

A Formalizable Proof of the No-Supervenience Theorem: A Diagonal Limitation on the Viability of Physicalist Theories of Consciousness.

Cathy M Reason

The no-supervenience theorem limits the capacity of physicalist theories to provide a comprehensive account of human consciousness. The proof of the theorem is difficult to formalize because it relies on both alethic and epistemic notions of possibility. This article outlines a formalizable proof using predicate modal logic in which the epistemic inferences are expressed in terms of an existing mathematical formalism, the inference device (Wolpert, 2008). The resulting proof shows definitely that any physicalist theory which describes a self-aware, intelligent system must be internally inconsistent.

Introduction

The no-supervenience theorem is a no-go theorem which establishes constraints on theories of consciousness by examining the general properties of sets of theories, without having to take into account the metaphysical qualities associated with individual members of those sets. The procedure for doing so was first outlined by Caplain (1995, 2000), and later developed into an informal proof, showing that no physical system capable of humanlike reasoning could perform the Cartesian cogito (Reason 2016, 2019; Reason and Shah 2021). However, it has not previously been possible to formalize this proof, because it depends critically on the difference between alethic and epistemic modality, and there does not yet exist any universally agreed formalization of modal logic which incorporates both alethic and epistemic interpretations. This is because modal logics are interpreted in terms of sets of possible worlds, and there is no generally satisfactory way of binding sets of alethically possible worlds to sets of epistemically possible worlds.

In this article, we get around this problem by adapting an existing mathematical formalism, the *inference device* (Wolpert 2008). Wolpert showed that all physical systems capable of observation, prediction and memory have a common mathematical structure. Any system with such a structure can be classed as an inference device. For our purposes, the exact details of this structure need not be considered; it is enough to define an inference device as a general mapping, which we shall call the *Wolpert mapping*. The concept of an inference device allows epistemic modal inferences to be codified formally without requiring an explicitly epistemic interpretation of modal logic. This allows the required inferences to be expressed formally in predicate modal logic, and avoids the problem of mixed interpretations. It should be noted that the notion of a physical system we use is considerably simpler and more limited in scope than Wolpert's original formalism, but is based on the same basic concept, that inference can be represented in terms of mappings within physical systems.

A Brief Summary of the Proof

The proof we shall present is mathematical in nature, and does not rely on any of the methodology usually found within the philosophy of mind. In particular, the proof is independent of any metaphysical interpretation (since any sound mathematical formalism must be valid under all interpretations). Since the mathematical derivation is necessarily rather dense and difficult to follow, here is a simply intuitive summary of the proof.

Let us assume that every mental process corresponds to some process in the brain, and in particular, that consciousness corresponds to some process we'll call the neural correlate of consciousness (NCC). Now it's clear that if every mental process corresponds to some brain process, then the thought "I think therefore I am" corresponds to the thought "If physicalism is true, then the NCC corresponding to 'I think therefore I am' works correctly".

Now obviously, if physicalism is true, then the thought "If physicalism is true, then the NCC corresponding to 'I think therefore I am' works correctly" must also correspond to some NCC, which we'll call NCC*. So the thought "If physicalism is true, then the thought "If physicalism is true, then the NCC corresponding to 'I think therefore I am' works correctly" is true if and only if NCC* works correctly. Now it is clear from this that we can only know if the NCC works correctly if we already know that NCC* works correctly. So NCC* cannot be the same brain state as NCC. And it is clear that, each time we deduce the need for a new state NCC*, we can deduce the need for a new state NCC** to establish the reliability of NCC*, such that NCC** cannot be the same state as NCC*, And one can thereby induce an infinite number of distinguishable brain states, each different from every other. And it is clear that no brain could be large enough to include so many states. Since the Cartesian Cogito implies an infinite number of distinguishable brain states, it necessarily follows that any mind or other entity which can perform the Cartesian Cogito, cannot be a physical system.

We shall now express this argument as a formalizable derivation.

A Note on the Use of Modal Logic

The proof uses modal logic, and in particular relies on the following equivalence:

$$\neg p \leftrightarrow \sim \diamond \sim p$$

Afficionados of modal logic will doubtless recognize that this equivalence -- which asserts that no proposition can be necessarily true in any language unless it is a theorem of that language -- is not generally true. However it *is* true in any axiomatization of modal logic where *only* the axioms of modal logic are allowed as axioms -- or what we shall henceforth call a *restricted axiomatization*. . For example, a model M comprising two possible worlds:

w1: P and Q
w2: P and ~Q

does not support the inference:

$$(P \rightarrow Q) \rightarrow (\diamond \sim Q \rightarrow \diamond \sim P)$$

But this is only true because the model implicitly assumes $\sim \diamond \sim P$ as an axiom, and since this axiom is not a theorem of predicate modal logic, it will not be an axiom in any restricted axiomatization of predicate modal logic. One can express this by saying that if the axiom or axioms which define a model are not necessary, then any implication contingent on those axioms is not generally necessary either, or alternatively, that if, for some axiom P which defines a model:

$$\sim P \rightarrow \diamond Q$$

then:

$$\diamond \sim P \rightarrow \diamond Q$$

It therefore necessarily follows that the equivalence:

$$\neg p \leftrightarrow \sim \diamond \sim p$$

can only be invalidated if additional axioms or postulates are added to the restricted axiomatization. The effect of this restriction is to limit the application of modal reasoning to a priori inferences. The restricted axiomatization is also effectively *monotonic*, which is to say, any conclusion derived from a set S of premises, is also valid for any superset of premises of which S is a subset. Any necessary propositions which are not theorems of the modal logic will therefore have to be inferred empirically, and for this we use the mechanism of the Wolpert inference device. Any full, unrestricted axiomatization is clearly not monotonic since it allows for the empirical inference of models which are not theorems. It is on this key point which the proof ultimately depends. In the following, proof, we shall assume that any system can rely on its ability to reason using the restricted axiomatization of predicate modal logic -- which is to say, the restricted set of axioms and all theorems deducible from them. Any propositions outside of the restricted set must be inferred using the mechanism of the Wolpert inference device.

Outline of the Proof

We first assume some restricted axiomatization of first-order modal predicate logic.¹ Next we define a set Z of what may be called "facts about the world", and denote by $p(Z)$ any partition of this set which contains only facts which are true at some time t. The subset $p(Z)$ can be regarded as the set of facts in Z which are true whenever some proposition p is true. We also define a physical system as some set of states, together with a set of dynamical rules linking those states. (Mathematically a physical system can be regarded as a *category* whose objects correspond to states and whose morphisms correspond to transitions between states.) We shall define $M(t)$ to be the state of system M at time t, where t can be thought of as simply an arbitrary

¹A fully formal proof would also require some axiomatization of set theory, since sets play a role in the proof. However, since set theory can itself be expressed in first-order predicate logic, we shall make no further mention of this and include the axioms of set theory within the restricted axiomatization.

parameter. For convenience, the parameter t will subsequently be dropped from the notation. We shall assume that M is capable of reasoning using predicate modal logic.

We next define an *observer*, which we represent as a simplified version of a Wolpert inference device. An observer is a physical system O which, when working correctly, evolves to a special state $W(p)$ (or the *Wolpert* state for p) such that O evolves to the state $W(p)$ only if p is true. Whenever O evolves to $W(p)$ and p is true, we shall say that $W(p)$ has the value TRUE. In future we shall drop the notation $p(Z)$ and simply use p to denote the subset of Z which is true whenever the proposition p is true. We shall define a *physical process* to refer to any subset or subcategory of a physical system. We can define a Wolpert state as *accurate* and *reliable* for some proposition p using *modal logic* if:

$$\sim\Diamond\sim(W(p) \supset p)$$

This simply says that, if the device O is operating correctly, then O cannot evolve to the state $W(p)$ unless p is true. Informally, we can say that $W(p)$ is the state to which some device O must evolve if O has asked the question "Is p true?" $W(p)$ is equivalent to the answer YES to this question, and hence $W(p)$ represents O 's knowledge of the facts denoted by p .

We next need to define the notion of a *real* process, as opposed to a merely physical one. We define the set of *real* processes to be the set of all processes Φ such that, for two observers O_A and O_B , the Wolpert states $W_A(\Phi \neq \emptyset)$ and $W_B(\Phi \neq \emptyset)$ both have the value TRUE, and $A \neq B$. More generally, we can define a *real property* to be any subset x of Z such that $W_A(x)$ and $W_B(x)$ both have the value TRUE and, $A \neq B$. This more general definition we shall refer to as the *realism postulate*². We shall also define the set of *subjective* processes to be the set of all processes Ψ for which the realism postulate does not hold. This somewhat complicated bit of notation simply expresses rigorously the notion that any *real* process should be an *objective* process, which is to say, it should, in principle, be observable by multiple witnesses. (Alternative definitions of objectivity can be used without loss of generality.)

We now define a *physicalist theory* as any theory which stipulates that every subjective process implies the reality of some real process, which is to say:

$$\Psi \supset \Phi$$

We shall refer to this as the *physicalism postulate*. We shall describe as *physicalist* any theory which satisfies this axiom.

Now let X be some real process. We shall say that X is a process of type P if it performs a mapping (the *Wolpert mapping*) such that:

$$O \rightarrow W(p) \text{ if and only if } p \text{ is true.}$$

² There is no need to add this postulate, or the subsequent physicalism postulate, to the restricted axiomatization. They should instead be regarded as the antecedents of material conditionals.

We shall say that X is a process of type R if it performs a mapping (the *anti-Wolpert* mapping) such that:

$O \rightarrow W(p)$ if and only if p is untrue.

Let S(X) be any set of real processes sufficient to enable a Wolpert device to establish some proposition p, subject to the condition that every X is a process of type P -- which is to say, not a process of type R.

Now define the proposition "X is not a process of type R", or:

$X \neq R^3$

Now it is clear from the postulates of realism and physicalism, that if X is real and $X = P$, then P must also be real and so $X = P$ must be a real property. Since $X = P$ implies $X \neq R$, this means $X \neq R$ is also a real property⁴. But no single observer can prove *a priori* if a property is observable by others since

$(O_A \neq \emptyset) \supset (O_B \neq \emptyset)$

where $A \neq B$, is not provable in the restricted axiomatization. This can be expressed in modal logic as:

$\diamond \sim ((O_A \neq \emptyset) \supset (O_B \neq \emptyset))$

Hence the inference:

$W(X \neq R) \supset (X \neq R)$

is not generally valid. From this it follows that:

$W(p) \supset p$

is not generally valid either. According to the restricted axiomatization of predicate modal logic, this is equivalent to:

$\diamond \sim (W(p) \supset p)^5$

We shall refer to this fact as the *principle of empiricism*. In plain English, this principle says that no single observer can infer *a priori*, from the restricted axioms of predicate modal logic, whether any given real process is a process of type P or of type R. We can express this using modal logic as:

³ Note the condition $X \neq R$ is automatically satisfied if $X = \emptyset$ -- in other words, if X does not exist.

⁴ One can assume for simplicity that $X = P$ and $X \neq R$ are equivalent, but it is not actually necessary.

⁵ This equivalence applies only if no further relevant axioms are assumed. For example, Kripke (1986) has proposed an additional axiom of the form $W(q) \rightarrow \sim \diamond \sim q$ for certain values of q (the case of so-called a posteriori necessities). However this axiom is not a theorem of predicate modal logic, and so, by the principle of empiricism, is not necessarily true unless yet further axioms are assumed.

$$\diamond(W(p) \& \sim p)$$

Now, we shall stipulate that M can reason using first-order predicate modal logic. It follows from any restricted axiomatization of predicate modal logic that:

$$W_M(\diamond(W_M(p) \& \sim p)) = \text{TRUE}$$

From which it follows that:

$$W_M(\diamond \sim(W_M(p) \supset p)) = \text{TRUE}$$

And so $W_M(p)$ clearly contradicts the definition of a reliable Wolpert state. So we can conclude that, given the restricted axiomatizations of predicate modal logic with the postulates of physicalism and realism, no real physical system which operates as a Wolpert inference device can accurately infer p.

To get around this, one would have to add additional axioms, such as $X \neq R$ and $W_M(X \neq R) = \text{TRUE}$, to the restricted axiomatization. But by the physicalism postulate, any Wolpert state such as $W_M(X \neq R) = \text{TRUE}$ implies some real process X_W to perform the necessary Wolpert mapping, and by the principle of empiricism, there is no *a priori* way that M can be sure that X_W is a process of type P. Indeed, for any set of processes $S(X)$, it will always be the case that:

$$\diamond(X = R) \text{ for all } X \in S(X)$$

unless $(X \neq R)$ for all $X \in S(X)$ is already known. In which case there must be some process X_{diagonal} which maps M to the Wolpert state:

$$W_M(W_M(X \neq R)) = \text{TRUE for all } X \in S(X)$$

Now, if X_{diagonal} is a member of $S(X)$, then M can only be sure that X_{diagonal} is accurate by assuming it axiomatically, since X_{diagonal} is capable of generating the state:

$$W_M(W_M(X_{\text{diagonal}} \neq R)) = \text{TRUE}$$

regardless of whether X_{diagonal} performs a Wolpert mapping or an anti-Wolpert mapping. In formal terms this means that:

$$\diamond(W_M(W_M(X_{\text{diagonal}} \neq R)) = \text{TRUE}) \neq \text{TRUE}$$

is provable in predicate modal logic, given the postulates of realism and physicalism. Or in plain English, it is provably possible that whatever M "knows" about the reliability of its own knowledge is, simply, wrong. It necessarily follows that, if M is capable of reasoning in the restricted axiomatization, then M itself can prove that all of its knowledge could be wrong. One could only circumvent this by adding further axioms, such as unconditionally assuming that X_{diagonal} must be reliable. But unconditionally assuming the reliability of X_{diagonal} clearly violates the physicalism postulate. And if X_{diagonal} is not a member of $S(X)$, then this violates the definition of $S(X)$. So we can say definitively that no system which satisfies the definition of

physicalism, and is capable of reasoning using predicate modal logic, can establish any empirical proposition p . And since we can define some proposition q thus:

q : "The proposition p can be established as true with probability of at least k "

where k is a real number $0 \leq k \leq 1$, we can also prove in predicate modal logic that M cannot establish any empirical proposition p with any quantifiable degree of confidence, without making additional axiomatic assumptions which are provably incompatible with physicalism.

Some General Remarks on the Theorem

The first point to note, is that the diagonal contradiction arises from the stipulation that real processes are objective. Although the expression $W(p) = \text{TRUE}$ also induces a potentially infinite number of Wolpert states, this does not imply a contradiction, since the Wolpert state is a theoretical construct and any number of Wolpert states could in principle be generated by the same physical process. But because the physical processes are required to be objective, the principle of empiricism induces a non-terminating sequence of physical processes, and this is what generates the contradiction.

Secondly, we note that should there exist some subset $\omega(Z)$, such that $W_M(\omega) = \text{TRUE}$ can accurately be determined by M , then M is performing some function which is inconsistent with any physicalist theory. Reason and Shah (2021) referred to such a function as an *omega function*. One example of such a function which can be performed by conscious human beings is the Cartesian cogito. There are numerous different interpretations of the cogito, but for our purposes, we can describe a system as *omega-capable* if it can perform just one of them, and it does not matter which one. For simplicity, we shall say that a conscious human being is omega-capable if they can determine accurately that they are not in a dreamless sleep at some time t .⁶ In general, however, we can say that no physicalist theory can describe a system which is both omega-capable and capable of reasoning using predicate modal logic, without being inconsistent.

A few minor points should be cleared up here. Since the condition $X \neq R$ will be satisfied even if X does not exist, it is not necessary for M to "believe" the physicalism postulate; in other words, it is not necessary to assume the postulate:

$$\sim \diamond \sim (W_M(\Psi \supset \Phi) = \text{TRUE})$$

This is an important point, because one of the most common reasons for misunderstanding the proof turns on an implicit assumption of exactly this postulate.⁷ A second point is that we do not have to assume that every real process X is a either

⁶ The precise Cartesian cogito requires a little more work, since the definition of a type R process for such an omega function is actually self-contradictory -- it clearly makes no sense to define a process which inaccurately tells its owner that it exists. For the cogito one needs to think not in terms of the *accuracy* of processes, but in terms of the *existence of processes*. For an illustration of how this can be done, see the Cartesian lemma from Reason (2019).

⁷ This is my experience from a variety of personal communications.

process of type P or of type R. We only need to assume:

$$(X = R) \supset (X \neq P)$$

not

$$(X = R) \leftrightarrow (X \neq P)$$

One might be tempted to assume that even the first condition might be violated according to processes operating according to "quantum logic", according to which X might be a process of type P *and* a process of type R *simultaneously*. But this only works if one is prepared to allow W(p) to be both TRUE and UNTRUE simultaneously, and such an interpretation of an observable physical state has no meaning in any logic, quantum or otherwise⁸.

A final point, which is subtle but extremely important, should also be made; the theorem applies strictly not to systems, but to *theoretical models* of systems. It does not really mean anything to say that no physical system can be omega-capable. All one can say is that no *physicalist model* of a system can be omega-capable. This is important, because many philosophers of mind are deeply unhappy at the idea that such a limitation on the power of physical systems can be proved theoretically. Indeed, they are right to be unhappy about this, but that is not actually what we have demonstrated. What we have shown is that no *physicalist theory* can describe any system which is both omega-capable and capable of reasoning using predicate modal logic without being inconsistent. This subtle but significant difference should never be forgotten or overlooked.

Discussion

It is evident from private discussions I have had with various philosophers and other consciousness researchers, that many of them are deeply reluctant to accept this result. There appear to be three main reasons for this. Firstly, the result rules out a thesis, that there exist viable physicalist theories of consciousness, which decades of philosophical research have been dedicated to defending. Secondly, the no-supervenience theorem is a definitive result in a field in which, probably, not all that many people expect there to be definitive results of any sort. And thirdly, because the result is a *theorem* about a class of theories and not a theory in itself, it relies on a method of proof which many consciousness researchers are simply not familiar with. Hence the necessity for the present formalizable proof. It should also be noted that a *formalizable* proof is not the same thing as a *formal* proof. A formalizable proof simply presents the inferential steps in sufficient detail that the formal proof of each step should be a mere technical detail; but it is a matter of judgment exactly when this is achieved.

A no-go theorem can be thought of as a proof in some language L, that no theory T expressed in L, can have a certain set of properties. In this case, L is predicate modal

⁸ There are paraconsistent logics whose interpretations include states such as "true + false", but in these interpretations, true and false do not have their usual classical meaning.

logic, and T is any member of the class of all physicalist theories (or, more generally the class of all *supervenient* theories). The proof of such a theorem must be expressed much more rigorously and precisely than is usually the case with philosophical arguments. The proof used here is of a type known in mathematics as a *diagonal method*, for which no satisfactory analog exists in analytic philosophy of mind.

We have stipulated that M must be capable of using predicate modal logic. Although it is not really necessary, it makes the proof clearer and easier to follow if we also allow M to assume that it can rely on its ability to use predicate modal logic. This simply means we can ignore any questions which arise as to the reliability of Wolpert states representing facts which are both a priori and necessary. This may seem somewhat contrived and artificial, but the consequence of not doing this is that *every* proposition then becomes undecidable for M, and hence by default M cannot be omega-capable. So stipulating that M rely on its use of predicate modal logic turns out to be the conservative choice.
