Abstract

In this paper, a delay compensation design method based on PDE backstepping is developed for a two-dimensional reaction-diffusion partial differential equation (PDE) with bilateral input delays. The PDE is defined in a rectangular domain, and the bilateral control is imposed on a pair of opposite sides of the rectangle. To represent the delayed bilateral inputs, we introduce two 2-D transport PDEs that form a cascade system with the original PDE. A novel set of backstepping transformations is proposed for delay compensator design, including one Volterra integral transformation and two affine Volterra integral transformations. Unlike the kernel equation for 1-D PDE systems with delayed boundary input, the resulting kernel equations for the 2-D system have singular initial conditions governed by the Dirac Delta function. Consequently, the kernel solutions are written as a double trigonometric series with singularities. To address the challenge of stability analysis posed by the singularities, we prove a set of inequalities by using the Cauchy-Schwarz inequality, the 2-D Fourier series, and the Parseval's theorem. A numerical simulation illustrates the effectiveness of the proposed delay-compensation method.

Key words: 2-D Reaction-Diffusion; Input delay; Backstepping; Bilateral boundary control.

1 Introduction

Reaction-diffusion equations are usually used to describe the density concentration of a substance, a population change in time and space, governed by Fick's law and reaction factors, such as chemical reaction, birth, and death. Many of these processes are unstable due to the reaction terms, naturally applied in chemical reactions [1], thermal fluids [2], population dynamics [3], etc., which gives rise to various challenges for control de-

sign, especially for the problem with delay which would greatly increase the difficulty of stabilizing the unstable system [4].

In past decades, the delay-compensated control for the reaction-diffusion equation has been well developed. An early work is [5], which considers the stabilization of a reaction-diffusion PDE with arbitrary long input delay by the PDE backstepping boundary controller. [6,7,8,9,10,11] extend the method of [5] to solve different delay-compensated control problems for reaction-diffusion systems, in which, [6] studies the problem of prescribed-time stabilization for a reaction-diffusion PDE with constant input delay. In [8], a delay compensator is designed for distributed in-domain control. A state delay problem is considered in [10], and solved by a backstepping controller. The spatially-varying delay compensator is designed in [9], while an unknown input delayed control problem is solved by a delay-adaptive predictor controller in [7]. The output regulator delay is worked out in [11]. By a similar approach, [12] presents the control design for the Stefan problem under actuator delay. Different from the above papers, [13] applies Lyapunov-Krasovskii functional methods and a linear

operator inequality to solve the delay compensation problem and achieve the exponential stability of the system with time-varying delays. Another paper using Lyapunov-Krasovskii functional methods is [14], in which the authors design a new sub-predictor-based T-S fuzzy control law that can achieve compensation for large delay via using the proposed observer. Besides, [15] designs a stabilizing feedback boundary control for a reaction-diffusion PDE with input delay by using the spectral decomposition method and Artstein transformation, whereas [16] applies a similar method to design PI regulation of a reaction-diffusion PDE with delay. Another way to compensate for the input delay is predictor feedback control which stabilizes systems via predicting the future value of the state [17,18]. [17] proposes a global stabilization strategy for the nonlinear system with delayed input, and [18] handles the reaction-diffusion PDE with delay and data sampling based on observer. A similar study is reported in [19], the Lyapunov functions and Halanays inequality are applied for finite-dimensional observer-based control of a reaction-diffusion PDE with fast-varying unknown input and known output delays.

The bilateral control can reduce control efforts compared to the unilateral control, especially for the system with large unstable coefficients [20], so more attention has been paid to bilateral control, such as [21,22,23]. In [23], the authors employ the PDE backstepping method to design a nonlinear bilateral full-state feedback controller for a class of viscous Hamilton-Jacobi PDEs. Another important result is reported in [21], bilateral backstepping boundary controller is developed for a reaction-diffusion PDE in n -D domain symmetric about the x -axis. Based on state feedback and state estimation, [22] uses the backstepping method and fold approach to construct the bilateral output-feedback controller for an unstable 1-D reaction-diffusion system with spatially-varying reaction. In addition, bilateral control has also been applied into practice, for example, traffic flow control [24], the tracking adaptive control issue of the master-slave flexible system [25].

Although high-dimensional models have more applications, such as current reaction in tokamak device [26] and temperature control of screw extruders [27], fewer research work addresses delayed PDEs in the high-dimensional domain. An example is [28], which proposes a H_∞ robust controller for 2-D diffusion systems with small delayed pointlike measurements and small delayed input by using the Lyapunov-Krasovskii functional approach. For a particular cylindrical surface, [29] stabilizes an unstable 2-D reaction-diffusion equation with input delay by the PDE backstepping. In the paper, we consider a bilateral input delay problem of a reaction-diffusion system in a rectangular domain. An example application of the considered model is extruder temperature control by heating/cooling cylindrical barrels. Since the temperature is symmetrical with the central axis of the cylinder, the temperature distribution is the same for each section crossing the central

axis. Hence, the PDE domain defined in the cylinder can be simplified to a 2-D rectangle. Owing to two actuators being subject to delays, the classical backstepping transformation [5] is no longer applicable. We propose a novel set of backstepping transformations containing a Volterra transformation [20,21] and two affine Volterra transformations. Since the 4-D kernel functions in the affine Volterra transformations depend on the 2-D kernel function in the Volterra transformation at one of their boundaries, a Dirac Delta function is employed to build this relationship by reducing one dimension. Thus, the resulting kernel equations involve Dirac delta function as their initial conditions. We solve the kernel equations, express the solution as double series, and prove the series converges, including the convergence of the series at singularity $s = 0$, $x = \theta$ to the initial conditions governed by Dirac delta function. The singularity in 2-D domain poses more challenges for the proof of the operator boundedness than that in 1-D because it needs to compute the H^1 norm of the delayed actuator state in 2-D domain, rather than the L^2 norm in 1-D domain. We solve the difficulty by proving a group of inequalities containing integration of kernel functions by using 2-D Fourier series [30], Cauchy-Schwarz inequality and Parseval's theorem, and then obtain the exponential stability of the closed-loop system in terms of L^2 norm for the state and H^1 norm for the actuator states. Finally, the theoretical results are demonstrated on a 2-D square domain by simulation.

The contribution of this paper is summarized as:

- First, we propose a novel set of backstepping transformations to solve the bilateral control problem of a 2-D reaction-diffusion system in presence of input delays for both actuators.
- To address the stability analysis challenge posed by the singularity, we prove a group of inequalities containing integration of kernel functions by using Cauchy-Schwarz inequality, 2-D Fourier series, and Parseval's theorem.

This paper is organized as follows. Section 2 presents the control design for the system with input delay. The stability analysis is shown in Section 3 and supportive simulation results are provided in Section 4. The paper ends with concluding remarks and future works presented in Section 5.

Notation 1 In this paper, the following notations are used to define the domains:

$$\mathcal{D}_1 = \{(x, y) \mid -L \leq x \leq L, -l \leq y \leq l\},$$

$$\mathcal{D}_2 = \{(x, s) \mid -L \leq x \leq L, 0 \leq s \leq \tau\},$$

$$\Gamma_1 = \{(y, \xi) \mid -l \leq y \leq l, -y \leq \xi \leq y\},$$

$$\Gamma_2 = \{(x, \theta, s, \xi) \mid -L \leq x, \theta \leq L, 0 \leq s \leq \tau, -y \leq \xi \leq y\}.$$

We also define the norms for $f(x, y) \in L^2(\mathcal{D}_1)$,

$$\|f\|_{L^2}^2 = \int_{-L}^L \int_{-l}^l f^2(x, y) dy dx,$$

$$\|f\|_{H^1}^2 = \|f\|_{L^2}^2 + \|f_x\|_{L^2}^2 + \|f_y\|_{L^2}^2,$$

and for $g(x, s) \in L^2(\mathcal{D}_2)$,

$$\begin{aligned} \|g\|_{L^2}^2 &= \int_{-L}^L \int_0^\tau g^2(x, s) ds dx, \\ \|g\|_{H^1}^2 &= \|g\|_{L^2}^2 + \|g_x\|_{L^2}^2 + \|g_s\|_{L^2}^2. \end{aligned}$$

2 Controller design

2.1 Problem description

Consider the following unstable 2-D reaction-diffusion system with input delay $\tau > 0$ on opposite boundaries $y = l$ and $y = -l$,

$$u_t(x, y, t) = u_{xx}(x, y, t) + u_{yy}(x, y, t) + \lambda u(x, y, t), \quad (1)$$

$$u(L, y, t) = u(-L, y, t) = 0, \quad (2)$$

$$u(x, l, t) = U_1(x, t - \tau), \quad (3)$$

$$u(x, -l, t) = U_2(x, t - \tau), \quad (4)$$

$$u(x, y, 0) = u_0(x, y), \quad (5)$$

where $(x, y) \in \mathcal{D}_1$, $t > 0$. The reaction coefficient $\lambda > 0$. $U_1(x, t - \tau)$ and $U_2(x, t - \tau)$ are the control inputs that will be determined later.

Introduce two 2-D transport PDEs representation of the delay on the distributed inputs, which results in the following equivalent cascade system:

$$u_t(x, y, t) = u_{xx}(x, y, t) + u_{yy}(x, y, t) + \lambda u(x, y, t), \quad (6)$$

$$u(-L, y, t) = u(L, y, t) = 0, \quad (7)$$

$$u(x, l, t) = v_1(x, 0, t), \quad (8)$$

$$u(x, -l, t) = v_2(x, 0, t), \quad (9)$$

$$u(x, y, 0) = u_0(x, y), \quad (10)$$

$$\partial_t v_1(x, s, t) = \partial_s v_1(x, s, t), \quad (11)$$

$$\partial_t v_2(x, s, t) = \partial_s v_2(x, s, t), \quad (12)$$

$$v_1(x, \tau, t) = U_1(x, t), \quad (13)$$

$$v_2(x, \tau, t) = U_2(x, t), \quad (14)$$

$$v_1(x, s, 0) = v_{10}(x, s), \quad (15)$$

$$v_2(x, s, 0) = v_{20}(x, s), \quad (16)$$

where $(x, s) \in \mathcal{D}_2$ for states $v_1(\cdot, \cdot, t)$ and $v_2(\cdot, \cdot, t)$.

2.2 The backstepping transformation

Apply the PDE backstepping method for control design. First, introduce a stable target system:

$$w_t(x, y, t) = w_{xx}(x, y, t) + w_{yy}(x, y, t), \quad (17)$$

$$w(-L, y, t) = w(L, y, t) = 0, \quad (18)$$

$$w(x, l, t) = z_1(x, 0, t), \quad (19)$$

$$w(x, -l, t) = z_2(x, 0, t), \quad (20)$$

$$w(x, y, 0) = w_0(x, y), \quad (21)$$

$$\partial_t z_1(x, s, t) = \partial_s z_1(x, s, t), \quad (22)$$

$$\partial_t z_2(x, s, t) = \partial_s z_2(x, s, t), \quad (23)$$

$$z_1(x, \tau, t) = 0, \quad (24)$$

$$z_2(x, \tau, t) = 0, \quad (25)$$

$$z_1(x, s, 0) = z_{10}(x, s), \quad (26)$$

$$z_2(x, s, 0) = z_{20}(x, s), \quad (27)$$

where the transport systems z_1 and z_2 have mild solutions:

$$z_i(x, s, t) = \begin{cases} z_{i0}(x, s+t), & 0 < s+t \leq \tau \\ 0, & \tau < s+t \end{cases}, \quad i = 1, 2, \quad (28)$$

which implies $z_i(x, s, t)$ is stable in finite time. To transform the original cascade system (6)-(16) into (17)-(27), we propose a set of backstepping integral transformations as follows:

$$w(x, y, t) = u(x, y, t) - \int_{-y}^y p(y, \xi) u(x, \xi, t) d\xi, \quad (29)$$

$$\begin{aligned} z_1(x, s, t) &= v_1(x, s, t) \\ &- \int_{-L}^L \int_{-l}^l \gamma_1(x, \theta, s, \xi) u(\theta, \xi, t) d\xi d\theta \\ &- \int_{-L}^L \int_0^s \partial_\xi \gamma_1(x, \theta, s-r, l) v_1(\theta, r, t) dr d\theta \\ &+ \int_{-L}^L \int_0^s \partial_\xi \gamma_1(x, \theta, s-r, -l) v_2(\theta, r, t) dr d\theta, \end{aligned} \quad (30)$$

$$\begin{aligned} z_2(x, s, t) &= v_2(x, s, t) \\ &- \int_{-L}^L \int_{-l}^l \gamma_2(x, \theta, s, \xi) u(\theta, \xi, t) d\xi d\theta \\ &- \int_{-L}^L \int_0^s \partial_\xi \gamma_2(x, \theta, s-r, l) v_1(\theta, r, t) dr d\theta \\ &+ \int_{-L}^L \int_0^s \partial_\xi \gamma_2(x, \theta, s-r, -l) v_2(\theta, r, t) dr d\theta, \end{aligned} \quad (31)$$

where $\partial_\xi \gamma_i(\cdot, \cdot, \cdot, l) = \frac{\partial \gamma_i(\cdot, \cdot, \cdot, \xi)}{\partial \xi} |_{\xi=l}$, $i = 1, 2$, transformation (29) is the Volterra transformation, transformations (30) and (31) are the affine Volterra transformations. The kernel function $p(y, \xi)$ is defined in domain Γ_1 , and γ_1 and γ_2 are both defined in Γ_2 .

According to [20,21], the kernel function $p(y, \xi)$ satisfies the following PDE:

$$p_{yy}(y, \xi) - p_{\xi\xi}(y, \xi) = \lambda p(y, \xi), \quad (32)$$

$$p(y, y) = -\frac{\lambda}{2} y, \quad (33)$$

$$p(y, -y) = 0, \quad (34)$$

whose solution is written as:

$$p(y, \xi) = -\frac{\text{sgn}(y)}{2} \sqrt{\lambda \frac{y+\xi}{y-\xi}} I_1 \left(\sqrt{\lambda(y^2 - \xi^2)} \right), \quad (35)$$

where $I_1(\cdot)$ is the first-order modified Bessel function of the first kind. The approach to solving the equation (32)-(34) can be found in [20,31].

After a lengthy computation based on the equivalent relation between system (6)-(16) and system (17)-(27), one can get the equations of kernels γ_i , $i = 1, 2$:

$$\begin{aligned} \partial_s \gamma_1(x, \theta, s, \xi) &= \partial_{\xi\xi} \gamma_1(x, \theta, s, \xi) + \partial_{\theta\theta} \gamma_1(x, \theta, s, \xi) \\ &+ \lambda \gamma_1(x, \theta, s, \xi), \end{aligned} \quad (36)$$

$$\gamma_1(x, L, s, \xi) = \gamma_1(x, -L, s, \xi) = 0, \quad (37)$$

$$\gamma_1(x, \theta, s, l) = \gamma_1(x, \theta, s, -l) = 0, \quad (38)$$

$$\gamma_1(x, \theta, 0, \xi) = p(l, \xi) \delta(x - \theta), \quad (39)$$

$$\begin{aligned} \partial_s \gamma_2(x, \theta, s, \xi) &= \partial_{\xi} \gamma_2(x, \theta, s, \xi) + \partial_{\theta\theta} \gamma_2(x, \theta, s, \xi) \\ &\quad + \lambda \gamma_2(x, \theta, s, \xi), \end{aligned} \quad (40)$$

$$\gamma_2(x, L, s, \xi) = \gamma_2(x, -L, s, \xi) = 0, \quad (41)$$

$$\gamma_2(x, \theta, s, l) = \gamma_2(x, \theta, s, -l) = 0, \quad (42)$$

$$\gamma_2(x, \theta, 0, \xi) = -p(-l, \xi) \delta(x - \theta), \quad (43)$$

where $\delta(\cdot)$ is the Dirac delta function.

Applying the method of separation of variables, one gets the solutions of kernel functions γ_1 and γ_2 :

$$\begin{aligned} \gamma_1(x, \theta, s, \xi) &= \frac{1}{L} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} e^{\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2} + \lambda\right)s} \\ &\quad \cdot p_{1m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi), \end{aligned} \quad (44)$$

$$\begin{aligned} \gamma_2(x, \theta, s, \xi) &= -\frac{1}{L} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} e^{\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2} + \lambda\right)s} \\ &\quad \cdot p_{2m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi), \end{aligned} \quad (45)$$

where

$$\text{for } n = 1, 2, \dots, \quad \varphi_n(\cdot) = \sin\left(\frac{n\pi}{2L}(\cdot + L)\right), \quad (46)$$

$$\text{for } m = 1, 2, \dots, \quad \phi_m(\xi) = \sin\left(\frac{m\pi}{2l}(\xi + l)\right), \quad (47)$$

$$p_{im} = \frac{1}{l} \int_{-l}^l \phi_m(\xi) p((-1)^{i-1}l, \xi) d\xi, \quad i = 1, 2. \quad (48)$$

Remark 1 It is easy to prove that kernels γ_1 and γ_2 are convergent as $s > 0$. As $s = 0$, take γ_1 as an example,

$$\begin{aligned} \gamma_1(x, \theta, 0, \xi) &= \frac{1}{L} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} p_{1m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi) \\ &= p(l, \xi) \sum_{n=1}^{\infty} \frac{1}{L} \varphi_n(x) \varphi_n(\theta). \end{aligned}$$

It is well known [32] that the Dirac Delta function can be expressed by $\delta(x - \theta) = \sum_{n=1}^{\infty} \frac{1}{L} \varphi_n(x) \varphi_n(\theta)$, which gives the initial condition (39). Consequently, kernels γ_1 and γ_2 have singularities at $s = 0$ and $x = \theta$ which are governed by the Delta function.

Combining the boundary conditions (13), (14) and (24), (25), substituting $s = \tau$ into transformations (30) and (31), we can get the delay-compensated actuators as follows:

$$\begin{aligned} U_1(x, t) &= \int_{-L}^L \int_{-l}^l \gamma_1(x, \theta, \tau, \xi) u(\theta, \xi, t) d\xi d\theta \\ &\quad + \int_{-L}^L \int_{t-\tau}^t \partial_{\xi} \gamma_1(x, \theta, t-r, l) U_1(\theta, r) dr d\theta \\ &\quad - \int_{-L}^L \int_{t-\tau}^t \partial_{\xi} \gamma_1(x, \theta, t-r, -l) U_2(\theta, r) dr d\theta, \quad (49) \\ U_2(x, t) &= \int_{-L}^L \int_{-l}^l \gamma_2(x, \theta, \tau, \xi) u(\theta, \xi, t) d\xi d\theta \\ &\quad + \int_{-L}^L \int_{t-\tau}^t \partial_{\xi} \gamma_2(x, \theta, t-r, l) U_1(\theta, r) dr d\theta \end{aligned}$$

$$- \int_{-L}^L \int_{t-\tau}^t \partial_{\xi} \gamma_2(x, \theta, t-r, -l) U_2(\theta, r) dr d\theta. \quad (50)$$

It shows that control U_1 and U_2 are coupled by both historical inputs as feedback in each controller.

2.3 Inverse transformation

A direct way to show the invertibility of the transformation (29)-(31) is to derive its inverse. First, define the inverse transformation as follows,

$$u(x, y, t) = w(x, y, t) + \int_{-y}^y q(y, \xi) w(x, \xi, t) d\xi, \quad (51)$$

$$\begin{aligned} v_1(x, s, t) &= z_1(x, s, t) \\ &\quad + \int_{-L}^L \int_{-l}^l \eta_1(x, \theta, s, \xi) w(\theta, \xi, t) d\xi d\theta \\ &\quad + \int_{-L}^L \int_0^s \partial_{\xi} \eta_1(x, \theta, s-r, l) z_1(\theta, r, t) dr d\theta \\ &\quad - \int_{-L}^L \int_0^s \partial_{\xi} \eta_1(x, \theta, s-r, -l) z_2(\theta, r, t) dr d\theta, \end{aligned} \quad (52)$$

$$\begin{aligned} v_2(x, s, t) &= z_2(x, s, t) \\ &\quad + \int_{-L}^L \int_{-l}^l \eta_2(x, \theta, s, \xi) w(\theta, \xi, t) d\xi d\theta \\ &\quad + \int_{-L}^L \int_0^s \partial_{\xi} \eta_2(x, \theta, s-r, l) z_1(\theta, r, t) dr d\theta \\ &\quad - \int_{-L}^L \int_0^s \partial_{\xi} \eta_2(x, \theta, s-r, -l) z_2(\theta, r, t) dr d\theta, \end{aligned} \quad (53)$$

the kernels q , η_1 , and η_2 are expressed as

$$q(y, \xi) = -\frac{\text{sgn}(y)}{2} \sqrt{\lambda \frac{y+\xi}{y-\xi}} J_1\left(\sqrt{\lambda(y^2 - \xi^2)}\right), \quad (54)$$

$$\begin{aligned} \eta_1(x, \theta, s, \xi) &= \frac{1}{L} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} e^{\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2}\right)s} \\ &\quad \cdot q_{1m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi), \end{aligned} \quad (55)$$

$$\begin{aligned} \eta_2(x, \theta, s, \xi) &= -\frac{1}{L} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} e^{\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2}\right)s} \\ &\quad \cdot q_{2m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi), \end{aligned} \quad (56)$$

where $J_1(\cdot)$ is the first-order Bessel function, and $q_{im} = \frac{1}{l} \int_{-l}^l \sin\left(\frac{m\pi}{2l}(\xi + l)\right) q((-1)^{i-1}l, \xi) d\xi$, $i = 1, 2$.

It is worth discussing the difference in control design between identical delay values and distinct delay values. In the following remark, we give some hints for control design when the input delays are different.

Remark 2 Let τ_1 and τ_2 denote distinct delay values for boundary control U_1 and U_2 , respectively. Without loss of generality, assume that $\tau_1 < \tau_2$. The integral transformations (29) and (30) can be kept unchanged, but the integral interval and the integrated state of (31) are modified as follows:

$$z_2(x, s, t) = v_2(x, s, t)$$

$$\begin{aligned}
& - \int_{-L}^L \int_{-l}^l \gamma_2(x, \theta, s, \xi) u(\theta, \xi, t) d\xi d\theta \\
& - \int_{-L}^L \int_0^{\phi(s)} \partial_\xi \gamma_2(x, \theta, s-r, l) z_1(\theta, r, t) dr d\theta \\
& + \int_{-L}^L \int_0^s \partial_\xi \gamma_2(x, \theta, s-r, -l) v_2(\theta, r, t) dr d\theta, \quad (57)
\end{aligned}$$

with

$$\phi(s) = \begin{cases} s, & s \leq \tau_1 \\ \tau_1, & \tau_1 < s \end{cases}. \quad (58)$$

Based on the transformation, one can obtain a set of kernel equations in a similar method. Due to the space constraints, we omit the details of the control design for the different input delays.

3 Stability analysis

Theorem 1 For any initial conditions $(u_0, v_{10}, v_{20}) \in L^2(\mathcal{D}_1) \times H^1(\mathcal{D}_2) \times H^1(\mathcal{D}_2)$ and the compatible conditions holding

$$u_0(L, y) = 0, \quad u_0(-L, y) = 0, \quad (59)$$

$$u_0(x, l) = v_{10}(x, 0), \quad u_0(x, -l) = v_{20}(x, 0), \quad (60)$$

$$v_{10}(x, \tau) = U_1(x, 0), \quad v_{20}(x, \tau) = U_2(x, 0), \quad (61)$$

the closed-loop system (6)-(16) with the delay-compensated actuators (49) and (50) admits a unique solution that satisfies

$$\begin{aligned}
& \|u(t)\|_{L^2}^2 + \|v_1(t)\|_{H^1}^2 + \|v_2(t)\|_{H^1}^2 \\
& \leq \alpha_1 e^{-\beta_1 t} (\|u_0\|_{L^2}^2 + \|v_{10}\|_{H^1}^2 + \|v_{20}\|_{H^1}^2), \quad (62)
\end{aligned}$$

for constants $\alpha_1, \beta_1 > 0$.

The theorem states that the closed-loop (6)-(16) is exponentially stable, so is the original system (1)-(5).

Before proving the stability, we first discuss the well-posedness of PDE (6)-(16) with control (49) and (50). The target system (17)-(27) is a standard 2-D heat equation with nonhomogeneous boundary conditions at $y = l$ and $y = -l$ and the boundary conditions are given by $z_i, i = 1, 2$ which have been solved explicitly, so (17)-(27) has a unique solution [33]. Since the transformations (29), (30) and (31) are invertible and bounded, the original system (6)-(16) with control (49) and (50) has a unique solution as well.

The proof of the stability includes two steps. First, we prove the stability of the target system (17)-(27) by introducing a change of variable. Second, we show the norm equivalence between cascade system (u, v_1, v_2) and the target system (w, z_1, z_2) . Combining the above two steps, we finally reach Theorem 1.

Introduce the change of variable as

$$m(x, y, t) = w(x, y, t) - \frac{y+l}{2l} z_1(x, 0, t) + \frac{y-l}{2l} z_2(x, 0, t), \quad (63)$$

which transforms the target system (17)-(27) into

$$\begin{aligned}
m_t &= m_{xx} + m_{yy} + \frac{(y+l)}{2l} \partial_{xx} z_1(x, 0, t) \\
& - \frac{(y-l)}{2l} \partial_{xx} z_2(x, 0, t) - \frac{(y+l)}{2l} \partial_t z_1(x, 0, t)
\end{aligned}$$

$$+ \frac{(y-l)}{2l} \partial_t z_2(x, 0, t), \quad (64)$$

$$m(-L, y, t) = m(L, y, t) = 0, \quad (65)$$

$$m(x, -l, t) = m(x, l, t) = 0, \quad (66)$$

$$m(x, y, 0) = m_0(x, y), \quad (67)$$

$$\partial_t z_1(x, s, t) = \partial_s z_1(x, s, t), \quad (68)$$

$$\partial_t z_2(x, s, t) = \partial_s z_2(x, s, t), \quad (69)$$

$$z_1(x, \tau, t) = 0, \quad (70)$$

$$z_2(x, \tau, t) = 0, \quad (71)$$

$$z_1(x, s, 0) = z_{10}(x, s), \quad (72)$$

$$z_2(x, s, 0) = z_{20}(x, s). \quad (73)$$

Proposition 1 For any initial conditions $(w_0, z_{10}, z_{20}) \in L^2(\mathcal{D}_1) \times H^1(\mathcal{D}_2) \times H^1(\mathcal{D}_2)$, and the compatible conditions satisfying

$$w_0(L, y) = 0, \quad w_0(-L, y) = 0, \quad (74)$$

$$w_0(x, l) = z_{10}(x, 0), \quad w_0(x, -l) = z_{20}(x, 0), \quad (75)$$

$$z_{10}(x, \tau) = 0, \quad z_{20}(x, \tau) = 0, \quad (76)$$

the system (17)-(27) admits a unique solution and the equilibrium $(w, z_1, z_2) \equiv 0$ is exponentially stable, in particular, there exist constants $\alpha_2, \beta_2 > 0$, such that

$$\begin{aligned}
& \|w(t)\|_{L^2}^2 + \|z_1(t)\|_{H^1}^2 + \|z_2(t)\|_{H^1}^2 \\
& \leq \alpha_2 e^{-\beta_2 t} (\|w_0\|_{L^2}^2 + \|z_{10}\|_{H^1}^2 + \|z_{20}\|_{H^1}^2). \quad (77)
\end{aligned}$$

Proof First, define a Lyapunov function as

$$\begin{aligned}
V_1(t) &= \int_{-L}^L \int_{-l}^l m^2 dy dx + \int_{-L}^L \int_0^\tau e^{bs} (z_1^2 + (\partial_x z_1)^2 + \\
& (\partial_s z_1)^2) ds dx + \int_{-L}^L \int_0^\tau e^{bs} (z_2^2 + (\partial_x z_2)^2 + (\partial_s z_2)^2) ds dx,
\end{aligned}$$

with the constant $b > 0$.

Then, applying the integration by parts, combining (64)-(73) and Cauchy-Schwarz inequality, we get

$$\begin{aligned}
& \frac{d}{dt} \int_{-L}^L \int_{-l}^l m^2 dy dx \leq -(2 - \mu_1 - \mu_2) \int_{-L}^L \int_{-l}^l m_x^2 dy dx \\
& - 2 \int_{-L}^L \int_{-l}^l m_y^2 dy dx + \frac{8l}{3\mu_1} \int_{-L}^L (\partial_x z_1(x, 0, t))^2 dx \\
& + \frac{8l}{3\mu_2} \int_{-L}^L (\partial_x z_2(x, 0, t))^2 dx + \frac{8l}{3\mu_3} \int_{-L}^L (\partial_t z_1(x, 0, t))^2 dx \\
& + \frac{8l}{3\mu_4} \int_{-L}^L (\partial_t z_2(x, 0, t))^2 dx + (\mu_3 + \mu_4) \int_{-L}^L \int_{-l}^l m^2 dy dx, \\
& \frac{d}{dt} \int_{-L}^L \int_0^\tau e^{bs} (z_1^2 + (\partial_x z_1)^2 + (\partial_s z_1)^2) ds dx \\
& + \frac{d}{dt} \int_{-L}^L \int_0^\tau e^{bs} (z_2^2 + (\partial_x z_2)^2 + (\partial_s z_2)^2) ds dx \\
& = - \int_{-L}^L (z_1^2(x, 0, t) + (\partial_x z_1(x, 0, t))^2 + (\partial_t z_1(x, 0, t))^2) dx \\
& - b \int_{-L}^L \int_0^\tau e^{bs} (z_1^2 + (\partial_x z_1)^2 + (\partial_t z_1)^2) ds dx
\end{aligned}$$

$$\begin{aligned}
& - \int_{-L}^L (z_2^2(x, 0, t) + (\partial_x z_2(x, 0, t))^2 + (\partial_t z_2(x, 0, t))^2) dx \\
& - b \int_{-L}^L \int_0^\tau e^{bs} (z_2^2 + (\partial_x z_2)^2 + (\partial_t z_2)^2) ds dx.
\end{aligned}$$

Applying the Poincaré inequality, i.e.,

$$\frac{1}{4L^2} \int_{-L}^L \int_{-l}^l m^2 dy dx \leq \int_{-L}^L \int_{-l}^l m_x^2 dy dx, \quad (78)$$

$$\frac{1}{4l^2} \int_{-L}^L \int_{-l}^l m^2 dy dx \leq \int_{-L}^L \int_{-l}^l m_y^2 dy dx, \quad (79)$$

we infer that

$$\begin{aligned}
\dot{V}_1(t) & \leq -b \int_{-L}^L \int_0^\tau e^{bs} (z_1^2 + (\partial_t z_1)^2 + (\partial_x z_1)^2) ds dx \\
& - \left(\frac{2 - \mu_1 - \mu_2}{4L^2} + \frac{1}{2l^2} - \mu_3 - \mu_4 \right) \int_{-L}^L \int_{-l}^l m^2 dy dx \\
& - b \int_{-L}^L \int_0^\tau e^{bs} (z_2^2 + (\partial_t z_2)^2 + (\partial_x z_2)^2) ds dx \\
& - \left(1 - \frac{8l}{3\mu_1} \right) \int_{-L}^L (\partial_x z_1(x, 0, t))^2 dx \\
& - \left(1 - \frac{8l}{3\mu_2} \right) \int_{-L}^L (\partial_x z_2(x, 0, t))^2 dx \\
& - \left(1 - \frac{8l}{3\mu_3} \right) \int_{-L}^L (\partial_t z_1(x, 0, t))^2 dx \\
& - \left(1 - \frac{8l}{3\mu_4} \right) \int_{-L}^L (\partial_t z_2(x, 0, t))^2 dx \\
& - \int_{-L}^L z_1^2(x, 0, t) dx - \int_{-L}^L z_2^2(x, 0, t) dx, \quad (80)
\end{aligned}$$

where $\frac{2 - \mu_1 - \mu_2}{4L^2} + \frac{1}{2l^2} - \mu_3 - \mu_4 > 0$, $1 - \frac{8l}{3\mu_i} > 0$, $i = 1, 2, 3, 4$. Then, there exist constants $\alpha_3 > 0$ and $\beta_3 > 0$, such that

$$V_1 \leq \alpha_3 e^{-\beta_3 t} V_1(0). \quad (81)$$

To prove the stability of target system (17)-(27), we define

$$\begin{aligned}
V_2(t) & = \int_{-L}^L \int_{-l}^l w^2 dy dx + \int_{-L}^L \int_0^\tau (z_1^2 + (\partial_x z_1)^2 + \\
& (\partial_s z_1)^2) ds dx + \int_{-L}^L \int_0^\tau (z_2^2 + (\partial_x z_2)^2 + (\partial_s z_2)^2) ds dx.
\end{aligned}$$

By a lengthy calculation, one can get that

$$\alpha_4 V_2 \leq V_1 \leq \beta_4 V_2, \quad (82)$$

where $\alpha_4 = \frac{1}{4}$, $\beta_4 = 3 + e^{b\tau}$, which gives the norm equivalence between V_1 and V_2 . Hence,

$$V_2 \leq \alpha_2 e^{-\beta_2 t} V_2(0). \quad (83)$$

This proposition has been proved.

Before proceeding, we present the following definition of the Fourier series.

Definition 1 According to [30], (P296), it is known that $\{\varphi_n(x) | n \in N^+\}$ and $\{\phi_m(y) | m \in N^+\}$ defined in (46) and (47) are orthogonal eigenfunc-

tions, respectively. For functions $h(y) \in L^2([-l, l])$, $f(x, y) \in L^2(\mathcal{D}_1)$, and $g(x, s) \in L^2(\mathcal{D}_2)$, it holds [34]

$$h(y) = \sum_{m=1}^{\infty} h_m \phi_m(y), \quad (84)$$

$$f(x, y) = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} a_{n,m}(f) \varphi_n(x) \phi_m(y), \quad (85)$$

$$g(x, s) = \sum_{n=1}^{\infty} g_n(s) \varphi_n(x), \quad (86)$$

where the Fourier coefficients

$$h_m = \frac{1}{l} \int_{-l}^l h(\xi) \phi_m(\xi) d\xi, \quad (87)$$

$$a_{n,m}(f) = \frac{1}{Ll} \int_{-L}^L \int_{-l}^l f(\theta, \xi) \varphi_n(\theta) \phi_m(\xi) d\xi d\theta, \quad (88)$$

$$g_n(s) = \frac{1}{L} \int_{-L}^L g(\theta, s) \varphi_n(\theta) d\theta. \quad (89)$$

From the Parseval's theorem, we know $\|h\|_{L^2}^2 = l \sum_{m=1}^{\infty} h_m^2$, $\|f\|_{L^2}^2 = Ll \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} a_{n,m}^2(f)$, and $\|g(x, s)\|_{L^2}^2 = L \sum_{n=1}^{\infty} \int_0^\tau g_n^2(s) ds$.

The following lemmas will be used in the proof of the norm equivalence between the original system and the target system.

Lemma 1 For function $p(l, \xi)$, $\xi \in [-l, l]$, there exist positive constants M_i , $i = 1, 2, 3, 4$, such that $\|p(l, \xi)\|_{L^2}^2 \leq M_1$, $\|p_\xi(l, \xi)\|_{L^2}^2 \leq M_2$, $\|p_{\xi\xi}(l, \xi)\|_{L^2}^2 \leq M_3$, $p_\xi^2(l, \xi)|_{\xi=l} = M_4$.

One can use Parseval's theorem and Fourier series to prove lemma 1. Here the proof is omitted and we refer the reader to [5].

Lemma 2 For variables $(x, \theta, s, \xi) \in \Gamma_2$, and functions $f \in L^2(\mathcal{D}_1)$ and $g \in L^2(\mathcal{D}_2)$, there exist positive constants A_i, B_i , $i = 1, 2$, such that

$$\begin{aligned}
& \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \gamma_i(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \\
& \leq A_i \|f\|_{L^2}^2, \quad (90)
\end{aligned}$$

$$\begin{aligned}
& \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_\xi \gamma_i(x, \theta, s-r, \pm l) g(\theta, r) dr d\theta \right|^2 ds dx \\
& \leq B_i \|g\|_{L^2}^2. \quad (91)
\end{aligned}$$

Proof According to Definition 1, we know that p_{1m} defined in (48) is the Fourier coefficient of $p(l, \xi)$, i.e.,

$$p(l, \xi) = \sum_{m=1}^{\infty} p_{1m} \phi_m(\xi). \quad (92)$$

As $i = 1$, applying the Cauchy-Schwarz inequality, then combining (44), and Lemma 1, it gets

$$\int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \gamma_1(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx$$

$$\begin{aligned}
&\leq e^{2\lambda\tau} l^2 \int_{-L}^L \int_0^\tau \sum_{m=1}^\infty e^{\frac{-m^2\pi^2 s}{2l^2}} p_{1m}^2 \sum_{m=1}^\infty \left(\sum_{n=1}^\infty e^{\frac{-n^2\pi^2 s}{4L^2}} \right. \\
&\quad \cdot \varphi_n(x) a_{n,m}(f) \left. \right)^2 ds dx \\
&\leq e^{2\lambda\tau} l^2 L \int_0^\tau \sum_{m=1}^\infty p_{1m}^2 \sum_{m=1}^\infty \sum_{n=1}^\infty a_{n,m}^2(f) ds \\
&\leq \tau e^{2\lambda\tau} \|p(l, \xi)\|_{L^2}^2 \|f\|_{L^2}^2 = A_1 \|f\|_{L^2}^2.
\end{aligned}$$

Employing a similar approach, one can get the same result as $i = 2$ for inequality (90).

Before proceeding, based on (92), the Parseval's theorem, and the definition of $\phi_m(\xi)$ which is shown in (47), we can get

$$p_\xi(l, \xi) = \sum_{m=1}^\infty p_{1m} \phi'_m(\xi), \|p_\xi(l, \xi)\|_{L^2}^2 = l \sum_{m=1}^\infty \frac{m^2 \pi^2}{4l^2} p_{1m}^2.$$

For the inequality (91), since the proof process of four different cases of inequality (91) is similar, we just show the case as the kernel is $\partial_\xi \gamma_1(x, \theta, s - r, l)$.

Based on (44), using the Cauchy-Schwarz inequality, Definition 1 and Lemma 1, one gets

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_\xi \gamma_1(x, \theta, s - r, l) g(\theta, r) dr d\theta \right|^2 ds dx \right. \\
&\leq e^{2\lambda\tau} \int_0^\tau \int_0^s \sum_{m=1}^\infty e^{\frac{-m^2\pi^2(s-r)}{2l^2}} \sum_{m=1}^\infty \frac{m^2\pi^2}{4l^2} p_{1m}^2 dr \\
&\quad \cdot \int_{-L}^L \int_0^s \left(\sum_{n=1}^\infty e^{\frac{-n^2\pi^2(s-r)}{2L^2}} \varphi_n(x) \frac{1}{L} \int_{-L}^L \varphi_n(\theta) \right. \\
&\quad \cdot g(\theta, r) d\theta \left. \right)^2 dr dx ds \\
&\leq e^{2\lambda\tau} \frac{L}{l} \|p_\xi(l, \xi)\|_{L^2}^2 \sum_{m=1}^\infty \frac{2l^2}{m^2\pi^2} \int_0^\tau \int_0^s \sum_{n=1}^\infty e^{\frac{-n^2\pi^2(s-r)}{L^2}} \\
&\quad \cdot g_n^2(s) dr ds \\
&\leq e^{2\lambda\tau} LM_2 \sum_{m=1}^\infty \frac{2l}{m^2\pi^2} \int_0^\tau \int_0^\tau \sum_{n=1}^\infty g_n^2(r) dr ds \\
&\leq e^{2\lambda\tau} \tau M_2 \sum_{m=1}^\infty \frac{2l}{m^2\pi^2} \|g\|_{L^2}^2 \leq B_1 \|g\|_{L^2}^2.
\end{aligned}$$

The inequality (91) gets proven, and the proof of this lemma is completed.

Remark 3 Lemma 2 implies that the backstepping transformations (30) and (31) are bounded, despite there being singularities in the kernel functions.

To prove the norm equivalence between the input $v_i(x, s, t)$, $i = 1, 2$ and $z_i(x, s, t)$, $i = 1, 2$, we propose the following two lemmas.

Lemma 3 For variables $(x, \theta, s, \xi) \in \Gamma_2$ and function $f(x, y) \in L^2(\mathcal{D}_1)$, $g(x, s) \in L^2(\mathcal{D}_2)$, there exist positive constants C_{ij} , D_{ij} , $i = 1, 2$, $j = 1, 2$, such that

$$\begin{aligned}
&\int_{-L}^L \int_0^\tau \left(\sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(n\pi)^2}{4L^2} \right. \\
&\quad \gamma_i(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \left. \right)^2 ds dx \leq C_{1i} \|f_x\|_{L^2}^2, \quad (93)
\end{aligned}$$

$$\begin{aligned}
&\int_{-L}^L \int_0^\tau \left(\sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(m\pi)^2}{4l^2} \right. \\
&\quad \gamma_i(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \left. \right)^2 ds dx \leq C_{2i} \|f_y\|_{L^2}^2, \quad (94)
\end{aligned}$$

$$\begin{aligned}
&\int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_0^s \frac{(n\pi)^2}{4L^2} \right. \\
&\quad \cdot \partial_\xi \gamma_i(x, \theta, s - r, \pm l) g(\theta, r) dr d\theta \left. \right|^2 ds dx \leq D_{1i} \|g_x\|_{L^2}^2, \quad (95)
\end{aligned}$$

$$\begin{aligned}
&\int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_0^s \frac{(m\pi)^2}{4l^2} \right. \\
&\quad \cdot \partial_\xi \gamma_i(x, \theta, s - r, \pm l) g(\theta, r) dr d\theta \left. \right|^2 ds dx \leq D_{2i} \|g\|_{L^2}^2. \quad (96)
\end{aligned}$$

The proof of this lemma is shown in Appendix A.

Lemma 4 For any variables $(x, \theta, s, \xi) \in \Gamma_2$, and any functions $f \in L^2(\mathcal{D}_1)$, $g \in L^2(\mathcal{D}_2)$, there exist positive constants E_i , F_i , G_i , H_i , K_i , $i = 1, 2$, such that

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \partial_s \gamma_i(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \right. \\
&\leq E_i (\|f\|_{L^2}^2 + \|f_x\|_{L^2}^2 + \|f_y\|_{L^2}^2), \quad (97)
\end{aligned}$$

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_{\xi s} \gamma_i(x, \theta, s - r, \pm l) g(\theta, r) dr d\theta \right|^2 ds dx \right. \\
&\leq F_i (\|g\|_{L^2}^2 + \|g_x\|_{L^2}^2), \quad (98)
\end{aligned}$$

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \partial_\xi \gamma_i(x, \theta, 0, \pm l) g(\theta, s) d\theta \right|^2 ds dx \right. \\
&\leq G_i \|g\|_{L^2}^2, \quad (99)
\end{aligned}$$

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \partial_x \gamma_i(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \right. \\
&\leq H_i \|f_x\|_{L^2}^2, \quad (100)
\end{aligned}$$

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_{\xi x} \gamma_i(x, \theta, s - r, \pm l) g(\theta, r) dr d\theta \right|^2 ds dx \right. \\
&\leq K_i \|g_x\|_{L^2}^2. \quad (101)
\end{aligned}$$

Proof For all inequalities, we just prove the case of $i = 1$ ($\xi = l$ if it is in the inequality), the other cases can be proved in the same way.

First, for the inequality (97), using (44), the fundamental inequality, (90) in Lemma 2 and (93), (94) in Lemma 3, it gets

$$\begin{aligned}
&\left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \partial_s \gamma_1(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \right. \\
&\leq 3\lambda^2 \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \gamma_1(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \\
&\quad + 3 \int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(n\pi)^2}{4L^2} \gamma_1(x, \theta, s, \xi) \right. \\
&\quad \cdot f(\theta, \xi) d\xi d\theta \left. \right|^2 ds dx
\end{aligned}$$

$$\begin{aligned}
& + 3 \int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(m\pi)^2}{4l^2} \gamma_1(x, \theta, s, \xi) \right. \\
& \quad \cdot f(\theta, \xi) d\xi d\theta \left. \right|^2 ds dx \\
& \leq 3(\lambda^2 A_1 \|f\|_{L^2}^2 + C_{11} \|f_x\|_{L^2}^2 + C_{21} \|f_y\|_{L^2}^2).
\end{aligned}$$

For the next inequality, employing (44), the fundamental inequality, (91) in Lemma 2 and (95), (96) in Lemma 3, one gets

$$\begin{aligned}
& \left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_{\xi s} \gamma_1(x, \theta, s-r, l) g(\theta, r) dr d\theta \right|^2 ds dx \right. \\
& \leq 3\lambda^2 \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_{\xi} \gamma_1(x, \theta, s-r, l) g(\theta, r) dr d\theta \right|^2 ds dx
\end{aligned}$$

$$\begin{aligned}
& + 3 \int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_0^s \frac{(m\pi)^2}{4l^2} \partial_{\xi} \gamma_1(x, \theta, s-r, l) \right. \\
& \quad \cdot g(\theta, r) dr d\theta \left. \right|^2 ds dx \\
& \leq 3(\lambda^2 B_1 \|g\|_{L^2}^2 + D_{11} \|g_x\|_{L^2}^2 + D_{21} \|g\|_{L^2}^2).
\end{aligned}$$

For inequality (99), applying (44), the Cauchy-Schwarz inequality, (39) and Lemma 1, one can infer that

$$\begin{aligned}
& \left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \partial_{\xi} \gamma_1(x, \theta, 0, l) g(\theta, s) d\theta \right|^2 ds dx \right. \\
& = p_{\xi}^2(l, \xi) |_{\xi=l} \int_{-L}^L \int_0^\tau \left(\sum_{n=1}^\infty g_n(s) \varphi_n(x) \right)^2 ds dx \\
& = p_{\xi}^2(l, \xi) |_{\xi=l} \|g\|_{L^2}^2 \leq M_4 \|g\|_{L^2}^2 = G_1 \|g\|_{L^2}^2.
\end{aligned}$$

Combining inequality (93), the equation $\int_{-L}^L (\varphi'(x))^2 dx = \frac{n^2 \pi^2}{4L^2} \int_{-L}^L \varphi_n^2(x) dx = \frac{n^2 \pi^2}{4L^2} L$, and through the proof process similar to the proof of Lemma 3, one gets

$$\begin{aligned}
& \left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_{-l}^l \partial_x \gamma_1(x, \theta, s, \xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \right. \\
& \leq e^{2\lambda\tau} l^2 \int_{-L}^L \int_0^\tau \sum_{m=1}^\infty e^{-\frac{m^2 \pi^2 s}{2l^2}} p_{1m}^2 \sum_{m=1}^\infty \left(\sum_{n=1}^\infty e^{-\frac{n^2 \pi^2 s}{4L^2}} \right. \\
& \quad \cdot \varphi'_n(x) a_{n,m}(f) \left. \right)^2 ds dx \\
& \leq e^{2\lambda\tau} l^2 L \int_0^\tau \sum_{m=1}^\infty p_{1m}^2 \sum_{m=1}^\infty \sum_{n=1}^\infty e^{-\frac{n^2 \pi^2 s}{2L^2}} \frac{n^2 \pi^2}{4L^2} a_{n,m}^2(f) ds \\
& \leq H_1 \|f_x\|_{L^2}^2.
\end{aligned}$$

For the inequality (101), applying (105) in Appendix A and the approach similar to the proof of the inequality (95), we can get

$$\begin{aligned}
& \left| \int_{-L}^L \int_0^\tau \left| \int_{-L}^L \int_0^s \partial_{\xi x} \gamma_1(x, \theta, s-r, l) g(\theta, r) dr d\theta \right|^2 ds dx \right. \\
& = \int_{-L}^L \int_0^\tau \left(\int_{-L}^L \int_0^s \sum_{n=1}^\infty \sum_{m=1}^\infty e^{-\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2} + \lambda\right)(s-r)} \right.
\end{aligned}$$

$$\begin{aligned}
& \quad \cdot (-1)^m \frac{m\pi}{2l} p_{1m} \frac{1}{L} \varphi'_n(x) \varphi_n(\theta) g(\theta, r) dr d\theta \left. \right)^2 ds dx \\
& = \int_{-L}^L \int_0^\tau \left(\int_{-L}^L \int_0^s \sum_{n=1}^\infty \sum_{m=1}^\infty e^{-\left(-\frac{(n\pi)^2}{4L^2} - \frac{(m\pi)^2}{4l^2} + \lambda\right)(s-r)} \right. \\
& \quad \cdot (-1)^m \frac{m\pi}{2l} p_{1m} \frac{1}{L} \frac{n\pi}{2L} \varphi_n(x) \varphi_n(\theta) g(\theta, r) dr d\theta \left. \right)^2 ds dx \\
& \leq L \int_0^\tau \sum_{m=1}^\infty \frac{m^2 \pi^2}{4l^2} p_{1m}^2 \sum_{m=1}^\infty \int_0^s e^{2\left(-\frac{m^2 \pi^2}{4l^2} + \lambda\right)(s-r)} \\
& \quad \cdot \left(\sum_{n=1}^\infty \int_0^s \frac{n^2 \pi^2}{4L^2} g_n^2(r) dr \right)^2 ds \\
& \leq \tau e^{2\lambda\tau} \frac{L}{l} \|p_{\xi}(l, \xi)\|_{L^2}^2 \sum_{m=1}^\infty \frac{2l^2}{m^2 \pi^2} \sum_{n=1}^\infty \int_0^\tau \frac{n^2 \pi^2}{4L^2} g_n^2(r) dr \\
& \leq K_1 \|g_x\|_{L^2}^2.
\end{aligned}$$

This inequality gets proven.

So far, we have proved this lemma.

The following proposition states that the original system (6)-(16) and the target system (17)-(27) are equivalent in the sense of norm.

Proposition 2 There exist positive constants α_5 and β_5 , such that

$$\begin{aligned}
& \alpha_5 (\|u\|_{L^2}^2 + \|v_1\|_{H^1}^2 + \|v_2\|_{H^1}^2) \\
& \leq \|w\|_{L^2}^2 + \|z_1\|_{H^1}^2 + \|z_2\|_{H^1}^2 \\
& \leq \beta_5 (\|u\|_{L^2}^2 + \|v_1\|_{H^1}^2 + \|v_2\|_{H^1}^2). \quad (102)
\end{aligned}$$

According to the transformations (29)-(31), utilizing fundamental inequality, Cauchy-Schwarz inequality, and Lemma 1, 2, 4, we can prove this lemma. Here is omitted.

4 Simulation

In this section, we provide an example to illustrate the effectiveness of the proposed delay-compensated bilateral control for the PDE system. In the numerical example, the domain is defined as $\mathcal{D}_1 = [-1, 1] \times [-1, 1]$, and choose time delay $\tau = 1s$, initial condition $u_0 = 2(\sin(\pi x) + 1)(\cos(\pi y) + 1)$. We apply the finite difference method by discretizing the domain by step sizes $\Delta x = 0.02$, $\Delta y = 0.02$, $\Delta s = 0.01$ and $\Delta t = 0.01$.

The dynamics for both compensated and uncompensated cases with $\lambda = 7$ are shown in Figure 1, respectively. To observe the effectiveness of the delay-compensated control actuators, the variation of norm under three different parameters is demonstrated. The norm of state diverges in the case without delay compensated control in Figure 2 (a). Figure 2 (b) illustrates the convergence rate of the state with delay compensation. The dynamics and norm of $U_1(x, t)$ are shown in Figure 3 when $\lambda = 7$.

5 Conclusion

This paper presents bilateral actuators for reaction-diffusion with arbitrarily large input delay in a rectangular domain. To design the bilateral delay-compensated actuators, we propose a novel set of backstepping trans-

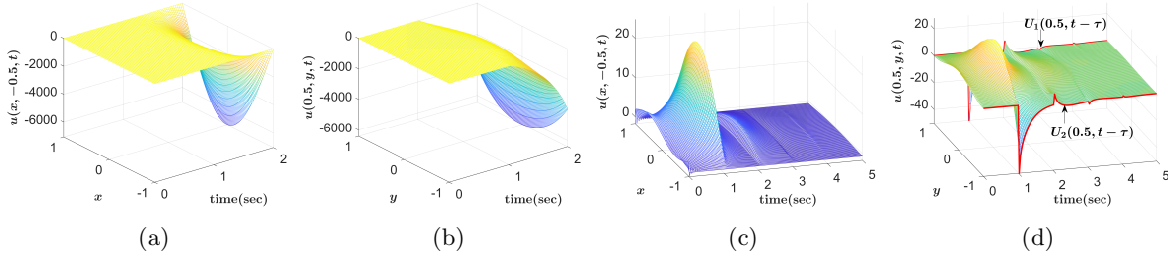

Fig. 1. The dynamics of the state with $\lambda = 7$. (a) $u(x, -0.5, t)$ without delay compensation. (b) $u(0.5, y, t)$ without delay compensation. (c) $u(x, -0.5, t)$ with delay compensation. (d) $u(0.5, y, t)$ with delay compensation.

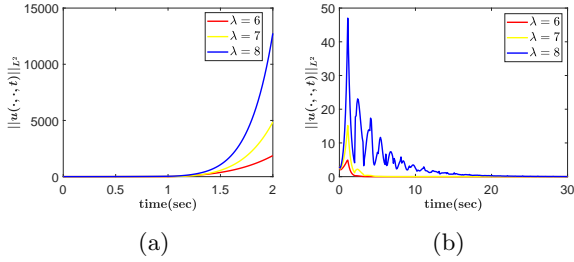

Fig. 2. The norm $\|u(x, y, t)\|_{L^2}$. (a) Without delay compensation. (b) With delay compensation.

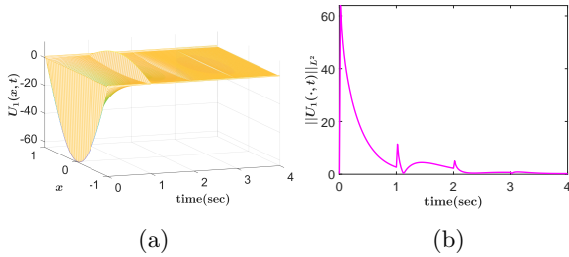

Fig. 3. The actuator $U_1(\cdot, t)$ with $\lambda = 7$. (a) Dynamics. (b) $\|U_1(\cdot, t)\|_{L^2}$.

formations, which results in the kernel functions being expressed by double trigonometric series with singularities. The main difficulty is to prove the norm equivalence in the sense of H^1 norm between the target system and the cascade system based on the kernel functions containing singularities in the rectangular domain. To overcome this difficulty, the Cauchy-Schwarz inequality, the 2-D Fourier series, and the Parseval's theorem are applied in the proving. Another difficulty is to prove the exponential stability of the target which demands designing a change of variables for target system. Finally, we apply the Lyapunov function to prove the exponential stability of the closed-loop system. Future research will consider control design problems with non-constant input delays, such as delays varying with spatial parameters or varying with time.

Appendix A The proof of Lemma 3

Proof Combining (44) and Definition 1, it infers that

$$\begin{aligned}
& \int_{-L}^L \int_0^\tau \left(\sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(n\pi)^2}{4L^2} \gamma_1(x, \theta, s, \xi) \right. \\
& \quad \left. \cdot f(\theta, \xi) d\xi d\theta \right)^2 ds dx \\
& \leq e^{2\lambda\tau} \int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_{-l}^l \frac{(n\pi)^2}{4L^2} e^{-\frac{(n\pi)^2 s}{4L^2}} \right. \\
& \quad \left. \cdot e^{-\frac{(m\pi)^2 s}{4L^2}} \frac{1}{L} p_{1m} \varphi_n(x) \varphi_n(\theta) \phi_m(\xi) f(\theta, \xi) d\xi d\theta \right|^2 ds dx \\
& \leq e^{2\lambda\tau} l^2 \int_{-L}^L \int_0^\tau \sum_{m=1}^\infty e^{-\frac{(m\pi)^2 s}{2l^2}} p_{1m}^2 \sum_{m=1}^\infty \left(\sum_{n=1}^\infty \frac{n\pi}{2L} e^{-\frac{(n\pi)^2 s}{4L^2}} \right. \\
& \quad \left. \cdot \varphi_n(x) \frac{n\pi}{2L} a_{n,m}(f) \right)^2 ds dx \\
& \leq e^{2\lambda\tau} M_1 l L \sum_{m=1}^\infty \sum_{n=1}^\infty \frac{n^2 \pi^2}{4L^2} \int_0^\tau e^{-\frac{(n\pi)^2 s}{2L^2}} \frac{n^2 \pi^2}{4L^2} a_{n,m}^2(f) ds \\
& \leq e^{2\lambda\tau} M_1 l L \sum_{m=1}^\infty \sum_{n=1}^\infty \frac{n^2 \pi^2}{4L^2} a_{n,m}^2(f) \leq C_1 \|f_x\|_{L^2}^2.
\end{aligned}$$

By a similar process, we can prove the inequality (94).

For (95), according to the Fourier series of $g(x, s)$ and $p(l, \xi)$ defined in (86) and (92), we can get

$$g_x(x, s) = \sum_{n=1}^\infty g_n(s) \varphi'_n(x), \quad (103)$$

$$p_{\xi\xi}(l, \xi) = - \sum_{m=1}^\infty \frac{m^2 \pi^2}{4l^2} p_{1m} \phi_m(x), \quad (104)$$

then, combining the Parseval's theorem, it gets

$$\|g_x(x, s)\|_{L^2}^2 = L \sum_{n=1}^\infty \frac{(n\pi)^2}{4L^2} \int_0^\tau g_n^2(s) ds, \quad (105)$$

$$\|p_{\xi\xi}(l, \xi)\|_{L^2}^2 = l \sum_{m=1}^\infty \frac{m^4 \pi^4}{16l^4} p_{1m}^2. \quad (106)$$

Finally, utilizing the Cauchy-Schwarz inequality, Lemma 1, (105) and (106), we can infer that

$$\begin{aligned}
& \int_{-L}^L \int_0^\tau \left| \sum_{n=1}^\infty \sum_{m=1}^\infty \int_{-L}^L \int_0^s \frac{n^2 \pi^2}{4L^2} \right. \\
& \quad \left. \cdot \partial_\xi \gamma_1(x, \theta, s-r, l) g(\theta, r) dr d\theta \right|^2 ds dx \\
& \leq \int_{-L}^L \int_0^\tau \sum_{m=1}^\infty \frac{m^4 \pi^4}{16l^4} p_{1m}^2 \sum_{m=1}^\infty \frac{4l^2}{m^2 \pi^2} \left(\sum_{n=1}^\infty \int_0^s \frac{n^2 \pi^2}{4L^2} \varphi_n(x) \right. \\
& \quad \left. \cdot e^{(\frac{-m^2 \pi^2}{4l^2} + \frac{-n^2 \pi^2}{4L^2} + \lambda)(s-r)} g_n(r) dr \right)^2 ds dx
\end{aligned}$$

$$\begin{aligned}
&\leq e^{2\lambda\tau} L l \sum_{m=1}^{\infty} \frac{m^4 \pi^4}{16l^4} p_{1m}^2 \sum_{m=1}^{\infty} \frac{4l}{m^2 \pi^2} \int_0^{\tau} \sum_{n=1}^{\infty} \int_0^s \left(\frac{n\pi}{2L} g_n(r) \right)^2 dr \\
&\quad \cdot \int_0^s \frac{n^2 \pi^2}{4L^2} e^{-\frac{n^2 \pi^2}{2L^2}(s-r)} dr ds \\
&\leq e^{2\lambda\tau} L \tau \|p_{\xi\xi}(l, \xi)\|_{L^2}^2 \sum_{n=1}^{\infty} \int_0^{\tau} \left(\frac{n\pi}{2L} g_n(r) \right)^2 dr \\
&\leq e^{2\lambda\tau} \tau M_3 \|g_x\|_{L^2}^2.
\end{aligned}$$

This inequality gets proved. By a similar approach, we can prove (96).
