#### Abstract

Let $\left(Z_{n}\right)_{n \geq 0}$ be a supercritical branching process in an independent and identically distributed random environment. We establish an optimal convergence rate in the Wasserstein- 1 distance for the process $\left(Z_{n}\right)_{n \geq 0}$, which completes a result of Grama et al. [Stochastic Process. Appl., 127(4), 1255-1281, 2017]. Moreover, an exponential nonuniform Berry-Esseen bound is also given. At last, some applications of the main results to the confidence interval estimation for the criticality parameter and the population size $Z_{n}$ are discussed.

Keywords: Branching processes; Random environment; Wasserstein-1 distance; Nonuniform Berry-Esseen bounds

## 1. Introduction

Branching process in a random environment (BPRE) initially introduced by Smith and Wilkinson [13] is a generalization of the Galton-Watson process. Denote by $\xi=\left(\xi_{0}, \xi_{1}, \ldots\right)$ a sequence of independent and identically distributed (i.i.d.) random variables, where $\xi_{n}$ stands for the random environment in the $n$-th generation. Then the branching process $\left(Z_{n}\right)_{n \geq 0}$ in the random environment $\xi$ is defined as follows:

$$
Z_{0}=1, Z_{n+1}=\sum_{i=1}^{Z_{n}} X_{n, i}, n \geq 0
$$

where $X_{n, i}$ represents the number of offspring produced by the $i$-th particle in the $n$-th generation. The distribution of $X_{n, i}$ depending on the environment $\xi_{n}$ is denoted by $p\left(\xi_{n}\right)=\left\{p_{k}\left(\xi_{n}\right)=\mathbb{P}\left(X_{n, i}=k \mid \xi_{n}\right): k \in \mathbb{N}\right\}$. Suppose that given $\xi_{n},\left(X_{n, i}\right)_{i \geq 1}$ is a sequence of i.i.d. random variables; moreover, $\left(X_{n, i}\right)_{i \geq 1}$ is independent of $\left(Z_{1}, \ldots, Z_{n}\right)$. Let $\left(\Gamma, \mathbb{P}_{\xi}\right)$ be the probability space under which the process is defined

[^0]when the environment $\xi$ is given, where $\mathbb{P}_{\xi}$ is usually called the quenched law. The state space of the random environment $\xi$ is denoted by $\Theta$ and the total probability space can be regarded as the product space $\left(\Theta^{\mathbb{N}} \times \Gamma, \mathbb{P}\right)$, where $\mathbb{P}(\mathrm{d} x, \mathrm{~d} \xi)=\mathbb{P}_{\xi}(\mathrm{d} x) \tau(\mathrm{d} \xi)$. That is, for any measurable positive function $g$ defined on $\Theta^{\mathbb{N}} \times \Gamma$, we have
$$
\int g(x, \xi) \mathbb{P}(\mathrm{d} x, \mathrm{~d} \xi)=\iint g(x, \xi) \mathbb{P}_{\xi}(\mathrm{d} x) \tau(\mathrm{d} \xi)
$$
where $\tau$ represents the distribution law of the random environment $\xi$. We usually call $\mathbb{P}$ the annealed law. And $\mathbb{P}_{\xi}$ can be regarded as the conditional probability of $\mathbb{P}$ given the environment $\xi$. The expectations with respect to $\mathbb{P}_{\xi}$ and $\mathbb{P}$ are denoted by $\mathbb{E}_{\xi}$ and $\mathbb{E}$, respectively. For any environment $\xi$, integer $n \geq 0$ and real number $p>0$, define
$$
m_{n}^{(p)}=m_{n}^{(p)}(\xi)=\sum_{i=0}^{\infty} i^{p} p_{i}\left(\xi_{n}\right), \quad m_{n}=m_{n}(\xi)=m_{n}^{(1)}(\xi)
$$

Then

$$
m_{0}^{(p)}=\mathbb{E}_{\xi} Z_{1}^{p} \quad \text { and } \quad m_{n}=\mathbb{E}_{\xi} X_{n, i}, \quad i \geq 1
$$

Consider the following random variables

$$
\Pi_{0}=1, \Pi_{n}=\Pi_{n}(\xi)=\prod_{i=0}^{n-1} m_{i}, \quad n \geq 1
$$

It is easy to see that

$$
\mathbb{E}_{\xi} Z_{n+1}=\mathbb{E}_{\xi}\left[\sum_{i=1}^{Z_{n}} X_{n, i}\right]=\mathbb{E}_{\xi}\left[\mathbb{E}_{\xi}\left(\sum_{i=1}^{Z_{n}} X_{n, i} \mid Z_{n}\right)\right]=\mathbb{E}_{\xi}\left[\sum_{i=1}^{Z_{n}} m_{n}\right]=m_{n} \mathbb{E}_{\xi} Z_{n}
$$

Then by recursion, we get $\Pi_{n}=\mathbb{E}_{\xi} Z_{n}$. Denote by

$$
X=\log m_{0}, \quad \mu=\mathbb{E} X \quad \text { and } \quad \sigma^{2}=\mathbb{E}(X-\mu)^{2}
$$

The branching process $\left(Z_{n}\right)_{n \geq 0}$ is called supercritical, critical or subcritical according to $\mu>0, \mu=0$ or $\mu<0$, respectively. Hence $\mu$ is known as the criticality parameter. Over all the paper, assume that

$$
\begin{equation*}
p_{0}\left(\xi_{0}\right)=0 \text { a.s. } \tag{1.1}
\end{equation*}
$$

The condition (1.1) means that each particle has at least one offspring, which implies $X \geq 0$ a.s. and hence $Z_{n} \geq 1$ a.s. for any $n \geq 1$.

Limit theorems for BPRE have attracted a lot of interests since the seminal work of Smith and Wilkinson [13]. For critical and subcritical BPRE, the study mainly focuses on the survival probability and conditional limit theorems for the branching processes, see, for instance, Vatutin [15] and Afanasyev et al. [1, 2]. For the supercritical BPRE, a number of researches focused on the central limit theorem, moderate and large deviations; see Böinghoff and Kersting [5], Huang and Liu [11], Böinghoff [4], Li et al. [12], Grama et al. [10], Wang and Liu [16], Fan et al. [8] and Gao [9].

The aim of this paper is to establish optimal convergence rates in the Wasserstein- 1 distance for the branching process in a random environment. We first recall the definition of the Wasserstein- 1 distance. Let $\mathcal{L}(\mu, \nu)$ be a set of probability laws on $\mathbb{R}^{2}$ with marginals $\mu$ and $\nu$. The Wasserstein- 1 distance between $\mu$ and $\nu$ is defined as follows:

$$
W_{1}(\mu, \nu)=\inf \left\{\int|x-y| \mathbb{P}(\mathrm{d} x, \mathrm{~d} y): \mathbb{P} \in \mathcal{L}(\mu, \nu)\right\} .
$$

In particular, if $\mu_{X}$ is the distribution of $X$ and $\nu$ is the standard normal distribution, then we have

$$
W_{1}\left(\mu_{X}, \nu\right)=d_{w}(X):=\int_{-\infty}^{+\infty}|\mathbb{P}(X \leq x)-\Phi(x)| \mathrm{d} x .
$$

The following convergence rate in the Wasserstein-1 distance between $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$ and the standard normal random variable is due to Grama et al. [10]. Assume that there exists a constant $\varepsilon>0$ such that

$$
\begin{equation*}
\mathbb{E}|X|^{3+\varepsilon}<\infty . \tag{1.2}
\end{equation*}
$$

Grama et al. [10] have established the following convergence rate in the Wasserstein-1 distance:

$$
\begin{equation*}
d_{w}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}\right) \leq \frac{C}{\sqrt{n}}, \tag{1.3}
\end{equation*}
$$

where $C$ is a positive constant. In this paper, we are going to extend this result to the case $X$ having a moment of order $2+\delta, \delta \in(0,1]$. We get the following convergence rate in the Wasserstein- 1 distance for $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$. Assume that there exist two constants $p>1$ and $\delta \in(0,1]$ such that

$$
\begin{equation*}
\mathbb{E} X^{2+\delta}<\infty \quad \text { and } \quad \mathbb{E}\left(\frac{Z_{1}}{m_{0}}\right)^{p}<\infty \tag{1.4}
\end{equation*}
$$

then it holds

$$
\begin{equation*}
d_{w}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}\right) \leq \frac{C}{n^{\delta / 2}} . \tag{1.5}
\end{equation*}
$$

Moreover, the same result holds when $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$ is replaced by $\frac{n \mu-\log Z_{n}}{\sigma \sqrt{n}}$. Notice that the last convergence rate on the right-hand side of (1.5) coincides with the best possible convergence rate in the Wasserstein- 1 distance for random walks with finite $2+\delta$ moments, and therefore inequality (1.5) is also the best possible. In addition, when $X$ has an exponential moment and satisfies $\mathbb{E} \frac{Z_{1}^{p}}{m_{0}}<\infty$, we also establish a nonuniform Berry-Esseen bound with exponential decaying rate (see Theorem 2.2).

The paper is organized as follows. The main results are stated in Section 2. The applications and the proofs of the main results are given in Sections 3 and 4, respectively.

## 2. Main results

Throughout the paper, denote by $X_{i}=\log m_{i}, i \geq 0$. Evidently, $\left(X_{i}\right)_{i \geq 0}$ is a sequence of i.i.d. random variables depending only on the environment $\xi$. Let $\left(S_{n}\right)_{n \geq 0}$ be the random walk associated
with the branching process, which is defined as follows:

$$
S_{0}=0, S_{n}=\log \Pi_{n}=\sum_{i=0}^{n-1} X_{i}, n \geq 1
$$

Then we have the following decomposition of $\log Z_{n}$, that is

$$
\begin{equation*}
\log Z_{n}=S_{n}+\log W_{n}, \tag{2.6}
\end{equation*}
$$

where $W_{n}=\frac{Z_{n}}{\Pi_{n}}$. The normalized population size $\left(W_{n}\right)_{n \geq 0}$ is a non-negative martingale under both $\mathbb{P}$ and $\mathbb{P}_{\xi}$, with respect to the natural filtration $\left(\mathcal{F}_{n}\right)_{n \geq 0}$, defined by

$$
\mathcal{F}_{0}=\sigma\{\xi\}, \mathcal{F}_{n}=\sigma\left\{\xi, X_{k, i}, 0 \leq k \leq n-1, i \geq 1\right\}, n \geq 1 .
$$

By Doob's martingale convergence theorem and Fatou's lemma, we can obtain that $W_{n}$ converges a.s. to a finite limit $W$ and $\mathbb{E} W \leq 1$. We assume the following conditions throughout this paper:

$$
\begin{equation*}
\sigma \in(0, \infty) \quad \text { and } \quad \mathbb{E} \frac{Z_{1}}{m_{0}} \log Z_{1}<\infty \tag{2.7}
\end{equation*}
$$

The first condition above together with (1.1) imply in particular that

$$
Z_{1} \geq 1 \quad \text { a.s. } \quad \text { and } \quad \mathbb{P}\left(Z_{1}=1\right)=\mathbb{E} p_{1}\left(\xi_{0}\right)<1 .
$$

The second condition in (2.7) implies that $W_{n}$ converges to $W$ in $\mathbb{L}^{1}$ and

$$
\mathbb{P}(W>0)=\mathbb{P}\left(Z_{n} \xrightarrow{n \rightarrow \infty} \infty\right)=\lim _{n \rightarrow \infty} \mathbb{P}\left(Z_{n}>0\right)>0 .
$$

(See for instance Tanny [14] and Grama et al. [10]). Therefore, it follows with the assumption (1.1) that $W>0$ and $Z_{n} \xrightarrow{n \rightarrow \infty} \infty$ a.s.

Consider the following assumptions:
(A1) There exists a constant $\delta \in(0,1]$, such that

$$
\mathbb{E} X^{2+\delta}=\mathbb{E}\left(\log m_{0}\right)^{2+\delta}<\infty .
$$

(A2) There exists a constant $p>1$ such that

$$
\mathbb{E} \frac{m_{0}^{(p)}}{m_{0}^{p}}<\infty
$$

Under the conditions above, we obtain the following bound for the Wasserstein- 1 distance between $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$ and the standard normal random variable.

Theorem 2.1. Suppose that the conditions (A1) and (A2) are satisfied. Then

$$
d_{w}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}\right) \leq \frac{C}{n^{\delta / 2}} .
$$

Moreover, the same inequality holds when $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$ is replaced by $-\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$.

Next, we consider the following stronger conditions than (A1) and (A2):
(A3) There exists a constant $\lambda_{0}>0$ such that

$$
\mathbb{E} e^{\lambda_{0} X}=\mathbb{E} m_{0}^{\lambda_{0}}<\infty .
$$

(A4) There exists a constant $p>1$ such that

$$
\mathbb{E} \frac{Z_{1}^{p}}{m_{0}}=\mathbb{E} \frac{m_{0}^{(p)}}{m_{0}}<\infty .
$$

We have the following nonuniform Berry-Esseen bound with exponential decay rate under the conditions (A3) and (A4), which is of independent interest. Such type of result can be found in Fan et al. [7], where an exponential nonuniform Berry-Esseen bound for martingales has been established.

Theorem 2.2. Suppose that the conditions (A3) and (A4) are satisfied. Then for any $x \in \mathbb{R}$,

$$
\begin{equation*}
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \leq C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{\hat{x}^{2}}{2}\right\}, \tag{2.8}
\end{equation*}
$$

where $\hat{x}=\frac{|x|}{\sqrt{1+c|x| / \sqrt{n}}}$.
In Grama et al. [10], Cramér moderate deviations (cf. Theorem 1.3) have been obtained under the conditions (A3) and (A4). Compared to their results, the interesting feature of (2.8) is that it holds for any $x \in \mathbb{R}$ rather than only for $0<|x|=o(\sqrt{n})$.

## 3. Application to Interval Estimation

In this section, we will discuss some applications of the main results to the confidence interval estimation for the criticality parameter $\mu$ and the population size $Z_{n}$.

### 3.1. Confidence Intervals for $\mu$

When $\sigma$ is known, Theorem 2.1 can be applied to construct the confidence interval for $\mu$.
Proposition 3.1. Suppose that the conditions (A1) and (A2) are satisfied. Let $\kappa_{n} \in(0,1)$, such that

$$
\begin{equation*}
\left|\log \kappa_{n}\right|=o(\log n), \quad n \rightarrow \infty . \tag{3.9}
\end{equation*}
$$

Then for $n$ large enough, $\left[A_{n}, B_{n}\right]$, with

$$
A_{n}=\frac{\log Z_{n}}{n}-\frac{\sigma \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)}{\sqrt{n}} \quad \text { and } \quad B_{n}=\frac{\log Z_{n}}{n}+\frac{\sigma \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)}{\sqrt{n}}
$$

is a $1-\kappa_{n}$ confidence interval for $\mu$.

Proof. Inequality (4.42) implies that

$$
\begin{equation*}
\frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right)}{1-\Phi(x)}=1+o(1) \quad \text { and } \quad \frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right)}{\Phi(-x)}=1+o(1) \tag{3.10}
\end{equation*}
$$

uniformly for $0 \leq x=o(\sqrt{\log n})$. For $p \searrow 0$, the quantile function of the standard normal distribution has the following asymptotic expansion

$$
\Phi^{-1}(p)=-\sqrt{\log \frac{1}{p^{2}}-\log \log \frac{1}{p^{2}}-\log (2 \pi)}+o(1)
$$

In particular, when $\kappa_{n}$ satisfies the condition (3.9), the upper $\left(1-\kappa_{n} / 2\right)$-th quantile of standard normal distribution satisfies $\Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)=-\Phi^{-1}\left(\frac{\kappa_{n}}{2}\right)=O\left(\sqrt{\left|\log \kappa_{n}\right|}\right)$, is of order $o(\sqrt{\log n})$. Then, applying the last equality to (3.10), we have as $n \rightarrow \infty$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right) \sim \frac{\kappa_{n}}{2} \tag{3.11}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-\Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right) \sim \frac{\kappa_{n}}{2} . \tag{3.12}
\end{equation*}
$$

Therefore, as $n \rightarrow \infty$,

$$
\begin{equation*}
\mathbb{P}\left(-\Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right) \leq \frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right) \sim 1-\kappa_{n} \tag{3.13}
\end{equation*}
$$

which implies $\mu \in\left[A_{n}, B_{n}\right]$ with probability $1-\kappa_{n}$ for $n$ large enough.

### 3.2. Confidence Intervals for $Z_{n}$

When parameters $\mu$ and $\sigma$ are known, we can also apply Theorem 2.1 and Theorem 2.2 to construct confidence intervals for $Z_{n}$. Such type of results can be used to predict the future population size $Z_{n}$.

Proposition 3.2. Let $\kappa_{n} \in(0,1)$. Consider the following two groups of conditions:
(B1) Suppose that the conditions (A1) and (A2) are satisfied, and that

$$
\begin{equation*}
\left|\log \kappa_{n}\right|=o(\log n), \quad n \rightarrow \infty \tag{3.14}
\end{equation*}
$$

(B2) Suppose that the conditions (A3) and (A4) are satisfied, and that

$$
\begin{equation*}
\left|\log \kappa_{n}\right|=o\left(n^{1 / 3}\right), \quad n \rightarrow \infty \tag{3.15}
\end{equation*}
$$

If (B1) or (B2) holds, then for $n$ large enough, $\left[A_{n}, B_{n}\right]$ is the confidence interval of $Z_{n}$ with confidence level $1-\kappa_{n}$, where

$$
A_{n}=\exp \left\{n \mu-\sigma \sqrt{n} \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right\} \quad \text { and } \quad B_{n}=\exp \left\{n \mu+\sigma \sqrt{n} \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right\}
$$

Proof. Assume (B1). By inequality (4.42) and (3.13), we have

$$
\begin{aligned}
& \mathbb{P}\left(-\Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right) \leq \frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right) \\
= & \mathbb{P}\left(\exp \left\{n \mu-\sigma \sqrt{n} \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right\} \leq Z_{n} \leq \exp \left\{n \mu+\sigma \sqrt{n} \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right\}\right) \sim 1-\kappa_{n},
\end{aligned}
$$

as $n \rightarrow \infty$. From the equality above, when $n$ is large enough, $\left[A_{n}, B_{n}\right]$ is the confidence interval for $Z_{n}$ with confidence level $1-\kappa_{n}$.

Now, assume (B2). By Theorem 2.2, we have

$$
\begin{equation*}
\frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right)}{1-\Phi(x)}=1+o(1) \quad \text { and } \quad \frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right)}{\Phi(-x)}=1+o(1) \tag{3.16}
\end{equation*}
$$

uniformly for $0 \leq x=o\left(n^{1 / 6}\right)$, as $n \rightarrow \infty$. When $\kappa_{n}$ satisfies the condition (3.15), the upper $\left(1-\kappa_{n} / 2\right)$-th quantile of the standard normal distribution satisfies $\Phi^{-1}\left(1-\kappa_{n} / 2\right)=-\Phi^{-1}\left(\kappa_{n} / 2\right)=$ $O\left(\sqrt{\left|\log \kappa_{n}\right|}\right)$, which is of order $o\left(n^{1 / 6}\right)$. Then by (3.16), we get

$$
\mathbb{P}\left(-\Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right) \leq \frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq \Phi^{-1}\left(1-\frac{\kappa_{n}}{2}\right)\right) \sim 1-\kappa_{n}
$$

as $n \rightarrow \infty$. From the equality above, the result still holds.

## 4. Proof of Main Results

In this section, we give the proofs of Theorems 2.1 and 2.2 respectively.

### 4.1. Preliminary Lemmas for Theorem 2.1

For the sum of independent random variables, Bikelis [3] gives the following nonuniform BerryEsseen bound.

Lemma 4.1. Let $Y_{1}, \ldots, Y_{n}$ be independent random variables satisfying $\mathbb{E} Y_{i}=0$ and $\mathbb{E}\left|Y_{i}\right|^{2+\delta}<\infty$, $i=1, \ldots, n$, for some positive constant $\delta \in(0,1]$. Assume that $\sum_{i=1}^{n} \mathbb{E} Y_{i}^{2}=1$. Then for any $x \in \mathbb{R}$,

$$
\left|\mathbb{P}\left(\sum_{i=1}^{n} Y_{i} \leq x\right)-\Phi(x)\right| \leq \frac{C}{1+|x|^{2+\delta}} \sum_{i=1}^{n} \mathbb{E}\left|Y_{i}\right|^{2+\delta}
$$

For the convergence rate of $W_{n}$, we also have the following result. See Lemmas 2.3 and 2.4 in Grama et al. [10]. See also [8].
Lemma 4.2. Assume (A1) and (A2). Then for any $q \in(1,1+\delta)$,

$$
\begin{equation*}
\mathbb{E}|\log W|^{q}<\infty \tag{4.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\sup _{n \in \mathbb{N}} \mathbb{E}\left|\log W_{n}\right|^{q}<\infty . \tag{4.18}
\end{equation*}
$$

Lemma 4.3. Assume (A1) and (A2). Then there exists constant $\gamma \in(0,1)$, such that for any $n \geq 0$,

$$
\mathbb{E}\left|\log W_{n}-\log W\right| \leq C \gamma^{n} .
$$

Using the lemmas above, we obtain the following lemma, which is a refinement of Lemma 2.5 in Grama et al. [10].

Lemma 4.4. Assume (A1) and (A2). Then for any $x \in \mathbb{R}$ and $\delta^{\prime} \in(0, \delta)$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} \tag{4.19}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right) \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} . \tag{4.20}
\end{equation*}
$$

Proof. We only prove the inequality (4.19), as (4.20) can be proved in the same way. When $x>\frac{\sqrt{n} \mu}{\sigma}$, we have

$$
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) \leq \mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right)
$$

which implies (4.19) by Lemma 4.1. When $x<-\frac{\sqrt{n} \mu}{\sigma}$, it follows from the fact that $Z_{n} \geq 1$ a.s.,

$$
\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq-\frac{\sqrt{n} \mu}{\sigma}
$$

Then for any $x<-\frac{\sqrt{n} \mu}{\sigma}$,

$$
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right)=0 .
$$

Thus for any $|x|>\frac{\sqrt{n} \mu}{\sigma}$, (4.19) holds.
Next, we prove that for any $|x| \leq \frac{\sqrt{n} \mu}{\sigma}$, (4.19) holds. Let's consider the following notations

$$
Y_{m, n}=\sum_{i=m+1}^{n} \frac{X_{i}-\mu}{\sigma \sqrt{n}}, \quad Y_{n}=Y_{0, n}, \quad V_{m}=\frac{\log W_{m}}{\sigma \sqrt{n}} \quad \text { and } \quad D_{m, n}=V_{n}-V_{m}
$$

Set $\alpha_{n}=\frac{1}{\sqrt{n}}$ and $m=[\sqrt{n}]$, where $[t]$ stands for the largest integer less than $t$. From (2.6), we get

$$
\begin{array}{r}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) \leq \mathbb{P}\left(Y_{n}+V_{m} \leq x+\alpha_{n}, Y_{n} \geq x\right) \\
+\mathbb{P}\left(\left|D_{m, n}\right|>\alpha_{n}\right) . \tag{4.21}
\end{array}
$$

For the second term on the right-hand side of (4.21), using Markov's inequality and Lemma 4.3, for any $|x| \leq \frac{\sqrt{n} \mu}{\sigma}$, there exists a constant $\gamma \in(0,1)$ such that

$$
\begin{align*}
\mathbb{P}\left(\left|D_{m, n}\right|>\alpha_{n}\right) \leq \frac{\mathbb{E}\left|D_{m, n}\right|}{\alpha_{n}} & =\frac{\sqrt{n} \mathbb{E}\left|\log W_{n}-\log W_{m}\right|}{\sigma \sqrt{n}} \leq C \gamma^{m} \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.22}
\end{align*}
$$

The last line is obtained from the fact that $n^{\delta / 2}\left(1+n^{(1+\delta) / 2}\right) \gamma^{m}=o(1), n \rightarrow \infty$. For the first term on the right-hand side of (4.21), we use a decomposition to dominate it. Let

$$
G_{m, n}(x)=\mathbb{P}\left(Y_{m, n} \leq x\right), G_{n}(x)=\mathbb{P}\left(Y_{n} \leq x\right) \quad \text { and } v_{m}(\mathrm{~d} s, \mathrm{~d} t)=\mathbb{P}\left(Y_{m} \in \mathrm{~d} s, V_{m} \in \mathrm{~d} t\right) .
$$

Since $Y_{m, n}$ and $\left(Y_{m}, V_{m}\right)$ are independent, we have

$$
\begin{align*}
& \mathbb{P}\left(Y_{n}+V_{m} \leq x+\alpha_{n}, Y_{n} \geq x\right) \\
& =\mathbb{P}\left(Y_{m, n}+Y_{m}+V_{m} \leq x+\alpha_{n}, Y_{m, n}+Y_{m} \geq x\right) \\
& =\iint \mathbb{P}\left(Y_{m, n}+s+t \leq x+\alpha_{n}, Y_{m, n}+s \geq x\right) v_{m}(\mathrm{~d} s, \mathrm{~d} t) \\
& =\iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}}\left(G_{m, n}\left(x-s-t+\alpha_{n}\right)-G_{m, n}(x-s)\right) v_{m}(\mathrm{~d} s, \mathrm{~d} t) . \tag{4.23}
\end{align*}
$$

Notice that $\left(X_{i}\right)_{i \geq 1}$ are i.i.d., so $\sum_{i=m+1}^{n} X_{i}$ and $\sum_{i=1}^{n-m} X_{i}$ follow the same distribution. We have

$$
\begin{equation*}
G_{m, n}(x)=\mathbb{P}\left(\sum_{i=m+1}^{n} \frac{X_{i}-\mu}{\sigma \sqrt{n}} \leq x\right)=G_{n-m}\left(\frac{x \sqrt{n}}{\sqrt{n-m}}\right)=G_{n-m}\left(x\left(1+R_{n}\right)\right), \tag{4.24}
\end{equation*}
$$

where $R_{n}=\sqrt{\frac{n}{n-m}}-1$ satisfying $0 \leq R_{n} \leq \frac{C}{\sqrt{n}}$. By the mean value theorem, we deduce that for any $x \in \mathbb{R}$,

$$
\begin{align*}
\left|\Phi\left(x\left(1+R_{n}\right)\right)-\Phi(x)\right| & \leq R_{n}\left|x \frac{1}{\sqrt{2 \pi}} \exp \left\{-\frac{x^{2}}{2}\right\}\right| \leq C \frac{1}{\sqrt{n}}\left|x \exp \left\{-\frac{x^{2}}{2}\right\}\right| \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.25}
\end{align*}
$$

It can be obtained from Lemma 4.1 that

$$
\begin{align*}
\left|G_{n-m}\left(x\left(1+R_{n}\right)\right)-\Phi\left(x\left(1+R_{n}\right)\right)\right| & =\left|\mathbb{P}\left(\sum_{i=1}^{n-m} \frac{X_{i}-\mu}{\sigma \sqrt{n-m}} \leq \frac{x \sqrt{n}}{\sqrt{n-m}}\right)-\Phi\left(\frac{x \sqrt{n}}{\sqrt{n-m}}\right)\right| \\
& \leq C \frac{1}{(n-m)^{\delta / 2}} \frac{1}{1+\left|x\left(1+R_{n}\right)\right|^{2+\delta}} \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.26}
\end{align*}
$$

Combining (4.24)-(4.26) together, we get

$$
\left|G_{m, n}(x)-\Phi(x)\right| \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}}
$$

Therefore, by (4.23), we have

$$
\begin{equation*}
\mathbb{P}\left(Y_{n}+V_{m} \leq x+\alpha_{n}, Y_{n} \geq x\right) \leq J_{1}+J_{2}+J_{3} \tag{4.27}
\end{equation*}
$$

where

$$
\begin{aligned}
J_{1} & =\iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}}\left|\Phi\left(x-s-t+\alpha_{n}\right)-\Phi(x-s)\right| v_{m}(\mathrm{~d} s, \mathrm{~d} t) \\
J_{2} & =C \frac{1}{n^{\delta / 2}} \iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}} \frac{1}{1+|x-s|^{2+\delta}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)
\end{aligned}
$$

and

$$
J_{3}=C \frac{1}{n^{\delta / 2}} \iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}} \frac{1}{1+\left|x-s-t+\alpha_{n}\right|^{2+\delta}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)
$$

For $J_{1}$, by the mean value theorem, it holds

$$
\begin{aligned}
& \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}}\left|\Phi\left(x-s-t+\alpha_{n}\right)-\Phi(x-s)\right| \\
\leq & C\left|-t+\alpha_{n}\right| \exp \left\{-\frac{x^{2}}{8}\right\}+\left|-t+\alpha_{n}\right| \mathbf{1}_{\left\{|s| \geq 1+\frac{1}{4}|x|\right\}}+\left|-t+\alpha_{n}\right| \mathbf{1}_{\left\{|t| \geq 1+\frac{1}{4}|x|\right\}}
\end{aligned}
$$

and thus we have

$$
\begin{equation*}
J_{1} \leq J_{11}+J_{12}+J_{13} \tag{4.28}
\end{equation*}
$$

where

$$
\begin{aligned}
& J_{11}=C \iint\left|-t+\alpha_{n}\right| \exp \left\{-\frac{x^{2}}{8}\right\} v_{m}(\mathrm{~d} s, \mathrm{~d} t) \\
& J_{12}=\iint\left|-t+\alpha_{n}\right| \mathbf{1}_{\left\{|s| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)
\end{aligned}
$$

and

$$
J_{13}=\iint\left|-t+\alpha_{n}\right| \mathbf{1}_{\left\{|t| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)
$$

Firstly, considering $J_{11}$, it follows from Lemma 4.2 that for any $x \in \mathbb{R}$,

$$
\begin{align*}
J_{11} & \leq C \exp \left\{-\frac{x^{2}}{8}\right\}\left(\mathbb{E}\left|V_{m}\right|+\alpha_{n}\right) \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} \tag{4.29}
\end{align*}
$$

For $J_{12}$, Let $\tau, \iota>1$, and satisfy $\frac{1}{\tau}+\frac{1}{\iota}=1$. By Hölder's inequality, we have the following estimate: for any $x \in \mathbb{R}$,

$$
\begin{align*}
J_{12} & \leq \iint|t| \mathbf{1}_{\left\{|s| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)+\alpha_{n} \int \mathbf{1}_{\left\{|s| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} s) \\
& \leq\left(\int|t|^{\tau} v_{m}(\mathrm{~d} t)\right)^{\frac{1}{\tau}}\left(\int \mathbf{1}_{\left\{|s| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} s)\right)^{\frac{1}{\iota}}+\frac{1}{\sqrt{n}} \mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{4}|x|\right) \\
& \leq C \frac{1}{\sqrt{n}}\left[\mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{4}|x|\right)\right]^{\frac{1}{l}}+\frac{1}{\sqrt{n}} \mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{4}|x|\right) . \tag{4.30}
\end{align*}
$$

From Lemma 4.1, we get

$$
\begin{align*}
\mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{4}|x|\right)= & \mathbb{P}\left(Y_{m} \geq 1+\frac{1}{4}|x|\right)+\mathbb{P}\left(Y_{m} \leq-1-\frac{1}{4}|x|\right) \\
\leq & 1-\Phi\left(\left(1+\frac{1}{4}|x|\right) \frac{\sqrt{n}}{\sqrt{m}}\right)+\Phi\left(-\left(1+\frac{1}{4}|x|\right) \frac{\sqrt{n}}{\sqrt{m}}\right) \\
& +C \frac{1}{1+((1+|x| / 4) \sqrt{n} / \sqrt{m})^{2+\delta}} \sum_{i=1}^{m} \mathbb{E}\left|\frac{X_{i}-\mu}{\sigma \sqrt{m}}\right|^{2+\delta} \\
\leq & C \frac{1}{n^{(1+\delta) / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.31}
\end{align*}
$$

If $\delta^{\prime}=\frac{3+2 \delta}{\iota}-\delta$, we can obtain

$$
\begin{equation*}
\delta^{\prime}=3+\delta-\frac{3+2 \delta}{\tau} \tag{4.32}
\end{equation*}
$$

Substituting (4.31) into (4.30), we get, for any $|x| \leq \mu \sqrt{n} / \sigma$,

$$
\begin{equation*}
J_{12} \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} . \tag{4.33}
\end{equation*}
$$

Next, we turn to $J_{13}$. Set $p=\frac{\delta^{\prime}+\delta}{2}$. Using Markov's inequality and Lemma 4.2, we have for any $|x| \leq \frac{\sqrt{n} \mu}{\sigma}$,

$$
\begin{align*}
J_{13} & \leq \int|t| \mathbf{1}_{\left\{|t| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} t)+\int \alpha_{n} \mathbf{1}_{\left\{|t| \geq 1+\frac{1}{4}|x|\right\}} v_{m}(\mathrm{~d} t) \\
& \leq \int \frac{|t|^{p}}{(1+|x| / 4)^{p}}|t| v_{m}(\mathrm{~d} t)+\frac{1}{\sqrt{n}} \mathbb{P}\left(\left|V_{m}\right| \geq 1+\frac{1}{4}|x|\right) \\
& \leq \frac{1}{(1+|x| / 4)^{p}} \mathbb{E}\left|V_{m}\right|^{1+p}+\frac{1}{\sqrt{n}} \frac{1}{(1+|x| / 4)^{1+p}} \mathbb{E}\left|V_{m}\right|^{1+p} \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} . \tag{4.34}
\end{align*}
$$

Combining (4.28)-(4.34), we get

$$
\begin{equation*}
J_{1} \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} \tag{4.35}
\end{equation*}
$$

Now we discuss the upper bounds for $J_{2}$ and $J_{3}$ respectively. By an argument similar to that of (4.31), we can obtain for any $x \in \mathbb{R}$,

$$
\begin{align*}
J_{2} & =C \frac{1}{n^{\delta / 2}} \iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}} \frac{1}{1+|x-s|^{2+\delta}} v_{m}(\mathrm{~d} s, \mathrm{~d} t) \\
& \leq C \frac{1}{n^{\delta / 2}}\left(\int_{|s|<1+|x| / 2} \frac{1}{1+|x-s|^{2+\delta}} v_{m}(\mathrm{~d} s)+\int_{|s| \geq 1+|x| / 2} \frac{1}{1+|x-s|^{2+\delta}} v_{m}(\mathrm{~d} s)\right) \\
& \leq C \frac{1}{n^{\delta / 2}}\left[\frac{1}{1+|x / 2|^{2+\delta}}+\mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{2}|x|\right)\right] \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.36}
\end{align*}
$$

For $J_{3}$, using an argument similar to that of (4.31) and (4.34), we have for any $|x| \leq \frac{\sqrt{n} \mu}{\sigma}$,

$$
\begin{align*}
J_{3}= & C \frac{1}{n^{\delta / 2}} \iint \mathbf{1}_{\left\{t \leq \alpha_{n}\right\}} \frac{1}{1+|x-s-t|^{2+\delta}} v_{m}(\mathrm{~d} s, \mathrm{~d} t) \\
\leq & C \frac{1}{n^{\delta / 2}}\left(\iint_{|s+t|<2+|x| / 2} \frac{1}{1+|x / 2|^{2+\delta}} v_{m}(\mathrm{~d} s, \mathrm{~d} t)\right. \\
& \left.+\int_{|s| \geq 1+|x| / 4} v_{m}(\mathrm{~d} s)+\int_{|t| \geq 1+|x| / 4} v_{m}(\mathrm{~d} t)\right) \\
\leq & C \frac{1}{n^{\delta / 2}}\left[\frac{1}{1+|x / 2|^{2+\delta}}+\mathbb{P}\left(\left|Y_{m}\right| \geq 1+\frac{1}{4}|x|\right)+\mathbb{P}\left(\left|V_{m}\right| \geq 1+\frac{1}{4}|x|\right)\right] \\
\leq & C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} . \tag{4.37}
\end{align*}
$$

Then, substituting (4.35)-(4.37) into (4.27), we get

$$
\begin{equation*}
\mathbb{P}\left(Y_{n}+V_{m} \leq x+\alpha_{n}, Y_{n} \geq x\right) \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} \tag{4.38}
\end{equation*}
$$

Finally, from (4.21), (4.22) and (4.38), we have (4.19) holds for any $|x| \leq \frac{\sqrt{n} \mu}{\sigma}$.

### 4.2. Proof of Theorem 2.1

From (2.6), it holds

$$
\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}=\frac{S_{n}-n \mu}{\sigma \sqrt{n}}+\frac{\log W_{n}}{\sigma \sqrt{n}}
$$

By Lemma 4.1 and (A1), we have

$$
\begin{align*}
\left|\mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| & \leq C \sum_{i=1}^{n} \mathbb{E}\left|\frac{X_{i}-\mu}{\sigma \sqrt{n}}\right|^{2+\delta} \frac{1}{(1+|x|)^{2+\delta}} \\
& \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{2+\delta}} \tag{4.39}
\end{align*}
$$

Notice that

$$
\begin{align*}
& \mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right) \\
= & \mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)+\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}}>x\right) \\
= & \mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)+\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}}>x\right) \\
& \quad-\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x, \frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right) . \tag{4.40}
\end{align*}
$$

Applying Lemma 4.4 to the last equality, we get for any $x \in \mathbb{R}$,

$$
\begin{equation*}
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)\right| \leq C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} \tag{4.41}
\end{equation*}
$$

Combining (4.39) and (4.41), we have for any $x \in \mathbb{R}$,

$$
\begin{align*}
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \leq & \left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)\right| \\
& +\left|\mathbb{P}\left(\frac{S_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \\
\leq & C \frac{1}{n^{\delta / 2}} \frac{1}{1+|x|^{1+\delta^{\prime}}} . \tag{4.42}
\end{align*}
$$

Thus

$$
\begin{aligned}
d_{w}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}\right) & =\int_{-\infty}^{\infty}\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \mathrm{d} x \\
& \leq \frac{C}{n^{\delta / 2}} \int_{-\infty}^{\infty} \frac{1}{1+|x|^{1+\delta^{\prime}}} \mathrm{d} x \\
& \leq \frac{C}{n^{\delta / 2}}
\end{aligned}
$$

which gives the first desired inequality of Theorem 2.1. By a similar argument, it is easy to show that the same result holds when $\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$ is replaced by $-\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}$.

### 4.3. Preliminary Lemmas for Theorem 2.2

To prove Theorem 2.2, we shall make use of the following lemma (see Theorem 3.1 in Grama et al. [10]). The lemma shows that conditions (A3) and (A4) imply the existence of a harmonic moment of positive order $a_{0}$.

Lemma 4.5. Assume (A3) and (A4). Then there exists a positive $a_{0}$ such that

$$
\begin{equation*}
\mathbb{E} W^{-a_{0}}<\infty \quad \text { and } \quad \sup _{n \in \mathbb{N}} \mathbb{E} W_{n}^{-a_{0}}<\infty . \tag{4.43}
\end{equation*}
$$

The next lemma shows that in the case of i.i.d., Cramér's condition (A3) and Bernstein's condition $\left(\mathbf{A 3}^{\prime}\right)$ are equivalent. See Fan et al. [6].
Lemma 4.6. Condition (A3) is equivalent to the following condition ( $\boldsymbol{A}^{\prime} \mathbf{\prime}^{\prime}$. There exists a constant $H>0$ such that for any $k \geq 2$,

$$
\begin{equation*}
\mathbb{E}(X-\mu)^{k} \leq \frac{1}{2} k!H^{k-2} \mathbb{E}(X-\mu)^{2} \tag{4.44}
\end{equation*}
$$

The following lemma gives two Bernstein type inequalities for $\log Z_{n}$.
Lemma 4.7. Suppose that the conditions (A3) and (A4) are satisfied. Then for any $x \geq 0$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) \leq 2 \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.45}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right) \leq C \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.46}
\end{equation*}
$$

where $c, C$ are two positive constants.
Proof. Since the Cramér's condition (A3) is equivalent to the Bernstein condition (A3'), we only need to prove Lemma 4.7 under the conditions ( $\mathbf{A} \mathbf{3}^{\prime}$ ) and (A4).

We first give a proof for (4.45). Denote

$$
\eta_{n, i}=\frac{X_{i}-\mu}{\sigma \sqrt{n}}, i=1, \ldots, n
$$

It's easy to see that

$$
\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}=\sum_{i=1}^{n} \eta_{n, i}+\frac{\log W_{n}}{\sigma \sqrt{n}}
$$

where $\sum_{i=1}^{n} \eta_{n, i}$ is a sum of i.i.d. random variables. Then we have for any $x \geq 0$,

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) & =\mathbb{P}\left(\sum_{i=1}^{n} \eta_{n, i}+\frac{\log W_{n}}{\sigma \sqrt{n}} \geq x\right) \\
& \leq I_{1}+I_{2} \tag{4.47}
\end{align*}
$$

where

$$
I_{1}=\mathbb{P}\left(\sum_{i=1}^{n} \eta_{n, i} \geq x-\frac{x^{2}}{\sigma \sqrt{n}}\right) \quad \text { and } \quad I_{2}=\mathbb{P}\left(\frac{\log W_{n}}{\sigma \sqrt{n}} \geq \frac{x^{2}}{\sigma \sqrt{n}}\right) .
$$

Applying Bernstein's inequality to $I_{1}$, we obtain for any $x \in\left[0, \frac{\sigma \sqrt{n}}{2}\right)$,

$$
\begin{equation*}
I_{1} \leq \exp \left\{-\frac{x^{2}\left(1-\frac{x}{\sigma \sqrt{n}}\right)^{2}}{2\left(1+\frac{H}{\sigma \sqrt{n}} x\left(1-\frac{x}{\sigma \sqrt{n}}\right)\right)}\right\} \leq \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.48}
\end{equation*}
$$

By Markov's inequality and the fact $\mathbb{E} W_{n}=1$, we have for any $x \in\left[0, \frac{\sigma \sqrt{n}}{2}\right)$,

$$
\begin{equation*}
I_{2}=\mathbb{P}\left(W_{n} \geq \exp \left\{x^{2}\right\}\right) \leq \exp \left\{-x^{2}\right\} \mathbb{E} W_{n}=\exp \left\{-x^{2}\right\} \tag{4.49}
\end{equation*}
$$

Combining (4.47)-(4.49) together, we find that (4.45) holds for any $x \in\left[0, \frac{\sigma \sqrt{n}}{2}\right.$. When $x \geq \frac{\sigma \sqrt{n}}{2}$, it holds that

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \geq x\right) \leq I_{3}+I_{4} \tag{4.50}
\end{equation*}
$$

where

$$
I_{3}=\mathbb{P}\left(\sum_{i=1}^{n} \eta_{n, i} \geq \frac{x}{2}\right) \quad \text { and } \quad I_{4}=\mathbb{P}\left(\frac{\log W_{n}}{\sigma \sqrt{n}} \geq \frac{x}{2}\right)
$$

By the same arguments as the proofs of $I_{1}$ and $I_{2}$, we have for any $x \geq \frac{\sigma \sqrt{n}}{2}$,

$$
\begin{equation*}
I_{3} \leq \exp \left\{-\frac{(x / 2)^{2}}{2\left(1+\frac{H}{\sigma \sqrt{n}} \frac{x}{2}\right)}\right\} \leq \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.51}
\end{equation*}
$$

and

$$
\begin{equation*}
I_{4} \leq \exp \left\{-\frac{x \sigma \sqrt{n}}{2}\right\} \mathbb{E} W_{n} \leq \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.52}
\end{equation*}
$$

with $c$ large enough. Combining (4.50)-(4.52) together, we get (4.45) for $x \geq \frac{\sigma \sqrt{n}}{2}$.
Next, we will prove (4.46). Let $a_{0}$ be a positive constant given by Lemma 4.5. Then it holds for any $x \geq 0$,

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right) & =\mathbb{P}\left(-\sum_{i=1}^{n} \eta_{n, i}-\frac{\log W_{n}}{\sigma \sqrt{n}} \geq x\right) \\
& \leq I_{5}+I_{6} \tag{4.53}
\end{align*}
$$

where

$$
I_{5}=\mathbb{P}\left(-\sum_{i=1}^{n} \eta_{n, i} \geq x-\frac{x^{2}}{a_{0} \sigma \sqrt{n}}\right) \quad \text { and } \quad I_{6}=\mathbb{P}\left(-\frac{\log W_{n}}{\sigma \sqrt{n}} \geq \frac{x^{2}}{a_{0} \sigma \sqrt{n}}\right)
$$

The upper bounds for $I_{5}$ and $I_{6}$ are given respectively as follows. Using Bernstein's inequality, we get for any $x \in\left[0, \frac{a_{0} \sigma \sqrt{n}}{2}\right)$,

$$
\begin{equation*}
I_{5} \leq \exp \left\{-\frac{x^{2}\left(1-\frac{x}{a_{0} \sigma \sqrt{n}}\right)^{2}}{2\left(1+\frac{H}{\sigma \sqrt{n}} x\left(1-\frac{x}{a_{0} \sigma \sqrt{n}}\right)\right)}\right\} \leq \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.54}
\end{equation*}
$$

And by Markov's inequality, we get for any $x \in\left[0, \frac{a_{0} \sigma \sqrt{n}}{2}\right)$,

$$
\begin{align*}
I_{6} & =\mathbb{P}\left(\log W_{n} \leq-\frac{x^{2}}{a_{0}}\right)=\mathbb{P}\left(W_{n}^{-a_{0}} \geq \exp \left\{x^{2}\right\}\right) \\
& \leq \exp \left\{-x^{2}\right\} \mathbb{E} W_{n}^{-a_{0}}<\infty \tag{4.55}
\end{align*}
$$

Combining (4.53)-(4.55) together, we get (4.46) for any $x \in\left[0, \frac{a_{0} \sigma \sqrt{n}}{2}\right)$. When $x \geq \frac{a_{0} \sigma \sqrt{n}}{2}$, it holds that

$$
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right) \leq I_{7}+I_{8}
$$

where

$$
I_{7}=\mathbb{P}\left(-\sum_{i=1}^{n} \eta_{n, i} \geq \frac{x}{2}\right) \quad \text { and } \quad I_{8}=\mathbb{P}\left(-\frac{\log W_{n}}{\sigma \sqrt{n}} \geq \frac{x}{2}\right) .
$$

Again by Bernstein's inequality, we obtain for any $x \geq \frac{a_{0} \sigma \sqrt{n}}{2}$,

$$
I_{7} \leq \exp \left\{-\frac{(x / 2)^{2}}{2\left(1+\frac{H}{\sigma \sqrt{n}} \frac{x}{2}\right)}\right\} \leq \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\}
$$

And by the same arguments as the proof of $I_{6}$, we can get for any $x \geq \frac{a_{0} \sigma \sqrt{n}}{2}$,

$$
I_{8}=\mathbb{P}\left(\log W_{n} \leq-\frac{\sigma \sqrt{n} x}{2}\right) \leq \exp \left\{-\frac{a_{0} \sigma \sqrt{n} x}{2}\right\} \mathbb{E} W_{n}^{-a_{0}} \leq C \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\}
$$

This completes the proof of lemma.
The following lemma is a direct consequence of Theorem 1.3 in [10] and its detailed proof can be found in [10].
Lemma 4.8. Assume (A3) and (A4). Then for any $x \in\left[0, n^{1 / 4}\right]$,

$$
\left|\log \frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right)}{1-\Phi(x)}\right| \leq C \frac{1+x^{3}}{\sqrt{n}}
$$

and

$$
\left|\log \frac{\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq-x\right)}{\Phi(-x)}\right| \leq C \frac{1+x^{3}}{\sqrt{n}} .
$$

4.4. Proof of Theorem 2.2

When $x \in\left[0, n^{1 / 4}\right]$, by the first inequality in Lemma 4.8 , we get

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x) & =-\left[\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right)-(1-\Phi(x))\right] \\
& \geq-\left[(1-\Phi(x)) \exp \left\{C \frac{1+x^{3}}{\sqrt{n}}\right\}-(1-\Phi(x))\right] \\
& =-(1-\Phi(x))\left(\exp \left\{C \frac{1+x^{3}}{\sqrt{n}}\right\}-1\right) \tag{4.56}
\end{align*}
$$

From the inequality $e^{x}-1 \leq x e^{x}(x \geq 0)$, we have

$$
\begin{equation*}
\exp \left\{C \frac{1+x^{3}}{\sqrt{n}}\right\}-1 \leq C \frac{1+x^{3}}{\sqrt{n}} \exp \left\{C \frac{1+x^{3}}{\sqrt{n}}\right\} \tag{4.57}
\end{equation*}
$$

Using the inequalities

$$
\begin{equation*}
\frac{e^{-x^{2} / 2}}{\sqrt{2 \pi}(1+x)} \leq 1-\Phi(x) \leq \frac{e^{-x^{2} / 2}}{\sqrt{\pi}(1+x)}, \quad x \geq 0 \tag{4.58}
\end{equation*}
$$

and the inequalities (4.56) and (4.57), we get

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x) & \geq-\frac{C\left(x^{2}+1-x\right)}{\sqrt{2 \pi n}} \exp \left\{-\frac{x^{2}}{2}+C \frac{1+x^{3}}{\sqrt{n}}\right\} \\
& \geq-C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{x^{2}}{2}+C \frac{x^{3}}{\sqrt{n}}\right\} \tag{4.59}
\end{align*}
$$

For any $x \in\left[0, n^{1 / 4}\right]$, it holds

$$
1-C \frac{x}{\sqrt{n}}=\frac{1}{1+\sum_{k=1}^{\infty}(C x / \sqrt{n})^{k}}=\frac{1}{1+C x / \sqrt{n}\left(\frac{1}{1-C x / \sqrt{n}}\right)} \geq \frac{1}{1+C x / \sqrt{n}} .
$$

Thus, we have for any $x \in\left[0, n^{1 / 4}\right]$,

$$
\begin{equation*}
\exp \left\{-\frac{x^{2}}{2}+C \frac{x^{3}}{\sqrt{n}}\right\}=\exp \left\{-\frac{x^{2}}{2}\left(1-C \frac{x}{\sqrt{n}}\right)\right\} \leq \exp \left\{-\frac{x^{2}}{2(1+C x / \sqrt{n})}\right\} \tag{4.60}
\end{equation*}
$$

Applying (4.60) to (4.59), we obtain for any $x \in\left[0, n^{1 / 4}\right]$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x) \geq-C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} . \tag{4.61}
\end{equation*}
$$

Next, we prove the upper bound of $\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)$. Again using the first inequality in Lemma 4.8, we get

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x) & =-\left[\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right)-(1-\Phi(x))\right] \\
& \leq-\left[(1-\Phi(x)) \exp \left\{-C \frac{1+x^{3}}{\sqrt{n}}\right\}-(1-\Phi(x))\right] \\
& =-(1-\Phi(x))\left(\exp \left\{-C \frac{1+x^{3}}{\sqrt{n}}\right\}-1\right) . \tag{4.62}
\end{align*}
$$

From the inequality $e^{x}-1 \geq x, x \leq 0$, we have for any $x \leq 0$,

$$
\begin{equation*}
\exp \left\{-C \frac{1+x^{3}}{\sqrt{n}}\right\}-1 \geq-C \frac{1+x^{3}}{\sqrt{n}} \tag{4.63}
\end{equation*}
$$

Applying (4.58) and (4.63) to (4.62), we obtain

$$
\begin{align*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x) & \leq \frac{C\left(1+x^{2}-x\right)}{\sqrt{\pi n}} \exp \left\{-\frac{x^{2}}{2}\right\} \\
& \leq C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.64}
\end{align*}
$$

Combining (4.61) and (4.64) together, we get for any $x \in\left[0, n^{1 / 4}\right]$,

$$
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \leq C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\}
$$

When $x>n^{1 / 4}$, we have

$$
\begin{align*}
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| & =\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right)-(1-\Phi(x))\right| \\
& \leq \mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right)+1-\Phi(x) . \tag{4.65}
\end{align*}
$$

By the first inequality in Lemma 4.7 and Lemma 4.6, it follows that for any $x>n^{1 / 4}$,

$$
\begin{equation*}
\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}}>x\right) \leq C \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.66}
\end{equation*}
$$

Notice that

$$
\begin{equation*}
1-\Phi(x) \leq \frac{e^{-x^{2} / 2}}{\sqrt{\pi}(1+x)} \leq \frac{1}{1+x} \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\} \tag{4.67}
\end{equation*}
$$

And it holds for any $x>n^{1 / 4}$,

$$
\begin{equation*}
\frac{1}{\sqrt{n}}\left(1+x^{2}\right) \geq 1 \quad \text { and } \quad \frac{1}{1+x} \leq \frac{1}{\sqrt{n}}\left(1+x^{2}\right) . \tag{4.68}
\end{equation*}
$$

Combining (4.58) and (4.65)-(4.68) together, we get

$$
\left|\mathbb{P}\left(\frac{\log Z_{n}-n \mu}{\sigma \sqrt{n}} \leq x\right)-\Phi(x)\right| \leq C \frac{1}{\sqrt{n}}\left(1+x^{2}\right) \exp \left\{-\frac{x^{2}}{2(1+c x / \sqrt{n})}\right\}
$$

which gives the desired inequality for $x>n^{1 / 4}$.
For the case when $x<0$, it can be proved in a similar way, but (4.58) is replaced by

$$
\frac{e^{-x^{2} / 2}}{\sqrt{2 \pi}(1+|x|)} \leq \Phi(x) \leq \frac{e^{-x^{2} / 2}}{\sqrt{\pi}(1+|x|)}, \quad x \leq 0
$$

and the second inequalities in Lemma 4.7 and Lemma 4.8 are used for the cases $x \in\left(-\infty,-n^{1 / 4}\right)$ and $x \in\left[-n^{1 / 4}, 0\right]$, respectively.
