(Dated: July 10, 2023)

We study the phase diagram of a resistively shunted Josephson junction (RSJJ) in the framework of the boundary sine-Gordon model. Using the non-perturbative functional renormalization group (FRG) we find that the transition is not controlled by a single fixed point but by a line of fixed points, and compute the continuously varying critical exponent  $\nu$ . We argue that the conductance also varies continuously along the transition line. In contrast to the traditional phase diagram of the RSJJ—an insulating ground state when the shunt resistance  $R$  is larger than  $R_q = h/(2e)^2$  and a superconducting one when  $R < R_q$ —the FRG predicts the transition line in the plane  $(\alpha, E_J/E_C)$  to bend in the region  $\alpha = R_q/R < 1$  but we cannot discard the possibility of a vertical line at  $\alpha = 1$  ( $E_J$  and  $E_C$  denote the Josephson and charging energies of the junction, respectively). Our results regarding the phase diagram and the nature of the transition are compared with Monte Carlo simulations and numerical renormalization group results.

## I. INTRODUCTION.

Although the resistively shunted Josephson junction (RSJJ) is one of the best studied examples of dissipative quantum systems [1], its basic properties are still a

matter of debate. Since the seminal work of Schmid and Bulgadaev (SB) on the quantum Brownian particle in a periodic potential (a problem that can be mapped on the RSJJ) [2, 3], the conventional view is that the junction is insulating when the shunt resistance  $R$  is larger than the quantum of resistance  $R_q = h/q^2$  ( $q = 2e$  is the Cooper pair charge) and superconducting when  $R < R_q$  [4–7] but for a long time there has been little experimental evidence [8–11]. In a recent experiment no sign of the expected insulating phase was observed and the very existence of the dissipative quantum phase transition at  $R = R_q$  has been questioned [12, 13], whereas the observation of the Schmid transition has been reported in another experiment [14]. On the other hand, using both the numerical renormalization group (NRG) and the functional renormalization group (FRG), it has been shown that when  $\alpha = R_q/R < 1$  an insulating-superconducting transition can be induced by varying the ratio  $E_J/E_C$  between the Josephson coupling energy and the charging energy [15, 16], but these conclusions have been questioned [17].

In this paper, we reconsider the superconductor-insulator transition in a RSJJ in the framework of the boundary sine-Gordon model originally studied by SB and defined by the Euclidean (imaginary-time) action [18]

$$S[\varphi] = \frac{1}{2} \sum_{\omega_n} \left( \frac{\alpha}{2\pi} |\omega_n| + \frac{\omega_n^2}{2E_C} \right) |\varphi(i\omega_n)|^2 - E_J \int_0^\beta d\tau \cos \varphi(\tau), \quad (1)$$

where  $\alpha = R_q/R$ ,  $E_J$  is the Josephson coupling energy,  $E_C = q^2/2C_J$  the charging energy and  $C_J$  the capacitance of the junction (Fig. 1). The field  $\varphi$ , which stands for the superconducting order parameter phase difference across the junction, is a noncompact variable which satisfies periodic boundary conditions in imaginary time,  $\varphi(0) = \varphi(\beta)$ , and  $\omega_n = 2n\pi T$  ( $n$  integer) is a bosonic

Figure 1. Resistively shunted Josephson junction. The capacitance  $C_J$  determines the charging energy  $E_C = (2e)^2/2C_J$  of the junction while the transparency of the tunnel barrier and the superconducting gap set the Josephson coupling energy  $E_J$ .

Matsubara frequency.  $\beta = 1/T$  is the inverse temperature and we consider only the zero-temperature limit  $\beta \rightarrow \infty$  (we set  $\hbar = k_B = 1$  throughout the paper). We assume a UV frequency cutoff  $W$ . The action (1) also describes a quantum Brownian particle in one dimension with coordinate  $\varphi$  and mass  $m = 1/2E_C$  moving in a periodic potential ( $\eta = \alpha/2\pi$  is then the friction coefficient in the classical limit) [2, 3, 5], and a Luttinger liquid in presence of an impurity (with  $K = 1/\alpha$  the Luttinger parameter) or a weak link (with  $K = \alpha$ ) [19–21].

We study the boundary sine-Gordon model (1) in the framework of the nonperturbative FRG [22–24], an approach which has proven very successful for the (1+1)-dimensional sine-Gordon model [25, 26]. We find that the transition is not controlled by a single fixed point but by a line of fixed points, and compute the continuously varying critical exponent  $\nu$  associated with the relevant direction about the fixed point. These results qualitatively agree with the Monte Carlo simulations of Werner and Troyer (WT) who showed that the correlation function  $\chi(\tau) = \langle e^{iq\varphi(\tau)} e^{-iq\varphi(0)} \rangle$  ( $|q| \leq 1/2$ ) exhibits continuously varying critical exponents along the transition line [27, 28]. Recent NRG calculations also imply that the transition line is a line of fixed points [15]. Although no precise calculations are performed, we argue that the conductance varies continuously along the transition line.

Unlike the traditional phase diagram of the RSJJ, where the transition between the insulating and superconducting phases is located at  $\alpha = 1$ , the FRG predicts the transition line in the plane  $(\alpha, E_J/E_C)$  to bend in the region  $\alpha = R_q/R < 1$ . The FRG is however not reliable in the limit  $\alpha \rightarrow 0$  since it predicts a phase transition at a finite value of  $E_J/E_C$  while in the absence of dissipation the ground state of the model (1) is known to be insulating. This leads us to propose two possible scenarios for the Schmid transition. In the first one, the transition line is vertical and located at  $\alpha = 1$ , as in the traditional phase diagram and in agreement with the Monte Carlo simulations of WT. In the second one, the transition line bends in the region  $\alpha < 1$ , as in the FRG and NRG calculations [15, 16], but eventually the critical value of  $E_J/E_C$  diverges as  $\alpha \rightarrow 0$ .

On the other hand we compute the phase mobility  $\mu(\omega)$  (i.e. the mobility of the Brownian particle) related to the

admittance  $Y(\omega) = q^2/\mu(\omega)$  of the RSJJ. The dc mobility  $\mu = \lim_{\omega \rightarrow 0} \mu(\omega)$  vanishes in the superconducting phase, and is equal to the mobility  $\mu_0 = 2\pi/\alpha = 1/\eta$  of the free particle in the insulating phase. The frequency dependence of the mobility in the superconducting phase is correctly obtained only for  $\alpha \gtrsim 2$ ; when  $1 \leq \alpha \lesssim 2$ , the FRG fails to capture the instantons connecting neighboring minima of the periodic potential. This does not prevent us to obtain the low-frequency behavior of the RSJJ; in the insulating phase  $Y(\omega \rightarrow 0) = 1/R$  whereas  $Y(\omega)$  is purely inductive at low frequencies in the superconducting phase. However the effective inductance is not determined by the “coherence”, i.e. the expectation value  $\langle \cos \varphi \rangle$ , which in fact remains nonzero in the insulating phase. We compare our results for  $\langle \cos \varphi \rangle$  and  $\langle \cos(\varphi/2) \rangle$  with results obtained from integrability methods and Monte Carlo simulations [28, 29].

## II. FRG FORMALISM.

Following the standard strategy of the nonperturbative functional renormalization group (FRG) we add to the action an infrared regulator term [22–24],

$$\Delta S_k[\varphi] = \frac{1}{2} \sum_{\omega_n} R_k(i\omega_n) \varphi(-i\omega_n) \varphi(i\omega_n), \quad (2)$$

which suppresses fluctuation modes whose frequency is smaller than the (running) frequency  $k$ , i.e.  $|\omega_n| \lesssim k$ , but leaves unaffected those with  $|\omega_n| \gtrsim k$ . The cutoff function is written in the form

$$R_k(i\omega_n) = \frac{\alpha}{2\pi} |\omega_n| r\left(\frac{|\omega_n|}{k}\right) + Z_{2,k} \omega_n^2 r\left(\frac{\omega_n^2}{k^2}\right), \quad (3)$$

where  $Z_{2,k} = \frac{1}{2\pi} \int_0^{2\pi} d\phi Z_{2,k}(\phi)$  is the field average of the function  $Z_{2,k}(\phi)$  defined in Eq. (8) and  $r(x) = 4(1-x)^2/x \Theta(1-x)$ . Including the second term in (3) allows us to consider the limit  $\alpha \rightarrow 0$ . The partition function

$$\mathcal{Z}_k[J] = \int \mathcal{D}[\varphi] e^{-S[\varphi] - \Delta S_k[\varphi] + \int_0^\beta d\tau J\varphi} \quad (4)$$

thus becomes  $k$  dependent. The expectation value of the field is given by

$$\phi(\tau) = \frac{\delta \ln \mathcal{Z}_k[J]}{\delta J(\tau)} = \langle \varphi(\tau) \rangle. \quad (5)$$

The scale-dependent effective action

$$\Gamma_k[\phi] = -\ln \mathcal{Z}_k[J] + \int_0^\beta d\tau J\phi - \Delta S_k[\phi] \quad (6)$$

is defined as a slightly modified Legendre transform which includes the subtraction of  $\Delta S_k[\phi]$ . Assuming that for  $k = k_{\text{in}}$  the fluctuations are completely frozen by the term  $\Delta S_{k_{\text{in}}}$ , which is the case when  $k_{\text{in}} \gg \min(W, E_C)$ ,

$\Gamma_{k_{\text{in}}}[\phi] = S[\phi]$ . On the other hand, the effective action of the original model (1) is given by  $\Gamma_{k=0}[\phi]$  since  $R_{k=0}$  vanishes. The nonperturbative FRG approach aims at determining  $\Gamma_{k=0}$  from  $\Gamma_{k_{\text{in}}}$  using Wetterich's equation [30–32]

$$\partial_t \Gamma_k[\phi] = \frac{1}{2} \text{Tr} \left\{ \partial_t R_k (\Gamma_k^{(2)}[\phi] + R_k)^{-1} \right\}, \quad (7)$$

where  $\Gamma_k^{(2)}$  is the second-order functional derivative of  $\Gamma_k$  and  $t = \ln(k/k_{\text{in}})$  a (negative) RG “time”.

### A. FE<sub>2</sub> expansion

In the frequency expansion to second order (FE<sub>2</sub>) [33], the scale-dependent effective action is approximated by

$$\Gamma_k[\phi] = \frac{Z_1}{2} \sum_{\omega_n} |\omega_n| \phi(-i\omega_n) \phi(i\omega_n) + \int_0^\beta d\tau \left[ \frac{1}{2} Z_{2,k}(\phi) (\partial_\tau \phi)^2 + U_k(\phi) \right] \quad (8)$$

with initial conditions

$$Z_1 = \frac{\alpha}{2\pi}, \quad Z_{2,k_{\text{in}}}(\phi) = \frac{1}{2E_C}, \quad U_{k_{\text{in}}}(\phi) = -E_J \cos \phi. \quad (9)$$

The effective potential  $U_k(\phi)$  is given by the effective action when the field  $\phi(\tau) \equiv \phi$  is time independent:  $\Gamma_k[\phi] = \beta U_k(\phi)$ . We anticipate the fact that  $Z_1$  is not renormalized and therefore remains equal to its initial value. The zeroth-order harmonic of  $Z_{2,k}(\phi)$  and the first-order harmonic of  $U_k(\phi)$  can be seen as renormalized values of the coupling constants  $1/2E_C$  and  $E_J$ , respectively, but the flow equation generates higher-order harmonics.

In practice, one introduces the dimensionless quantities

$$\tilde{U}_k(\phi) = \frac{U_k(\phi)}{k}, \quad \tilde{Z}_{2,k}(\phi) = k Z_{2,k}(\phi), \quad (10)$$

which ensure that the zero-temperature quantum phase transition between the superconducting and insulating phases corresponds to a fixed point of the flow equations. The latter, which are given in Appendix A, must be solved numerically.

### B. Mobility and admittance

In addition to the effective potential  $U_k(\phi)$ , whose RG flow indicates whether the RSJJ is insulating or superconducting, a fundamental quantity is the mobility  $\mu(i\omega_n) = |\omega_n| G(i\omega_n)$  of the quantum Brownian particle, i.e. its average (long-time) velocity when it is subjected to an external force. Since the phase propagator  $G_k(i\omega_n, \phi) = 1/\Gamma_k^{(2)}(i\omega_n, \phi)$  is given by the inverse of the two-point vertex, whose most general expression reads

$\Gamma_k^{(2)}(i\omega_n, \phi) = Z_1 |\omega_n| + \Delta_k(i\omega_n, \phi) + U_k''(\phi)$  (for a time-independent field), the scale-dependent mobility reads

$$\mu_k(i\omega_n) = \frac{|\omega_n|}{\frac{\alpha}{2\pi} |\omega_n| + \Delta_k(i\omega_n, 0) + U_k''(0)}. \quad (11)$$

We consider the vanishing field configuration  $\phi = 0$  since this corresponds to the minimum of the effective potential for any  $k > 0$ . In the FE<sub>2</sub>, the self-energy  $\Delta_k$  is approximated by its lowest-order derivative expansion, i.e.  $\Delta_k(i\omega_n, \phi) = Z_{2,k}(\phi) \omega_n^2$ . To obtain the frequency-dependent mobility  $\mu(\omega)$  in real time, one must first take the limit  $k \rightarrow 0$  and perform the analytic continuation  $i\omega_n \rightarrow \omega + i0^+$ ; the dc mobility is then given by  $\mu = \mu(\omega \rightarrow 0)$ . In the FE<sub>2</sub>, the determination of  $\Delta_k(i\omega_n, \phi)$  is however valid only in the limit  $|\omega_n| \ll k$ —for the same reason that the derivative expansion in the  $\varphi^4$  theory is valid only in the small-momentum limit  $|\mathbf{p}| \ll k$  [24]—and setting  $k \rightarrow 0$  followed by  $\omega \rightarrow 0$  (or  $\omega_n \rightarrow 0$ ) is not, at least in principle, possible. We shall see how Eq. (11) can nevertheless be used to obtain useful information about the mobility.

When the RSJJ is biased by an infinitesimal external time-dependent current  $I(t)$ , the mobility determines the induced voltage  $V(t)$  across the junction [7], i.e. the admittance

$$Y(\omega) = \frac{I(\omega)}{V(\omega)} = \frac{q^2}{\mu(\omega)} \quad (12)$$

for a sinusoidal current.

## III. THE SCHMID TRANSITION

### A. Phase diagram

Typical flow trajectories, shown in Figs. 2 and 3, are in agreement with previous results by Masuki *et al.* [15, 16]. When  $\alpha > 1$ , there is a (repulsive) trivial fixed point  $\tilde{U}'(\phi) = \tilde{Z}_2(\phi) = 0$  and all RG trajectories with initial condition  $\tilde{E}_{J,k_{\text{in}}} = E_J/k_{\text{in}} > 0$  flow to the strong coupling limit where both the effective potential  $\tilde{U}'(\phi)$  and  $\tilde{Z}_2(\phi)$  flow to infinity [35]: The system is in the superconducting phase. When  $\alpha < 1$ , in addition to the trivial fixed point  $\tilde{U}'(\phi) = \tilde{Z}_2(\phi) = 0$ , which is now attractive, we find a critical fixed point  $(\tilde{U}^{*'}(\phi), \tilde{Z}_2^*(\phi))$ , so that the trajectories can flow to either the trivial fixed point or the strong-coupling limit depending on the initial conditions at scale  $k = k_{\text{in}}$ . Thus the system can be either superconducting ( $\tilde{U}'_k, \tilde{Z}_{2,k} \rightarrow \infty$  for  $k \rightarrow 0$ ) or insulating ( $\tilde{U}'_k, \tilde{Z}_{2,k} \rightarrow 0$ ).

The location of the critical fixed point as  $\alpha$  varies can be obtained by solving the equations  $\partial_k \tilde{U}'_k(\phi) = \partial_k \tilde{Z}_{2,k}(\phi) = 0$  (Fig. 4). When  $\alpha \rightarrow 0$ , the action (1) corresponds to the one-dimensional sine-Gordon model and describes a frictionless quantum particle in a one-dimensional periodic potential. Since all quantum states

Figure 2. Flow diagram projected on the  $(1/\tilde{E}_{C,k}, \tilde{E}_{J,k})$  plane, where  $1/2\tilde{E}_{C,k}$ , and  $\tilde{E}_{J,k}$  denote the zeroth- and first-order harmonics of  $\tilde{Z}_{2,k}(\phi)$  and  $\tilde{U}_k(\phi)$ , respectively ( $\alpha = 0.6, 0.8, 1, 1.4$  from left to right). The red point shows the fixed point obtained by solving  $\partial_k \tilde{U}_k(\phi) = \partial_k \tilde{Z}_{2,k}(\phi) = 0$ . The red dashed lines, showing the effective initial conditions of the flow ( $1/\tilde{E}_{C,W} = W/E_C$ ,  $\tilde{E}_{J,W} = E_J/W$ ) at fixed  $E_J/E_C = 0.02$  when  $W$  is varied [34], indicate that a smaller bandwidth  $W$  favors the superconducting phase.

Figure 3. Flow diagram projected on the  $(1/\tilde{E}_{C,k}, \tilde{E}_{J,k})$  plane for  $\alpha = 0.6, 1$  and  $1.4$ . The line of critical fixed points for  $\alpha < 1$  is shown in red.

of the particle are extended, the ground state should be insulating in that limit, whatever the value of  $E_C$  and  $E_J$ . The existence of a fixed point at a finite value  $\tilde{E}_J^*/\tilde{E}_C^*$  when  $\alpha = 0$  is a known artifact of the FRG-FE<sub>2</sub> approach to the one-dimensional sine-Gordon model [36]. In the limit  $\alpha \rightarrow 0$ , we expect the fixed point (shown by a red dot in Fig. 4) to move to infinity, i.e.  $\tilde{E}_J^*/\tilde{E}_C^* \rightarrow \infty$ .

The phase diagram as a function of the bare parameters of the model is shown in Fig. 5. We find a transition between an insulating and a superconducting phase in the region  $\alpha < 1$ . In the large bandwidth limit  $W/E_C \gg 1$ , the transition line depends only on the ratio  $E_J/E_C$  and starts with an infinite slope:  $(E_J/E_C)_{\text{crit}} \sim (1 - \alpha)^{0.5}$  when  $\alpha \rightarrow 1^-$ . The transition line then bends towards the region  $\alpha < 1$ , a direct consequence of the existence of the line of critical fixed points shown in Fig. 4. The finite value of  $(E_J/E_C)_{\text{crit}}$  in the limit  $\alpha \rightarrow 0$  is due to  $\tilde{E}_J$  remaining finite; if  $\tilde{E}_J \rightarrow \infty$  when  $\alpha \rightarrow 0$  (as it should be, see the previous discussion) the RSJJ is

insulating whatever the value of the Josephson energy  $E_J$ . Two possible scenarios are shown in Fig. 5 (bottom panel). The first one is a vertical transition line located at  $\alpha = 1$ , as in the traditional picture of the Schmid transition and in agreement with the Monte Carlo simulations of WT in the large bandwidth limit  $W \gg E_C$  who find that the transition occurs at  $\alpha = 1.00(2)$  at least up to  $E_J/E_C \sim 0.5$  [27, 37]. In this scenario, the presence of the spurious fixed point at  $\alpha = 0$  invalidates the entire transition line obtained in the FE<sub>2</sub>, the only vestige of the true transition line being the vertical tangent at  $\alpha = 1$ . In the second scenario, the spurious fixed point at  $\alpha = 0$  invalidates the FE<sub>2</sub> result for  $\alpha \ll 1$  but the obtained transition line is correct in a finite interval near  $\alpha = 1$ . The NRG results of Masuki *et al.* [15] also yield a transition line that bends in the region  $\alpha < 1$  but with two qualitative differences with the FRG results reported

Figure 4. Location of the critical fixed point in the plane  $(1/\tilde{E}_C^*, \tilde{E}_J^*)$  as  $\alpha$  varies. The inset shows  $1/\tilde{E}_C^*$  and  $\tilde{E}_J^*$  vs  $\alpha$ . Near  $\alpha = 1$ ,  $1/\tilde{E}_C^* \sim 1 - \alpha$  and  $\tilde{E}_J^* \sim \sqrt{1 - \alpha}$ . The red point shows the (spurious) fixed point obtained when  $\alpha = 0$  (see text for a discussion).

Figure 5. (Top) Zero-temperature phase diagram of the RSJJ as a function of the bare parameters of the model ( $\alpha$ ,  $E_J$ ,  $1/E_C$  and  $W$ ) showing the insulating (I) and superconducting (SC) phases. The transition line depends only on the ratio  $E_J/E_C$  when  $W \gg E_C$ . The inset shows the phase diagram for  $W/E_C = 0.01$ . As explained in the text, the existence of a transition at a finite value  $(E_J/E_C)_{\text{crit}}$  when  $\alpha \rightarrow 0$  is an artifact of the FE<sub>2</sub>. (Bottom) Two possible scenarios for the Schmid transition taking into account the absence of transition in the limit  $\alpha \rightarrow 0$ .

here: The transition line exhibits a vanishing slope near  $\alpha = 1$  and a reentrance of the superconducting phase at small  $\alpha$  (which is hard to reconcile with the known phase diagram of the one-dimensional sine-Gordon model ( $\alpha = 0$ ), see the discussion above).

Moving away from the large bandwidth limit, at fixed  $E_C$ , favors the superconducting phase as shown in Fig. 2: Decreasing  $W$  will always change the initial conditions of the flow so as to make the system superconducting. Thus  $(E_J/E_C)_{\text{crit}}$  decreases when  $W$  is lowered. As shown in the inset of Fig. 5, we find that the transition persists in the limit  $1/E_C \rightarrow 0$  since  $(E_J/W)_{\text{crit}}$  remains finite. If, however, we take the limit  $W \rightarrow \infty$  (with  $W/E_C \rightarrow 0$ ) we find that the RSJJ is always in the insulating phase when  $\alpha < 1$ , in agreement with the SB phase diagram.

Figure 6. Fixed-point functions  $\tilde{U}^{*'}(\phi)$  and  $\tilde{Z}^{*'}(\phi)$  for  $\alpha = 0.8$ .

## B. Critical behavior

### 1. Critical exponent $\nu$

The functions  $\tilde{U}^{*'}(\phi)$  and  $\tilde{Z}^{*'}(\phi)$  at the fixed point controlling the phase transition are shown in Fig. 6 for  $\alpha = 0.8$ . The RG eigenvalue  $1/\nu$  associated with the relevant perturbation, shown in Fig 7, is determined by linearizing the flow about the fixed point.

Near  $\alpha = 1$ , the critical fixed point is close to the Gaussian fixed point and can be analyzed from perturbation theory. We use the harmonic expansion  $\tilde{U}_k(\phi) = \sum_{n=0}^{\infty} \tilde{u}_{n,k} \cos(n\phi)$  and  $\tilde{Z}_{2k}(\phi) = \sum_{n=0}^{\infty} \tilde{z}_{n,k} \cos(n\phi)$ , and expand the flow equations in powers of  $\epsilon = 1 - 1/\alpha$ . When  $\epsilon \rightarrow 0$ , the flow of  $\tilde{u}_{1,k}$  is initially much slower than the flow of all other coupling constants. After a transient regime, the values of  $\tilde{u}_{n \neq 1,k}$  and  $\tilde{z}_{n,k}$  are determined by  $\tilde{u}_{1,k}$  alone and all RG trajectories collapse on a single line, as shown in Figs. 2 and 3 for the trajectories projected on the plane  $(\tilde{z}_0, \tilde{u}_1)$ . The flow along this line is

Figure 7. Critical exponent  $\nu$  vs  $\alpha$ . The dashed (red) line shows the result  $1/\nu = 2(1 - \alpha)$  valid near  $\alpha = 1$ .

determined by the beta function

$$\partial_t \tilde{u}_{1,k} = \left( \frac{1}{\alpha} - 1 \right) \tilde{u}_{1,k} + \mathcal{F} \tilde{u}_{1,k}^3, \quad (13)$$

where  $\mathcal{F}$  is a complicated combination of threshold functions (see Appendix B for detail). Note that this beta function is not exact (to order  $\tilde{u}_{1,k}^3$ ) since it relies on the FE<sub>2</sub> expansion.

Linearizing the flow equation (13) about its nontrivial fixed point  $\tilde{u}_1^* = [(\alpha - 1)/\alpha \mathcal{F}]^{1/2}$  yields the critical exponent  $1/\nu = 2(1 - \alpha) + \mathcal{O}((1 - \alpha)^2)$ , regardless of the value of  $\mathcal{F}$ . Only the sign of  $\mathcal{F}$  matters (assuming  $\mathcal{F}$  to be nonzero) since it determines whether the fixed point  $\tilde{u}_1^*$  exists when  $\alpha < 1$  or  $\alpha > 1$ . The fixed point is repulsive if  $\alpha < 1$  ( $1/\nu > 0$ ) and attractive if  $\alpha > 1$  ( $1/\nu < 0$ ), in agreement with the trivial fixed point  $\tilde{u}_1 = 0$  being attractive if  $\alpha < 1$  and repulsive if  $\alpha > 1$ . A numerical evaluation yields  $\mathcal{F} < 0$  thus indicating that the nontrivial fixed point exists when  $\alpha < 1$ .

In their Monte Carlo simulations [27], WT also observed that the transition is not controlled by a single fixed point, but rather by a line of critical points: By considering the correlation function  $\langle e^{iq\varphi(\tau)} e^{-iq\varphi(0)} \rangle$  ( $|q| \leq 1/2$ ), they obtained continuously varying exponents along the transition line, in full agreement with the FRG analysis, see Sec. III B 2 (they did not compute the exponent  $1/\nu$ ). The NRG calculations of Masuki *et al.* also predict the Schmid transition to be controlled by a line of fixed points [15].

The bending of the transition line in the region  $\alpha < 1$  clearly simplifies the study of the critical behavior. For a vertical transition line at  $\alpha = 1$ , one would expect the cubic term  $\mathcal{F}$  and all higher-order terms in the beta function (13) to vanish, in order to ensure that the transition line is a fixed line. Although no detailed calculations seem to have been reported, there are various claims in the literature that the cubic term  $\mathcal{F}$  in the beta function vanishes [4, 5]. In the FE<sub>2</sub> expansion, the vanishing of the beta function at  $\alpha = 1$  is made impossible by the (spurious) fixed point at  $\alpha = 0$ , which is at the origin of the transition line in the region  $\alpha < 1$ .

## 2. Correlation function $\langle e^{\frac{i}{2}\varphi(\tau)} e^{-\frac{i}{2}\varphi(0)} \rangle$

Following WT [27, 28], we consider the correlation function

$$\chi(\tau) = \langle e^{\frac{i}{2}\varphi(\tau)} e^{-\frac{i}{2}\varphi(0)} \rangle. \quad (14)$$

The computation of its Fourier transform  $\chi_k(i\omega_n)$  for  $i\omega_n = 0$  is discussed in Appendix C. At criticality we find that  $\chi_k(i\omega_n = 0) \sim 1/k^{1-\gamma}$  diverges with some exponent  $1 - \gamma$ . By dimensional analysis, we then obtain  $\chi_{k=0}(i\omega_n) \sim 1/|\omega_n|^{1-\gamma}$  and

$$\chi_{k=0}(\tau) \sim \frac{1}{|\tau|^\gamma}. \quad (15)$$

Figure 8. Critical exponent  $\gamma$  associated with the correlation function  $\chi(\tau)$  [Eq. (14)].

The exponent  $\gamma$  is shown in Fig. 8. The limiting value  $\gamma \simeq 0.5$  when  $\alpha \rightarrow 1$  (i.e.  $E_J \rightarrow 0$ ) agrees with the result of Lukyanov and Werner obtained from integrability methods [28]. We note however that  $\gamma$  exhibits a maximum for  $\alpha \sim 0.9$  while they obtain a strictly monotonous exponent along the transition line.

## 3. Mobility and conductance

At the fixed point,  $Z_{2,k}(\phi) = \tilde{Z}_{2,k}(\phi)/k \rightarrow \tilde{Z}_2^*(\phi)/k$  for  $k \rightarrow 0$  whereas  $U_k(\phi) = k\tilde{U}_k(\phi) \rightarrow 0$ . The divergence of  $Z_{2,k}(\phi)$  is not a problem since  $Z_{2,k}(\phi)\omega_n^2$  remains finite in the domain of validity of the FE<sub>2</sub> ( $|\omega_n| \ll k$ ). It indicates however that the  $\omega_n^2$  dependence of the self-energy  $\Delta_k(i\omega_n, \phi)$  is not preserved by the RG flow in the regime  $k \ll |\omega_n|$  and one expects  $\Delta_{k=0}(i\omega_n, \phi) \sim |\omega_n|$  at low energies. Heuristically one can obtain this result by stopping the flow of  $Z_{2,k}(\phi)$  at  $k \sim |\omega_n|$  since one expects  $\omega_n$  to play the role of an infrared cutoff when computing the two-point vertex  $\Gamma_k^{(2)}(i\omega_n, \phi)$ . Assuming  $\Delta_k(i\omega_n, 0) = C|\omega_n|$ , with  $C$  a function of  $\alpha$ , one then deduces from (11) that at the Schmid transition the dc mobility

$$\mu = \frac{1}{\frac{\alpha}{2\pi} + C} \quad (16)$$

takes a nontrivial (i.e. different from 0 and  $2\pi/\alpha$ ) value that depends only on  $\alpha$ . As a result, the dc conductance  $\mathcal{G} = q^2/\mu$  also takes a nontrivial value. The FE<sub>2</sub> does not allow us to determine the value of the  $\alpha$ -dependent constant  $C$  but a more refined approximation scheme, e.g. the Blaizot–Mendez-Galain–Wchebor approximation [38–40], would yield the whole frequency dependence of the self-energy (regardless of the value of  $|\omega_n|/k$ ) and thus the mobility  $\mu$  and conductance  $\mathcal{G}$  along the transition line.

Figure 9.  $U'_k(\phi) = k\tilde{U}'_k(\phi)$  vs  $t = \ln k$  in the insulating (top) and superconducting (bottom) phases.  $E_* = \lim_{k \rightarrow 0} U''_k(0)$  vanishes in the former case but is finite in the latter as shown in Fig. 10. [ $E_J = 10^{-2}E_C$ ,  $W \rightarrow \infty$ ,  $\alpha = 0.6$  (top)  $\alpha = 1.4$  (bottom).]

#### IV. SUPERCONDUCTING AND INSULATING PHASES

##### A. RG flows

Figure 9 shows the flow of the function  $U'_k = k\tilde{U}'_k$  in the insulating and superconducting phases. Although  $U'_{k=0}(\phi) = 0$ , as imposed by the periodicity and convexity of the effective potential [41], the behavior near  $\phi = 0$  is markedly different in each phase. In the insulating phase,  $U'_k(\phi)$  decreases with  $k$  and  $U'_k(\phi) \rightarrow 0$  for all  $\phi$ . On the other hand, in the superconducting phase  $U''_k(\phi)$  reaches a nonzero value in the neighborhood of  $\phi = 0$ . Although this neighborhood shrinks as  $k \rightarrow 0$ , this implies that  $E_* = \lim_{k \rightarrow 0} U''_k(0)$  takes a nonzero value (Fig. 10);  $U'_k(\phi)$  converges non-uniformly towards  $U'_{k=0}(\phi) = 0$  [42]. We conclude that the characteristic energy scale  $E_*$  vanishes in the insulating phase but is nonzero in the superconducting phase where it varies as

$$E_* \sim E_C \left( \frac{E_J}{E_C} \right)^{\alpha/(\alpha-1)} \quad (17)$$

in the large bandwidth limit  $W \gg E_C$ , as shown in Fig. 10. When approaching the transition,  $E_*$  vanishes with the exponent  $\nu$ , i.e.  $E_* \sim (E_J - E_J^{(c)})^\nu$  if  $E_J$  is varied at fixed  $E_C$  (see Fig. 13).

The function  $Z_{2,k}(\phi)$  is shown in Fig. 11. While in the insulating phase  $Z_{2,k}(\phi)$  becomes constant for  $k \rightarrow 0$ , in the superconducting phase it is strongly non-monotonous, with a form that is reminiscent of the (1+1)-dimensional sine-Gordon model [25], and takes large values. At intermediate stages of the flow, when  $k \gg E_*$ , we find that  $-\partial_t \ln Z_{2,k}(0) \simeq 3 - 2/\alpha$  takes a  $k$ -independent value (Fig. 12), which indicates that the self-energy behaves as  $\Delta_{k=0}(i\omega_n) \sim |\omega_n|^{2/\alpha-1}$  when  $|\omega_n| \gg E_*$ . The flow of  $Z_{2,k}(\phi)$  however always stops when  $k \ll E_*$  and  $Z_{2,k}(\phi)$  reaches a nonzero value, implying that the self-energy  $\Delta_{k=0}(i\omega_n, \phi) \sim \omega_n^2$  is a quadratic function of the frequency for  $\omega_n \rightarrow 0$  (as in the insulating phase).

These results imply that the propagator can be written in the form

$$G_{k=0}(i\omega_n) = \frac{1}{\frac{\alpha}{2\pi}|\omega_n| + E_*} \quad (18)$$

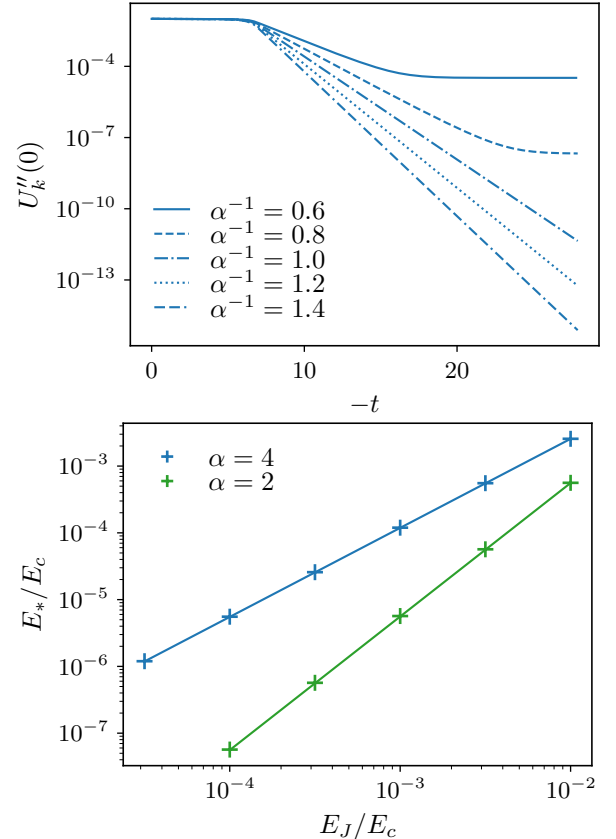

Figure 10. (Top)  $U''_k(0)$  vs  $t = \ln k$  for various values of  $\alpha$  and  $E_J = 0.01$ ,  $1/E_C = 0.02$ .  $E_* = \lim_{k \rightarrow 0} U''_k(0)$  takes a nonzero value in the superconducting phase. (Bottom)  $E_*$  vs  $E_J$  in the superconducting phase. The solid lines show the power law behaviour  $E_* \sim E_J^{\alpha/(\alpha-1)}$ .

Figure 11.  $Z_{2,k}(\phi)$  vs  $t = \ln k$  in the insulating (top) and superconducting (bottom) phases. [ $E_J = 10^{-2} E_C$ ,  $W \rightarrow \infty$ ,  $\alpha = 0.6$  (top)  $\alpha = 1.4$  (bottom)]

in the low-energy limit (neglecting the  $\omega_n^2$  term). In the insulating phase the propagator  $G_{k=0}$  is field independent whereas Eq. (18) holds for  $\phi = 0$  in the superconducting phase. Equation (18) is correct in the insulating phase (where  $E_* = 0$ ) and in the superconducting phase when  $\alpha \gtrsim 2$ ; in the latter case the physics is dominated by small fluctuations of the phase about the minima of the periodic potential  $-E_J \cos(\varphi)$ . On the other hand, Equation (18) is not correct when  $1 \leq \alpha \lesssim 2$ , a regime where transitions between neighboring minima (instan-  
tons) play a crucial role [43].

## B. Mobility and admittance

The real part of the mobility  $\mu(\omega) = \mu'(\omega) + i\mu''(\omega)$  is deduced from (18),

$$\mu'(\omega) = \frac{\alpha}{2\pi} \frac{\omega^2}{\left(\frac{\alpha}{2\pi}\omega\right)^2 + E_*^2}. \quad (19)$$

Thus the dc mobility  $\mu(\omega = 0)$  is equal to  $2\pi/\alpha = \mu_0$  in the insulating phase and vanishes in the superconducting phase (Fig. 13). However, the expression of the propagator (18) being incorrect when  $1 \leq \alpha \lesssim 2$ , the frequency

Figure 12. (Top)  $-\partial_t \ln Z_{2,k}(0)$  vs  $t = \ln k$ . (Bottom) The value of  $-\partial_t \ln Z_{2,k}(0)$  on the plateau (as shown in the top panel) vs  $\alpha$ . [ $E_J/E_C = 2 \cdot 10^{-5}$ ,  $W \rightarrow \infty$ .]

dependence of the mobility (19) is not correct in this regime and should vanish as

$$\mu'(\omega) \sim |\omega|^{2\alpha-2} \quad (20)$$

when  $\omega \rightarrow 0$  [44–46]. The behavior of the self-energy,  $\Delta_k(i\omega_n) \sim |\omega_n|^{2/\alpha-1}$ , in the frequency range  $|\omega_n| \gg E_*$  allows us to recover the perturbative (high-frequency) expansion of the mobility  $\mu'(\omega) = \mu_0 - \text{const} |\omega|^{2/\alpha-2}$  [20], but the FE<sub>2</sub> expansion fails to reproduce the low-energy behavior (20).

From (12), we deduce the low-frequency behavior of the admittance [47]

$$Y(\omega) = \begin{cases} \frac{1}{R} & \text{(I),} \\ \frac{1}{R} + \frac{i}{L_{\text{eff}}(\omega + i0^+)} & \text{(SC).} \end{cases} \quad (21)$$

Thus the junction has a vanishing transmission in the insulating phase (I) —the whole current flowing through the resistor— and behaves as an effective inductance  $L_{\text{eff}} = 1/q^2 E_*$  in the superconducting phase (SC). At the beginning of the flow (i.e. at the classical level), where  $U_{k_{\text{in}}}(\phi) = -E_J \cos \phi$ , one finds the expected re-

Figure 13. Energy scale  $E_*$ , dc mobility  $\mu = \mu(\omega = 0)$ , coherence  $\langle \cos \varphi \rangle$  and current-current correlation function  $\chi_{II}^R(0)$  vs  $E_J$  in the large bandwidth limit  $W/E_C \rightarrow \infty$  for  $\alpha \simeq 0.909$ . The transition occurs for  $E_J^{(c)}/E_C \simeq 0.0432$ . The inset shows the divergence of  $1/E_*$  in the superconducting phase as the transition is approached. The blue line is a fit  $1/E_* \sim (E_J - E_J^{(c)})^{-\nu}$  with the exponent  $\nu \simeq 5.3$  obtained from the linearized flow equations (Fig. 4, bottom panel).

sult  $1/L_{\text{eff},k_{\text{in}}} = q^2 U_{k_{\text{in}}}''(0) = q^2 E_J$ . Note that the inductive response in the superconductive phase follows solely from the vanishing of the self-energy for  $\omega_n \rightarrow 0$ , i.e.  $\Delta_k(i\omega_n = 0, \phi) = 0$ . The value of  $E_* = \lim_{k \rightarrow 0} U_k''(0)$ , and whether it vanishes or not, however requires to solve the FRG flow equations.

### C. Coherence and current-current correlation function

The expectation value  $\langle \cos \varphi \rangle$  is computed by adding to the action a time-independent external complex source  $h$ . The effective potential  $U_k(\phi, h^*, h)$  is then a function of  $\phi$ ,  $h^*$  and  $h$  and  $\langle \cos \varphi \rangle = -U^{(1,0)}(0)$  where  $U^{(1,0)}(\phi) = \partial_{h^*} U(\phi, h^*, h)|_{h^*=h=0}$  (see Appendix C for details). Contrary to the NRG result of Ref. [15], we find that the coherence  $\langle \cos \varphi \rangle$  never vanishes, although it becomes very small in the insulating phase (see the inset in Fig. 14), and does not allow one to discriminate between the superconducting and insulating ground states of the RSJJ (Fig. 13).

If we expand the potential  $U^{(1,0)}(\phi) = \sum_{n=0}^{\infty} u_n^{(1,0)} \cos(n\phi)$  in circular harmonics, we observe that in the insulating phase (where we would naively expect the coherence to vanish since the effective potential is irrelevant), the nonzero value of  $U^{(1,0)}(0)$  is entirely due to the zeroth-order harmonic amplitude  $u_0^{(1,0)}$  so that the nonzero value of the coherence comes from the dependence of the free energy on the external source  $h$ . Even though the Josephson coupling is irrelevant in the insulating phase, the coherence cannot be simply computed from the Gaussian action obtained

Figure 14. Expectation value  $\langle \cos \varphi \rangle$  vs  $\alpha$  in the superconducting phase when  $1/E_C = 0$ . The lines show the exact result obtained from integrability methods [29].

by setting  $E_J = 0$  (in which case one would find  $\langle \cos \varphi \rangle = 0$ ), we must keep track of the contribution of the high-energy modes to the free energy and its dependence on the external source  $h$ .

Because of the U(1) invariance of the action (1), i.e. the invariance in the shift  $\varphi(\tau) \rightarrow \varphi(\tau) + a$  of the field by an arbitrary constant, the coherence is related to the current-current correlation function  $\chi_{II}^R(\omega)$  (with  $I = qE_J \sin \varphi$  the current through the junction) by [48]

$$q^2 E_J \langle \cos \varphi \rangle - \chi_{II}^R(\omega = 0) = 0, \quad (22)$$

which is the analog of the  $f$ -sum rule in electron systems with  $q^2 E_J \langle \cos \varphi \rangle$  playing the role of the diamagnetic term. This relation is well satisfied by the FRG results (Fig. 13).

The free energy  $f = -\frac{1}{\beta} \ln \mathcal{Z}$  of the boundary sine-Gordon model is known exactly in the superconducting phase when  $\alpha > 2$  and  $1/E_C = 0$  [29]. Using  $\langle \cos \varphi \rangle = -\partial f / \partial E_J$ , one obtains

$$\langle \cos \varphi \rangle = \frac{\Gamma\left(\frac{\alpha-2}{2\alpha-2}\right) \Gamma\left(\frac{1}{2\alpha-2}\right)}{2\pi^{3/2} \left(1 - \frac{1}{\alpha}\right) \frac{E_J}{2bW}} \left(\frac{\pi E_J}{2bW\Gamma(1/\alpha)}\right)^{\alpha/(\alpha-1)}. \quad (23)$$

Note that a finite UV cutoff  $W$  is necessary to make the boundary sine-Gordon model well defined when  $1/E_C = 0$ .  $b$  is a scale factor depending on the implementation of the UV cutoff; for a hard cutoff,  $b = e^\gamma/2$  with  $\gamma$  the Euler constant [25]. Figure 14 shows that the FRG reproduces the exact result (23) with a very good accuracy.

Finally we discuss the expectation value  $\langle \cos(\varphi/2) \rangle$ , whose exact expression has been conjectured by Fateev *et al.* in the case  $1/E_C = 0$  and  $W < \infty$  (see Eq. (3) in Ref. [29]). It has also been computed by Lukyanov and Werner in the case  $1/E_C > 0$  and  $W \rightarrow \infty$  [28]. Figure 15 shows a comparison with the FRG results. In both cases ( $1/E_C = 0, W < \infty$  and  $1/E_C > 0, W \rightarrow \infty$ ), there is a good agreement for  $\alpha \gtrsim 2$ , which deteriorates

Figure 15. Expectation value  $\langle \cos(\varphi/2) \rangle$  obtained from the FRG and compared with the conjecture of Fateev *et al.* [29] in the case  $1/E_C = 0$ ,  $W < \infty$ , and the Monte Carlo simulations of Lukyanov and Werner [28] in the case  $1/E_C > 0$ ,  $W \rightarrow \infty$ .

as  $\alpha$  approaches one, again a sign that the FE<sub>2</sub> is not reliable in the range  $1 \leq \alpha \lesssim 2$ .

## V. CONCLUSION

Our FRG study of the RSJJ has met with mixed success. On the one hand, it clearly shows that the Schmid transition is not controlled by a single fixed point but by a line of critical fixed points, in agreement with the conclusions of Werner, Troyer and Lukyanov based on Monte Carlo simulations and integrability methods [27, 28]. The same conclusion can be drawn from the NRG calculations of Masuki *et al.* [15].

On the other hand there are strong discrepancies regarding the location of the transition line in the plane  $(\alpha, E_J/E_C)$ . In the large bandwidth limit  $W/E_C \gg 1$ , Werner and Troyer find a vertical line located at  $\alpha = 1$  with an accuracy of 2% (so that the transition can only be induced by varying  $\alpha$ ), the NRG indicates that the

transition line is curved in the region  $\alpha < 1$  in a concave way (except for a surprising reentrance of the superconducting phase at small  $\alpha$ ), whereas the FRG gives a convex transition line which starts with an infinite slope at  $\alpha = 1$ . As already pointed out, the FRG fails in the limit  $\alpha \rightarrow 0$  and its prediction for the location of the transition line may not be reliable even in the vicinity of  $\alpha = 1$ . These disagreements clearly call for further studies, in particular numerical. The FRG also fails to capture the correct frequency dependence of the mobility in the superconducting phase when  $1 \leq \alpha \lesssim 2$ .

These two shortcomings —the spurious phase transition at  $\alpha = 0$  and the inability to capture the frequency dependence of the mobility when  $1 \leq \alpha \lesssim 2$ — can be ascribed to the failure of the FRG in describing the instantons between neighboring minima of the periodic potential. This is in sharp contrast with the (1+1) sine-Gordon model where a derivative expansion of the effective action to second order is sufficient to compute the mass of the solitons and the lowest-lying breather (soliton-antisoliton bounded state) with high accuracy [25]. The description of topological defects is an open issue in the FRG approach. Besides the topological excitations of the (1+1)-dimensional sine-Gordon model, the FRG provides us with a good description of the vortices and the Berezinskii-Kosterlitz-Thouless transition in the two-dimensional O(2) model [49–51], but a good description of the kinks in the one-dimensional Ising has still not been achieved [52]. Whether or not the FRG approach, used here in combination with a second-order frequency expansion, can be improved in order to describe the instantons of the boundary sine-Gordon model is an open issue.

## ACKNOWLEDGMENT

We thank C. Altimiras, P. Azaria, D. Esteve, S. Florens, P. Joyez, P. Lecheminant, H. le Sueur, C. Mora, I. Safi, H. Saleur, G. Takacs and W. Zwerger for discussions and/or correspondence.

## Appendix A: Flow equations

The flow equations of  $U_k(\phi)$  and  $Z_{2,k}(\phi)$  are obtained by relating these two quantities to the two-point vertex

$$\Gamma_k^{(2)}(i\omega_n, \phi) = Z_1 |\omega_n| + Z_{2,k}(\phi) \omega_n^2 + U_k''(\phi) \quad (\text{A1})$$

in a time-independent field  $\phi(\tau) = \phi$ . Thus we have

$$\begin{aligned} \partial_t U_k''(\phi) &= \partial_t \Gamma_k^{(2)}(0, \phi), \\ \partial_t Z_{2,k}(\phi) &= \partial_t \frac{\Gamma_k^{(2)}(i\omega_1, \phi) - \Gamma_k(0, \phi)}{\omega_1^2} \end{aligned} \quad (\text{A2})$$

where  $\omega_1 = 2\pi T$  and we use a discrete frequency derivative for  $Z_{2,k}(\phi)$ .  $\Gamma_k^{(2)}$  satisfies the flow equation

$$\begin{aligned} \partial_t \Gamma_k^{(2)}(i\omega_\nu, \phi) = \sum_{\omega_n} \partial_t R_k(i\omega_n) & \left\{ -\frac{1}{2} G_k(i\omega_n, \phi)^2 \Gamma_k^{(4)}(i\omega_\nu, -i\omega_\nu, i\omega_n, -i\omega_n, \phi) \right. \\ & \left. + G_k(i\omega_n, \phi)^2 \Gamma_k^{(3)}(i\omega_\nu, i\omega_n, -i\omega_{n+\nu}, \phi) G_k(i\omega_{n+\nu}, \phi) \Gamma_k^{(3)}(-i\omega_\nu, i\omega_{n+\nu}, -i\omega_n, \phi) \right\}, \end{aligned} \quad (\text{A3})$$

where all quantities are evaluated in a time-independent field  $\phi$ . In the limit  $T \rightarrow 0$ , the Matsubara frequency becomes a continuous variable and the discrete sums can be replaced by integrals. Likewise the discrete derivative in (A2) becomes a standard derivative. However, the propagator  $G_k(i\omega_n)$  being a non-analytic function of  $\omega_n$ , care must be taken when taking the derivative wrt  $\omega_\nu^2$  of the rhs of (A3) since a naive expansion in  $\omega_\nu$  of the integrand may give wrong results [53, 54].

The flow equations for the dimensionless functions defined in (10) read

$$\partial_t \tilde{U}_k'' = -\tilde{U}_k'' + 2l_2^3 \tilde{U}_k''' \tilde{Z}'_{2,k} + l_0^3 \tilde{U}_k''''^2 - \frac{1}{2} l_0^2 \tilde{U}_k^{(4)} + l_4^3 \tilde{Z}'_{2,k}{}^2 - \frac{1}{2} l_2^2 \tilde{Z}''_{2,k}, \quad (\text{A4})$$

$$\begin{aligned} \partial_t \tilde{Z}_{2,k} = \tilde{Z}_{2,k} + \frac{1}{2\tilde{\omega}_1^2} & \left\{ 2l_0^{2,1}(i\tilde{\omega}_1)[\tilde{U}_k'''' + \tilde{\omega}_1^2 \tilde{Z}'_{2,k}]^2 + 4\tilde{\omega}_1 l_1^{2,1}(i\tilde{\omega}_1) \tilde{U}_k'''' \tilde{Z}'_{2,k} + 4l_2^{2,1}(i\tilde{\omega}_1) \tilde{U}_k'''' \tilde{Z}'_{2,k} \right. \\ & \left. - 4l_2^3 \tilde{U}_k'''' \tilde{Z}'_{2,k} - 2l_0^3 \tilde{U}_k''''^2 \right. \\ & \left. + 4\tilde{\omega}_1^3 l_1^{2,1}(i\tilde{\omega}_1) \tilde{Z}'_{2,k}{}^2 + 6\tilde{\omega}_1^2 l_2^{2,1}(i\tilde{\omega}_1) \tilde{Z}'_{2,k}{}^2 - l_0^2 \tilde{\omega}_1^2 \tilde{Z}''_{2,k} + 4\tilde{\omega}_1 l_3^{2,1}(i\tilde{\omega}_1) \tilde{Z}'_{2,k}{}^2 \right. \\ & \left. + 2l_4^{2,1}(i\tilde{\omega}_1) \tilde{Z}'_{2,k}{}^2 - 2l_4^3 \tilde{Z}'_{2,k}{}^2 \right\}, \end{aligned} \quad (\text{A5})$$

where  $\tilde{\omega}_n = \omega_n/k = 2\pi n\tilde{T}$  with  $\tilde{T} = 1/\tilde{\beta} = T/k$  the dimensionless temperature. The prime, double prime, etc., denote derivatives wrt  $\phi$ . We have introduced the threshold functions

$$\begin{aligned} l_p^m &= \frac{1}{\tilde{\beta}} \sum_{\tilde{\omega}_n} \dot{R}_k(i\tilde{\omega}_n) \tilde{G}_k(i\tilde{\omega}_n, \phi)^m |\tilde{\omega}_n|^p, \\ l_p^{m_1, m_2}(i\tilde{\omega}_\nu) &= \frac{1}{\tilde{\beta}} \sum_{\tilde{\omega}_n} \dot{R}_k(i\tilde{\omega}_n) \tilde{G}_k(i\tilde{\omega}_n, \phi)^{m_1} \tilde{G}_k(i\tilde{\omega}_{n+\nu}, \phi)^{m_2} \tilde{\omega}_n^p \end{aligned} \quad (\text{A6})$$

and the dimensionless cutoff function and its time derivative,

$$\tilde{R}_k(i\tilde{\omega}_n) = \frac{R_k(i\omega_n)}{k} = \frac{\alpha}{2\pi} |\tilde{\omega}_n| r(|\tilde{\omega}_n|) + k Z_{2,k} \tilde{\omega}_n^2 r(\tilde{\omega}_n^2), \quad (\text{A7})$$

$$\dot{\tilde{R}}_k(i\tilde{\omega}_n) = \frac{\partial_t R_k(i\omega_n)}{k} = -\frac{\alpha}{2\pi} \tilde{\omega}_n^2 r'(|\tilde{\omega}_n|) - 2k Z_{2,k} \tilde{\omega}_n^4 r'(\tilde{\omega}_n^2) + k \partial_t Z_{2,k} \tilde{\omega}_n^2 r(\tilde{\omega}_n^2), \quad (\text{A8})$$

where

$$\tilde{G}_k(i\tilde{\omega}_n, \phi) = k G_k(i\omega_n, \phi) = \frac{1}{\frac{\alpha}{2\pi} |\tilde{\omega}_n| + \tilde{Z}_2(\phi) \tilde{\omega}_n^2 + \tilde{U}_k''(\phi) + \tilde{R}_k(i\tilde{\omega}_n)} \quad (\text{A9})$$

is the dimensionless propagator in a time-independent field  $\phi(\tau) = \phi$ . In the zero-temperature limit, the Matsubara sums in (A6) become integrals over the continuous variable  $\tilde{\omega}$ ,

$$\frac{1}{\tilde{\beta}} \sum_{\tilde{\omega}_n} \rightarrow \int_{-\infty}^{\infty} \frac{\tilde{\omega}}{2\pi} \quad (T \rightarrow 0). \quad (\text{A10})$$

To alleviate the notations, we do not write explicitly the dependence of the threshold functions on  $k$ ,  $\tilde{Z}_{2,k}(\phi)$  and  $\tilde{U}_k''(\phi)$ .

For  $\tilde{Z}_{2,k}(\phi) = \tilde{U}_k''(\phi) = 0$  and in the limit  $T \rightarrow 0$ ,

$$\bar{l}_0^2 = l_0^2|_{\tilde{Z}_{2,k}=\tilde{U}_k''=0} = \int_{-\infty}^{\infty} \frac{d\tilde{\omega}}{2\pi} \dot{\tilde{R}}_k(i\tilde{\omega}) \tilde{G}_k(i\tilde{\omega})^2 = -\frac{2}{\alpha} \int_0^{\infty} d\tilde{\omega} \frac{r'(\tilde{\omega})}{[1+r(\tilde{\omega})]^2} = \frac{2}{\alpha}. \quad (\text{A11})$$

The threshold function  $\bar{l}_0^2$  is universal, i.e. independent of the cutoff function  $R_k$ , provided that  $r(0) = \infty$  and  $r(\infty) = 0$ .

## Appendix B: Perturbation theory from truncated flow equations

We use the flow equations to reconstruct the perturbation theory near  $\alpha = 1$  where the critical point is close to the Gaussian fixed point. In a first step, we approximate  $U_k(\phi)$  and  $Z_{2,k}(\phi)$  by retaining only the coupling constants that are nonzero for the initial condition at  $k = k_{\text{in}}$ , i.e.

$$U_k(\phi) = -E_{J,k} \cos \phi, \quad Z_{2,k}(\phi) = \frac{1}{2E_{C,k}}. \quad (\text{B1})$$

Anticipating that the fixed point values  $1/\tilde{E}_C^*$  and  $\tilde{E}_J^*$  of the dimensionless coupling constants  $1/\tilde{E}_{C,k} = k/E_{C,k}$  and  $\tilde{E}_{J,k} = E_{J,k}/k$  are of order  $\epsilon = 1/\alpha - 1$  and  $\sqrt{\epsilon}$ , respectively, we include in the flow equations all terms up to order  $\epsilon^{3/2}$ . To do so, one must expand the threshold functions as follows,

$$l_p^m = \bar{l}_p^m - m[\tilde{U}_k''(\phi)\bar{l}_p^{m+1} + \tilde{Z}_{2,k}(\phi)\bar{l}_{p+2}^{m+1}] + \frac{1}{2}(m^2 + m)\tilde{U}_k''(\phi)^2\bar{l}_p^{m+2}, \quad (\text{B2})$$

where  $\bar{l}_p^m = l_p^m|_{\tilde{U}_k''=\tilde{Z}_{2,k}=0}$ . For simplicity, we consider here the cutoff function  $R_k(i\tilde{\omega}_n) = (\alpha/2\pi)|\tilde{\omega}_n|r(|\tilde{\omega}_n|)$ . This yields the flow equations

$$\begin{aligned} k\partial_k \frac{1}{\tilde{E}_{C,k}} &= \frac{1}{\tilde{E}_{C,k}} + \bar{l}_0^{2,1'}\tilde{E}_{J,k}^2, \\ k\partial_k \tilde{E}_{J,k} &= \tilde{E}_{J,k} \left( -1 + \frac{1}{\alpha} \right) - \frac{1}{2}\bar{l}_2^3 \frac{\tilde{E}_{J,k}}{\tilde{E}_{C,k}} + \frac{3}{8}\bar{l}_0^4 \tilde{E}_{J,k}^3, \end{aligned} \quad (\text{B3})$$

where

$$\bar{l}_p^{m_1, m_2'} = \begin{cases} \lim_{\tilde{\omega} \rightarrow 0} \frac{\bar{l}_p^{m_1, m_2}(i\tilde{\omega}) - \bar{l}_p^{m_1+m_2}}{\tilde{\omega}^2} = \partial_{\tilde{\omega}^2} \bar{l}_p^{m_1, m_2}(i\tilde{\omega}) \Big|_{\tilde{\omega}=0} & (p \text{ even}), \\ \lim_{\tilde{\omega} \rightarrow 0} \frac{\bar{l}_p^{m_1, m_2}(i\tilde{\omega})}{\tilde{\omega}} = \partial_{\tilde{\omega}} \bar{l}_p^{m_1, m_2}(i\tilde{\omega}) \Big|_{\tilde{\omega}=0} & (p \text{ odd}), \end{cases} \quad (\text{B4})$$

using  $\bar{l}_p^{m_1, m_2}(i\tilde{\omega} = 0) = \bar{l}_p^{m_1+m_2}(0)$  for  $p$  even (odd). We denote by  $\bar{l}_p^{m_1, m_2}(i\tilde{\omega})$  the function  $l_p^{m_1, m_2}(i\tilde{\omega})$  in the limit  $\tilde{U}_k'' = \tilde{Z}_{2,k} = 0$ . The parameters  $\bar{l}_2^3 > 0$ ,  $\bar{l}_0^4 > 0$  and  $\bar{l}_0^{2,1'} < 0$  in (B3) are real numbers whose values depend on the function  $r$  discriminating between low ( $|\omega_n| \lesssim k$ ) and high ( $|\omega_n| \gtrsim k$ ) frequency modes.

When  $\alpha \rightarrow 1$ , the running of the variable  $1/\tilde{E}_{C,k}$  is initially much faster than that of  $\tilde{E}_{J,k}$ ; after a transient regime the value of  $1/\tilde{E}_{C,k}$  is entirely determined by the value of  $\tilde{E}_{J,k}$ ,

$$\frac{1}{\tilde{E}_{C,k}} = -\bar{l}_0^{2,1'}\tilde{E}_{J,k}^2. \quad (\text{B5})$$

In other words, all RG trajectories in the  $(1/\tilde{E}_{C,k}, \tilde{E}_{J,k})$  plane collapse on a single line as shown in Figs. 2 and 3: For a general discussion of this ‘‘large-river effect’’, see Refs. [55, 56]. The flow equation on that line is deduced from (B3) and (B5),

$$k\partial_k \tilde{E}_{J,k} = \tilde{E}_{J,k} \left( -1 + \frac{1}{\alpha} \right) + \left( \frac{3}{8}\bar{l}_0^4 + \frac{1}{2}\bar{l}_2^3\bar{l}_0^{2,1'} \right) \tilde{E}_{J,k}^3. \quad (\text{B6})$$

We thus obtain the nontrivial fixed point

$$\tilde{E}_J^* = \left( \frac{8(\alpha - 1)/\alpha}{4\bar{l}_2^3\bar{l}_0^{2,1'} + 3\bar{l}_0^4} \right)^{1/2}, \quad \frac{1}{\tilde{E}_C^*} = -\frac{8\bar{l}_0^{2,1'}(\alpha - 1)/\alpha}{4\bar{l}_2^3\bar{l}_0^{2,1'} + 3\bar{l}_0^4}. \quad (\text{B7})$$

Depending on the sign of  $4\bar{l}_2^3\bar{l}_0^{2,1'} + 3\bar{l}_0^4$ , this fixed point exists for  $\alpha > 1$  or  $\alpha < 1$ . Linearizing the flow equation (B6) yields the critical exponent

$$\frac{1}{\nu} = 2 \left( \frac{1}{\alpha} - 1 \right) \quad \text{for } \alpha \rightarrow 1. \quad (\text{B8})$$

The same result can be obtained by linearizing Eqs. (B3) about the fixed point (B7).

To ensure that Eq. (B8) is correct one should also consider the coupling constants that are not included in the ansatz (B1). We thus use the harmonic expansion

$$\tilde{U}_k(\phi) = \sum_{n=0}^{\infty} \tilde{u}_{n,k} \cos(n\phi), \quad \tilde{Z}_{2k}(\phi) = \sum_{n=0}^{\infty} \tilde{z}_{n,k} \cos(n\phi) \quad (\text{B9})$$

and expand the flow equations in powers of  $\epsilon = 1/\alpha - 1$ . In addition to (B2) one must expand the threshold function

$$\begin{aligned} l_p^{m_1, m_2}(i\tilde{\omega}_\nu) &= \bar{l}_p^{m_1, m_2}(i\tilde{\omega}_\nu) - m_1 [\tilde{U}_k''(\phi) \bar{l}_p^{m_1+1, m_2}(i\tilde{\omega}_\nu) + \tilde{Z}_{2,k}(\phi) \bar{l}_p^{m_1+1, m_2}(i\tilde{\omega}_\nu)] + \frac{1}{2}(m_1^2 + m_1) \tilde{U}_k''(\phi)^2 \bar{l}_p^{m_1+2, m_2}(i\tilde{\omega}_\nu) \\ &\quad - m_2 [\tilde{U}_k''(\phi) \bar{l}_p^{m_1, m_2+1}(i\tilde{\omega}_\nu) + \tilde{Z}_{2,k}(\phi) \bar{l}_p^{m_1, m_2+1}(i\tilde{\omega}_\nu)] + \frac{1}{2}(m_2^2 + m_2) \tilde{U}_k''(\phi)^2 \bar{l}_p^{m_1, m_2+2}(i\tilde{\omega}_\nu) \\ &\quad + m_1 m_2 \tilde{U}_k''(\phi)^2 \bar{l}_p^{m_1+1, m_2+1}(i\tilde{\omega}_\nu). \end{aligned} \quad (\text{B10})$$

Near the fixed point,  $\tilde{u}_{1,k} = \mathcal{O}(\sqrt{\epsilon})$ ,  $\tilde{z}_{0,k}, \tilde{z}_{2,k}, \tilde{u}_{n>1,k} = \mathcal{O}(\epsilon)$  and  $\tilde{z}_{n \neq 0,2,k} = \mathcal{O}(\epsilon^{3/2})$ . Using the fact that the running of  $\tilde{u}_{1,k}$  is initially much slower than the other variables, after a transient regime we find

$$\begin{aligned} \tilde{z}_{0,k} &= -\frac{1}{2} \bar{l}_0^{2,1'} \tilde{u}_{1,k}^2, \\ \tilde{z}_{1,k} &= -\frac{\alpha}{4(1+\alpha)} [32 \bar{l}_0^{2,1'} \tilde{u}_{2,k} + (\bar{l}_0^{2,2'} + 2 \bar{l}_0^{3,1'}) \tilde{u}_{1,k}^2 - 8(\bar{l}_1^{2,1'} + \bar{l}_2^{2,1'}) \tilde{z}_{2,k}] \tilde{u}_{1,k}, \\ \tilde{z}_{2,k} &= \frac{\alpha}{2(4+\alpha)} \bar{l}_0^{2,1'} \tilde{u}_{1,k}^2, \\ \tilde{u}_{2,k} &= \frac{\alpha}{4(\alpha-4)} (\bar{l}_0^3 \tilde{u}_{1,k}^2 - 2 \bar{l}_2^2 \tilde{z}_{2,k}) \end{aligned} \quad (\text{B11})$$

to leading order in  $\epsilon$ , and

$$\partial_t \tilde{u}_{1,k} = \left( \frac{1}{\alpha} - 1 \right) \tilde{u}_{1,k} + \frac{1}{8} \{ 3 \bar{l}_0^4 \tilde{u}_{1,k}^3 + 2 [8 \bar{l}_0^3 \tilde{u}_{2,k} - 2 \bar{l}_2^3 (2 \tilde{z}_{0,k} + \tilde{z}_{2,k})] \tilde{u}_{1,k} - 4 \bar{l}_2^2 \tilde{z}_{1,k} \} \quad (\text{B12})$$

including all terms of order  $\epsilon^{3/2}$ . Equations (B11) and (B12) lead to (13), where  $\mathcal{F}$  is a complicated combination of the threshold functions  $\bar{l}_p^m$  and  $\bar{l}_p^{m_1, m_2'}$ .

### Appendix C: Coherence and current-current correlation function

To compute the expectation value  $\langle \cos \varphi \rangle$  and the zero-frequency limit of the current-current correlation function  $\chi_{II}(i\omega_n)$ , one must introduce a time-independent external complex source  $h$  in the action (1), i.e. consider

$$S - \int_0^\beta d\tau (h^* e^{i\varphi(\tau)} + h e^{-i\varphi(\tau)}). \quad (\text{C1})$$

In the FE<sub>2</sub> the effective action takes the form (8) where however the functions  $Z_{2,k}(\phi, h^*, h)$  and  $U_k(\phi, h^*, h)$  depend on  $h^*$  and  $h$ . We can now use

$$\begin{aligned} \langle \cos \varphi \rangle &= \frac{1}{\beta} \frac{\partial \ln \mathcal{Z}(h^*, h)}{\partial h} \Big|_{h^*=h=0}, \\ \chi_{II}(i\omega_n = 0) &= -\frac{q^2 E_J^2}{4\beta} \left( \frac{\partial^2}{\partial h^{*2}} + \frac{\partial^2}{\partial h^2} - 2 \frac{\partial^2}{\partial h^* \partial h} \right) \ln \mathcal{Z}(h^*, h) \Big|_{h^*=h=0}, \end{aligned} \quad (\text{C2})$$

where  $\mathcal{Z}(h^*, h)$  is the partition function obtained from (C1). These equations can be rewritten in terms of the effective potential  $U(\phi, h^*, h) \equiv U_{k=0}(\phi, h^*, h)$  and  $G(i\omega_n, \phi) \equiv G_{k=0}(i\omega_n, \phi)$  [57],

$$\langle \cos \varphi \rangle = -U^{(1,0)}(0), \quad (\text{C3})$$

$$\begin{aligned} \chi_{II}(i\omega_n = 0) &= -\frac{q^4 E_J^2}{4} \left\{ -U^{(2,0)}(0) - U^{(0,2)}(0) + 2U^{(1,1)}(0) \right. \\ &\quad \left. + G(0,0) [U^{(1,0)'}(0)^2 + U^{(0,1)'}(0)^2 - 2U^{(1,0)'}(0)U^{(0,1)'(0)}] \right\}, \end{aligned} \quad (\text{C4})$$

where we use the notation  $U^{(i,j)}(\phi) = \partial_{h^*}^i \partial_h^j U(\phi)|_{h^*=h=0}$  and the prime denotes a derivation with respect to  $\phi$ .  $U^{(i,j)}(\phi)$  can be obtained from the flow equations of  $U_k^{(i,j)}(\phi)$  (which we do not show here).

A similar method can be used to obtain the expectation value  $\langle \cos(\varphi/2) \rangle$  as well as  $\chi(i\omega_n = 0)$  where  $\chi(\tau) = \langle e^{\frac{i}{2}\varphi(\tau)} e^{-\frac{i}{2}\varphi(0)} \rangle$ .
