Fourier–Mukai numbers of K3 categories of very general special cubic fourfolds

Yu-Wei Fan Kuan-Wen Lai

Abstract

We give counting formulas for the number of Fourier–Mukai partners of the K3 category of a very general special cubic fourfold.

1 Introduction

Let $X \subseteq \mathbb{P}^5$ be a smooth cubic hypersurface over \mathbb{C} . Then its bounded derived category of coherent sheaves has a semiorthogonal decomposition

$$
\mathrm{D}^{\mathrm{b}}(X)=\langle \mathcal{A}_X, \mathcal{O}_X, \mathcal{O}_X(1), \mathcal{O}_X(2) \rangle
$$

where the subcategory \mathcal{A}_X is called the K3 category of X. In contrast to its common usage in the literature, we say two cubic fourfolds are Fourier–Mukai partners, or FM-partners for short, if their K3 categories are equivalent. The number of FM-partners of a cubic fourfold up to isomorphism is finite [\[Huy17,](#page-7-0) Theorem 1.1]. Moreover, this number is equal to 1 if the cubic is very general, or more precisely, if the lattice

$$
H^{2,2}(X,\mathbb{Z}) \coloneqq H^4(X,\mathbb{Z}) \cap H^2(X,\Omega_X^2)
$$

is spanned by the square of the hyperplane class $h := c_1(\mathcal{O}_X(1))$ [\[Huy17,](#page-7-0) Theorem 1.5 (i)].

A cubic fourfold X is *special* if $H^{2,2}(X,\mathbb{Z})$ has rank at least 2. In this situation, there exists a rank 2 saturated sublattice $h^2 \in K \subseteq H^{2,2}(X,\mathbb{Z})$. Special cubic fourfolds having such a sublattice K with $\text{disc}(K) = d$ form an irreducible divisor \mathcal{C}_d in the moduli space, which is nonempty if and only if $d > 8$ and $d \equiv 0, 2 \pmod{6}$ [\[Has00,](#page-7-1) Theorem 1.0.1]. In this paper, we call $X \in \mathcal{C}_d$ very general if $H^{2,2}(X,\mathbb{Z})$ has rank exactly 2.

To state our main theorem, let us first consider the ring \mathbb{Z}_{2d} of integers modulo 2d and denote its subset of square roots of unity as

$$
\left(\mathbb{Z}_{2d}^\times\right)_2 \coloneqq \left\{ n \in \mathbb{Z}_{2d}^\times \mid n^2 \equiv 1 \pmod{2d} \right\}.
$$

Using the Chinese remainder theorem, one can verify that

$$
\left| \left(\mathbb{Z}_{2d}^{\times} \right)_2 \right| = \begin{cases} 4 & \text{if } d = 2^{a+1} \\ 2^{k+1} & \text{if } d = 2p_1^{e_1} \cdots p_k^{e_k} \\ 2^{k+2} & \text{if } d = 2^{a+1}p_1^{e_1} \cdots p_k^{e_k} \end{cases}
$$

where $a, k \geq 1$ and every p_i is an odd prime.

Theorem 1.1. Let $X \in \mathcal{C}_d$ be a very general member and $FM(X)$ be the set of isomorphism classes of FM-partners of X.

- If $d \not\equiv 0 \pmod{3}$, then $|\text{FM}(X)| = \frac{1}{4}$ $\frac{1}{4}$ $\Big|$ $\Big(\mathbb{Z}_2^{\times}$ $\begin{bmatrix} \times \\ 2d \end{bmatrix}$ $\begin{bmatrix} 1 \end{bmatrix}$
- If $d \equiv 0 \pmod{3}$ and $d \not\equiv 0 \pmod{9}$, then $|\text{FM}(X)| = \frac{1}{8}$ $\frac{1}{8}$ $\Big|$ $\Big(\mathbb{Z}_2^{\times}$ $\begin{bmatrix} \times \\ 2d \end{bmatrix}$ $_2$ $\Big|$.
- If $d \equiv 0 \pmod{9}$ and $\frac{d}{18} \equiv 1 \pmod{3}$, then $|\text{FM}(X)| = \frac{1}{4}$ $\frac{1}{4}$ $\left(\mathbb{Z}_{2a}^{\times} \right)$ $\begin{bmatrix} \times \\ 2d \end{bmatrix}$ $\begin{bmatrix} 1 \end{bmatrix}$
- If $d \equiv 0 \pmod{9}$ and $\frac{d}{18} \equiv 2 \pmod{3}$, then $|\text{FM}(X)| = \frac{1}{2}$ $\frac{1}{2}$ $\Big|$ $\Big(\mathbb{Z}_2^{\times}$ $\begin{bmatrix} \times \\ 2d \end{bmatrix}$ $\begin{bmatrix} 1 \end{bmatrix}$
- If $d \equiv 0 \pmod{27}$, then $|\text{FM}(X)| = \frac{3}{4}$ $\frac{3}{4}$ $\left| \left(\mathbb{Z}_2^{\times} \right) \right|$ $\begin{bmatrix} \times \\ 2d \end{bmatrix}$ $_2$ $\Big|$.

The first two cases, namely, the cases when $d \not\equiv 0 \pmod{9}$, were proved in our earlier work [\[FL23,](#page-7-2) Proposition 2.6]. Therefore, we will treat only the cases when $d \equiv 0 \pmod{9}$ in this paper. This condition implies $d \equiv 0 \pmod{18}$ and we will mostly work with

$$
d' \coloneqq \frac{d}{18}
$$

throughout the paper. According to our theorem, if $d \neq 0 \pmod{27}$, then $|FM(X)|$ is a power of 2. If $d \equiv 0 \pmod{27}$, then $|FM(X)| = 3 \cdot 2^n$ for some integer $n \ge 0$. It would be interesting to understand the origin of the factor 3 from a geometric perspective. We remark that the case when the cubic fourfold has an associated K3 surface was treated previously by Pertusi [\[Per21,](#page-7-3) Theorem 1.1].

Our proof of the theorem is mainly based on works by Addington–Thomas [\[AT14\]](#page-7-4) and Huybrechts [\[Huy17\]](#page-7-0) as these works turn the original problem into a problem about counting certain overlattices. In Section [2,](#page-1-0) we briefly review the background and set up necessary notations along the way. In Section [3,](#page-3-0) we introduce the overlattices produced naturally by FM-partners and translate the counting problem for one to the other. In Section [4,](#page-5-0) we count the number of overlattices and finish the proof of the main theorem.

Acknowledgments The second author is supported by the ERC Synergy Grant HyperK (ID: 854361).

2 Mukai lattices of the K3 categories

The topological K-theory $K_{top}(X)$ a cubic fourfold is a free abelian group equipped with a natural integral bilinear pairing $\chi(\cdot, \cdot)$. It contains the subgroup

$$
K_{\text{top}}(\mathcal{A}_X) \coloneqq \{ \kappa \in K_{\text{top}}(X) \mid \chi([\mathcal{O}_X(i)], \kappa) = 0 \text{ for } i = 0, 1, 2 \},
$$

called the *Mukai lattice of* A_X , and it has a polarized Hodge structure of K3 type. Indeed, the pairing $\chi(\cdot, \cdot)$ is symmetric on $K_{top}(\mathcal{A}_X)$ and so turns it into a lattice. On the other hand, the Mukai vector defines an embedding

$$
K_{\mathrm{top}}(X) \longrightarrow H^*(X, \mathbb{Q}): E \longmapsto \mathrm{ch}(E) \cdot \sqrt{\mathrm{td}(X)}
$$

which endows $K_{\text{top}}(\mathcal{A}_X)$ a Hodge structure by taking the restriction of the Hodge structure on $H^4(X,\mathbb{Z})$. By [\[Huy17,](#page-7-0) Theorem 1.5 (iii)], two very general special cubic fourfolds are FM-partners if and only if there exists a Hodge isometry between their Mukai lattices.

Following our previous work [\[FL23\]](#page-7-2), we define $H(A_X, \mathbb{Z}) := K_{top}(A_X)(-1)$. As an abstract lattice, it is unimodular of signature (4, 20), so we have

$$
\widetilde{H}(\mathcal{A}_X, \mathbb{Z}) \cong E_8(-1)^{\oplus 2} \oplus U^{\oplus 4} \qquad \text{where} \qquad U = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.
$$
 (2.1)

Let us further define $N(A_X) := \widetilde{H}^{1,1}(A_X, \mathbb{Z})$ and $T(A_X) := N(A_X)^{\perp \widetilde{H}(A_X, \mathbb{Z})}$. The projections of the classes $[\mathcal{O}_{\text{line}}(1)]$ and $[\mathcal{O}_{\text{line}}(2)]$ to $K_{\text{top}}(\mathcal{A}_X)$ induces two elements $\lambda_1, \lambda_2 \in N(\mathcal{A}_X)$ which span the sublattice

$$
A_2(X) := \langle \lambda_1, \lambda_2 \rangle \cong \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \subseteq N(\mathcal{A}_X).
$$

By [\[AT14,](#page-7-4) Proposition 2.3], there is a commutative diagram of Hodge structures

$$
A_2(X)^{\perp \widetilde{H}(\mathcal{A}_X,\mathbb{Z})} \xrightarrow{\sim} \langle h^2 \rangle^{\perp H^4(X,\mathbb{Z})(-1)} = H^4(X,\mathbb{Z})_{\text{prim}}(-1)
$$

$$
\downarrow \qquad \qquad \int \qquad \qquad \downarrow
$$

$$
T(\mathcal{A}_X) \xrightarrow{\sim} H^{2,2}(X,\mathbb{Z})^{\perp H^4(X,\mathbb{Z})(-1)}
$$

where the horizontal maps are isomorphisms.

From now on, we fix a very general $X \in \mathcal{C}_d$ with $d \equiv 0 \pmod{9}$. Let us denote for short that $T := T(\mathcal{A}_X)$ and $S := N(\mathcal{A}_X) \cap A_2(X)^{\perp N(\mathcal{A}_X)}$. Then a direct computation using the fact that $d \equiv 0 \pmod{6}$ gives

$$
H^{2,2}(X,\mathbb{Z}) \cong \begin{pmatrix} 3 & 0 \\ 0 & 6d' \end{pmatrix} \quad \text{whence} \quad N(\mathcal{A}_X) \cong \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & 0 \\ 0 & 0 & -6d' \end{pmatrix}.
$$

Denote by $\{\lambda_1, \lambda_2, \ell\}$ the standard basis for $N(\mathcal{A}_X)$ so that $\ell^2 = -6d'$. Then

$$
S = \langle \ell \rangle \qquad \text{whence} \qquad S^* / S = \left\langle \frac{\ell}{6d'} \right\rangle \cong \mathbb{Z}_{6d'}.
$$
 (2.2)

Let us also give an explicit formula for the discriminant group of T.

Lemma 2.1. There exists $t_1, t_2 \in T$ with $t_1^2 = -6$, $t_2^2 = 6d'$, and $t_1t_2 = 0$ such that

$$
T^*/T = \left\langle \frac{t_1}{3} \right\rangle \oplus \left\langle \frac{t_2}{6d'} \right\rangle \cong \mathbb{Z}_3 \oplus \mathbb{Z}_{6d'}.
$$

Proof. As a result of $[Nik79, Theorem 1.14.4]$, we can fix an isomorphism (2.1) such that the basis elements for $N(\mathcal{A}_X)$ are identified as

$$
\lambda_1 = e_1 + f_1,
$$
\n $\lambda_2 = e_2 + f_2 - e_1,$ \n $\ell = e_3 - (3d')f_3$

where $\{e_i, f_i\}$, $i = 1, 2, 3$, are the standard bases for the last three copies of U. This isomorphism identifies T with the sublattice $E_8(-1)^{\oplus 2} \oplus U \oplus A_2(-1) \oplus \mathbb{Z}(6d')$ where

$$
A_2(-1) = \langle e_1 - f_1 - e_2, e_2 - f_2 \rangle
$$
 and $\mathbb{Z}(6d') = \langle e_3 + (3d')f_3 \rangle$.

Take $t_1 \coloneqq e_1 - f_1 - 2e_2 + f_2$ and $t_2 \coloneqq e_3 + (3d')f_3$ respectively from these factors. Then a direct computation shows that they satisfy the requirements. \Box

3 FM-partners and two types of overlattices

Let us retain the setting from the previous section and define $\mathcal{M}_{S,T}$ to be the set of even overlattices $L \supseteq S \oplus T$ with $\text{disc}(L) = 3$ such that $S, T \subseteq L$ are both saturated. Our goal is to turn the original counting problem to the counting on the set $\mathcal{M}_{S,T}$. Let us start by showing that the elements of $\mathcal{M}_{S,T}$ can be divided into two types.

Using $[S^*:S] = 6d'$ and $[T^*:T] = 18d'$, one can deduce from the chain of inclusions

$$
S \oplus T \subseteq L \subseteq L^* \subseteq S^* \oplus T^*
$$

that $[L: S \oplus T] = [S^* \oplus T^* : L^*] = 6d'$. Now, as $S, T \subseteq L$ are saturated, the projections

$$
L^* / (S \oplus T) \longrightarrow S^* / S \cong \mathbb{Z}_{6d'} \tag{3.1}
$$

$$
L^* / (S \oplus T) \longrightarrow T^* / T \cong \mathbb{Z}_3 \oplus \mathbb{Z}_{6d'}
$$
\n
$$
(3.2)
$$

are both surjective. In particular, the second map is an isomorphism as the orders of the two groups are both $18d'$. Hence, there exist integers b_1 and b_2 such that

$$
L^*/(S \oplus T) = \left\langle \frac{b_1 \ell + t_1}{3} \right\rangle \oplus \left\langle \frac{b_2 \ell + t_2}{6d'} \right\rangle \tag{3.3}
$$

where ℓ, t_1, t_2 are as in (2.2) and Lemma [2.1.](#page-2-2)

The subgroup $L/(S \oplus T) \subseteq L^*/(S \oplus T)$ has index 3, so its image under [\(3.2\)](#page-3-1) followed by the projection to the factor $\mathbb{Z}_{6d'}$ is either $\mathbb{Z}_{2d'}$ or $\mathbb{Z}_{6d'}$. We can use (3.3) to deduce an explicit expression for $L/(S \oplus T)$ in each of the two cases as follows:

(I) If the image is $\mathbb{Z}_{2d'}$, then

$$
L/(S \oplus T) = \left\langle \frac{b_1 \ell + t_1}{3} \right\rangle \oplus \left\langle \frac{b_2 \ell + t_2}{2d'} \right\rangle.
$$

In view of the surjectivity of (3.1) , we may assume that

$$
0 \le b_1 < 3
$$
 and $0 \le b_2 < 2d'$ with $gcd(b_1, 3) = gcd(b_2, 2d') = 1.$ (3.4)

(II) If the image is $\mathbb{Z}_{6d'}$, then

$$
L/(S \oplus T) = \left\langle \frac{k t_1}{3} + \frac{b_3 \ell + t_2}{6d'} \right\rangle \quad \text{for some} \quad 0 \le k < 3.
$$

Here $b_3 = 2d'kb_1 + b_2$. In view of the surjectivity of (3.1) , we may assume that

 $0 \le b_3 < 6d'$ with $gcd(b_3, 6d') = 1.$ (3.5)

In order to relate the set $\mathcal{M}_{S,T}$ to the set of FM-partners, let us consider the set $FM(X)$ of triples (Y, ϕ, ψ) where

- $Y \in FM(X)$,
- $\phi: S \longrightarrow S_Y := N(\mathcal{A}_Y) \cap A_2(Y)^{\perp N(\mathcal{A}_Y)}$ is an isometry of rank 1 lattices,
- $\psi: T \longrightarrow T_Y := T(\mathcal{A}_Y)$ is a Hodge isometry.

Lemma 3.1. The forgetful map

$$
FM(X) \longrightarrow FM(X) : (Y, \phi, \psi) \longmapsto Y
$$

is 4-to-1. Therefore, we have $|FM(X)| = \frac{1}{4}$ $\frac{1}{4}$ |FM(X)|.

Proof. For each $Y \in FM(X)$, there are exactly two isometries $\phi \colon S \longrightarrow S_Y$ which are different by a sign. On the other hand, there exists a Hodge isometry $\psi \colon T \longrightarrow T_Y$ due to [\[Huy17,](#page-7-0) Theorem 1.5 (iii)]. Because the only Hodge isometries on T are ± 1 [\[Huy16,](#page-7-6) Corollary 3.3.5], the only Hodge isometries from T to T_Y are $\pm \psi$. This shows that the preimage over $Y \in FM(X)$ consists of $(Y, \pm \phi, \pm \psi)$, so the statement follows. \Box

For each $(Y, \phi, \psi) \in \widetilde{FM}(X)$, one can verify that the pullback

$$
L_{(Y,\phi,\psi)} := (\phi \oplus \psi)^* \left(A_2(Y)^{\perp \widetilde{H}(\mathcal{A}_Y,\mathbb{Z})} \right) \subseteq S^* \oplus T^*
$$

is an element of \mathcal{M}_{ST} . This defines a map

$$
FM(X) \longrightarrow \mathcal{M}_{S,T} : (Y, \phi, \psi) \longmapsto L_{(Y, \phi, \psi)}.
$$
\n(3.6)

Due to the Torelli theorem [\[Voi86\]](#page-7-7), if (Y, ϕ, ψ) and (Y', ϕ', ψ') have the same image under this map, then $Y \cong Y'$. Hence, the forgetful map in Lemma [3.1](#page-4-0) factors as

This shows that every fiber of [\(3.6\)](#page-4-1) is contained in a fiber of the forgetful map. Moreover, the map is surjective due to the surjectivity of the period map [\[Laz10,](#page-7-8) Theorem 1.1]; see the end of [\[FL23,](#page-7-2) Proof of Lemma 2.7] for the details.

Lemma 3.2. Map [\(3.6\)](#page-4-1) is 2-to-1. As a result, we have $|\text{FM}(X)| = \frac{1}{2}$ $\frac{1}{2}$ | $\mathcal{M}_{S,T}$ |.

Proof. It is easy to see that $L_{(Y,\phi,\psi)} = L_{(Y,-\phi,-\psi)}$ for every $(Y,\phi,\psi) \in FM(X)$. As a consequence, the fiber $\{(Y, \pm \phi, \pm \psi)\}\subseteq \text{FM}(X)$ over each $Y \in \text{FM}(X)$ is mapped by (3.6) as the set $\{L_{(Y,\phi,\psi)}, L_{(Y,-\phi,\psi)}\}$. To prove the statement, it suffices to verify $L_{(Y,\phi,\psi)} \neq L_{(Y,-\phi,\psi)}$, that is, one gets a different lattice after replacing ℓ with $-\ell$.

First suppose that $L := L_{(Y,\phi,\psi)}$ satisfies [\(I\).](#page-3-4) Assume, to the contrary, that L remains the same after replacing ℓ with $-\ell$. This assumption implies that

$$
\frac{b_1\ell+t_1}{3} = \pm \left(\frac{-b_1\ell+t_1}{3}\right)
$$

within the \mathbb{Z}_3 factor of $L/(S \oplus T) \cong \mathbb{Z}_3 \oplus \mathbb{Z}_{2d'}$, which gives $\frac{2b_1}{3}\ell = 0$ or $\frac{2}{3}t_1 = 0$. Note that the latter case does not occur. In the former case, we get $b_1 \equiv 0 \pmod{3}$, but this contradicts the fact that $gcd(b_1, 3) = 1$.

Now suppose that L satisfies [\(II\).](#page-3-5) Assume again to the contrary that L remains the same after replacing ℓ with $-\ell$. In this case, we get

$$
\frac{kt_1}{3} + \frac{b_3\ell + t_2}{6d'} = \pm \left(\frac{kt_1}{3} + \frac{-b_3\ell + t_2}{6d'}\right) \in L/(S \oplus T) \cong \mathbb{Z}_{6d'},
$$

which implies $\frac{b_3}{3d'}\ell = 0$ or $\frac{2k}{3}t_1 + \frac{2}{3d}$ $\frac{2}{3d'}t_2 = 0$. The latter case does not occur. In the former case, we get $b_3 \equiv 0 \pmod{3d}$, but this contradicts the fact that $gcd(b_3, 6d') = 1$.

We have proved the first statement, which gives $|FM(X)| = 2|\mathcal{M}_{S,T}|$. It then follows from Lemma [3.1](#page-4-0) that $|FM(X)| = \frac{1}{4}$ $\frac{1}{4}$ |FM(X)| = $\frac{1}{2}$ $\frac{1}{2}$ | $\mathcal{M}_{S,T}$ |. \Box

4 Counting the number of overlattices

It remains to count the number of elements in \mathcal{M}_{ST} , or more precisely, to count the number of lattices of the forms (I) and (II) which are even. Let us start by proving a basic property about square roots of unity.

Lemma 4.1. Let n be a positive integer. Then the number of integers $0 \leq b < 2n$ which satisfy $b^2 \equiv 1 \pmod{4n}$ is equal to $\frac{1}{2} | \tilde{Z}_{4n}^{\times}$ $\binom{1}{4n}_2$.

Proof. For each b satisfying the hypothesis, the integers b and $b + 2n$ represent distinct elements in $(\mathbb{Z}_{4n}^{\times})$ $\left(\frac{\times}{4n}\right)_2$. This proves the statement. 口

Let us first count even overlattices of Type (I) .

Lemma 4.2. Elements in $\mathcal{M}_{S,T}$ of Type [\(I\)](#page-3-4) exist only if $d' \equiv 2 \pmod{3}$. If this condition holds, then there are $\left| \left(\mathbb{Z}_4^{\times} \right) \right|$ $\begin{pmatrix} x \\ 4d' \end{pmatrix}$ $\begin{pmatrix} 1 \\ m \end{pmatrix}$ many of them.

Proof. An overlattice of Type [\(I\)](#page-3-4) has the form

$$
L = S + T + \left\langle \frac{b_1 \ell + t_1}{3} \right\rangle + \left\langle \frac{b_2 \ell + t_2}{2d'} \right\rangle
$$

where (b_1, b_2) are as in [\(3.4\)](#page-3-6). Such a lattice is even, that is, belongs to $\mathcal{M}_{S,T}$, if and only if

$$
\left(\frac{b_1\ell+t_1}{3}\right)^2 = -\frac{2}{3}\left(b_1^2d'+1\right) \in 2\mathbb{Z} \qquad \Longleftrightarrow \qquad d' \equiv 2 \pmod{3}
$$

and

$$
\left(\frac{b_2\ell+t_2}{2d'}\right)^2=-\frac{3}{2d'}\left(b_2^2-1\right)\ \in\ 2\mathbb{Z}\qquad\Longleftrightarrow\qquad b_2^2\equiv 1\pmod{4d'}.
$$

From here, we see that even overlattices of Type [\(I\)](#page-3-4) exist only if $d' \equiv 2 \pmod{3}$. In this situation, the number of such lattices equals the number of pairs (b_1, b_2) which satisfy

$$
b_1 \in \{1, 2\}
$$
 and $0 \le b_2 < 2d'$ with $b_2^2 \equiv 1 \pmod{4d'}$.

By Lemma [4.1,](#page-5-1) the number of choices for b_2 is equal to $\frac{1}{2} \left| \left(\mathbb{Z}_4^{\times} \right) \right|$ $\begin{pmatrix} x \\ 4d' \end{pmatrix}$. Since there are two choices for b_1 , the number of desired (b_1, b_2) is equal to $|(\mathbb{Z}_4^{\times})$ $\begin{bmatrix} 2 \ 4d' \end{bmatrix}_2$. \Box

Recall that an overlattice of Type [\(II\)](#page-3-5) has the form

$$
L = S + T + \left\langle \frac{b_3\ell + 2d'kt_1 + t_2}{6d'} \right\rangle
$$

where $0 \leq k < 3$ and b_3 is as in [\(3.5\)](#page-3-7). This lattice is even if and only if

$$
\left(\frac{b_3\ell + 2d'kt_1 + t_2}{6d'}\right)^2 = -\frac{1}{6d'}\left(b_3^2 + 4d'k^2 - 1\right) \in 2\mathbb{Z}.
$$
 (4.1)

Let us count the number of such overlattices case-by-case.

Lemma 4.3. There are $\frac{1}{2}$ $\left| \left(\mathbb{Z}_1^{\times} \right) \right|$ $\sum_{12d'}^{x}$ any elements in $\mathcal{M}_{S,T}$ of Type [\(II\)](#page-3-5) with $k=0$. *Proof.* When $k = 0$, condition (4.1) reduces to

$$
-\frac{1}{6d'}\left(b_3^2 - 1\right) \in 2\mathbb{Z} \qquad \Longleftrightarrow \qquad b_3^2 \equiv 1 \pmod{12d'}.
$$

By Lemma [4.1,](#page-5-1) the number of choices for b_3 is equal to $\frac{1}{2} | \left(\mathbb{Z}_{12}^{\times} \right) |$ $\left.\begin{array}{c} \times \\ 12d' \end{array}\right)_2\right].$

Now we consider the cases when $k = 1, 2$.

Lemma 4.4. Elements in $\mathcal{M}_{S,T}$ of Type [\(II\)](#page-3-5) with $k = 1$ exist only if $d' \equiv 0 \pmod{3}$. If this holds, then there are $\frac{1}{2}$ $\left| \left(\mathbb{Z}_4^{\times} \right) \right|$ $\left(\begin{array}{c} \times \\ 4d' \end{array}\right)_2$ many of them. The same statement holds for $k=2$.

Proof. When $k = 1$ (resp. $k = 2$), condition [\(4.1\)](#page-6-0) is equivalent to

$$
b_3^2 + 4d' - 1 \equiv 0 \pmod{12d'}.
$$
\n(4.2)

 \Box

Since $b_3^2 \equiv 1 \pmod{3}$, the above relation modulo 3 gives $d' \equiv 0 \pmod{3}$. Now write

$$
b_3 = b_4 + 2d'm
$$
 with $0 \le b_4 < 2d'$.

Then (3.5) holds if and only if $m \in \{0, 1, 2\}$ and $gcd(b_4, 2d') = 1$. From (4.2) , we get

$$
b_3^2 + 4d' - 1 \equiv b_4^2 + 4d'(mb_4 + d'm^2 + 1) - 1 \equiv 0 \pmod{12d'}.
$$
 (4.3)

This relation modulo $4d'$ gives

$$
b_4^2 \equiv 1 \pmod{4d'}.\tag{4.4}
$$

We claim that for each such b_4 , whether $m = 0, 1, 2$ is uniquely determined. Indeed, if we write $b_4^2 = 1 + 4d'r$ with r an integer, then

$$
b_4^2 + 4d'(mb_4 + d'm^2 + 1) - 1 = 4d'(r + mb_4 + d'm^2 + 1).
$$

Inserting this into [\(4.3\)](#page-6-2) with $d' \equiv 0 \pmod{3}$ in mind reduces the relation to

$$
r + mb_4 + 1 \equiv 0 \pmod{3}.
$$

Then the claim follows as $b_4 \neq 0 \pmod{3}$. By Lemma [4.1,](#page-5-1) the number of $0 \leq b_4 < 2d'$ satisfying [\(4.4\)](#page-6-3) is equal to $\frac{1}{2}$ $\left| \left(\mathbb{Z}_4^{\times} \right) \right|$ $\left(\begin{matrix} x \\ 4d' \end{matrix}\right)_2$. This completes the proof. П

Proof of Theorem [1.1.](#page-1-1) By Lemmas [4.2,](#page-5-2) [4.3,](#page-6-4) [4.4,](#page-6-5) the numbers of elements in $\mathcal{M}_{S,T}$ of different types and values of d' can be organized into a table:

		$d' \equiv 0 \pmod{3}$ $d' \equiv 1 \pmod{3}$ $d' \equiv 2 \pmod{3}$	
			$\left \left(\mathbb{Z}_{4d'}^{\times} \right)_2 \right $
(II) with $k=0$	$\frac{1}{2}$ $\left(\mathbb{Z}_{12d'}^{\times} \right)_2$	$\frac{1}{2} (\mathbb{Z}_{12d'}^{\times})_{2} $	$\frac{1}{2}$ $\left(\mathbb{Z}_{12d'}^{\times} \right)_2$
(II) with $k=1$	$\frac{1}{2}$ $\left(\mathbb{Z}_{4d'}^{\times} \right)$ ₂		
(II) with $k=2$	$\frac{1}{2}$ $\left(\mathbb{Z}_{4d'}^{\times} \right)_2$		
$ \mathcal{M}_{S,T} $	$\frac{3}{2}$ $\left(\mathbb{Z}_{4d'}^{\times} \right)$ ₂	$\left \left(\mathbb{Z}_{4d'}^{\times} \right)_2 \right $	$2\left\lfloor \left(\mathbb{Z}_{4d'}^{\times} \right)_2 \right\rfloor$

The formulas can then be deduced from Lemma [3.2](#page-4-2) and a direct computation.
