#### Abstract

Given a subgroup H of a group (G, +), a (G, H, k, 1) difference family (DF) is a set  $\mathcal{F}$  of k-subsets of G such that  $\{f - f' : f, f' \in F, f \neq f', F \in \mathcal{F}\} = G \setminus H$ . Let  $g\mathbb{Z}_{gh}$  is the subgroup of order h in  $\mathbb{Z}_{gh}$  generated by g. A  $(\mathbb{Z}_{gh}, g\mathbb{Z}_{gh}, k, 1)$ -DF is called cyclic and written as a (gh, h, k, 1)-CDF. This paper shows that for  $h \in \{2, 3, 6\}$ , there exists a (gh, h, 4, 1)-CDF if and only if  $gh \equiv h \pmod{12}$ ,  $g \geq 4$  and  $(g, h) \notin \{(9, 3), (5, 6)\}$ . As a corollary, it is shown that a 1-rotational S(2, 4, v) exists if and only if  $v \equiv 4 \pmod{12}$  and  $v \neq 28$ . This solves the long-standing open problem on the existence of a 1-rotational S(2, 4, v). As another corollary, we establish the existence of an optimal (v, 4, 1)-optical orthogonal code with  $\lfloor (v - 1)/12 \rfloor$  codewords for any positive integer  $v \equiv 1, 2, 3, 4, 6 \pmod{12}$  and  $v \neq 25$ . We also give applications of our results to cyclic group divisible designs with block size four and optimal cyclic 3-ary constant-weight codes with weight four and minimum distance six.

**Keywords**: difference family; cyclic group divisible design; 1-rotational Steiner system; cyclic constant-weight code; optical orthogonal code

### 1 Introduction

Throughout this paper, every union of sets will be understood as multiset union with multiplicities of elements preserved. Denote by  $\mathbb{Z}_v$  the cyclic group of order v.

Let H be a subgroup of a finite group (G, +) and let k be an integer satisfying  $2 \leq k \leq |G|$ . A (G, H, k, 1)-relative difference family (briefly DF) is a set  $\mathcal{F}$  of k-subsets of G (called base blocks) such that the list

$$\Delta \mathcal{F} := \bigcup_{F \in \mathcal{F}} \Delta F := \bigcup_{F \in \mathcal{F}} \{f - f' : f, f' \in F, f \neq f'\}$$

<sup>\*</sup>Supported by NSFC under Grant 11971053

<sup>&</sup>lt;sup>†</sup>Supported by NSFC under Grant 12271023

<sup>&</sup>lt;sup>‡</sup>Supported by NSFC under Grant 11771227

covers each element of  $G \setminus H$  exactly once and each element of H zero time. There are (|G| - |H|)/(k(k-1)) base blocks in a (G, H, k, 1)-DF and hence, a necessary condition for the existence of such a family is  $|G| \equiv |H| \pmod{k(k-1)}$ . Another obvious necessary condition is  $|G| \ge k|H|$ ; otherwise, given any base block  $F \in \mathcal{F}$ , there exist two elements of F that lie in a same right coset of H in G, a contradiction.

#### **Lemma 1.1.** If there exists a (G, H, k, 1)-DF, then $|G| \equiv |H| \pmod{k(k-1)}$ and $|G| \ge k|H|$ .

When H consists only of the identity  $1_G$  of G, a  $(G, 1_G, k, 1)$ -DF is often written as a (G, k, 1)-DF. When G is a cyclic group, a (G, H, k, 1)-DF is said to be *cyclic* and written as a (|G|, |H|, k, 1)-CDF.

Difference families arose from the study of designs with a given group of automorphisms. We here only briefly recall what has been done for cyclic difference families with base block size three or four. The reader is referred to [2, 3] for more topics on difference families.

As far back as 1939, Peltesohn [32] showed that for  $h \in \{1,3\}$ , a (gh, h, 3, 1)-CDF exists if and only if  $gh \equiv h \pmod{6}$  and  $(g, h) \neq (3, 3)$ . This gives a solution to the Heffter's difference problems [25, 26] that yield the existence of cyclic Steiner triple systems (see Chapter VII.4 in [3]). For general h, Wang and Chang [36, Theorem 3.11] in 2009 proved that a (gh, h, 3, 1)-CDF exists if and only if (1)  $gh \equiv h \pmod{6}$  and  $g \ge 4$ ; (2)  $g \not\equiv 2, 3 \pmod{4}$  when  $h \equiv 2 \pmod{4}$ . This implies the existence of cyclic group divisible designs with block size three without short orbits (see [36, Theorem 5.4]).

When  $p \equiv 1 \pmod{12}$  is a prime, Bose [5] provided a sufficient condition for the existence of a (p, 4, 1)-CDF admitting a multiplier of order 3, and the necessary and sufficient condition for this special kind of CDFs was established by Buratti in [7]. Improving Buratti's work in [8], Chen and Zhu [17] showed that a (p, 4, 1)-CDF exists for any prime  $p \equiv 1 \pmod{12}$ . Even though a (v, 4, 1)-CDF of composite order  $v = v_1v_2$  can be obtained by means of recursive constructions in the hypothesis that a  $(v_i, 4, 1)$ -CDF exists (cf. [9]) or by direct constructions with nice algebraic properties (cf. [12]), no infinite family of (v, 4, 1)-CDFs such that v can run over a congruent class was known until quite recently. Zhang, Feng and Wang [38] recently developed an efficient direct construction method to establish the existence of (gh, h, 4, 1)-CDFs for  $h \in \{1, 4\}$ , which solves the long-standing open problem on the existence of cyclic Steiner systems with block size four.

**Theorem 1.1.** [38] For  $h \in \{1, 4\}$ , there exists a (gh, h, 4, 1)-CDF if and only if  $gh \equiv h \pmod{12}$  and  $(g, h) \notin \{(25, 1), (4, 4), (7, 4)\}$ .

This paper is a continuation of the study of [38]. As the main result of this paper, we are to prove the following theorem.

**Theorem 1.2.** For  $h \in \{2,3,6\}$ , there exists a (gh, h, 4, 1)-CDF if and only if  $gh \equiv h \pmod{12}$ ,  $g \ge 4$  and  $(g, h) \notin \{(9,3), (5,6)\}$ .

Section 2.1 gives a proof of Theorem 1.2. In Section 2.2, using a recursive construction, we construct more new infinite families of cyclic difference families (see Theorem 2.1). Section 3 is devoted to providing applications of cyclic difference families to cyclic group divisible designs (see Theorem 3.1), 1-rotational Steiner systems (see Theorem 3.2), optimal cyclic constant-weight codes (see Theorem 3.3) and optimal optical orthogonal codes (see Theorem 3.4). Concluding remarks are given in Section 4.

Table 1: Coefficients in the first 6t - 18 base blocks in Lemma 2.1

## **2** Existence of (gh, h, 4, 1)-cyclic difference families

### **2.1** The cases h = 2, 3 and 6

For positive integers a, b and c such that  $a \leq b$  and  $a \equiv b \pmod{c}$ , we set  $[a, b]_c := \{a + ci : 0 \leq i \leq (b-a)/c\}$ . When c = 1,  $[a, b]_1$  is simply written as [a, b].

**Lemma 2.1.** For  $h \in \{2, 3, 6\}$ , there exists a (gh, h, 4, 1)-CDF for any  $gh \equiv h \pmod{12}$  and  $gh \ge 218$ .

**Proof.** Let gh = 72t + 12x + h, where  $t \ge 3$  and  $0 \le x \le 5$ . Then a (gh, h, 4, 1)-CDF contains 6t + x base blocks. We give a direct construction for such a CDF here. All base blocks are divided into two parts. The first part consists of 6t - 18 base blocks:

$$\begin{split} F_{1,i} &= \{0, \quad 43t+a_1+i, \quad 31t+a_2+2i, \quad 8t+a_3+3i\}, \\ F_{2,i} &= \{0, \quad 23t+b_1+i, \quad 5t+b_2+2i, \quad 8t+b_3+3i\}, \\ F_{3,i} &= \{0, \quad 41t+c_1+i, \quad 25t+c_2+2i, \quad 8t+c_3+3i\}, \\ F_{4,i} &= \{0, \quad 35t+d_1+i, \quad 5t+d_2+2i, \quad d_3+3i\}, \\ F_{5,i} &= \{0, \quad 47t+e_1+i, \quad 19t+e_2+2i, \quad e_3+3i\}, \\ F_{6,i} &= \{0, \quad 21t+f_1+i, \quad 13t+f_2+2i, \quad f_3+3i\}, \end{split}$$

where  $1 \leq i \leq t-2$  and  $i \neq \lfloor t/2 \rfloor$ , and  $a_j, b_j, c_j, d_j, e_j, f_j$  are shown in Table 1. The remaining 18 + x base blocks are listed in Appendix A according to the parity of t. Write  $\mathcal{F}_r = \{F_{r,i} : 1 \leq i \leq t-2, i \neq \lfloor t/2 \rfloor\}$  for  $1 \leq r \leq 6$ , and denote by  $\mathcal{F}'$  the set consisting of the remaining 18 + x base blocks. It remains to check that  $\mathcal{F} = (\bigcup_{r=1}^6 \mathcal{F}_r) \cup \mathcal{F}'$  forms a (gh, h, 4, 1)-CDF.

We take the case h = 2, x = 0 and  $t \equiv 1 \pmod{2}$  for example to show that  $\mathcal{F}$  forms a (2g, 2, 4, 1)-CDF. For convenience, for any  $F \in \mathcal{F}$ , if  $x, y \in F$  and x > y, we call x - y(mod gh) a positive difference from F, and  $y - x \pmod{gh}$  a negative difference from F. The collection of all positive differences (resp. negative differences) in  $\Delta F$  is denoted by  $\Delta^+ F$  (resp.

Table 2: Differences from the first 6t - 18 base blocks in Lemma 2.1 when h = 2, x = 0 and t is odd

 $\Delta^{-}F$ ). Write  $\Delta^{+}\mathcal{F}_{r} = \bigcup_{F \in \mathcal{F}_{r}} \Delta^{+}F$  and  $\Delta^{-}\mathcal{F}_{r} = \bigcup_{F \in \mathcal{F}_{r}} \Delta^{-}F$  for  $1 \leq r \leq 6$ . We list all positive differences from  $\mathcal{F}_{r}$  with  $1 \leq r \leq 6$  in Table 2, and if a positive difference is greater than 36t + 1, then we list its corresponding negative difference. We also list all differences less than 36t + 1 from the remaining 18 base blocks, written as  $B_{l}$  with  $1 \leq l \leq 18$ , in Table 3. It is readily checked that  $\Delta \mathcal{F} = \mathbb{Z}_{72t+2} \setminus \{0, 36t + 1\}$ , and hence  $\mathcal{F}$  is a (2g, 2, 4, 1)-CDF.

One can examine all the other cases similarly. To facilitate the reader to check the correctness of our results, we provide a computer code written by GAP [35]. The reader can get a copy of the computer code from [40].

We remark that the structure of the first 6t - 18 base blocks in this proof is exactly the same

Table 3: Differences less than 36t + 1 from the remaining 18 base blocks in Lemma 2.1 when h = 2, x = 0 and t is odd

as the structure of the first 6t-18 base blocks in the proof for the existence of (gh, h, 4, 1)-CDFs with  $h \in \{1, 4\}$  in [38, Lemmas 4, 5 and Theorem 5]. We just need to choose appropriate parameters  $a_j, b_j, c_j, d_j, e_j, f_j$  by hand and then find the remaining 18 + x base blocks by computer search such that  $\mathcal{F}$  forms our required difference families. It often took us around a half day to choose an appropriate set of  $a_j, b_j, c_j, d_j, e_j, f_j$  for each given h and x, and then the time used to search for the remaining 18 + x base blocks by an ordinary personal computer was ranged from one day to three days.

The following lemma will be used to show the existence of (gh, h, 4, 1)-CDFs with  $h \in \{2, 3\}$  and small g's later. We outline its proof for completeness.

- **Lemma 2.2.** (1) [6, Lemma 6.10] There exists a (2p, 2, 4, 1)-CDF for any prime  $p \equiv 1 \pmod{6}$ .
  - (2) [31] There exists a (3p, 3, 4, 1)-CDF for any prime  $p \equiv 1 \pmod{4}$ .

**Proof.** Let  $\omega$  be a primitive root of unity in the finite field  $\mathbb{F}_p$ . Let  $\varepsilon = \omega^{(p-1)/6}$  if  $p \equiv 1 \pmod{6}$ , and  $\varepsilon = \omega^{(p-1)/4}$  if  $p \equiv 1 \pmod{4}$ . Then

$$\{(0,0), (1,\omega^i), (1,\varepsilon^2\cdot\omega^i), (1,\varepsilon^4\cdot\omega^i)\}, \quad 0\leqslant i<(p-1)/6,$$

forms a (2p, 2, 4, 1)-CDF over  $\mathbb{Z}_2 \times \mathbb{Z}_p \cong \mathbb{Z}_{2p}$  for any prime  $p \equiv 1 \pmod{6}$ , and

$$\{(0,\omega^i), (0,\varepsilon^2 \cdot \omega^i), (1,\varepsilon \cdot \omega^i), (1,\varepsilon^3 \cdot \omega^i)\}, \quad 0 \le i < (p-1)/4,$$

forms a (3p, 3, 4, 1)-CDF over  $\mathbb{Z}_3 \times \mathbb{Z}_p \cong \mathbb{Z}_{3p}$  for any prime  $p \equiv 1 \pmod{4}$ .

Applying a standard recursive construction (see Construction 2.1 below) together with the use of the above lemma, Yin [37] established the following results implicitly.

- **Lemma 2.3.** (1) [37, Theorem 4.9] There exists a (2g, 2, 4, 1)-CDF for any positive integer g such that each prime factor of g is 1 modulo 6.
  - (2) [37, Theorem 4.10] There exists a (3g, 3, 4, 1)-CDF for any positive integer g such that each prime factor of g is 1 modulo 4.

**Lemma 2.4.** There exists a (2g, 2, 4, 1)-CDF for any integer  $g \equiv 1 \pmod{6}$  and  $7 \leq g \leq 103$ .

**Proof.** For  $g \in \{25, 55, 85\}$ , we list all the base blocks below.

For all the other cases of g, apply Lemma 2.3.

**Lemma 2.5.** There exists a (3g, 3, 4, 1)-CDF for any integer  $g \equiv 1 \pmod{4}$ ,  $5 \leq g \leq 69$  and  $g \neq 9$ .

**Proof.** For  $g \in \{21, 33, 45, 49, 57, 69\}$ , we list all the base blocks below.

For all the other cases of g, apply Lemma 2.3.

The proof of Lemma 2.6 in [16] implies that if there exists a skew starter in  $\mathbb{Z}_g$ , then there exists a (6g, 6, 4, 1)-CDF. Since a skew starter in  $\mathbb{Z}_g$  exists for any g such that gcd(g, 150) = 1 or 25 by [16, Theorem 1.2], and a skew starter in  $\mathbb{Z}_{35}$  exists by [16, Lemma 2.4], we have the following result, (1) of which was first stated explicitly in [24, Lemma 2.6].

#### Lemma 2.6. [16]

- (1) There exists a (6g, 6, 4, 1)-CDF for any positive integer g such that gcd(g, 150) = 1 or 25.
- (2) There exists a (210, 6, 4, 1)-CDF.

We remark that Buratti [10, Theorem 4.1] provided a nice explicit construction for the existence of a (6p, 6, 4, 1)-CDF for any odd prime  $p \neq 5$  according to whether p is or is not a Fermat prime.

**Lemma 2.7.** There exists a (6g, 6, 4, 1)-CDF for any odd integer  $7 \leq g \leq 35$ .

**Proof.** For  $g \in \{9, 15, 27\}$ , a (6g, 6, 4, 1)-CDF exists by [24, Lemma 4.2]. For  $g \in \{21, 33\}$ , we list all the base blocks below.

g = 21: {0, 19, 62, 79},  $\{0, 2, 8, 78\},\$  $\{0, 3, 12, 35\},\$  $\{0, 13, 31, 65\}, \{0, 15, 22, 115\},\$  $\{0, 1, 5, 46\},\$  $\{0, 25, 53, 82\}, \{0, 27, 37, 86\}.$  $\{0, 16, 55, 106\},\$  $\{0, 24, 38, 96\},\$ g = 33: {0, 49, 88, 125},  $\{0, 2, 9, 74\},\$  $\{0, 17, 35, 69\}, \{0, 38, 94, 138\},\$  $\{0, 25, 83, 106\},\$  $\{0, 14, 29, 170\},\$  $\{0, 4, 12, 82\},\$  $\{0, 21, 45, 130\},\$  $\{0, 3, 13, 179\}, \{0, 30, 105, 148\},\$  $\{0, 31, 86, 127\},\$  $\{0, 1, 6, 54\},\$  $\{0, 40, 91, 137\}, \{0, 11, 27, 90\}, \{0, 47, 114, 134\},\$  $\{0, 59, 95, 121\}.$ 

For all the other cases of g, apply Lemma 2.6.

Now we are in a position to give a proof of Theorem 1.2.

**Proof of Theorem 1.2.** By Lemma 1.1, a (gh, h, 4, 1)-CDF exists only if  $gh \equiv h \pmod{12}$  and  $g \ge 4$ . It is known that there is no (gh, h, 4, 1)-CDF for  $(g, h) \in \{(9, 3), (5, 6)\}$  (cf. [10, 34]). Combining the results of Lemmas 2.1, 2.4, 2.5 and 2.7, one can complete the proof.

### 2.2 General cases

Difference matrices have proved to be a very useful tool for constructing cyclic relative difference families. Let (G, +) be a finite group of order v and  $k \ge 2$  be an integer. A (v, k, 1)-difference matrix (DM) over G, or briefly (G, k, 1)-DM, is a  $k \times v$  matrix  $D = (d_{ij})$  with entries from Gsuch that for any two distinct rows x and y, the multiset of differences  $\{d_{xj} - d_{yj} : 1 \le j \le v\}$ contains each element of G exactly once. A  $(\mathbb{Z}_v, k, 1)$ -DM is often called cyclic and denoted by a (v, k, 1)-CDM.

The following construction is a standard recursive construction for cyclic relative difference families.

**Construction 2.1.** [28] If there exist a (gn, g, k, 1)-CDF and an (h, k, 1)-CDM, then there exists a (gnh, gh, k, 1)-CDF. Furthermore, if there exists a (gh, g, k, 1)-CDF, then there exists a (ghn, g, k, 1)-CDF.

Evans [19] constructed a (v, 4, 1)-CDM for any odd integer  $v \ge 5$  and v is not divisible by 9. Zhang, Feng and Wang [39] solved the case  $v \equiv 9 \pmod{18}$ .

**Lemma 2.8.** [19, 39] A(v, 4, 1)-CDM exists if and only if  $v \ge 5$  is odd and  $v \ne 9$ .

By Lemma 1.1, a (4h, h, 4, 1)-CDF exists only if  $h \equiv 0 \pmod{4}$ . Since a (4h, h, 4, 1)-CDF yields a strictly cyclic group divisible design of type  $h^4$  with block size four, which can produce an (h, 4, 1)-CDM (cf. [3, Theorem VIII.3.6]), it follows from Lemma 2.8 that we have the following lemma.

**Lemma 2.9.** There does not exist a (4h, h, 4, 1)-CDF for any positive integer h.

**Theorem 2.1.** There exists a (gh, h, 4, 1)-CDF if and only if  $gh \equiv h \pmod{12}$  and  $g \ge 5$  except for  $(g, h) \in \{(9, 3), (5, 6)\}$  and except possibly for

- (1)  $h \equiv 1, 5, 7, 11 \pmod{12}$  and g = 25,
- (2)  $h \in \{9, 27\}$  and  $g \equiv 1 \pmod{4}$ ,
- (3)  $h \equiv 3,9 \pmod{12}$  and g = 9,
- (4)  $h \equiv 8, 16 \pmod{24}$  and  $g \equiv 1 \pmod{3}$ ,
- (5)  $h \equiv 4, 20 \pmod{24}$  and g = 7,
- (6)  $h \equiv 6 \pmod{12}$  and g = 5,
- (7) h = 18 and  $g \equiv 1 \pmod{2}$ ,
- (8)  $h = 54 \text{ and } g \equiv 3, 5 \pmod{6}$ ,
- (9)  $h \equiv 0 \pmod{24}$  and  $g \ge 5$ ,
- (10)  $h \equiv 12 \pmod{24}$ ,  $g \equiv 0, 2 \pmod{3}$  and  $g \ge 5$ ,
- (11)  $h \in \{12, 36\}, g \equiv 1 \pmod{3}$  and  $g \ge 10$ .

**Proof.** By Lemmas 1.1 and 2.9, a (gh, h, 4, 1)-CDF exists only if  $g \ge 5$  and  $h(g-1) \equiv 0$  (mod 12), that is, (i)  $h \equiv 1, 5, 7, 11 \pmod{12}$  and  $g \equiv 1 \pmod{12}$ , (ii)  $h \equiv 2, 10 \pmod{12}$  and  $g \equiv 1 \pmod{6}$ , (iii)  $h \equiv 3, 9 \pmod{12}$  and  $g \equiv 1 \pmod{4}$ , (iv)  $h \equiv 4, 8 \pmod{12}$  and  $g \equiv 1 \pmod{3}$ , (v)  $h \equiv 6 \pmod{12}$  and  $g \equiv 1 \pmod{2}$ , (vi)  $h \equiv 0 \pmod{12}$  and  $g \ge 5$ .

For  $h \equiv 1, 5, 7, 11 \pmod{12}$ ,  $g \equiv 1 \pmod{12}$  and  $g \neq 25$ , apply Construction 2.1 with a (g, 1, 4, 1)-CDF (from Theorem 1.1) and an (h, 4, 1)-CDM (from Lemma 2.8) to obtain a (gh, h, 4, 1)-CDF.

For  $h \equiv 2, 10 \pmod{12}$  and  $g \equiv 1 \pmod{6}$ , apply Construction 2.1 with a (2g, 2, 4, 1)-CDF (from Theorem 1.2) and an (h/2, 4, 1)-CDM.

For  $h \equiv 3, 9 \pmod{12}$ ,  $g \equiv 1 \pmod{4}$ ,  $h \notin \{9, 27\}$  and  $g \neq 9$ , apply Construction 2.1 with a (3g, 3, 4, 1)-CDF (from Theorem 1.2) and an (h/3, 4, 1)-CDM.

For  $h \equiv 4, 20 \pmod{24}$ ,  $g \equiv 1 \pmod{3}$  and  $g \ge 10$ , apply Construction 2.1 with a (4g, 4, 4, 1)-CDF (from Theorem 1.1) and an (h/4, 4, 1)-CDM.

For  $h \equiv 6 \pmod{12}$ ,  $g \equiv 1 \pmod{2}$ ,  $h \notin \{18, 54\}$  and  $g \ge 7$ , apply Construction 2.1 with a (6g, 6, 4, 1)-CDF (from Theorem 1.2) and an (h/6, 4, 1)-CDM. For h = 54 and  $g \equiv 1 \pmod{6}$ , apply Construction 2.1 with a (2g, 2, 4, 1)-CDF (from Theorem 1.2) and a (27, 4, 1)-CDM.

For  $h \equiv 12 \pmod{24}$ ,  $g \equiv 1 \pmod{3}$ ,  $h \ge 60$  and  $g \ge 10$ , apply Construction 2.1 with a (4g, 4, 4, 1)-CDF (from Theorem 1.1) and an (h/4, 4, 1)-CDM. For  $h \equiv 12 \pmod{24}$ , g = 7,  $h \ge 60$  and  $h \ne 108$ , start from an (84, 12, 4, 1)-CDF whose base blocks are listed below:

and then apply Construction 2.1 with an (h/12, 4, 1)-CDM. By [13, Lemma 3.10], there exists a  $(36 \times 7, 36, 4, 1)$ -CDF. By [13, Theorem 3.9], there exists a  $(108 \times 7, 108, 4, 1)$ -CDF.

# 3 Applications

### 3.1 Cyclic group divisible designs

A group divisible design (GDD) is a triple  $(V, \mathcal{G}, \mathcal{B})$ , where V is a set of points,  $\mathcal{G}$  is a partition of V into groups, and  $\mathcal{B}$  is a family of subsets of V (called *blocks*) such that every block intersects any given group in at most one point, and every two points belonging to distinct groups are contained in exactly one block. A k-GDD of type  $h^g$  is a GDD in which the size of each block is k and there are g groups of size h. For more details on group divisible designs, the reader is referred to [4, 22].

An automorphism of a GDD  $(V, \mathcal{G}, \mathcal{B})$  is a permutation on V leaving  $\mathcal{G}$  and  $\mathcal{B}$  invariant, respectively. A k-GDD of type  $h^g$  is said to be *cyclic* if it admits an automorphism consisting of a cycle of length gh. Without loss of generality, we regard  $\mathbb{Z}_{gh}$  as an automorphism group of a cyclic k-GDD of type  $h^g$ . If the stabilizer of any block of a cyclic GDD of type  $h^g$  in  $\mathbb{Z}_{gh}$ is trivial, then the GDD is called *strictly cyclic*. The blocks of a strictly cyclic k-GDD of type  $h^g$  can be partitioned into orbits under  $\mathbb{Z}_{gh}$ . Choose any fixed block from each orbit and then call them base blocks. These base blocks form a (gh, h, k, 1)-CDF. Therefore, a strictly cyclic k-GDD of type  $h^g$  yields a (gh, h, k, 1)-CDF, and vice versa. Combining Theorem 2.1, we have the following theorem.

**Theorem 3.1.** There exists a strictly cyclic 4-GDD of type  $h^g$  if and only if  $gh \equiv h \pmod{12}$ and  $g \ge 5$  except for  $(g,h) \in \{(9,3), (5,6)\}$  and except possibly for

- (1)  $h \equiv 1, 5, 7, 11 \pmod{12}$  and g = 25,
- (2)  $h \in \{9, 27\}$  and  $g \equiv 1 \pmod{4}$ ,
- (3)  $h \equiv 3,9 \pmod{12}$  and g = 9,
- (4)  $h \equiv 8, 16 \pmod{24}$  and  $g \equiv 1 \pmod{3}$ ,
- (5)  $h \equiv 4, 20 \pmod{24}$  and g = 7,
- (6)  $h \equiv 6 \pmod{12}$  and g = 5,
- (7)  $h = 18 \text{ and } g \equiv 1 \pmod{2}$ ,

- (8)  $h = 54 \text{ and } g \equiv 3, 5 \pmod{6}$ ,
- (9)  $h \equiv 0 \pmod{24}$  and  $g \ge 5$ ,
- (10)  $h \equiv 12 \pmod{24}$ ,  $g \equiv 0, 2 \pmod{3}$  and  $g \ge 5$ ,
- (11)  $h \in \{12, 36\}, g \equiv 1 \pmod{3}$  and  $g \ge 10$ .

#### **3.2** 1-rotational Steiner systems

A k-GDD of type 1<sup>v</sup> is often called a *Steiner system* and denoted by an S(2, k, v). An S(2, k, v) is said to be 1-*rotational* if it admits an automorphism consisting of one fixed point and a cycle of length v-1. A 1-rotational S(2, k, v) defined on X may be assumed to have  $X = \mathbb{Z}_{v-1} \cup \{\infty\}$  with the 1-rotational automorphism given by  $i \to i+1 \pmod{v-1}$  for  $i \in \mathbb{Z}_{v-1}$  and  $\infty \to \infty$ .

Phelps and Rosa [33] showed that a 1-rotational S(2, 3, v) exists if and only if  $v \equiv 3, 9 \pmod{24}$ . It was conjectured in [34, Section 3.2] that a 1-rotational S(2, 4, v) exists if and only if  $v \equiv 4 \pmod{12}$  and  $v \neq 28$ . Applying Theorem 1.2, we can confirm this conjecture.

**Theorem 3.2.** There exists a 1-rotational S(2, 4, v) if and only if  $v \equiv 4 \pmod{12}$  and  $v \neq 28$ .

**Proof.** The necessity follows from [34, Section 3.2]. To show the sufficiency, take a (v - 1, 3, 4, 1)-CDF,  $\mathcal{F}$ , with  $v \equiv 4 \pmod{12}$  and  $v \neq 28$  from Theorem 1.2. Then it is readily checked that  $\{\{f_1 + t, f_2 + t, f_3 + t, f_4 + t\} : F = \{f_1, f_2, f_3, f_4\} \in \mathcal{F}, t \in \mathbb{Z}_{v-1}\} \cup \{\{t, \frac{v-1}{3} + t, \frac{2(v-1)}{3} + t, \infty\} : 0 \leq t < \frac{v-1}{3}\}$  forms a 1-rotational S(2, 4, v).

For more information on 1-rotational Steiner systems, the reader is referred to [2, 27].

#### 3.3 Optimal cyclic constant-weight codes

A q-ary code C of length n is a set of vectors in  $\{0, 1, \ldots, q-1\}^n$ . An element in C is called a codeword. For two codewords  $u = (u_i)_{0 \leq i \leq n-1}$  and  $v = (v_i)_{0 \leq i \leq n-1}$ , the Hamming distance between u and v is  $d_H(u, v) = |\{0 \leq i \leq n-1 : u_i - v_i \neq 0\}|$ . The Hamming weight of u is the Hamming distance between u and the zero vector 0. A code is said to be of constant-weight wif the Hamming weight of each codeword is a constant w. A code C is said to have minimum distance d if  $d_H(u, v) \geq d$  for all distinct  $u, v \in C$ . A q-ary code of length n, minimum distance d and constant-weight w is denoted by an  $(n, d, w)_q$  code.

An  $(n, d, w)_q$  code C is said to be *cyclic* if  $(u_0, u_1, \ldots, u_{n-1}) \in C$  implies  $(u_1, u_2, \ldots, u_{n-1}, u_0) \in C$ . We use the notation  $CA_q(n, d, w)$  to denote the largest possible number of codewords among all cyclic  $(n, d, w)_q$  codes with given parameters n, d, w and q. A cyclic  $(n, d, w)_q$  code is called *optimal* if it has  $CA_q(n, d, w)$  codewords.

Lan, Chang and Wang [29] gave an equivalent definition of a cyclic  $(n, d, w)_q$  code from a set-theoretic perspective. Let  $\mathcal{C}$  be a cyclic  $(n, d, w)_q$  code. For each  $u = (u_i)_{0 \leq i \leq n-1} \in \mathcal{C}$ , construct a *w*-subset  $B_u$  of  $\mathbb{Z}_n \times \{1, 2, \ldots, q-1\}$  such that  $(i, u_i) \in B_u$  if and only if  $u_i$  is nonzero. Let  $\mathcal{C}' = \{B_u : u \in \mathcal{C}\}$ . For any codeword  $B = \{(i_1, a_1), (i_2, a_2), \ldots, (i_w, a_w)\} \in \mathcal{C}'$ , define the projection p(B) of B to be the set  $p(B) = \{i_1, i_2, \ldots, i_w\}$ . For any  $B_u, B_v \in \mathcal{C}'$ , define the distance  $d_H(B_u, B_v)$  to be  $d_H(u, v)$ . It is readily checked that  $d_H(B_u, B_v) = 2w - |p(B_u) \cap$  $p(B_v)| - |B_u \cap B_v|$ . Then a cyclic  $(n, d, w)_q$  code  $\mathcal{C}$  is a set of w-subsets of  $\mathbb{Z}_n \times \{1, 2, \ldots, q-1\}$ satisfying that (1) for any  $B \in \mathcal{C}$ , the cardinality of p(B) is w; (2)  $d_H(A, B) \geq d$  for any distinct codewords  $A, B \in \mathcal{C}$ ; (3) if  $B \in \mathcal{C}$ , then  $B + 1 \in \mathcal{C}$ , where  $B + 1 = \{(x + 1 \pmod{n}, a) : (x, a) \in$  $B\}$ . **Lemma 3.1.** [30, Lemma 3.4] For any positive integer n,

$$CA_3(n, 6, 4) \leqslant C(n) := \begin{cases} n \lfloor \frac{n-1}{6} \rfloor, & \text{if } n \text{ is odd or } n \equiv 2 \pmod{6}; \\ n \lfloor \frac{n-1}{6} \rfloor + \frac{n}{2}, & \text{if } n \equiv 0, 4 \pmod{6}. \end{cases}$$

By [30, Construction 5.3], if there exists a (gh, h, 4, 1)-CDF with  $h \in \{1, 2, 3\}$ , then there exists an optimal cyclic  $(gh, 6, 4)_3$  code with  $2gh\lfloor (gh - 1)/12 \rfloor = gh(gh - h)/6$  codewords. It follows from Theorems 1.1 and 1.2 that an optimal cyclic  $(n, 6, 4)_3$  code with C(n) codewords exists for any  $n \equiv 1, 2, 3 \pmod{12}$  and  $n \notin \{25, 27\}$ . For  $n \in \{25, 27\}$ , an optimal cyclic  $(n, 6, 4)_3$  code with C(n) codewords exists by [30, Lemma 3.5]. By [30, Theorems 5.7 and 5.8], there exists an optimal cyclic  $(n, 6, 4)_3$  code with C(n) codewords for any  $n \equiv 6 \pmod{12}$  or  $n \equiv 0 \pmod{24}$ . Therefore, we have the following result.

**Theorem 3.3.** There exists an optimal cyclic  $(n, 6, 4)_3$  code with C(n) codewords for any positive integer  $n \equiv 1, 2, 3, 6 \pmod{12}$  or  $n \equiv 0 \pmod{24}$ .

### 3.4 Optimal optical orthogonal codes

The study of optical orthogonal codes was first motivated by an application in a fiber optic code-division multiple access channel which requires binary sequences with good correlation properties (cf. [18]).

Let v and k be positive integers. A (v, k, 1) optical orthogonal code (briefly (v, k, 1)-OOC), C, is a family of (0, 1)-sequences (called *codewords*) of *length* v and *weight* k satisfying the following two properties (all subscripts are reduced modulo v):

- (1)  $\sum_{0 \le t \le v-1} x_t x_{t+i} \le 1$  for any  $\mathbf{x} = (x_0, x_1, \dots, x_{v-1}) \in \mathcal{C}$  and any integer  $i \ne 0 \pmod{v}$  (the auto-correlation property);
- (2)  $\sum_{0 \le t \le v-1} x_t y_{t+i} \le 1$  for any  $\mathbf{x} = (x_0, x_1, \ldots, x_{v-1}) \in \mathcal{C}$ ,  $\mathbf{y} = (y_0, y_1, \ldots, y_{v-1}) \in \mathcal{C}$  with  $\mathbf{x} \neq \mathbf{y}$ , and any integer *i* (the cross-correlation property).

A convenient way of viewing OOCs is from a set-theoretic perspective. A (v, k, 1)-OOC can be defined as a set of k-subsets (corresponding to codewords) of  $\mathbb{Z}_v$  whose list of differences does not contain repeated elements (cf. [37, Theorem 2.1]). A (v, k, 1)-OOC is said to be *J*-optimal if the size of the set of missing differences (in  $\mathbb{Z}_v$ ) of this OOC is less than or equal to k(k-1), and hence a J-optimal (v, k, 1)-OOC contains  $\lfloor \frac{v-1}{k(k-1)} \rfloor$  codewords.  $\lfloor \frac{v-1}{k(k-1)} \rfloor$  is an upper bound of the number of codewords of a (v, k, 1)-OOC, and is often referred to as the Johnson bound.

**Theorem 3.4.** There exists a J-optimal (v, 4, 1)-OOC for any positive integer  $v \equiv 1, 2, 3, 4, 6 \pmod{12}$  or  $v \equiv 0 \pmod{24}$  with the only definite exception of v = 25.

**Proof.** Since a (gh, h, 4, 1)-CDF with  $h \in \{1, 2, 3, 4, 6\}$  contains  $\frac{gh-h}{12} = \lfloor \frac{gh-1}{12} \rfloor$  base blocks, every CDF from Theorems 1.1 and 1.2 implies the existence of a J-optimal (gh, 4, 1)-OOC. Therefore, there exists a J-optimal (v, 4, 1)-OOC for any  $v \equiv 1, 2, 3, 4, 6 \pmod{12}$  and  $v \notin \{16, 18, 25, 27, 28, 30\}$ . By [1, Theorem 1.6], there exists a J-optimal (v, 4, 1)-OOC for  $v \in \{16, 18, 27, 28, 30\}$  and there is no J-optimal (25, 4, 1)-OOC. By [13, Theorem 6.12], there exists a J-optimal (v, 4, 1)-OOC for any  $v \equiv 0 \pmod{24}$ .

We remark that Ge and Yin [24, Theorem 6.5] also established the existence of a J-optimal (v, 4, 1)-OOC for any  $v \equiv 6 \pmod{12}$  by using different construction methods. For more information on J-optimal (v, 4, 1)-OOC, the reader is referred to [10, 11, 14, 15, 16, 20, 21, 23, 37].

### 4 Concluding remarks

By utilizing the method presented in [38], we established the existence of (gh, h, 4, 1)-CDFs with  $h \in \{2, 3, 6\}$  and  $gh \equiv h \pmod{12}$  in Theorem 1.2. It shows that the method is flexible and powerful for constructing many kinds of cyclic designs with block size four even though it looks mysterious.

Theorem 2.1 provides more new infinite families of (gh, h, 4, 1)-CDFs by using a standard recursive construction. Completing the existence of (gh, h, 4, 1)-CDFs for all admissible parameters g and h will be a complicated and difficult work.

In order to facilitate the reader for further study, we here summarize main known results on the existence of (gh, h, 4, 1)-CDFs not covered by Theorems 1.1 and 2.1 below.

**Remark 4.1.** (1) [13, Theorem 3.9] There exists a (gh, h, 4, 1)-CDF for  $h \in \{18, 60, 72, 96, 108\}$  and all g such that gcd(g, 150) = 1 or 25.

- (2) [13, Lemmas 3.4, 3.5, 3.10 and 3.11] There exists a (ph, h, 4, 1)-CDF for  $h \in \{36, 48\}$  and any prime p > 5.
- (3) [24, Lemma 6.3] Let g be a positive integer whose prime factors are all congruent to 1 modulo 4 and greater than 5. Then there exists a (12g, 12, 4, 1)-CDF.
- (4) [24, Lemmas 5.2 and 5.3] There exists a  $(24 \cdot 3^{2t}w, 24, 4, 1)$ -CDF for any integer  $t \ge 0$  and all w such that gcd(w, 6) = 1.
- (5) [14, Lemma 4.8] There exists a  $(2^{s+4}, 2^s, 4, 1)$ -CDF for any integer  $s \ge 3$ .
- (6) [15, Lemma 4.4] Let  $s \in \{3, 4, 5, 6\}$ . There exists a  $(2^{4n+s}, 2^s, 4, 1)$ -CDF for any positive integer n.
- (7) [15, Theorem 4.16] Let  $s \in \{3, 4, 5, 6\}$ . There exists a  $(2^{s}p, 2^{s}, 4, 1)$ -CDF for any prime  $p \equiv 1 \pmod{6}$  except possibly for (p, s) = (7, 6).
