) to further satisfy that

$$
\begin{equation*}
D(0) \neq 0, \quad Q(0)(-1) \neq 0 \tag{5.12}
\end{equation*}
$$

Let

$$
E_{i}(\rho)=\{x<-1: Q(\rho)(x)=0\}
$$

be the set of eigenvalues of $M_{i}(\rho)$ less than -1 .
Lemma 5.5. If $E_{i}(0)=\emptyset$, then there exists a further small $r>0$ such that $-\frac{1}{\lambda} \notin E_{i}(\rho)$ for all $\lambda \in(0,1)$ and $\rho \in \overline{\mathbb{B}}_{r}(0)$.

Proof. Suppose not; then there are $\lambda_{j} \in(0,1)$ and $\rho_{j} \rightarrow 0$ such that $-\frac{1}{\lambda_{j}} \in$ $E_{i}\left(\rho_{j}\right)$. Thus $Q\left(\rho_{j}\right)\left(-\frac{1}{\lambda_{j}}\right)=0$ and $-\frac{1}{\lambda_{j}} \mathbf{u}_{j}=M_{i}\left(\rho_{j}\right) \mathbf{u}_{j}$ for some unit vector $\mathbf{u}_{j}$. Let via a subsequence $\lambda_{j} \rightarrow \lambda \in[0,1]$ and $\mathbf{u}_{j} \rightarrow \mathbf{u}$, which yields $-\mathbf{u}=$ $\lambda M_{i}(0) \mathbf{u}$; thus $\lambda \neq 0$ and $Q(0)\left(-\frac{1}{\lambda}\right)=0$. If $\lambda \neq 1$ then $-\frac{1}{\lambda} \in E_{i}(0)$, a contradiction. If $\lambda=1$ then $Q(0)(-1)=0$, contradicting (5.12).
Lemma 5.6. Assume $E_{i}(0)=\left\{x_{1}^{0}, x_{2}^{0}, \cdots, x_{k}^{0}\right\} \neq \emptyset$, where $k \in[1, n-1]$ and $x_{1}^{0}<x_{2}^{0}<\cdots<x_{k}^{0}<-1$. Then

$$
E_{i}(\rho)=\left\{x_{1}(\rho), \cdots, x_{k}(\rho)\right\},
$$

where $x_{1}(\rho)<\cdots<x_{k}(\rho)<-1$ are continuous functions on $\overline{\mathbb{B}}_{r}(0)$ for a further small $r>0$ such that $x_{j}(0)=x_{j}^{0}$ for $j=1, \cdots, k$.

Proof. It is well-known [14] that around each simple zero $x_{j}^{0}$ of $Q(0)(x)$ there exists a simple zero $x_{j}(\rho)$ of $Q(\rho)(x)$, where $x_{j}(\rho)$ is $C^{\infty}$ on the coefficients of $Q(\rho)(x)$ and thus is $C^{\infty}$ on $\rho \in \overline{\mathbb{B}}_{r}(0)$ for a further small $r>0$ such that $x_{j}(0)=x_{j}^{0}$ for $j=1, \cdots, k$. This proves

$$
\left\{x_{1}(\rho), \cdots, x_{k}(\rho)\right\} \subseteq E_{i}(\rho)
$$

We show that there exists a further small $r>0$ such that

$$
E_{i}(\rho)=\left\{x_{1}(\rho), \cdots, x_{k}(\rho)\right\} \quad \forall \rho \in \overline{\mathbb{B}}_{r}(0)
$$

Suppose not; then there exist $\rho_{j} \rightarrow 0$ and $y_{j} \in E_{i}\left(\rho_{j}\right)$ such that $y_{j} \notin$ $\left\{x_{1}(\rho), \cdots, x_{k}(\rho)\right\}$. Since the sets $\left\{E_{i}\left(\rho_{j}\right)\right\}_{j=1}^{k}$ are uniformly bounded, we assume $y_{j} \rightarrow \bar{y} \leq-1$ and $Q(0)(\bar{y})=0$. Thus $\bar{y} \neq-1$ and hence $\bar{y} \in E_{i}(0)$, say $\bar{y}=x_{1}^{0}$. We write

$$
Q\left(\rho_{j}\right)(x)=\left(x-x_{1}\left(\rho_{j}\right)\right) \cdots\left(x-x_{k}\left(\rho_{j}\right)\right)\left(x-y_{j}\right)\left(x^{n-1-k-1}+\cdots\right) .
$$

Thus $Q(0)(x)=\left(x-x_{1}^{0}\right)^{2} \cdots\left(x-x_{k}^{0}\right)\left(x^{n-1-k-1}+\cdots\right)$, which implies $x_{1}^{0}$ is a zero of $Q(0)(x)$ of multiplicity at least 2 , a contradiction.

Lemma 5.7. Assume $E_{i}(0)=\left\{x_{1}^{0}, x_{2}^{0}, \cdots, x_{k}^{0}\right\} \neq \emptyset$. We can further adjust $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$ so that

$$
\begin{equation*}
\operatorname{adj}\left(x_{j}^{0} I-M_{i}(0)\right) D \pi_{i}(0) z_{i}(0) \neq 0 \quad \forall j=1, \cdots, k . \tag{5.13}
\end{equation*}
$$

Proof. Since $M_{i}(0)$ is a rational (thus analytic) function of ( $\left.H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$, by the analytic implicit function theorem (see [9, 21) it follows that each simple eigenvalue $x_{j}^{0}$ of $M_{i}(0)$ is an analytic function of $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$ and so is the function

$$
\left[\operatorname{adj}\left(x_{j}^{0} I-M_{i}(0)\right)\right]\left[\operatorname{adj} D \pi_{i}(0)\right] z_{i}(0)
$$

The zero set of a nonzero analytic function is a null set. Thus we can further adjust $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$ so that

$$
\operatorname{adj}\left(x_{j}^{0} I-M_{i}(0)\right) D \pi_{i}(0) z_{i}(0) \neq 0 \quad \forall j=1, \cdots, k .
$$

Remark 5.1. If $n=2$, when $E_{i}(0) \neq \emptyset$, then $E_{i}(\rho)=\left\{4+\operatorname{tr} M_{i}(\rho)\right\}$ is a singleton. In this case the simple eigenvalue $x^{0}$ of $M_{i}(0)$ equals $4+\operatorname{tr} M_{i}(0)$, which is a rational function of $\left(H_{1}^{0}, \cdots, H_{N}^{0}, U_{0}\right)$.
Lemma 5.8. There exists a further small $r>0$ such that, given any $i \in$ $\{1, \cdots, N\}, \lambda \in(0,1)$ and $\rho \in \overline{\mathbb{B}}_{r}(0)$, one has

$$
\operatorname{adj}\left[D \pi_{i}(\rho)+\lambda D z_{i}(\rho)\right] z_{i}(\rho) \neq 0
$$

whenever $\operatorname{det}\left[D \pi_{i}(\rho)+\lambda D z_{i}(\rho)\right]=0$.
Proof. Note that $\operatorname{det}\left[D \pi_{i}(\rho)+\lambda D z_{i}(\rho)\right]=0$ for $\lambda \in(0,1)$ if and only if $-\frac{1}{\lambda} \in E_{i}(\rho)$. If $E_{i}(0)=\emptyset$ for some $i$, then by Lemma 5.5, no such condition
is possible for this $i$ and all $\rho \in \overline{\mathbb{B}}_{r}(0)$. If $E_{i}(0) \neq \emptyset$ for some $i$, then by (5.13), we take a further small $r>0$ so that

$$
\left[\operatorname{adj}\left(x_{j}(\rho) I-M_{i}(\rho)\right)\right]\left[\operatorname{adj} D \pi_{i}(\rho)\right] z_{i}(\rho) \neq 0 \quad \forall \rho \in \overline{\mathbb{B}}_{r}(0), \quad 1 \leq j \leq k
$$

for each $i$ with $E_{i}(0) \neq \emptyset$. The result follows because if $-\frac{1}{\lambda}=x_{j}(\rho)$ then

$$
\begin{gathered}
\operatorname{adj}\left[D \pi_{i}(\rho)+\lambda D z_{i}(\rho)\right] z_{i}(\rho) \\
=(-\lambda)^{4 n-1}\left[\operatorname{adj}\left(x_{j}(\rho) I-M_{i}(\rho)\right)\right]\left[\operatorname{adj} D \pi_{i}(\rho)\right] z_{i}(\rho) \neq 0 .
\end{gathered}
$$

Proposition 5.9. The set $\Sigma(\lambda)$ is open for all $0<\lambda \leq 1$.
Proof. Let $\bar{\xi} \in \Sigma(\lambda)$. Then for some $i \in\{1, \cdots, N\}, 0 \leq \bar{\lambda}<\lambda$ and $\bar{\rho} \in$ $\mathbb{B}_{r}(0)$, we have

$$
\bar{\xi}=\bar{\lambda} \xi_{i}(\bar{\rho})+(1-\bar{\lambda}) \pi_{i}(\bar{\rho})=\pi_{i}(\bar{\rho})+\bar{\lambda} z_{i}(\bar{\rho}) .
$$

We show that there exists $\epsilon>0$ such that $\mathbb{B}_{\epsilon}(\bar{\xi}) \subset \Sigma(\lambda)$; this proves the openness of $\Sigma(\lambda)$.

Case 1: Assume $\operatorname{det}\left[D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})\right] \neq 0$. Then by the inverse function theorem, there exist $\epsilon>0$ and $s>0$ with $B_{s}(\bar{\rho}) \subset \mathbb{B}_{r}(0)$ such that

$$
\mathbb{B}_{\epsilon}(\bar{\xi}) \subset\left(\pi_{i}+\bar{\lambda} z_{i}\right)\left(\mathbb{B}_{s}(\bar{\rho})\right) \subset\left(\pi_{i}+\bar{\lambda} z_{i}\right)\left(\mathbb{B}_{r}(0)\right)=S_{i}(\bar{\lambda}) \subset \Sigma(\lambda) .
$$

Case 2: Assume $\operatorname{det}\left[D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})\right]=0$. In this case, $\bar{\lambda} \neq 0$; thus $0<\bar{\lambda}<\lambda$. Consider the function

$$
H(\rho, \xi)=\pi_{i}(\rho)+[\bar{\lambda}+(\rho-\bar{\rho}) \cdot \bar{b}] z_{i}(\rho)-\xi
$$

for all $\rho \in \overline{\mathbb{B}}_{r}(0)$ and $\xi \in \mathbb{R}^{2 \times n} \times \mathbb{R}^{2 \times n}$, where $\bar{b}=\operatorname{adj}\left[D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})\right] z_{i}(\bar{\rho}) \neq$ 0 (by Lemma 5.8). Note that $H(\bar{\rho}, \bar{\xi})=0$, and

$$
\frac{\partial H}{\partial \rho}(\bar{\rho}, \bar{\xi})=D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})+z_{i}(\bar{\rho}) \otimes \bar{b}
$$

Thus,

$$
\begin{aligned}
& \operatorname{det} \frac{\partial H}{\partial \rho}(\bar{\rho}, \bar{\xi})=\operatorname{det}\left[D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})+z_{i}(\bar{\rho}) \otimes \bar{b}\right] \\
& \quad=\operatorname{adj}\left[D \pi_{i}(\bar{\rho})+\bar{\lambda} D z_{i}(\bar{\rho})\right] z_{i}(\bar{\rho}) \cdot \bar{b}=|\bar{b}|^{2} \neq 0
\end{aligned}
$$

Hence by the implicit function theorem, there exist balls $\mathbb{B}_{s}(\bar{\rho}) \subset \mathbb{B}_{r}(0)$ and $\mathbb{B}_{\epsilon}(\bar{\xi})$ such that for all $\xi \in \mathbb{B}_{\epsilon}(\bar{\xi})$ there exists a $\rho \in \mathbb{B}_{s}(\bar{\rho})$ such that $H(\rho, \xi)=0$ and, with $s>0$ being further small,

$$
0<\bar{\lambda}+(\rho-\bar{\rho}) \cdot \bar{b}<\lambda ;
$$

therefore, $\mathbb{B}_{\epsilon}(\bar{\xi}) \subset S_{i}(\bar{\lambda}+(\rho-\bar{\rho}) \cdot \bar{b}) \subset \Sigma(\lambda)$ also holds in this case.

Proposition 5.10. There exists a number $\delta_{1} \in(0,1)$ such that the family $\left\{S_{i}(\lambda)\right\}_{i=1}^{N}$ is disjoint and open for all $\delta_{1} \leq \lambda<1$.

Proof. Let

$$
x_{0}=\max _{1 \leq i \leq N, E_{i}(0) \neq \emptyset, \rho \in \overline{\mathbb{B}}_{r}(0)} E_{i}(\rho) .
$$

Then $x_{0}<-1$. Let $\delta_{1} \in\left(-\frac{1}{x_{0}}, 1\right)$. Then $\delta_{1} \in(0,1)$. For all $\lambda \in\left[\delta_{1}, 1\right)$, it follows that $-\frac{1}{\lambda}$ is not an eigenvalue of $M_{i}(\rho)$ for any $i$ and $\rho$. Thus

$$
\operatorname{det}\left[D \pi_{i}(\rho)+\lambda D z_{i}(\rho)\right]=\operatorname{det} D \pi_{i}(\rho) \operatorname{det}\left[I+\lambda M_{i}(\rho)\right] \neq 0
$$

for all $1 \leq i \leq N, \rho \in \mathbb{B}_{r}(0)$ and $\lambda \in\left[\delta_{1}, 1\right)$. Hence, by the inverse function theorem, $S_{i}(\lambda)$ is open all $\lambda \in\left[\delta_{1}, 1\right)$. Finally, by (5.11), we can choose $\delta_{1}$ even closer to 1 such that $\left\{S_{i}(\lambda)\right\}_{i=1}^{N}$ is disjoint for all $\lambda \in\left[\delta_{1}, 1\right)$.
