ARTICLE HISTORY

Compiled August 1, 2023

ABSTRACT

Since 2005, the global flagship of outreach activities in high-energy physics have been the International Particle Physics Masterclasses. We report on a survey performed among the participants from Slovakia and the Czech Republic, where we have studied the impact of Masterclasses on their further careers and their attitude towards science and especially particle physics. More than a half of our respondents does not work in science or research and development. However, most of them report positive shift in their attitude towards science. A positive nudge to physics career is indicated among those being open to such a possibility.

KEYWORDS

International Particle Physics Masterclasses, Motivation

1. Introduction

In various areas of active (physics) research, often a large gap exists between the cutting edge results and the knowledge taught at secondary schools or distributed among the general public. This gap is partially filled by non-formal learning and outreach activities.

High-energy physics, a.k.a. particle physics, has been traditionally communicated rather intensely also outside of the field, as there has often been demand for the knowledge by the public. The reason is perhaps that HEP pursuits the most fundamental principles of our Universe, which is perceived as very exciting. Nevertheless, the appearance of this research field and its relation to the public are also very important for its own sustainability. Firstly, the complexity of the problems and the scale of HEP experiments require rather large numbers of top-qualified workforce which in longer-term perspective are recruited among the young people graduating from secondary schools. Secondly, particle physics belongs to those branches of science that eventually require building large and costly infrastructures. Hence, the support from the governments representing the tax-paying citizens—is vital. Outreach is the part of the strategy that addresses these issues. Thus the motivation for outreach is on all sides.

Since 2005—the 100th anniversary of Einstein's Annus Mirabilis—one of the internationally most important outreach activities in HEP has been developed: the Inter-

Email: boris.tomasik@cvut.cz

national Particle Physics Masterclasses (IMC). Institutes from Slovakia and the Czech Republic have participated in this initiative since its beginning.

Due to its general attraction and longevity one could expect that IMC have already influenced a generation of young people and motivated some of the careers towards HEP, or generally to STEM. Furthermore, it could have contributed to the perception of science among those who chose non-STEM careers. These are interesting hypotheses and until now we have had no data against which they could have been confronted. In this study, we report on a survey that addresses these hypotheses and demonstrates the long-term impact of IMC.

Our survey shows that while more participants chose careers outside science or research&development (R&D), the majority maintains positive attitude towards science. The recollections about IMC are mostly very positive.

We describe the International Particle Physics Masterclasses in the next Section. In Section 3 we explain how data were collected on which our survey is based. Results are presented in Section 4 and the conclusions are summarised in Section 5.

2. International Particle Physics Masterclasses

The principal idea that governs the Masterclasses is to provide the upper secondary level pupils the genuine experience of particle physics. The advertising mottos 'Hands on CERN' and 'Become a particle physicist for one day' give the first idea about its motivation and agenda. The event (almost) always takes place at a university or research institute that runs active research programme in particle physics. One of the aims is to also bring the pupils into the environment where research is performed.

The agenda of the event is planned for one day and the highlight is an analysis of data collected by one of the major particle physics experiments. Participants thus get hands-on experience mimicking the work of particle physicists.

No previous knowledge is necessary in order to participate in IMC. Therefore, the morning programme usually includes lectures that provide the elementary knowledge about theoretical concepts of particle physics and explain the basic experimental techniques used.

After the lunch, the actual hands-on activity is introduced and explained. Participants work on it individually or in pairs, and it takes about two hours. Currently, all four large experiments at the LHC (CERN) offer activities that are being used in Masterclasses. Some of the collaborations even prepared two different activities. In addition to CERN experiments there are exercises prepared by BELLE II (KEK Laboratory, Japan), MINER ν A (Fermi National Laboratory, USA), Pierre Auger (cosmic ray detection array, Argentina) and one activity prepared by GSI Darmstadt on particle therapy in oncology.

The international character of the research in particle physics is also illustrated in the subsequent videoconference. There, up to five institutes connect and discuss together with moderators from a major particle physics laboratory—their results. The videoconference is arranged by the global management of the event in such a way, that at all participating institutes the same hands-on activity has been performed. The participants in the videoconference may also pose questions about particle physics and related issues in general, which are answered by the moderators—who are professional physicists themselves.

The hands-on activity is rather involved. Such an endeavor, together with the international coordination of the videoconferences is only possible thanks to the joint effort managed by the International Particle Physics Outreach Group (IPPOG)¹. Formally, IPPOG is an international collaboration, hosted by CERN, and facilitating exchange of ideas as well as coordinating outreach activities in the participating countries and with the major particle physics laboratories and experiments.

For the first time on international level, IMC were organised by European Particle Physics Outreach Group (EPPOG) in 2005. It was in 2010 that EPPOG evolved internationally and became IPPOG. Today, each year about 13,000 pupils participate in IMC that take place at some 220 institutes from 55 countries.

More details about IMC can be found in the literature e.g. by Bilow and Kobel (2014); Bilow and Cecire (2022); Foka (2013); Kobel (2005), and the information about IPPOG can be obtained from their web-site.

3. Data collection

First survey which focussed on the performance of IMC was undertaken already in 2005 and reported by Kobel (2005).

Both Czech Republic and Slovakia have been participating in IMC since its first edition in 2005. Between 2011 and 2015 surveys were performed at most of the participating institutions in Slovakia and once also at the Czech Technical University in Prague, Czech Republic. Those surveys were mainly focused on the educational background of the participants and the assessment of the IMC with the aim to further develop and improve the event. Results were partly summarised by Beniačiková and Krišková (2011); Cecire et al. (2017); Tomášik and Goceliaková (2013) and/or used internally.

The surveys were performed by means of answer sheets that were (usually) distributed and collected just after the end of IMC while the participants were still at the venue. In one case two questionnaires were collected—one before and one after the IMC—in order to directly measure the impact of IMC. The total number of collected sets of answers over all years is somewhat below 1000. The surveys were anonymous. Nevertheless, in the end we suggested that if the participants agreed, they could leave us with their email addresses for the purpose of a later survey.

In April and May 2023 we have performed two new surveys, from which we present results in this paper.

Survey 1 has been performed among former participants of IMC, who left their email addresses with us. In this way we have retrieved 484 email addresses from the archived answer sheets.

We administered an anonymous online questionnaire that has been implemented with the help of google forms. In included 10 questions. We deliberately kept the form short in order not to discourage the participants from filling it in. The questions were in Slovak for participants from both Slovakia and Czech Republic. The questions, translated to English, are listed in Table 1. The first two questions serve statistic purposes, mainly. Q1.3 aims at reconstruction of the motivation prior to experiencing IMC. Questions Q1.4–Q1.8 explore the actual impact of IMC as perceived today. We will mention the comments that we received in Q1.9 below, and look at the correlation between the previous survey and this one thanks to emails collected in Q1.10.

Out of the 484 invitations to our survey, 133 messages bounced back as undeliverable,

Table 1. Questions asked in the questionnaire of Survey 1.

hence we assume that 351 messages were delivered. From those, 71 participants filled our online questionnaire. This is the sample we work with. Furthermore, 36 people revealed their email addresses and we were able to connect their responses with the ones that were collected in the past.

Survey 2 was performed in parallel to Survey 1 with the aim to identify if and how IMC influenced young researchers in HEP. In this case, we asked the senior faculty members and team leaders at relevant Czech and Slovak institutions to forward our invitation to the study to younger colleagues. The participation could not be enforced, thus the sample may be biased and possibly not all eligible people may have responded. We collected 19 responses in total. This number is to be compared with the relevant size of the community, which we estimate as 100 young HEP practitioners in the Czech Republic and 25 in Slovakia, totalling to 125. The numbers include young colleagues that—due to their age—could have participated in IMC and can be clearly assigned to research in HEP. This results in a group from master study level up to about 35 years of age. The numbers were estimated after requesting the (approximate) headcount from team leaders at all relevant institutions.

Since our surveys were anonymous, unless the respondents volunteered to reveal their identity, we do not have information about possible overlap between participants to Survey 1 and Survey 2. From anecdotal discussions we know that there is some overlap, but our method does not allow for a more detailed information.

The questions of Survey 2 are summarised in Table 2. Part of them is similar to

	Question	Mode of answer
Q2.1	In which year have you participated in Master- classes?	multiple choice
Q2.2	At which place have you participated in Master- classes?	multiple choice

Table 2. Questions asked in the questionnaire of Survey 2.

Survey 1, but in case of Survey 2 we know that the answers are given by practitioners in HEP. The other part of the questions thus rather aims on the research focus of the participants and the attitude to currently organised IMC.

For brevity, below we will refer to the respondents of Survey 1 as *fans*, while respondents of Survey 2 will be called *practitioners*.

4. Results

Histograms in Fig. 1 show the distribution of years when our respondents participated in IMC. Based on our data collection procedure it is not surprising that the fans mostly participated between 2011 and 2015, when the previous survey was performed. Individual cases outside of this time interval either indicate multiple participation to IMC by one respondent, or erroneous assignment of the year. There were 12 responses

Figure 1. Distribution of the years of participation to IMC for fans (dark columns) and practitioners (light columns).

which could not recall the actual year and they are not included here. The distribution of years is wider for the practitioners. Participation after 2019 indicates the survey leaked also to current bachelor-level students. We decided to keep their responses in the sample, thus making it more informative.

Next, we study to what extent IMC have directed our respondents towards a career in particle physics. In Figure 2 we combine the results from both surveys. In the general group of fans, people with the ambition to go to particle physics make up slight minority. Not surprisingly, more than a half of the practitioners were motivated to proceed to particle physics after they experienced IMC. Interestingly enough, according to Q2.3, 6 out of 19 practitioners had no such ambition before coming to IMC. Since they did end up as particle physicists, this means that they have changed their minds later. The impact of IMC in directing towards particle physics is also quite different in the two groups. While practitioners were clearly influenced, slight majority of the fans feel rather not influenced.

In order to understand the motivating effect better, we look in Figure 3 into the correlation of answers to Q1.3 and Q1.4, i.e., questions about the pre-existing ambition to study particle physics and the influence of IMC on personal motivation, for the sample of fans. The histogram shows a clear peak for people neither planning nor being influenced towards particle physics. Nevertheless, on the 'yes'-side of the histogram we see a hint of anti-correlation between the ambition (Q1.3) and decision influence (Q1.4): people with ambivalent attitude towards particle physics seem to be nudged towards it while those with positive attitude report no additional influence.

There are not enough data to produce a similar plot for the practitioners, hence we refrain from it.

We were interested in further evolution of the careers of former IMC participants. As can be seen in Figure 4, slightly more than a half of the fans actually work outside science and R&D. A more detailed information is summarised in Figure 5. By far the most populated profession group is related to IT. Another prominent group can be identified if we put together all healthcare-related professions. The education group mostly includes science teachers. In general, STEM-related careers prevail, with only 10 out of 71 respondents falling clearly out of this field, i.e., to social sciences, humanities, economy, or business.

Linking the current responses with those collected about ten years ago allows us to gain some insight into the evolution of career plans. The correlation of previous plans with current reality is analysed in Figure 6. It is based on the 36 responses that could have been linked. We divided all professions into 10 groups, see the caption. If there was no change of plans, data would be aligned along the diagonal. Such a trend is roughly visible, with two pronounced peaks; the main for IT and the next for physics. In addition to the diagonal there are hints of two more effects. Firstly, there is a group of respondents who originally planned various careers but ended up with physics. Secondly, a similar, though smaller group ended up finally in IT.

Another focus of our surveys was in the perception of particle physics and science, in general. We summarise in Figure 7 the answers to questions Q1.7, and Q1.8, which aim at the positive change in the attitude to science and research, and the interest in CERN and particle physics in general, respectively. In case of the attitude we see a positive effect of the IMC. In case of the interest in particle physics this is less pronounced.

It is interesting to see how the answers to Q1.7 and Q1.8 depend on the professional orientation of the respondent. To this end, we show in Figure 8 two-dimensional histogram that combines answers to these questions with those to Q1.5. The histograms demonstrate that both the positive shift in attitude to science and the interest in CERN and particle physics are more pronounced with respondents working in science or R&D.

Survey 2 also clearly showed that the practitioners who participated in IMC are

Figure 2. Distributions of answers to questions (from top to bottom) Q1.3, Q2.3, Q1.4, Q2.4.

Figure 3. Two-dimemnsional histogram of answers to questions Q1.3 (ambition) and Q1.4 (influence) for the sample of fans

Figure 4. Distribution of the answers to Q1.5: current career in science and R&D.

very happy to help with IMC at their institutes. Most of them work on experiments, in comparison to theory or phenomenology, which is usual distribution in HEP.

We would like to close this section with the messages that the respondents left us as free text. They unanimously evaluated IMC very positively even if they decided to choose a different career path. Some of these decisions were motivated by the financial attractiveness of the IT sector.

These answers illustrate that there seems to be a more profound idea that is communicated indirectly in the IMC events. It is related to the meaningfulness of the devoted (scientific) work, which is surely transferable beyond particle physics and is much more general asset in life.

Since it may be interesting, where possible we identified the gender of the respondent, which in Slovak language can be inferred from the form of the verbs used in the answers. There were 5 responses from males and 7 from females, while 8 responses could not be uniquely assigned. We did not collect the data on gender because we were not interested in this aspect. Nevertheless, the observed distribution is in agreement with our experience that the participants to IMC are rather balanced.

Selected messages follow:

• 'Very good event. (IT pays better.)'

Figure 5. Current distribution of professions within the sample of fans.

Figure 6. Histogram of career plans immediately after IMC vs. current reality. Coding of the profession groups: 1 physics; 2 particle physics; 3 science, research scientist; 4 IT, computer science; 5 data science; 6 business, economics; 7 engineering; 8 medicine and pharmacy; 9 education; 10 social sciences and humanities.

Figure 8. Two dimensional histograms of the combinations of answers to Q1.7 with Q1.5 (attitude to science and career in science or R&D, left) and Q1.8 with Q1.5 (interest in news from CERN and career in science or R&D, right).

('Veľmi dobré podujatie. (IT sektor platí lepšie.)')

- 'As a teacher I would recommend it to pupils interested in physics.'
 - ('Ako učiteľka by som to odporučila absolvovať žiakom so záujmom o fyziku.')
- 'I participated in Masterclasses 12 years ago and I still recollect it very well. It was tremendous experience for me as a student who was interested in physics and planned to study this specialisation. It showed me new possibilities and I gained new encouragement to proceed this way also to the university. I am thankful for this opportunity.'

('Podujatie Masterclasses som absolvovala pred 12timi rokmi a doteraz si na to veľmi dobre spomínam. Bola to úžasná skúsenosť pre mňa ako študentku, ktorá sa zaujímala o fyziku a mala v pláne ist študovať tento odbor. Ukázalo mi to nové možnosti a nabrala som ešte väčšie odhodlanie ísť touto cestou aj na vysokej škole. Som vďačná za túto príležitosť.')

• 'In my opinion, Masterclasses are a superb event. I would not say that it changed my opinion about science; I held it positive already before. It gave me kind of a first practical contact with science, how it works, what is the state of the art and what are open questions in the given area. It also helped me to grasp some things, that we learned in secondary school, because perhaps even our teachers did not understand them so deeply, so that they could present it so simply and logically. It was a contact with the fact that if you pursue something more deeply, it could make sense. I think that Masterclasses make sense, even if you finally decide to study something else than particle physics. Today, many projects are interdisciplinary and then it is an advantage if you had the possibility to get a flavor of the terminology and get some basic knowledge also from different specialisations.'

('Masterclasses je podľa mňa super podujatie. Nepovedala by som, že by mi to zmenilo názor na vedu, ten som mala už aj pred tým pozitívny. Dalo mi to taký prvý praktický kontakt s vedou, ako prebieha a čo state of the art a čo sú open questions v danej oblasti. Tiež mi to pomohlo pochopiť niektoré veci, pochopiť, ktoré sme sa učili na strednej, lebo asi ani naši učitelia tomu tak do hĺbky nerozumeli, aby to vedeli jednoducho a logicky podať. Bol to kontakt s tým, že keď sa človek niečomu venuje trochu viac do hĺbky, môže to dávať zmysel. Myslím si, že projekt Masterclasses má zmysel, aj keď sa človek nakoniec rozhodne robiť a študovať niečo iné ako časticovú fyziku. Veľa projektov je teraz medziodborových a tam je výhodou, ak má človek možnosť načuchnúť aj do terminológie a získať nejaké základné vedomosti aj z iných odborov.')

• 'I would like to praise the organisation of this event. During my study I participated in such events joyfully and often, and this one particularly stayed in my memory, because it seems to me that there I learned in a short time a lot, and it certainly increased my interest for this field, even though later—perhaps rather due to practical reasons—I decided to study informatics. Thank you!'

('Chcem pochváliť organizáciu tohoto podujatia. Počas štúdia som sa podobných akcií zúčastňovala rada a často, a tento mi obzvlášť utkvel v pamäti, lebo mám pocit, že som sa tam za krátky čas naučila veľa a určite to v tom čase zvýšilo môj záujem o tento obor, hoci som sa neskôr, možno viac z praktických dôvodov, rozhodla pre štúdium informatiky. Vďaka!')

 'Even though it was a long time ago, I have very good recollections of Masterclasses and I think that such activities are of great significance. Even if I did not study physics at last, but informatics, CERN still bugged me and finally I got there as a fellow and spent three years in the IT division. Just by chance, right now I am sitting in a train to Geneva on my way to visit my former colleagues.
:)'

('Aj keď to už bolo dávno, na Masterclasses mám veľmi dobré spomienky a myslím si, že takéto aktivity majú veľký význam. Aj keď som nakoniec nešla študovať fyziku, ale informatiku, CERN mi zostal ako chrobák v hlave a nakoniec som sa tam dostala na fellowship a strávila som tri roky v IT oddelení. Zhodou okolností práve sedím vo vlaku do Ženevy a idem pozrieť bývalých kolegov :)')

5. Conclusions

We found an indication in our data that International Particle Physics Masterclasses do have a nudging effect on participants who do not exclude the possibility of becoming a scientist or even particle physicist. They appear as very effective learning environment where in short time great experience is provided to those who participate.

Nevertheless, a larger portion of former participants does not pursue scientific career, or a career in R&D. IMC then provide a kind of cultural transfer in which the (good) practices followed in particle physics are exported to other fields and professions. In line with this, IMC contributes to the generally positive acceptance of science.

The recruiting function is often stressed and even mentioned frequently in an IMC event. ('You can become particle physicist and solve these open problems!') Nevertheless, it should be acknowledged and appreciated that perhaps more important impact of IMC is in the export of knowledge and culture beyond particle physics and enriching the future generation of citizens.

Acknowledgements

We thank Ivan Melo and Vojtěch Pleskot for insightful discussions that helped us in performing the reported survey, as well as critical reading and comments to the manuscript. We are grateful to the colleagues who provided inputs and forwarded our requests to participate in Survey 2: Pavol Bartoš, Jaroslav Bielčík, Marek Bombara, Peter Chochula, Michal Mereš, Vojtěch Pleskot, Marek Taševský, Martin Venhart. We also thank the students who helped us with processing data from the answer sheets: Natália Działak and Dominika Kružíková.

Funding

IMC and this study have been supported by the Ministry of Education, Science, Research and Sports of the Slovak Republic.
