### The Computation of the Euclidean Distance Degree for the Middle Catalacticant for the Binary Forms

Belal Sefat Panah

#### Abstract

The *n*-secant varieties to the Veronese embedding  $v_{2n}(\mathbb{P}^1)$  are hypersurfaces of degree n + 1, denoted by  $\sigma_n(v_{2n}(\mathbb{P}^1))$ . We compute the Euclidean distance degree EDdegree of  $\sigma_n(v_{2n}(\mathbb{P}^1))$  for  $n \leq 5$  with respect to the Bombieri-Weyl quadratic form, which is maybe the most interesting case. The output for  $n = 1, \ldots, 5$  is respectively 2, 7, 20, 53, 162. Our main tool is the topological Aluffi-Harris formula. This is the first case when the EDdegree of a *r*-secant variety to the Veronese embedding  $v_d(\mathbb{P}^m)$  is computed for  $r \geq 2$  and  $d \geq 3$ .

### 1 Introduction

The Euclidean distance degree ED degree of an algebraic variety X is the number of critical points of the squared distance function from a general point, as defined in [DHO<sup>+</sup>16]. Consider  $\sigma_r(v_n(\mathbb{P}^1))$ , which are the *r*-secant varieties of Veronese varieties of  $\mathbb{P}^1$ . The aim of this paper is to compute the EDdegree of  $\sigma_n(v_{2n}(\mathbb{P}^1))$ for the Bombieri-Weyl forms for  $n \leq 5$  and provide computational evidence for n = 6, 7. For a general quadratic forms these numbers are known from Catanese-Trifogli formula, while for the Bombieri-Weyl quadratic form the computation is still open and it is maybe the most interesting.  $\sigma_n(v_{2n}(\mathbb{P}^1))$  is a determinantal hypersurface of degree n + 1 in  $\mathbb{P}^{2n}$ , sometimes called the middle catalecticant hypersurface. Aluffi and Harris obtain in [AH18] a topological formula for the EDdegree of a smooth complex variety, but the main obstacle to use this formula is that the r-secant varieties of Veronese varieties are not smooth for r > 2. In [DHO<sup>+</sup>16], it was proven that the EDdegree of an algebraic variety is equal to the EDdegree of its dual. Fortunately the dual varieties of  $\sigma_n(v_{2n}(\mathbb{P}^1))$  are smooth varieties and we can directly apply the Aluffi and Harris formula. Before we compute the ED degree of  $\sigma_n(v_{2n}(\mathbb{P}^1))$ , we bring forward the Harmonic coordinate system and use it as the main tool to compute the EDdegree. Our main results are proved in  $\S^2$ . They can be resumed in the following

**Theorem 1.1.** Let  $X = \sigma_n(\nu_{2n}(\mathbb{P}^n))$ . Its EDdegree with respect to the Bombieri-Weyl quadratic form for  $n \leq 5$  is given by the following table

n	EDdegree $\sigma_n(\nu_{2n}(\mathbb{P}^n))$
1	2
2	7
3	20
4	53
5	162

The EDdegree of a r-secant variety to the Veronese embedding  $v_d(\mathbb{P}^m)$  was known before only for r = 1 (Cartwright-Sturmfels formula, see [DHO<sup>+</sup>16, Corollary 8.7]) and d = 2 (the case of symmetric matrices, classically known by Eckart-Young Theorem).

#### 1.1 Harmonic Coordinate System

**Definition 1.1.** Fix a nondegenerate quadratic form  $q \in \text{Sym}^d \mathbb{C}^2$ , in orthonormal coordinates we may assume  $q(x, y) = x^2 + y^2$ . The space of homogeneous polynomials of degree d in two variables  $\text{Sym}^d \mathbb{C}^2$  is not irreducible under the action of the orthogonal group SO(2), but it splits in several pieces which are irreducible and each piece is given by *harmonic polynomials*. The space  $H_d$  of harmonic polynomials of degree d is a 2-dimensional vector space spanned by  $(x - iy)^d$ ,  $(x + iy)^d$ . In  $\text{Sym}^2 \mathbb{C}^n$ , the harmonic subspace  $H_2$  corresponds to the space of traceless symmetric matrices. The splitting in irreducible SO(2)-modules is

$$\operatorname{Sym}^{d} \mathbb{C}^{2} = \bigoplus_{i=0}^{\lfloor d/2 \rfloor} q^{i} H_{d-2i}.$$
 (1)

**Definition 1.2** (Bombieri-Weyl Form). Let W be a space of dimension n+1, being equipped with a nondegenerate quadratic form  $q_W$ . Assume  $V = \text{Sym}^d W$ . We choose coordinates in W such that  $q_W = \sum_{i=0}^n x_i^2$ . There is a unique nondegenerate bilinear form Q such that

$$Q(x^d, y^d) = q_W(x, y)^d \quad \forall x, y \in W,$$
(2)

which is called the *Bombieri-Weyl* or *Frobenius* form. Since the vector space of symmetric tensors  $\operatorname{Sym}^d W$  admits a basis of rank-one elements  $\{x^d \mid x \in W\}$ , the formula (2) prescribes Q(f,g) for every  $f,g \in \operatorname{Sym}^d W$ , by linearity. For the symmetric tensors f and  $g \in \operatorname{Sym}^d W$ , the Bombieri-Weyl form has the coordinate expression

$$Q\Big(\sum_{|\alpha|=d} \binom{d}{\alpha} f_{\alpha} x^{\alpha}, \sum_{|\alpha|=d} \binom{d}{\alpha} g_{\alpha} x^{\alpha}\Big) = \sum_{|\alpha|=d} \binom{d}{\alpha} f_{\alpha} g_{\alpha}$$

and up to a scalar factor, has the M2 [GS] implementation

$$(1/d!) * diff(f,g)$$

**Proposition 1.1.** 1. i) The summands in (1) are orthogonal for the Bombieri-Weyl form.

2. ii) there is a scalar c, depending only on i, d, such that

$$Q(q^i f, q^i g) = cQ(f, g) \qquad \forall f, g \in \operatorname{Sym}^{d-2i} \mathbb{C}^2$$

3. iii) in particular the forms  $(x^2 + y^2)^{\alpha}(x + iy)^{\beta}$  and  $(x^2 + y^2)^{\alpha}(x - iy)^{\beta}$  are isotropic if  $\beta > 0$ .

**Lemma 1.1.** For  $0 \le j, k \le 2n$ , and  $n \ge 1$ , the bilinear product of  $\langle (x+iy)^{2n-j}(x-iy)^j, (x+iy)^{2n-k}(x-iy)^k \rangle$  is nonzero if and only if 2n = k+j.

*Proof.*  $(\Rightarrow)$  Suppose the product is nonzero. We split the case into the following conditions:

- (i) First, assume  $j, k \leq n$  therefore  $2n j \geq j, 2n k \geq k$ . The product can be rewritten as  $\langle (x + iy)^{2n-2j}(x^2 + y^2)^j, (x + iy)^{2n-2k}(x^2 + y^2)^k \rangle$ , since it is nonzero and by Prop. 1.1 i), j = k. Now by Prop. 1.1 iii) the product  $\langle (x + iy)^{2n-2j}(x^2 + y^2)^k, (x + iy)^{2n-2j}(x^2 + y^2)^k \rangle$  is nonzero if 2n 2j = 0, therefore n = j = k and 2n = j + k.
- (ii) Second, assume  $j, k \ge n$  therefore  $2n j \le j, 2n k \le k$ . The product can be rewritten as  $\langle (x^2 + y^2)^{2n-j}(x iy)^{2j-2n}, (x^2 + y^2)^{2n-k}(x iy)^{2k-2n} \rangle$ , since it is nonzero and by Prop. 1.1 i), 2n j = 2n k, therefore j = k. Now by Prop. 1.1 ii) the product  $\langle (x^2 + y^2)^{2n-j}(x iy)^{2j-2n}, (x^2 + y^2)^{2n-j}(x iy)^{2j-2n} \rangle$  is nonzero if 2j 2n = 0, therefore n = j = k and 2n = j + k.
- (iii) Third, assume  $j \leq n \leq k$  therefore  $2n j \geq j$ ,  $2n k \leq k$ . The product can be rewritten as  $\langle (x+iy)^{2n-2j}(x^2+y^2)^j, (x^2+y^2)^{2n-k}(x-iy)^{2k-2n} \rangle$ , since it is nonzero and by Prop. 1.1 i), j = 2n k, therefore 2n = j + k. By Symmetry same argument holds for  $k \leq n \leq j$ .

(⇐) Now suppose 2n = k + j, and  $j \ge k$  the product can be rewritten as  $\langle (x + iy)^{2n-j-k=0}(x - iy)^{j-k}(x^2 + y^2)^k, (x + iy)^{2n-2k}(x^2 + y^2)^k \rangle$ , if  $j \ge k$ , and by Prop. 1.1 i), it is nonzero. Same argument holds for  $j \le k$ .

We consider the last secant variety of  $v_{2n}(\mathbb{P}^1)$  that does not fill the ambient space, namely  $\sigma_n(v_{2n}(\mathbb{P}^1))$  which is a determinantal hypersurface of degree n+1in  $\mathbb{P}^{2n} = \mathbb{P}(\operatorname{Sym}^{2n}\mathbb{C}^2)$ . **Lemma 1.2.** The dual variety of  $\sigma_n(v_{2n}(\mathbb{P}^1))$  is the variety of squares

$$Sq_n = \{f^2 | f \in \operatorname{Sym}^n \mathbb{C}^2\}$$

Its projectivization in  $\mathbb{P}^{2n} = \mathbb{P}(\operatorname{Sym}^{2n} \mathbb{C}^2)$  is a smooth variety isomorphic to  $\mathbb{P}^n$ .

*Proof.* Apply [LS16, Corollary 3.1], with partition  $\lambda = 2^n$ ,  $\sigma_n$  is a hypersurface given by the determinant of middle Catalecticant map. Smoothness follows since  $GL(\text{Sym}^n \mathbb{C}^2)$  acts transitively on  $Sq_n$ .

With respect to a general quadratic form we have

**Proposition 1.2** (Catanese-Trifogli). With respect to a general quadratic form, the EDdegree of  $\sigma_n(v_{2n}(\mathbb{P}^1))$  is

$$\frac{3^{n+1}-1}{2}$$

*Proof.* This follows from Catanese-Trifogli formula applied to  $Sq_n$ , see for example [DHO<sup>+</sup>16, Corollary 6.1, Prop. 7.10].

The goal of this paper is to compute  $\text{EDdegree}\sigma_n(v_{2n}(\mathbb{P}^1))$  with respect to the Bombieri-Weyl quadratic form. By  $[\text{DHO}^+16$ , Theorem 5.2] we get that  $\text{EDdegree}(X) = \text{EDdegree}(X^{\vee})$  for any projective variety. The main advantage to use this formula in combination with Lemma 1.2 is that the dual variety  $\sigma_n(v_{2n}(\mathbb{P}^1))^{\vee} = Sq_n$  is a smooth variety. The isotropic quadric cuts  $Sq_n$  in a divisor of  $Sq_n$ . Since  $Sq_n$  is isomorphic to  $\mathbb{P}^n = \mathbb{P}(\text{Sym}^n \mathbb{C}^2)$ , we get in this way a quartic hypersurface  $\mathcal{Q}$  in  $\mathbb{P}^n$ . We will see at beginning of the proof of Theorem 1.2 that this quartic is singular at least at the two points corresponding to  $(x + iy)^n$  and  $(x - iy)^n$ . The following Theorem shows that the singular locus is indeed larger.

**Theorem 1.2.** The quartic

- $\mathcal{Q} = \{ f \in \operatorname{Sym}^{n} \mathbb{C}^{2} | \| f^{2} \|^{2} = 0, \text{ where the norm is the Bombieri-Weyl norm.} \},$
- (i) for  $n \ge 2N+1$ ,  $N \in \mathbb{N}^*$ , contains the N-osculating space of rational normal curve at  $(x+iy)^n$  and  $(x-iy)^n$ .
- (ii) for  $n \ge 3N + 1$ ,  $N \in \mathbb{N}^*$ , is singular at the N-osculating space of rational normal curve at  $(x + iy)^n$  and  $(x iy)^n$ .

*Proof.* Having Lemma 1.1 in mind, we choose homogeneous coordinates  $(z_0, \ldots, z_n)$  in  $\mathbb{P}^n$  defined by the following formula

$$f = \sum_{j=0}^{n} z_j (x + iy)^{n-j} (x - iy)^j,$$

so that the two points  $(x + iy)^n$  and  $(x - iy)^n$  have coordinates respectively  $(1, 0, \ldots, 0)$  and  $(0, \ldots, 0, 1)$ . The square  $f^2$  is given by

$$f^{2} = \sum_{j,k=0}^{n} z_{j} z_{k} (x + iy)^{2n-j-k} (x - iy)^{j+k},$$

and by Lemma 1.1 the equation of  $\mathcal{Q}$  contains the monomial  $z_j z_k z_p z_q$  only if j + k + p + q = 2n, namely if it is *isobaric* of weight 2n. In particular the two extreme monomials  $z_0^4$  and  $z_n^4$  do not appear in  $\mathcal{Q}$ , which shows immediately that the two points  $(x + iy)^n$  and  $(x - iy)^n$  belong to  $\mathcal{Q}$ . The N-osculating space at  $(x + iy)^n$  is spanned by  $\langle (x + iy)^n, (x + iy)^{n-1}(x - iy), (x + iy)^{n-2}(x - iy)^2, \ldots, (x + iy)^{n-N}(x - iy)^N \rangle$ . For proving the statement we should verify that

$$V(z_0,\ldots,z_N,0,\ldots,0) \subseteq V(\langle f^2,f^2 \rangle)$$

which means all partial derivatives vanish at the given point  $(z_0, \ldots, z_N, 0, \ldots, 0)$ , which corresponds to a general point on N-osculating space, vanish. We verify that the terms  $z_{i_1}z_{i_2}z_{i_2}z_{i_4}$  for  $i_1, i_2, i_3, i_4 \leq N$  will not appear in the expression of the equation of the quartic.

By the Lemma 1.1 this term appears when  $2n - i_1 - i_2 = i_3 + i_4$ , which means  $2n = \sum_{j=1}^{4} i_j \leq 4N$ , since each  $i_j$  is bounded by N, and this results  $n \leq 2N$ . Therefore for  $n \geq 2N + 1$  the quartic always contains the N-osculating space, and this proves (i).

For proving (ii), we need to verify that no terms in the form  $z_{i_1}^{m_1} z_{i_2}^{m_2} z_{i_2}^{m_3} z_{i_4}^{m_4}$ where  $i_1, i_2, i_3 \leq N$  and  $i_4 \leq n$ , appear in the equation of the quartic. By the **Lemma.** 1.1 this term appears when  $2n - i_1 - i_2 = i_3 + i_4$ , which means  $2n = \sum_{j=1}^{3} i_j + n \leq 3N + n$ , and this results  $n \leq 3N$ . Therefore for  $n \geq 3N + 1$ the quartic is singular at the N-osculating space of the rational normal curve at  $(x + iy)^n$  and  $(x - iy)^n$ .

**Conjecture.** For  $n \neq 3N + 1$ , there are no other singularities than the N-osculating spaces.

# 2 Computing the EDdegree of $\sigma_n(\nu_{2n}(\mathbb{P}^1))$

In [AH18] *Aluffi* and *Harris* showed that the EDdegree of a smooth complex variety is given by the following theorem:

**Theorem 2.1.** Let X be a smooth subvariety of  $\mathbb{P}^{n-1}$ , let Q be the quadric hypersurface corresponding to a nondegenerate quadratic form, assume  $X \not\subseteq Q$ . Then

$$EDdegree(X) = (-1)^{\dim X} \chi (X \setminus (Q \cup H)), \qquad (3)$$

where H is a general hyperplane, ED degree is computed with respect to Q and  $\chi$  is the ordinary topological Euler characteristic.

Then EDdegree(X) is given by

$$EDdegree(X) = (-1)^{\dim X} (\chi(X) - \chi(X \cap Q) - \chi(X \cap H) + \chi(X \cap Q \cap H)),$$
(4)

Since  $\sigma_n(\nu_{2n}(\mathbb{P}^1))$  are not smooth, we cannot directly apply the *Aluffi* formula on  $\sigma_n(\nu_{2n}(\mathbb{P}^1))$ . We will compute the EDdegree of  $\sigma_n(\nu_{2n}(\mathbb{P}^1))$  by its dual, since it is smooth, by Lemma 1.2.

**Theorem 2.2.** Let  $Y = \sigma_n(\nu_{2n}(\mathbb{P}^1))^{\vee} \simeq \mathbb{P}^n$ . Consider the quartic  $\mathcal{Q} = Y \cap Q \subset \sigma_n(\nu_{2n}(\mathbb{P}^1))^{\vee}$ , defined by the Bombieri-Weyl metric we have

$$\chi(Y \cap Q) = \begin{cases} n & \text{if } n \text{ is even} \\ n+1 & \text{if } n \text{ is odd} \end{cases}$$

Proof. We consider  $Y \cap Q$  as a quartic hypersurface embedded in  $\mathbb{P}^n$  with homogeneous coordinates  $(z_0, \ldots, z_n)$ . The multiplicative group  $\mathbb{C}^*$  acts on  $Y \cap Q$  by  $t \cdot z_i = t^{-n+2i}z_i$  for  $i = 0, \ldots, n$ . The fixed points of this action are  $e_i = (0, \ldots, 1, \ldots, 0)$  for  $i = 0, \ldots, n, i \neq n/2$  when n is even. Each fixed point  $e_j$  as above defines an attractive cell  $E_j = \{x \in Q | \lim_{t \to 0} t \cdot x = e_j\}$ . By [Kon78] each  $E_j$  is locally closed (this is called the Bialinicki-Birula decomposition in the smooth setting), since  $Y \cap Q$  is a normal variety. Each  $E_j$  is easily seen to be contractible. Hence

$$\chi(Y \cap Q) = \sum_{\substack{j = 0 \dots n \\ j \neq n/2}} \chi(E_j) = \sum_{\substack{j = 0 \dots n \\ j \neq n/2}} 1$$

and the thesis follows.

**Theorem 2.3.** Let  $Y = \sigma_n(\nu_{2n}(\mathbb{P}^1))^{\vee} \simeq \mathbb{P}^n$ , let H be a general hyperplane. Then  $Y \cap H$  is isomorphic to a smooth quadric of dimension n-1 and it satisfies

$$\chi(Y \cap H) = \begin{cases} n & \text{if } n \text{ is even} \\ n+1 & \text{if } n \text{ is odd} \end{cases}$$

*Proof.* The hyperplane H cuts  $Y \simeq \mathbb{P}^n$  in a quadratic hypersurface in  $\mathbb{P}^n$ .  $\Box$ 

Note by Theorem 2.2 and Theorem 2.3 it follows

$$\chi(Y \cap Q) = \chi(Y \cap H).$$

**Corollary 2.1.** With respect to the Bombieri-Weyl metric, the EDdegree of  $Y = \sigma_n(\nu_{2n}(\mathbb{P}^1))^{\vee} \simeq \mathbb{P}^n$  is

$$1 - n + \chi(Y \cap H \cap Q)$$
 if n is even

$$1 + n - \chi(Y \cap H \cap Q)$$
 if n is odd

*Proof.* Apply (4), Theorem 2.2 , Theorem 2.3 and the fact that  $\chi(Y) = \chi(\mathbb{P}^n) = n + 1$ .

**Theorem 2.4.** Consider the Veronese embedding of  $\nu_4(\mathbb{P}^1)$ . The EDdegree of  $\sigma_2(\nu_4(\mathbb{P}^1))$  for the Bombieri-Weyl quadratic form is given by 7.

*Proof.* For the Bombieri-Weyl quadratic form in [OSS14], the EDdegree of  $\sigma_2(\nu_4(\mathbb{P}^1))$  has been computed numerically. We will prove the statement, giving a theoretical argument. Let  $Y = \sigma_2(\nu_4(\mathbb{P}^1))^{\vee}$ . We compute now that the intersection  $Y \cap Q$  is the union of two conics tangent at two distinct points (and its Euler characteristic is 2). Indeed, for  $f \in \text{Sym}^4 \mathbb{C}^2$ , consider the harmonic coordinate system in §1.1

$$f = \sum_{j=0}^{2} z_j (x+iy)^{2-j} (x-iy)^j = z_0 (x+iy)^2 + z_1 (x^2+y^2) + z_2 (x-iy)^2, \quad (5)$$

the intersection of Y and Q is a quartic which is given by

 $\mathcal{Q} = \{f \mid \left\| f^2 \right\|^2 = 0, \text{ where the norm is Bombieri-Weyl norm.} \}$ 

By the formula of f in (5),  $f^2$  is given by

$$f^{2} = z_{0}^{2}(x+iy)^{4} + z_{2}^{2}(x-iy)^{4} + (x^{2}+y^{2})[2z_{0}z_{1}(x+iy)^{2} + 2z_{1}z_{2}(x-iy)^{2}] + (x^{2}+y^{2})^{2}[z_{1}^{2}+2z_{0}z_{2}].$$
(6)

Each lines of the equation (6) are orthogonal, and by simplifying and applying the Prop. 1.1 on  $||f^2||^2$  the quartic up to a scalar is given by

$$\mathcal{Q} = \left\| f^2 \right\|^2 = (2^9) z_0^2 z_2^2 + (2^9) z_0 z_1^2 z_2 + (2^6) z_1^4 + (2^9) z_0 z_1^2 z_2 + (2^9) z_0^2 z_2^2 
= 1024 z_0^2 z_2^2 + 64 z_1^4 + 1024 z_0 z_1^2 z_2 = 64 (16 z_0^2 z_2^2 + z_1^4 + 16 z_0 z_1^2 z_2) 
= 64 ((z_1^2 + 8 z_0 z_2) + \sqrt{48} z_0 z_2) ((z_1^2 + 8 z_0 z_2) - \sqrt{48} z_0 z_2).$$
(7)

the polynomial in  $z_1^2, z_0 z_2$  is consequences of SO(2)-invariant which is singular at two points (1, 0, 0), (0, 0, 1). The two conics in the last line of (7) are tangent at these two points. Since H does not cut the singular points of the quartic, the intersection  $(Y \cap H \cap Q)$  is given by eight distinct points. By applying Corollary 2.1 we get

$$EDdegree(\sigma_2(\nu_4(\mathbb{P}^1)) = EDdegree(\sigma_2(\nu_4(\mathbb{P}^1))^{\vee} = 1 - 2 + 8 = 7.$$

**Theorem 2.5.** Consider the Veronese embedding of  $\nu_6(\mathbb{P}^1)$ , The EDdegree of  $\sigma_3(\nu_6(\mathbb{P}^1))$  for the Bombieri-Weyl quadratic form is given by 20.

*Proof.* Let  $Y = \sigma_3(\nu_6(\mathbb{P}^1))^{\vee}$ . Consider the harmonic coordinate system and apply the same argument for Theorem 2.5 for  $f \in \text{Sym}^6 \mathbb{C}^2$ 

$$f = \sum_{j=0}^{3} z_j (x+iy)^{3-j} (x-iy)^j = z_0 (x+iy)^3 + z_3 (x-iy)^3 + (x^2+y^2) [z_1(x+iy) + z_2(x-iy)],$$

and  $f^2$  is given by

$$f^{2} = z_{0}^{2}(x+iy)^{6} + z_{3}^{2}(x-iy)^{6} + (x^{2}+y^{2})[2z_{0}z_{1}(x+iy)^{4} + 2z_{2}z_{3}(x-iy)^{4}] + (x^{2}+y^{2})^{2}[z_{1}^{2}(x+iy)^{2} + z_{2}^{2}(x-iy)^{2} + 2z_{0}z_{2}(x+iy)^{2} + 2z_{1}z_{3}(x-iy)^{2}] + (x^{2}+y^{2})^{3}[2z_{1}z_{2} + 2z_{0}z_{3}].$$
(8)

Each lines of the equation (8) are orthogonal, and by computing and applying the Prop. 1.1 on  $||f^2||^2$  by **M2**, the quartic up to a scalar is given by as follow

$$\mathcal{Q} = 5z_1^2 z_2^2 + 4z_0 z_2^3 + 4z_1^3 z_3 + 34z_0 z_1 z_2 z_3 + 33z_0^2 z_3^2.$$
(9)

Recalling Theorem 1.2, the quartic is singular at (1, 0, 0, 0), (0, 0, 0, 1). Moreover these points are the only singularity of the quartic, since the following system of partial equation of quartic has only solution in these two points (solved by **M2** [GS])

$$\begin{cases} 33z_0z_3^2 + 17z_1z_2z_3 + 2z_2^3 &= 0\\ 5z_1z_2^2 + 6z_1^2z_3 + 17z_0z_2z_3 &= 0\\ 5z_1^2z_2 + 6z_0z_2^2 + 17z_0z_1z_32 &= 0\\ 2z_1^3 + 17z_0z_1z_2 + 33z_0^2z_3 &= 0. \end{cases}$$

Since *H* does not cut the singular points of the quartic, the intersection  $(Y \cap H \cap Q)$  is a curve of type (a, b) = (4, 4) of degree (4 + 4) = 8 on a non-singular quadric surface in  $\mathbb{P}^3$  of genus ab - a - b + 1 = 9 ([Har77] exercise 5.6(c)). Therefore

$$\chi(Y \cap H \cap Q) = 2 - 2g = 2 - 18 = -16.$$

Subsequently by Corollary 2.1

EDdegree
$$(\sigma_3(\nu_6(\mathbb{P}^1)) = EDdegree(\sigma_3(\nu_6(\mathbb{P}^1))^{\vee} = 1 + 4 - (-16) = 20.$$

**Theorem 2.6.** Consider the Veronese embedding of  $\nu_8(\mathbb{P}^1)$ , The EDdegree of  $\sigma_4(\nu_8(\mathbb{P}^1))$  for the Bombieri-Weyl quadratic form is 53.

*Proof.* Let  $Y = \sigma_4(\nu_8(\mathbb{P}^1))^{\vee}$ . Consider the following harmonic coordinate system for  $f \in \text{Sym}^8(\mathbb{P}^1)$ ,

$$f = \sum_{j=0}^{4} z_j (x+iy)^{4-j} (x-iy)^j$$
  
=  $z_0 (x+iy)^4 + z_4 (x-iy)^4 + (z_1 (x+iy)^2 + z_3 (x-iy)^2) (x^2 + y^2)$   
+  $z_2 (x^2 + y^2)^2$ ,

therefore  $f^2$  is given by

$$\begin{aligned} f^2 &= z_0^2 (x+iy)^8 + z_4^2 (x-iy)^8 \\ &+ (x^2+y^2) [2z_0 z_1 (x+iy)^6 + 2z_4 z_3 (x-iy)^6] \\ &+ (x^2+y^2)^2 [z_1^2 (x+iy)^4 + z_3^2 (x-iy)^4 + 2z_0 z_3 (x+iy)^2 + 2z_0 z_2 (x+iy)^4 \\ &+ 2z_1 z_4 (x-iy)^2 + 2z_2 z_4 (x-iy)^4] \\ &+ (x^2+y^2)^3 [2z_1 z_2 (x+iy)^2 + 2z_2 z_3 (x-iy)^2] \\ &+ (x^2+y^2)^4 [z_2^2 + 2z_1 z_3 + 2z_0 z_4] \end{aligned}$$

Each lines of the equation is orthogonal, and the equation of the quartic is given by

 $Q = \{f | \|f^2\|^2 = 0, \text{ where the norm is Bombieri-Weyl norm.}\}.$ computing the equation by **M2** up to a scalar leads to

$$\mathcal{Q} = \|f\|^2 = z_2^4 + 14z_1z_2^2z_3 + 9z_1^2z_3^2 + 20z_0z_2z_3^2 + 20z_1^2z_2z_4 + 24z_0z_2^2z_4$$
(10)  
+ 88z\_0z\_1z\_3z\_4 + 144z\_0^2z\_4^2.

The quartic is singular at tangent space at the rational normal curve at the points  $(x + iy)^4$  and  $(x - iy)^4$ . In this case other singularities appear:

**Proposition 2.1.** The quartic (10) is singular in two tangent lines at  $(x + iy)^4$  and  $(x - iy)^4$  and a smooth conic. Moreover the equation of the conic is given by

$$\mathcal{Q} \cap \langle (x+iy)^4, (x-iy)^4, (x^2+y^2)^2 \rangle = \mathcal{Q} \cap \{z_1 = z_3 = 0\}.$$
 (11)

*Proof.* Decomposing the singularity of the quartic by M2 gives the following ideals:

{ideal
$$(z_4, z_3, z_2)$$
, ideal $(z_3, z_1, z_2^2 + 12z_0z_4)$ , ideal $(z_2, z_1, z_0)$ },

which represents two tangent line at (1, 0, 0, 0) and (0, 0, 0, 1) and a conic. The equation of the conic is given by the following system of equation

$$\begin{cases} z_1 = 0\\ z_3 = 0\\ z_2^2 + 12z_0z_4 = 0. \end{cases}$$

Since H cut the quartic in eight singular points, the intersection  $(Y \cap H \cap Q)$  has  $\chi$  obtained by subtracting 8 from the  $\chi$  of smooth complete intersection (4, 2) in  $\mathbb{P}^4$ . The complete intersection (4, 2) has  $\chi$  equal to 64, see [Dim12]. Hence  $\chi(Y \cap H \cap Q) = 64 - 8 = 56$ . Subsequently by Corollary 2.1

$$EDdegree(\sigma_4(\nu_8(\mathbb{P}^1)) = EDdegree(\sigma_4(\nu_8(\mathbb{P}^1))^{\vee} = 1 - 4 + 56 = 53.$$
(12)

**Theorem 2.7.** Consider the Veronese embedding of  $\nu_{10}(\mathbb{P}^1)$ , The EDdegree of  $\sigma_5(\nu_{10}(\mathbb{P}^1))$  for the Bombieri-Weyl quadratic form is 162.

Proof. Let  $Y = \sigma_2(\nu_5(\mathbb{P}^{10}))^{\vee}$ . As in the proof of Theorem 2.5 and Theorem 2.6, we consider the harmonic coordinate system  $(z_0, \ldots, z_5)$ , one can prove that the only singularities of  $\mathcal{Q}$  are the two lines  $\{z_0 = z_1 = 0\}$  and  $\{z_4 = z_5 = 0\}$ . The smooth complete intersection (4, 2) in  $\mathbb{P}^5$  is a Calabi-Yau 3fold of degree 8, whose  $\chi$  is given by the coefficient of  $t^3$  in the Taylor development

$$8\frac{(1+t)^6}{(1+2t)(1+4t)}$$

Such coefficient is -176. Our  $Y \cap H \cap Q$  has four singular points, obtained cutting the two previous lines with H which is a quadric hypersurface. It can be proved (e.g. computationally) that the Milnor number of each of these points is 5. It follows by [Dim12] that  $\chi(Y \cap H \cap Q) = -176 + 4 \cdot 5 = -156$ . We get from Corollary 2.1

$$EDdegree(\sigma_5(\nu_{10}(\mathbb{P}^1)) = EDdegree(\sigma_5(\nu_{10}(\mathbb{P}^1))^{\vee} = 1 + 5 - (-156) = 162.$$
(13)

The numerical result by using **Macaulay2** for the Bombieri-Weyl form for n = 1, ..., 7, computing the minimum distance from a random point with a parametrization of  $Sq_n$ , are listed in the following table, where we apply Corollary 2.1:

$X = \mathbb{P}^n$	$\chi(\mathcal{Q}\cap H)$	EDdegree $\sigma_n(\nu_{2n}(\mathbb{P})^n)$
n = 1	0	2
n=2	8	7
n = 3	-16	20
n = 4	56	53
n = 5	-156	162
n = 6	468	463
n = 7	-1304	1312

## Acknowledgement

I would like to thank my supervisor Professor Rashid Zaare Nahandi for encouraging me to do this project. A special acknowledgment goes to Professor Giorgio Ottaviani, my advisor, for his support and invaluable guidance throughout the research process. This article is part of my doctoral thesis.
