Abstract

We consider the critical temperature for superconductivity, defined via the linear BCS equation. We prove that at weak coupling the critical temperature for a sample confined to a quadrant in two dimensions is strictly larger than the one for a half-space, which in turn is strictly larger than the one for \mathbb{R}^2 . Furthermore, we prove that the relative difference of the critical temperatures vanishes in the weak coupling limit.

1 Introduction

Recent work [1, 2, 10–12] predicts the occurrence of boundary superconductivity in the BCS model. Close to edges superconductivity sets in at higher temperatures than in the bulk, and at corners the critical temperature appears to be even higher than at edges. Our goal is to provide a mathematically rigorous justification of these results. It was proved in [5, 9] that the system on half-spaces in dimensions $d \in \{1, 2, 3\}$ can have higher critical temperatures than on \mathbb{R}^d . Here, we extend this result for $d = 2$ and show that a quadrant has a higher critical temperature than a half-space, at least at weak coupling.

We consider the full plane, and the half- and quarter-spaces $\Omega_k = (0, \infty)^k \times \mathbb{R}^{2-k}$ for $k \in \{0, 1, 2\}$. We define the critical temperature as in [5, 9] using the operator

$$H_T^\Omega = \frac{-\Delta_x - \Delta_y - 2\mu}{\tanh\left(\frac{-\Delta_x - \mu}{2T}\right) + \tanh\left(\frac{-\Delta_y - \mu}{2T}\right)} - \lambda V(x - y) \quad (1.1)$$

acting in $L_{\text{sym}}^2(\Omega \times \Omega) = \{\psi \in L^2(\Omega \times \Omega) \mid \psi(x, y) = \psi(y, x) \text{ for all } x, y \in \Omega\}$, where $-\Delta$ denotes the Dirichlet or Neumann Laplacian and the subscript indicates on which variable it acts, T is the temperature, μ is the chemical potential, V is the interaction, and λ is the coupling constant. The first term is defined through functional calculus. For $V \in L^t(\mathbb{R}^2)$ with $t > 1$, the $H_T^{\Omega_k}$ are self-adjoint operators defined via the KLMN theorem [9, Remark 2.2].

The critical temperatures are defined as

$$T_c^k(\lambda) := \inf\{T \in (0, \infty) \mid \inf \sigma(H_T^{\Omega_k}) \geq 0\}. \quad (1.2)$$

The operator $H_T^{\Omega_k}$ is the Hessian of the BCS functional at the normal state [3]. In particular, the system is superconducting for $T < T_c^k(\lambda)$, when the normal state is not a minimizer of the BCS functional. A priori, superconductivity may also occur at temperatures $T > T_c^k(\lambda)$, when the normal state is a local minimum of the BCS functional, but not a global one. For

^{*}barbara.roos@ist.ac.at

[†]robert.seiringer@ist.ac.at

translation invariant systems, in particular for $\Omega_0 = \mathbb{R}^2$, this is not the case and the system is in the normal state if $T > T_c^0(\lambda)$ [4, 6], hence T_c^0 separates the normal and the superconducting phase. However, it remains an open question whether the same is true for T_c^1 and T_c^2 .

We prove that for small enough λ , the critical temperatures defined through the linear criterion (1.2) satisfy $T_c^2(\lambda) > T_c^1(\lambda)$. Together with the result from [9], we get the strictly decreasing sequence $T_c^2(\lambda) > T_c^1(\lambda) > T_c^0(\lambda)$ of critical temperatures at weak coupling.

Similarly to [9, Lemma 2.3], where it was shown that $T_c^1(\lambda) \geq T_c^0(\lambda)$ for all λ , the following Lemma is relatively easy to prove.

Lemma 1.1. *Let $\lambda, T > 0$ and $V \in L^t(\mathbb{R}^2)$ for some $t > 1$. Then $\inf \sigma(H_T^{\Omega_2}) \leq \inf \sigma(H_T^{\Omega_1})$.*

Its proof can be found in Section 2. In particular it follows that for all $\lambda > 0$, we have $T_c^2(\lambda) \geq T_c^1(\lambda)$. The difficulty lies in proving a strict inequality, which the rest of the paper will be devoted to. In order to prove $T_c^2(\lambda) > T_c^1(\lambda)$, we shall give a precise analysis of the asymptotic behavior of $H_{T_c^1(\lambda)}^{\Omega_1}$ as $\lambda \rightarrow 0$.

For $\mu > 0$ let $\mathcal{F} : L^1(\mathbb{R}^2) \rightarrow L^2(\mathbb{S}^1)$ act as the restriction of the Fourier transform to a sphere of radius $\sqrt{\mu}$, i.e., $\mathcal{F}\psi(\omega) = \hat{\psi}(\sqrt{\mu}\omega)$ and for $V \geq 0$ define $O_\mu = V^{1/2}\mathcal{F}^\dagger\mathcal{F}V^{1/2}$ on $L_s^2(\mathbb{R}^2) = \{\psi \in L^2(\mathbb{R}^2) | \psi(r) = \psi(-r)\}$. The operator O_μ is compact. For the desired asymptotic behavior of $H_{T_c^1(\lambda)}^{\Omega_1}$ we need that O_μ has a non-degenerate eigenvalue $e_\mu = \sup \sigma(O_\mu) > 0$ at the top of its spectrum [6, 7].

We require the following assumptions for our main result.

Assumption 1.2. Let $\mu > 0$. Assume that

- (i) $V \in L^1(\mathbb{R}^2) \cap L^t(\mathbb{R}^2)$ for some $t > 1$,
- (ii) V is radial, $V \neq 0$,
- (iii) $|\cdot|V \in L^1(\mathbb{R}^2)$,
- (iv) $V \geq 0$,
- (v) $e_\mu = \sup \sigma(O_\mu)$ is a non-degenerate eigenvalue.

Remark 1.3. Similarly to the three dimensional case discussed in [6, Section III.B.1], because of rotation invariance the eigenfunctions of O_μ are given, in radial coordinates $r \equiv (|r|, \varphi)$, by $V^{1/2}(r)e^{im\varphi}J_m(\sqrt{\mu}|r|)$, where J_m denote the Bessel functions and $m \in 2\mathbb{Z}$ since the functions must be even in r . The corresponding eigenvalues are

$$e_\mu^{(m)} = \frac{1}{2\pi} \int_{\mathbb{R}^2} V(r) |J_m(\sqrt{\mu}|r|)|^2 dr \quad (1.3)$$

and in particular $e_\mu^{(m)} = e_\mu^{(-m)}$. Assumption (v) therefore means that $e_\mu = e_\mu^{(0)}$ and that all other eigenvalues $e_\mu^{(m)}$ are strictly smaller. Hence, the eigenstate corresponding to e_μ has zero angular momentum. Analogously to the three dimensional case, a sufficient condition for (v) to hold is that $\hat{V} \geq 0$.

Our first main result is:

Theorem 1.4. *Let $\mu > 0$ and let V satisfy Assumption 1.2. Assume the same boundary conditions, either Dirichlet or Neumann, on Ω_1 and Ω_2 . Then there is a $\lambda_1 > 0$, such that for all $0 < \lambda < \lambda_1$, $T_c^2(\lambda) > T_c^1(\lambda)$.*

The second main result is that the relative difference in critical temperatures vanishes in the weak coupling limit.

Theorem 1.5. *Let $\mu > 0$ and let V satisfy Assumption 1.2. Assume either Dirichlet or Neumann boundary conditions on Ω_2 . Then*

$$\lim_{\lambda \rightarrow 0} \frac{T_c^2(\lambda) - T_c^0(\lambda)}{T_c^0(\lambda)} = 0. \quad (1.4)$$

Since $T_c^2(\lambda) \geq T_c^1(\lambda) \geq T_c^0(\lambda)$, this implies $\lim_{\lambda \rightarrow 0} \frac{T_c^2(\lambda) - T_c^1(\lambda)}{T_c^1(\lambda)} = 0$ and $\lim_{\lambda \rightarrow 0} \frac{T_c^1(\lambda) - T_c^0(\lambda)}{T_c^0(\lambda)} = 0$. The latter was already shown in [9] and we closely follow [9] to prove Theorem 1.5.

The paper is structured as follows. In Section 1.1 we explain the proof strategy for Theorem 1.4. Section 2 contains the proofs of some basic properties of H_T^Ω . Section 3 discusses the regularity and asymptotic behavior of the ground state of $H_T^{\Omega_1}$. In Section 4 we prove Lemma 1.8, the first key step in the proof of Theorem 1.4. The second key step, Lemma 1.9 is proved in Section 5. In Section 6 we prove Theorem 1.5. Section 7 contains the proofs of auxiliary Lemmas.

1.1 Proof strategy for Theorem 1.4

The proof of Theorem 1.4 is based on the variational principle. The idea is to construct a trial state for $H_{T_c^1(\lambda)}^{\Omega_2}$ involving the ground state of $H_{T_c^1(\lambda)}^{\Omega_1}$. However, the latter operator is translation invariant in the second component of the center of mass variable and therefore has purely essential spectrum. To work with an operator that has eigenvalues, we fix the momentum in the translation invariant direction, and choose it in order to minimize the energy.

Let $U : L^2(\mathbb{R}^2 \times \mathbb{R}^2) \rightarrow L^2(\mathbb{R}^2 \times \mathbb{R}^2)$ be the unitary operator switching to relative and center of mass coordinates $r = x - y$ and $z = x + y$, i.e. $U\psi(r, z) = \frac{1}{2}\psi((r+z)/2, (z-r)/2)$. We shall apply U to functions defined on a subset of $\Omega \subset \mathbb{R}^2 \times \mathbb{R}^2$, by identifying $L^2(\Omega)$ with the set of functions in $L^2(\mathbb{R}^2 \times \mathbb{R}^2)$ supported in Ω . The operator $UH_T^{\Omega_1}U^\dagger$, which is $H_T^{\Omega_1}$ transformed to relative and center of mass coordinates, acts on functions on $\tilde{\Omega}_1 \times \mathbb{R}$, where $\tilde{\Omega}_1 = \{(r, z_1) \in \mathbb{R}^3 \mid |r_1| < z_1\}$, and is translation invariant in z_2 . For every $q_2 \in \mathbb{R}$ let $H_T^1(q_2)$ be the operator obtained from $UH_T^{\Omega_1}U^\dagger$ by restricting to momentum q_2 in the z_2 direction. The operator $H_T^1(q_2)$ acts in $L_s^2(\tilde{\Omega}_1) = \{\psi \in L^2(\tilde{\Omega}_1) \mid \psi(r, z_1) = \psi(-r, z_1)\}$ and we have $\inf \sigma(H_{T_c^1(\lambda)}^{\Omega_1}) = \inf_{q_2 \in \mathbb{R}} \inf \sigma(H_T^1(q_2))$. We want to choose q_2 to be optimal. That this can be done is a consequence of the following Lemma, whose proof will be given in Section 2.2.

Lemma 1.6. *Let $T, \lambda, \mu > 0$ and $V \in L^t(\mathbb{R}^2)$ for some $t > 1$. The function $q_2 \mapsto \inf \sigma(H_T^1(q_2))$ is continuous, even and diverges to $+\infty$ as $|q_2| \rightarrow \infty$.*

Therefore, the infimum is attained and we can define $\eta(\lambda)$ to be the minimal number in $[0, \infty)$ such that $\inf \sigma(H_{T_c^1(\lambda)}^1(\eta(\lambda))) = \inf \sigma(H_{T_c^1(\lambda)}^{\Omega_1})$.

Next, we shall argue that $H_{T_c^1(\lambda)}^1(\eta(\lambda))$ indeed has a ground state, at least for small enough coupling, which allows us to construct the desired trial state. Let $\lambda_0 > 0$ be such that $T_c^1(\lambda) > T_c^0(\lambda)$ for $\lambda \leq \lambda_0$. Such a λ_0 exists by [9, Theorem 1.3].

Lemma 1.7. *Let $\mu > 0$, let V satisfy Assumption 1.2 and let $0 < \lambda \leq \lambda_0$. Then $H_{T_c^1(\lambda)}^1(\eta(\lambda))$ has an eigenvalue at the bottom of its spectrum.*

The proof of Lemma 1.7 can be found in Section 2.3. For $\lambda \leq \lambda_0$ let $\tilde{\Phi}_\lambda$ be the ground state of $H_{T_c^1(\lambda)}^1(\eta(\lambda))$. In the case $\eta(\lambda) = 0$, the operator $H_{T_c^1(\lambda)}^1(\eta(\lambda))$ commutes with reflections $r_2 \rightarrow -r_2$ and we may assume that $\tilde{\Phi}_\lambda$ is even or odd under this reflection. We extend the function $\tilde{\Phi}_\lambda$ (anti)symmetrically from $\tilde{\Omega}_1$ to \mathbb{R}^3 , such that the extended function Φ_λ satisfies $\Phi_\lambda((-r_1, r_2), -z_1) = \Phi_\lambda(r, z_1)$ and $\mp \Phi_\lambda((z_1, r_2), r_1) = \Phi_\lambda(r, z_1)$, where $-/+$ corresponds to Dirichlet/Neumann boundary conditions (see Figure 1 for an illustration). The function Φ_λ is the key ingredient for our trial state. Let $\chi_{\tilde{\Omega}_1}$ denote multiplication by the characteristic function of $\tilde{\Omega}_1$; then $\tilde{\Phi}_\lambda = \chi_{\tilde{\Omega}_1} \Phi_\lambda$. We choose the normalization such that $\|V^{1/2} \chi_{\tilde{\Omega}_1} \Phi_\lambda\|_2 = 1$,

Figure 1: Sketch of the (anti)symmetric extension of a function ψ defined on the upper right quadrant in the (r_1, z_1) -coordinates. The extension is defined by mirroring along the x_1 and y_1 -axes and multiplying by -1 for Dirichlet boundary conditions.

where $V^{1/2}\psi(r, z) = V^{1/2}(r)\psi(r, z)$. (Since $V \in L^t(\mathbb{R}^2)$ for some $t > 1$ and $\Phi_\lambda \in H^1(\mathbb{R}^3)$, it follows by the Hölder and Sobolev inequalities that $V^{1/2}\Phi_\lambda$ is an L^2 function [8].)

Our choice of trial state is

$$\begin{aligned} \psi_\lambda^\epsilon(r_1, r_2, z_1, z_2) = & (\Phi_\lambda(r_1, r_2, z_1)e^{i\eta(\lambda)z_2} + \Phi_\lambda(r_1, -r_2, z_1)e^{-i\eta(\lambda)z_2})e^{-\epsilon|z_2|} \\ & \mp (\Phi_\lambda(r_1, z_2, z_1)e^{i\eta(\lambda)r_2} + \Phi_\lambda(r_1, -z_2, z_1)e^{-i\eta(\lambda)r_2})e^{-\epsilon|r_2|} \end{aligned} \quad (1.5)$$

for some $\epsilon > 0$. Here and throughout the paper we use the convention that upper signs correspond to Dirichlet and lower signs to Neumann boundary conditions, unless stated otherwise. The function (1.5) is the natural generalization of the trial state for a half-space used in [9]. Note that ψ_λ^ϵ is the (anti)symmetrization of $\Phi_\lambda(r, z_1)e^{i\eta(\lambda)z_2 - \epsilon|z_2|}$ and satisfies the boundary conditions. The trial state vanishes if $\eta = 0$ and Φ_λ is odd under $r_2 \rightarrow -r_2$; our proof will implicitly show that at weak coupling Φ_λ must be even if $\eta = 0$. We shall prove the following two Lemmas in Sections 4 and 5, respectively.

Lemma 1.8. *Let $\mu > 0$, let V satisfy Assumption 1.2 and let $0 < \lambda \leq \lambda_0$. Then*

$$\lim_{\epsilon \rightarrow 0} \langle \psi_\lambda^\epsilon, UH_{T_c^1(\lambda)}^{\Omega_2} U^\dagger \psi_\lambda^\epsilon \rangle = \lambda(L_1 + L_2) \quad (1.6)$$

with

$$\begin{aligned} L_1 = & \int_{\tilde{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) \left(|\Phi_\lambda(r_1, r_2, z_1)|^2 + |\Phi_\lambda(r_1, z_2, z_1)|^2 \right. \\ & + \overline{\Phi_\lambda(r_1, r_2, z_1)} \Phi_\lambda(r_1, -r_2, z_1) e^{-2i\eta(\lambda)z_2} + \overline{\Phi_\lambda(r_1, z_2, z_1)} \Phi_\lambda(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \\ & \mp \overline{\Phi_\lambda(r_1, r_2, z_1)} \Phi_\lambda(r_1, z_2, z_1) e^{i\eta(\lambda)(r_2 - z_2)} \mp \overline{\Phi_\lambda(r_1, z_2, z_1)} \Phi_\lambda(r_1, r_2, z_1) e^{-i\eta(\lambda)(r_2 - z_2)} \\ & \left. \mp \overline{\Phi_\lambda(r_1, r_2, z_1)} \Phi_\lambda(r_1, -z_2, z_1) e^{-i\eta(\lambda)(r_2 + z_2)} \mp \overline{\Phi_\lambda(r_1, z_2, z_1)} \Phi_\lambda(r_1, -r_2, z_1) e^{i\eta(\lambda)(-r_2 + z_2)} \right) dr dz \end{aligned} \quad (1.7)$$

and

$$\begin{aligned}
L_2 = & - \int_{\tilde{\Omega}_1 \times \mathbb{R}} V(r) \left(|\Phi_\lambda(r_1, z_2, z_1)|^2 + \overline{\Phi_\lambda(r_1, z_2, z_1)} \Phi_\lambda(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) dr dz \\
\mp 2\pi \int_{\mathbb{R}^2} & \left(\overline{\widehat{\Phi}_\lambda(p_1, \eta(\lambda), q_1)} V \widehat{\chi_{\tilde{\Omega}_1} \Phi_\lambda(p_1, \eta(\lambda), q_1)} + \overline{\widehat{\Phi}_\lambda(p_1, -\eta(\lambda), q_1)} V \widehat{\chi_{\tilde{\Omega}_1} \Phi_\lambda(p_1, -\eta(\lambda), q_1)} \right) dp_1 dq_1,
\end{aligned} \tag{1.8}$$

where $\widehat{\psi}(p, q_1) = \int_{\mathbb{R}^3} \frac{e^{-ip \cdot r - iq_1 z_1}}{(2\pi)^{3/2}} \psi(r, z_1) dr dz_1$ denotes the Fourier transform and $\chi_{\tilde{\Omega}_1}$ denotes multiplication by the characteristic function of $\tilde{\Omega}_1$.

Lemma 1.9. *Let $\mu > 0$ and let V satisfy Assumption 1.2. As $\lambda \rightarrow 0$ we have $L_1 = O(1)$ and $L_2 \leq -\frac{C}{\lambda}$ for some constant $C > 0$.*

In particular, there is a $\lambda_1 > 0$ such that for all $0 < \lambda \leq \lambda_1$, $\lim_{\epsilon \rightarrow 0} \langle \psi_\lambda^\epsilon, U H_{T_c^1(\lambda)}^{\Omega_2} U^\dagger \psi_\lambda^\epsilon \rangle < 0$ and hence also $\inf \sigma(H_{T_c^1(\lambda)}^{\Omega_2}) < 0$. The final ingredient is the continuity of $\inf \sigma(H_T^{\Omega_2})$ in T , which can be proved analogously to [9, Lemma 4.1]. For $\lambda \leq \lambda_1$ we have for $T < T_c^1(\lambda)$ by Lemma 1.1 and the definition of T_c^1 that $\inf \sigma(H_T^{\Omega_2}) \leq \inf \sigma(H_T^{\Omega_1}) < 0$. We saw that $\inf \sigma(H_{T_c^1(\lambda)}^{\Omega_2}) < 0$ and thus by continuity there is an $\epsilon > 0$ such that for all $T \in (0, T_c^1(\lambda) + \epsilon]$ we have $\inf \sigma(H_T^{\Omega_2}) < 0$. In particular, $T_c^2(\lambda) > T_c^1(\lambda)$. This concludes the proof of Theorem 1.4.

Remark 1.10. Compared to the proof of $T_c^1(\lambda) > T_c^0(\lambda)$ in [9] there are two main differences and additional difficulties here. The first difference is that Φ_λ here depends on r and z_1 , and not just r . In particular, we need to understand the dependence and regularity of Φ_λ in z_1 . The second difference is that for the full space minimizer it was possible to prove that the optimal momentum in the translation invariant center of mass direction is zero, whereas here we have to work with the momentum $\eta(\lambda)$, which potentially is non-zero, and we need knowledge about its asymptotics for $\lambda \rightarrow 0$. As a consequence, we may have that $\Phi_\lambda(r_1, r_2, z_1) e^{i\eta(\lambda)z_2} \neq \Phi_\lambda(r_1, -r_2, z_1) e^{-i\eta(\lambda)z_2}$, which is why the expressions in Lemma 1.8 are twice as long as in the analogous ones in [9, Lemma 4.3].

Remark 1.11. The Assumptions 1.2 are almost identical to the assumptions for proving $T_c^1(\lambda) > T_c^0(\lambda)$ in dimension two in [9]. Here we additionally assume $V \geq 0$ because to compute the asymptotics of Φ_λ we apply [9, Theorem 1.7] and several Lemmas used in the proof thereof, which require $V \geq 0$. However, we do not expect this assumption to be necessary.

Remark 1.12. We expect that our method of proof can also be applied in the three-dimensional case. For a quarter space in $d = 3$, we conjecture that similarly to the case of a half-space [9], the three-dimensional analogues of L_1 and L_2 in Lemma 1.8 are of equal order and converge to some finite numbers as $\lambda \rightarrow 0$. The limits of L_1 and L_2 then need to be computed to determine whether $\lim_{\lambda \rightarrow 0} (L_1 + L_2) < 0$. In [9], the ground state on the full space could effectively be replaced by $\Phi_0 = (\int_{\mathbb{R}^3} V(r) j_3(r)^2 dr)^{-1} j_3$, with $j_3(r) = (2\pi)^{-3/2} \int_{\mathbb{S}^2} e^{i\sqrt{\mu} w \cdot r} d\omega$, in the limit $\lambda \rightarrow 0$. Motivated by the asymptotics of the half-space minimizer Φ_λ in two dimensions proved in Lemma 3.2, we expect that as $\lambda \rightarrow 0$, $\eta(\lambda) \rightarrow 0$ and the function Φ_λ behaves like Φ_0 in the r -variable, and concentrates at zero momentum in the z_1 direction. A combination of the methods used in [9] and the methods developed in this paper should then allow to compute the limit, and the expected result is

$$\lim_{\lambda \rightarrow 0} L_1 = 2 \int_{\mathbb{R}^4} \chi_{|z_2| < |r_2|} V(r) |\Phi_0(r) \mp \Phi_0(r_1, z_2, r_3)|^2 dr dz_2 \tag{1.9}$$

and

$$\lim_{\lambda \rightarrow 0} L_2 = -2 \int_{\mathbb{R}^4} V(r) |\Phi_0(r_1, z_2, r_3)|^2 dr dz_2 \mp \frac{2\pi}{\mu^{1/2}} \int_{\mathbb{R}^3} V(r) |\Phi_0(r)|^2 dr. \tag{1.10}$$

We therefore expect $T_c^2(\lambda) > T_c^1(\lambda)$ at weak enough coupling if V satisfies $\lim_{\lambda \rightarrow 0}(L_1 + L_2) < 0$, which due to radially of V and Φ_0 is the same condition as for $T_c^1(\lambda) > T_c^0(\lambda)$ in [9, Theorem 1.3]. In [9, Theorem 1.4 and Remark 1.5] this condition on V is further analyzed.

2 Basic properties of $H_T^{\Omega_1}$ and $H_T^{\Omega_2}$

In this section we shall introduce some notation that will be useful later on, and prove Lemmas 1.1, 1.6 and 1.7. The following functions will be important:

$$K_T(p, q) = \frac{p^2 + q^2 - 2\mu}{\tanh\left(\frac{p^2 - \mu}{2T}\right) + \tanh\left(\frac{q^2 - \mu}{2T}\right)}, \quad \text{and} \quad B_T(p, q) = \frac{1}{K_T(p + q, p - q)}. \quad (2.1)$$

We may write $B_{T, \mu}$ when the dependence on μ matters. The function K_T satisfies the following bounds [5, Lemma 2.1].

Lemma 2.1. *For every $T > 0$ there are constants $C_1(T, \mu), C_2(T, \mu) > 0$ such that $C_1(1 + p^2 + q^2) \leq K_T(p, q) \leq C_2(1 + p^2 + q^2)$.*

We will frequently use the following estimates for B_T [9, Eq. (2.3)]:

$$B_T(p, q) \leq \frac{1}{\max\{|p^2 + q^2 - \mu|, 2T\}} \quad \text{and} \quad B_T(p, q)\chi_{p^2 + q^2 > 2\mu > 0} \leq \frac{C(\mu)}{1 + p^2 + q^2}, \quad (2.2)$$

where $C(\mu)$ depends only on μ .

We use the notation $H_0^1(\Omega)$ for the Sobolev space of functions vanishing at the boundary of Ω . In the case of Dirichlet boundary conditions, the form domain corresponding to $H_T^{\Omega_k}$ is $D_k^D := \{\psi \in H_0^1(\Omega_k \times \Omega_k) | \psi(x, y) = \psi(y, x)\}$. For Neumann boundary conditions, one needs to replace the Sobolev space H_0^1 by H^1 to obtain D_k^N . Let K_T^Ω be the kinetic term in H_T^Ω . The corresponding quadratic form acts as

$$\langle \psi, K_T^\Omega \psi \rangle = \int_{\mathbb{R}^4} K_T(p, q) \left| \int_{\Omega^2} T_\Omega(x, p) T_\Omega(y, q) \psi(x, y) dx dy \right|^2 dp dq, \quad (2.3)$$

with

$$T_{\Omega_1}(x, p) = \frac{(e^{-ip_1 x_1} \mp e^{ip_1 x_1}) e^{-ip_2 x_2}}{2^{1/2} 2\pi}, \quad \text{and} \quad T_{\Omega_2}(x, p) = \frac{(e^{-ip_1 x_1} \mp e^{ip_1 x_1})(e^{-ip_2 x_2} \mp e^{ip_2 x_2})}{4\pi}. \quad (2.4)$$

As already mentioned in the Introduction, we shall use the convention that upper signs correspond to Dirichlet and lower signs to Neumann boundary conditions, unless stated otherwise. For the switch to relative and center of mass coordinates, it is convenient to define

$$t(p, q_1, r, z_1) = \frac{1}{2} \left(e^{-i(p_1 r_1 + q_1 z_1)} + e^{i(p_1 r_1 + q_1 z_1)} \mp e^{-i(p_1 z_1 + q_1 r_1)} \mp e^{i(p_1 z_1 + q_1 r_1)} \right) e^{-ip_2 r_2}. \quad (2.5)$$

Note that with $r = x - y$, $z = x + y$, $p' = (p - q)/2$ and $q' = (p + q)/2$ we have

$$T_{\Omega_1}(x, p) T_{\Omega_1}(y, p) = \frac{1}{(2\pi)^2} t(p', q', r, z_1) e^{-iq'_2 z_2} \quad (2.6)$$

and therefore

$$\langle \psi, UK_T^{\Omega_1} U^\dagger \psi \rangle = \int_{\mathbb{R}^4} B_T(p', q')^{-1} \left| \int_{\hat{\Omega}_1 \times \mathbb{R}} \frac{1}{(2\pi)^2} t(p', q', r, z_1) e^{-iq'_2 z_2} \psi(r, z) dr dz \right|^2 dp' dq'. \quad (2.7)$$

The operators $H_T^1(q_2)$ defined by restricting $UH_T^{\Omega_1}U^\dagger$ to momentum q_2 in z_2 -direction can thus be expressed as

$$\langle \psi, H_T^1(q_2)\psi \rangle = \langle \psi, K_T^1(q_2)\psi \rangle - \lambda \int_{\tilde{\Omega}_1} V(r)|\psi(r, z_1)|^2 dr dz_1 \quad (2.8)$$

where the kinetic term $K_T^1(q_2)$ on $L_s^2(\tilde{\Omega}_1)$ is given by

$$\langle \psi, K_T^1(q_2)\psi \rangle = \int_{\mathbb{R}^3} B_T(p, (q_1, q_2))^{-1} \left| \int_{\tilde{\Omega}_1} \frac{1}{(2\pi)^{3/2}} t(p, q_1, r, z_1) \psi(r, z_1) dr dz_1 \right|^2 dp dq_1. \quad (2.9)$$

It is convenient to introduce the Birman-Schwinger operators A_T^0 and A_T^1 corresponding to $H_T^{\Omega_0}$ and $H_T^{\Omega_1}$, respectively. Let A_T^0 be the operator with domain $L^2(\mathbb{R}^2 \times \mathbb{R}^2)$ restricted to functions satisfying $\psi(r, z) = \psi(-r, z)$ and given by

$$\langle \psi, A_T^0 \psi \rangle = \int_{\mathbb{R}^4} B_T(p, q) |\widehat{V^{1/2}\psi}(p, q)|^2 dp dq. \quad (2.10)$$

Define the operator A_T^1 on $\psi \in L_s^2(\tilde{\Omega}_1 \times \mathbb{R}) = \{\psi \in L^2(\tilde{\Omega}_1 \times \mathbb{R}) | \psi(r, z) = \psi(-r, z)\}$ via

$$\langle \psi, A_T^1 \psi \rangle = \int_{\mathbb{R}^4} B_T(p, q) \left| \int_{\tilde{\Omega}_1 \times \mathbb{R}} \frac{1}{(2\pi)^2} t(p, q_1, r, z_1) e^{-iq_2 z_2} V^{1/2}(r) \psi(r, z) dr dz \right|^2 dp dq. \quad (2.11)$$

For $j \in \{0, 1\}$, the operator A_T^j is the Birman-Schwinger operator corresponding to $H_T^{\Omega_j}$ in relative and center of mass variables [9, Section 6]. The Birman-Schwinger principle implies that $\text{sgn inf } \sigma(H_T^{\Omega_j}) = \text{sgn}(1/\lambda - \sup \sigma(A_T^j))$, where we use the convention that $\text{sgn } 0 = 0$.

Due to translation invariance in z_2 , for fixed momentum q_2 in this direction, we obtain the operators $A_T^1(q_2)$ on $\psi \in L_s^2(\tilde{\Omega}_1)$ given by

$$\langle \psi, A_T^1(q_2)\psi \rangle = \int_{\mathbb{R}^3} B_T(p, (q_1, q_2)) \left| \int_{\tilde{\Omega}_1} \frac{1}{(2\pi)^{3/2}} t(p, q_1, r, z_1) V^{1/2}(r) \psi(r, z_1) dr dz_1 \right|^2 dp dq_1. \quad (2.12)$$

The operator $A_T^1(q_2)$ is the Birman-Schwinger version of $H_T^1(q_2)$. In particular, $H_{T_c^1(\lambda)}^1(\eta(\lambda))$ has the eigenvalue zero at the bottom of its spectrum if and only if $1/\lambda$ is the largest eigenvalue of $A_{T_c^1(\lambda)}^1(\eta(\lambda))$.

Let $\iota : L^2(\tilde{\Omega}_1) \rightarrow L^2(\mathbb{R}^3)$ be the isometry

$$\iota \psi(r_1, r_2, z_1) = \frac{1}{\sqrt{2}} (\psi(r_1, r_2, z_1) \chi_{\tilde{\Omega}_1}(r, z_1) + \psi(-r_1, r_2, -z_1) \chi_{\tilde{\Omega}_1}(-r_1, r_2, -z_1)). \quad (2.13)$$

Using the definition of t in (2.5) and evenness of V in r_2 one can rewrite (2.12) as

$$\langle \psi, A_T^1(q_2)\psi \rangle = \int_{\mathbb{R}^3} B_T(p, q) \left| \frac{1}{\sqrt{2}} (\widehat{V^{1/2}\iota\psi}(p, q_1) \mp \widehat{V^{1/2}\iota\psi}((q_1, p_2), p_1)) \right|^2 dp dq_1 \quad (2.14)$$

Let F_2 denote the Fourier transform in the second variable $F_2\psi(r, q_1) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-iq_1 z_1} \psi(r, z_1) dz_1$ and F_1 the Fourier transform in the first variable $F_1\psi(p, q) = \frac{1}{2\pi} \int_{\mathbb{R}^2} e^{-ip \cdot r} \psi(r, q) dr$. Define the operators $G_T(q_2)$ on $L^2(\mathbb{R}^3)$ through

$$\langle \psi, G_T(q_2)\psi \rangle = \int_{\mathbb{R}^3} \overline{F_1 V^{1/2}\psi((q_1, p_2), p_1)} B_T(p, q) F_1 V^{1/2}\psi(p, q_1) dp dq_1. \quad (2.15)$$

Let $A_T^0(q_2)$ acting on $L_s^2(\mathbb{R}^2 \times \mathbb{R})$ be given by $\langle \psi, A_T^0(q_2)\psi \rangle = \int_{\mathbb{R}^3} B_T(p, q) |\widehat{V^{1/2}\psi}(p, q_1)|^2 dp dq_1$. It follows from (2.14) and $B_T(p, q) = B_T((q_1, p_2), (p_1, q_2))$ that

$$A_T^1(q_2) = \iota^\dagger (A_T^0(q_2) \mp F_2^\dagger G_T(q_2) F_2) \iota. \quad (2.16)$$

2.1 Proof of Lemma 1.1

Proof of Lemma 1.1. We proceed analogously to the proof of [9, Lemma 2.3]. Let S_l be the shift by l in the second component, i.e. $S_l\psi(x, y) = \psi((x_1, x_2 - l), (y_1, y_2 - l))$. Let ψ be a function in $D_1^{D/N}$ with bounded support, for the case of Dirichlet/Neumann boundary conditions, respectively. For l big enough, $S_l\psi$ is supported on $\Omega_2 \times \Omega_2$ and satisfies the boundary conditions. The goal is to prove that $\lim_{l \rightarrow \infty} \langle S_l\psi, H_T^{\Omega_2} S_l\psi \rangle = \langle \psi, H_T^{\Omega_1} \psi \rangle$. Then, since functions with bounded support are dense in $D_1^{D/N}$ (with respect to the Sobolev norm), the claim follows.

Note that $\langle S_l\psi, V S_l\psi \rangle = \langle \psi, V \psi \rangle$. Let $\tilde{\psi}$ be the (anti-)symmetric continuation of ψ from $\Omega_1 \times \Omega_1$ to $\mathbb{R}^2 \times \mathbb{R}^2$ as in Figure 1, giving $\tilde{\psi} \in H^1(\mathbb{R}^4)$. Furthermore, using symmetry of K_T in p_2 and q_2 one obtains

$$\begin{aligned} \langle S_l\psi, K_T^{\Omega_2} S_l\psi \rangle &= \frac{1}{4} \int_{\mathbb{R}^4} \overline{\tilde{\psi}(p, q)} K_T(p, q) \left[\widehat{\tilde{\psi}}(p, q) \mp \widehat{\tilde{\psi}}((p_1, -p_2), q) e^{i2lp_2} \mp \widehat{\tilde{\psi}}(p, (q_1, -q_2)) e^{i2lq_2} \right. \\ &\quad \left. + \widehat{\tilde{\psi}}((p_1, -p_2), (q_1, -q_2)) e^{i2l(p_2+q_2)} \right] dpdq \end{aligned} \quad (2.17)$$

for l big enough such that $S_l\psi$ is supported on $\Omega_2 \times \Omega_2$. The first term is exactly $\langle \psi, K_T^{\Omega_1} \psi \rangle$. Note that by the Schwarz inequality and Lemma 2.1, the function

$$(p, q) \mapsto \overline{\widehat{\tilde{\psi}}(p, q)} K_T(p, q) \widehat{\tilde{\psi}}((p_1, -p_2), q) \quad (2.18)$$

is in $L^1(\mathbb{R}^{2d})$ since $\tilde{\psi} \in H^1(\mathbb{R}^4)$. By the Riemann-Lebesgue Lemma, the second term in (2.17) vanishes for $l \rightarrow \infty$. By the same argument, also the remaining terms vanish in the limit. \square

2.2 Proof of Lemma 1.6

Proof of Lemma 1.6. For continuity, it suffices to prove that for all $T > 0$ and $\mu, Q_0, Q_1 \in \mathbb{R}$ there is a constant $C(T, \mu, Q_0, Q_1)$ such that for all $Q_0 < q_2, q'_2 < Q_1$ we have $|B_T(p, q)^{-1} - B_T(p, (q_1, q'_2))^{-1}| \leq C(T, \mu, Q_0, Q_1) |q_2 - q'_2| (1 + p^2 + q_1^2)$. The claim then follows analogously to the proof of [9, Lemma 4.1].

We write $B_T(p, q)^{-1} - B_T(p, (q_1, q'_2))^{-1} = (q'_2 - q_2) f(p, q, q'_2 - q_2) B_T^{-1}(p, (q_1, q'_2)) B_T^{-1}(p, q)$, where f is defined as in the following Lemma.

Lemma 2.2. *Let $T, \mu, Q_1 > 0$ and define the function $f : \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R} \rightarrow \mathbb{R}$ through*

$$f(p, q, x) = \frac{1}{x} (B_T(p, (q_1, q_2 + x)) - B_T(p, q)) \quad (2.19)$$

for $x \neq 0$ and $f(p, q, 0) = \partial_{q_2} B_T(p, q)$. Then f is continuous and for $|q_2| < Q_1$ there is a constant C depending only on T, μ and Q_1 such that

$$|f(p, q, x)| \leq \frac{C}{1 + p_1^2 + p_2^2 + q_1^2}. \quad (2.20)$$

The proof is provided in Section 7.1. Together with Lemma 2.1 the desired bound on $|B_T(p, q)^{-1} - B_T(p, (q_1, q'_2))^{-1}|$ follows.

The function $q_2 \rightarrow \inf \sigma(H_T^1(q_2))$ is even since by (2.8), (2.9) and radially of V we have $\langle \psi, H_T^1(-q_2)\psi \rangle = \langle \tilde{\psi}, H_T^1(q_2)\tilde{\psi} \rangle$, where $\tilde{\psi}(r, z_1) = \psi((r_1, -r_2), z_1)$. The divergence of $\inf \sigma(H_T^1(q_2))$ as $|q_2| \rightarrow \infty$ follows from (2.9) and (2.2). \square

2.3 Proof of Lemma 1.7

Proof of Lemma 1.7. According to (2.16), the half-space Birman-Schwinger operator $A_T^1(q_2)$ for $q_2 \in \mathbb{R}$ can be decomposed into a term involving $A_T^0(q_2)$ and a perturbation involving $G_T(q_2)$.

The operator $A_T^0(q_2)$ has purely essential spectrum and $a_T^0 := \sup \sigma(A_T^0) = \sup \sigma(A_T^0(0))$ [9, Lemma 2.4]. Below we shall prove that $G_T(q_2)$ is compact. The part of the spectrum of A_T^1 that lies above a_T^0 hence consists of eigenvalues.

Since $\sup \sigma(A_T^0)$ is strictly decreasing in T and $T_c^1(\lambda) > T_c^0(\lambda)$, $\sup \sigma(A_{T_c^1(\lambda)}^1(\eta(\lambda))) = \lambda^{-1} > a_{T_c^1(\lambda)}^0$. Hence λ^{-1} is an eigenvalue of $A_{T_c^1(\lambda)}^1(\eta(\lambda))$ and by the Birman-Schwinger principle $H_{T_c^1(\lambda)}^1(\eta(\lambda))$ has an eigenvalue at the bottom of the spectrum.

To prove compactness of $G_T(q_2)$ defined in (2.15), we prove that its Hilbert-Schmidt norm is finite. Writing out the Hilbert-Schmidt norm in terms of the integral kernel of $G_T(q_2)$ and carrying out the integrations over relative and center of mass coordinates, one obtains

$$\|G_T(q_2)\|_{\text{HS}}^2 = \int_{\mathbb{R}^4} |\widehat{V}(0, p_2 - p'_2)|^2 B_T(p, q) B_T((p_1, p'_2), q) dp_1 dq_1 dp_2 dp'_2. \quad (2.21)$$

By (2.2) and Young's inequality, this is bounded above by

$$C(T, \mu) \left(\int_{\mathbb{R}} |\widehat{V}(0, |p_2|)|^{2r} dp_2 \right)^{1/r} \int_{\mathbb{R}} \left(\int_{\mathbb{R}} \left(\frac{1}{1 + p_1^2 + q_1^2 + p_2^2} \right)^s dp_2 \right)^{2/s} dp_1 dq_1 \quad (2.22)$$

where $2 = 1/r + 2/s$. By assumption $V \in L^1 \cap L^t$ for some $t > 1$. Note that \widehat{V} is continuous by Riemann-Lebesgue and $\widehat{V} \in L^{t'} \cap L^\infty$ for some $t' < \infty$ by the Hausdorff-Young inequality. In particular, due to the radially of V , we can bound $\left(\int_{\mathbb{R}} |\widehat{V}(0, |p_2|)|^{2r} \right)^{1/r} \leq \|V\|_\infty^2 + \frac{1}{2\pi} \|\widehat{V}\|_{2r}^2$, which is finite for the choice $r = t'/2$. With this choice, we have $s > 1$. Note that $\left(\int_{\mathbb{R}} \left(\frac{1}{1 + p_1^2 + q_1^2 + p_2^2} \right)^s dp_2 \right)^{2/s} = \frac{C}{(1 + p_1^2 + q_1^2)^{2-1/s}}$ for some constant C . Hence the integral over p_1, q_1 in (2.22) is finite for $s > 1$. \square

3 Regularity and asymptotic behavior of the half-space ground state

In this section we prove some regularity and convergence results for Φ_λ (defined in Section 1.1), which we shall use later to prove Lemmas 1.8 and 1.9. The asymptotics of $T_c^0(\lambda)$ and $T_c^1(\lambda)$ for $\lambda \rightarrow 0$ are known:

Remark 3.1. It follows from [7, Theorem 2.5] that $|\lambda^{-1} - e_\mu \ln \frac{\mu}{T_c^0(\lambda)}| = O(1)$ for $\lambda \rightarrow 0$. Furthermore, [9, Theorem 1.7] implies that $\ln \frac{\mu}{T_c^0(\lambda)} - \ln \frac{\mu}{T_c^1(\lambda)} = o(1)$ for $\lambda \rightarrow 0$. Therefore, $|\lambda^{-1} - e_\mu \ln \frac{\mu}{T_c^1(\lambda)}| = O(1)$ as well. In particular, both $T_c^0(\lambda)$ and $T_c^1(\lambda) \rightarrow 0$ as $\lambda \rightarrow 0$ exponentially fast.

Let $\Psi_\lambda(r, z_1) := \frac{1}{\sqrt{2}} V^{1/2}(r) \Phi_\lambda(r, z_1) \chi_{|r_1| < |z_1|}$ as function on \mathbb{R}^3 . Note that $\|\Psi_\lambda\|_2 = 1$ due to the symmetry under $(r_1, z_1) \rightarrow -(r_1, z_1)$ and the normalization $\|V^{1/2} \chi_{\widehat{\Omega}_1} \Phi_\lambda\|_2 = 1$. The first convergence result describes the asymptotic behavior of $\eta(\lambda)$ and Ψ_λ as $\lambda \rightarrow 0$. According to the Birman-Schwinger principle, $\chi_{\widehat{\Omega}_1} \Psi_\lambda$ is an eigenvector of $A_{T_c^1(\lambda)}^1(\eta(\lambda))$ corresponding to the largest eigenvalue.

Let

$$j_2(r) := \frac{1}{2\pi} \int_{\mathbb{S}^1} e^{i\omega \cdot r \sqrt{\mu}} d\omega. \quad (3.1)$$

Due to assumptions 1.2(ii) and (v), the eigenvector corresponding to the largest eigenvalue e_μ of O_μ has angular momentum zero and is given by [9]

$$\psi^0(r) = \frac{V^{1/2}(r) j_2(r)}{\left(\int_{\mathbb{R}^2} V(r') j_2(r')^2 dr' \right)^{1/2}}. \quad (3.2)$$

Let $\mathbb{P} : L^2(\mathbb{R}^3) \rightarrow L^2(\mathbb{R}^3)$ denote the projection onto ψ^0 in the r -variable, i.e. $\mathbb{P}\psi(r, q_1) = \psi^0(r) \int_{\mathbb{R}^2} \psi^0(r') \psi(r', q_1) dr'$. For $0 \leq \beta < 1$ let \mathbb{Q}_β denote the projection onto small momenta in q_1 , i.e. $\mathbb{Q}_\beta \psi(r, q_1) = \psi(r, q_1) \chi_{\frac{|q_1|}{\sqrt{\mu}} < \left(\frac{T_c^1(\lambda)}{\mu}\right)^\beta}$. Let $\mathbb{P}^\perp = \mathbb{I} - \mathbb{P}$ and $\mathbb{Q}_\beta^\perp = 1 - \mathbb{Q}_\beta$.

Our first convergence result is that for $\lambda \rightarrow 0$ the minimizer of $H_{T_c^1(\lambda)}^{\Omega_1}$ concentrates at momentum zero in the center of mass variable. More precisely, $\eta(\lambda) \rightarrow 0$ and Ψ_λ concentrates at momentum zero in z_1 direction and approaches ψ^0 in the r -variables. This is made precise in the following Lemma, whose proof can be found in Section 3.1.

Lemma 3.2. *Let $\mu > 0$, V satisfy Assumption 1.2 and let $0 \leq \beta < 1$. For $\lambda \rightarrow 0$ we have*

- (i) $\eta(\lambda) = O(T_c^1(\lambda))$
- (ii) $\|\mathbb{P}^\perp F_2 \Psi_\lambda\|_2^2 = O(\lambda)$
- (iii) $\|\mathbb{Q}_\beta^\perp F_2 \Psi_\lambda\|_2^2 = O(\lambda)$

For the following regularity and convergence results we need to introduce some more notation. For a function f depending on two variables we define the mixed Lebesgue norm $\|f\|_{L_i^p L_j^q}$ for $\{i, j\} = \{1, 2\}$, as first taking the L^q -norm in the j -th variable and then taking the L^p -norm in the i -th variable. The following estimate is analogous to [9, Lemma 3.7] and follows from the Cauchy-Schwarz inequality.

Lemma 3.3. *Let $V \in L^1(\mathbb{R}^2)$ and $\psi \in L^2(\mathbb{R}^2 \times \mathbb{R})$. Then*

$$\begin{aligned} \|\widehat{V^{1/2}\psi}\|_{L_1^\infty L_2^2} &\leq \sup_p \left(\int_{\mathbb{R}} |\widehat{V^{1/2}\psi}(p, q_1)|^2 dq_1 \right)^{1/2} \\ &\leq \|\widehat{V^{1/2}\psi}\|_{L_2^2 L_1^\infty} = \left(\int_{\mathbb{R}} \sup_p |\widehat{V^{1/2}\psi}(p, q_1)|^2 dq_1 \right)^{1/2} \leq \frac{\|V\|_1^{1/2}}{2\pi} \|\psi\|_2. \end{aligned} \quad (3.3)$$

To simplify notation, we shall sometimes write T_c^1, η instead of $T_c^1(\lambda), \eta(\lambda)$. The eigenvalue equation $\chi_{\tilde{\Omega}_1} \Phi_\lambda = \lambda (K_{T_c^1(\lambda)}^1(\eta(\lambda))^{-1} V \chi_{\tilde{\Omega}_1} \Phi_\lambda$ combined with

$$\frac{1}{(2\pi)^{3/2}} \int_{\tilde{\Omega}_1} t(p, q_1, r, z_1) \Phi_\lambda(r, z_1) dr dz_1 = \frac{1}{2} \widehat{\Phi}_\lambda(p, q_1) \quad (3.4)$$

gives

$$\widehat{\Phi}_\lambda(p, q_1) = \frac{2\lambda}{(2\pi)^{3/2}} \int_{\tilde{\Omega}_1} B_{T_c^1(\lambda)}(p, (q_1, \eta(\lambda))) t(p, q_1, r', z'_1) V(r') \Phi_\lambda(r', z'_1) dr' dz'_1 \quad (3.5)$$

for $(p, q_1) \in \mathbb{R}^3$. We use (3.5) together with (2.5) and the definition of Ψ_λ to split Φ_λ into the sum $\Phi_\lambda^d \mp \Phi_\lambda^{ex}$, where

$$\Phi_\lambda^d(r, z_1) = \sqrt{2}\lambda \int_{\mathbb{R}^3} \frac{e^{i(p \cdot r + q_1 z_1)}}{(2\pi)^{3/2}} B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\Psi}_\lambda(p, q_1) dp dq_1 \quad (3.6)$$

and

$$\Phi_\lambda^{ex}(r, z_1) = \sqrt{2}\lambda \int_{\mathbb{R}^3} \frac{e^{i(p \cdot r + q_1 z_1)}}{(2\pi)^{3/2}} B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\Psi}_\lambda((q_1, p_2), p_1) dp dq_1. \quad (3.7)$$

For $j \in \{d, ex\}$ we further split $\Phi_\lambda^j = \Phi_\lambda^{j, <} + \Phi_\lambda^{j, >}$, where $\Phi_\lambda^{j, \#}$ for $\# \in \{<, >\}$ has the characteristic function $\chi_{p^2 + q_1^2 \# 2\mu}$ in the integrand. Furthermore, let $\Phi^\# = \Phi^{d, \#} \mp \Phi^{ex, \#}$.

The following three Lemmas contain regularity properties for Φ_λ , which are later used for dominated convergence arguments in the proof of Lemma 1.8. Furthermore, they also contain information about the weak coupling behavior of the different $\Phi_\lambda^{j, \#}$, which is important for the proof of Lemma 1.9. The first Lemma is useful to prove that L_1 is of order $O(1)$.

Lemma 3.4. *Let $\mu > 0$, let V satisfy Assumption 1.2 and let $0 < \lambda \leq \lambda_0$. Then $\|\Phi_\lambda\|_{L_1^\infty L_2^2} < \infty$. Furthermore, $\|\Phi_\lambda^d\|_{L_1^\infty L_2^2} = O(1)$ and $\|\Phi_\lambda^{ex, >}\|_{L_1^\infty L_2^2} = O(\lambda)$ as $\lambda \rightarrow 0$.*

To understand the asymptotics of L_2 the following result comes in handy.

Lemma 3.5. *Let $\mu > 0$, let V satisfy Assumption 1.2 and let $0 < \lambda \leq \lambda_0$. The function $(r, z) \mapsto V^{1/2}(r)|\Phi_\lambda(r_1, z_2, z_1)|$ is in $L^2(\mathbb{R}^4)$. Furthermore, as $\lambda \rightarrow 0$, the $L^2(\mathbb{R}^4)$ -norms of the functions $V^{1/2}(r)|\Phi_\lambda^>(r_1, z_2, z_1)|$, $V^{1/2}(r)|\Phi_\lambda^{d, <}(r_1, z_2, z_1)|$ and $V^{1/2}(r)|\Phi_\lambda^{ex, <}(r_1, z_2, z_1)|$ are of order $O(\lambda)$, $O(\lambda^{-1/2})$, and $O(\lambda^{1/2})$, respectively.*

This suggests that the only possible origin for divergence in L_2 lies in contributions from $V^{1/2}(r)|\Phi_\lambda^{d, <}(r_1, z_2, z_1)|$. In the proof of Lemma 1.9 we shall show that the L^2 norm of this term indeed grows as $\lambda^{-1/2}$, resulting in the $1/\lambda$ divergence of L_2 . Furthermore, we need the following for the proof of Lemma 1.8.

Lemma 3.6. *Let $\mu > 0$, let V satisfy Assumption 1.2 and let $0 < \lambda \leq \lambda_0$. Define the functions g_0 , g_+ and g_- on \mathbb{R}^2 as*

$$g_0(p_2, q_2) := \int_{\mathbb{R}^2} \overline{\widehat{\Phi}_\lambda(p, q_1)} V \widehat{\chi_{\tilde{\Omega}_1}} \widehat{\Phi}_\lambda(p_1, q_2, q_1) dp_1 dq_1 \quad (3.8)$$

and

$$g_\pm(p_2, q_2) := \int_{\mathbb{R}^2} \overline{\widehat{\Phi}_\lambda(p, q_1)} \left[B_{T_c}^{-1}(p, q) - B_{T_c}^{-1}(p, (q_1, \eta)) \right] \widehat{\Phi}_\lambda((p_1, \pm q_2), q_1) dp_1 dq_1. \quad (3.9)$$

The functions g_0 and g_\pm are continuous and bounded and $g_\pm(p_2, \eta) = 0$ for all $p_2 \in \mathbb{R}$.

The proofs of these three Lemmas are given in Sections 3.2 – 3.4.

3.1 Proof of Lemma 3.2

Proof of Lemma 3.2. Recall the operators A_T^0 , and A_T^1 from Section 2 and let $a_T^j = \sup \sigma(A_T^j)$. It follows from Lemma 1.1 and the Birman-Schwinger principle that $a_T^0 \leq a_T^1$ (for details see the proof of [9, Theorem 1.7]). According to [7, Lemma 3.4] for $T \rightarrow 0$ the asymptotic behavior of a_T^0 is given by $a_T^0 = e_\mu \ln(\mu/T) + O(1)$. Recall the decomposition of $A_T^1(q_2)$ in (2.16). The operator norm of $G_T(q_2)$ is bounded uniformly in T and q_2 according to [9, Lemma 6.1]. Recall that $\sqrt{2}\chi_{\tilde{\Omega}_1}\Psi_\lambda$ is a normalized eigenvector of $A_{T_c}^1(\lambda)(\eta(\lambda))$ and note that $\iota\sqrt{2}\chi_{\tilde{\Omega}_1}\Psi_\lambda = \Psi_\lambda$, where ι was defined in (2.13). With Remark 3.1, we have for $\lambda \rightarrow 0$

$$e_\mu \ln \mu/T_c^1(\lambda) + O(1) = a_{T_c^1}^0(\lambda) \leq a_{T_c^1}^1(\lambda) = \langle \Psi_\lambda, A_{T_c^1}^0(\lambda)(\eta(\lambda))\Psi_\lambda \rangle + O(1) \quad (3.10)$$

For $q \in \mathbb{R}^2$ let $B_T(\cdot, q)$ denote the operator on $L^2(\mathbb{R}^2)$ which acts as multiplication by $B_T(p, q)$ (defined in (2.1)) in momentum space. Note that

$$\langle \Psi_\lambda, A_{T_c^1}^0(\lambda)(\eta(\lambda))\Psi_\lambda \rangle = \int_{\mathbb{R}} \langle F_2\Psi_\lambda(\cdot, q_1), V^{1/2}B_{T_c^1}(\lambda)(\cdot, (q_1, \eta(\lambda)))V^{1/2}F_2\Psi_\lambda(\cdot, q_1) \rangle dq_1 \quad (3.11)$$

According to [9, Lemma 6.8], there is a constant $C(\mu, V)$, such that for all $q \in \mathbb{R}^2$ and $\psi \in L_s^2(\mathbb{R}^2)$ with $\|\psi\|_2 = 1$

$$\langle \psi, V^{1/2}B_T(\cdot, q)V^{1/2}\psi \rangle \leq \langle \psi, O_\mu\psi \rangle \ln \left(\min \left\{ \frac{\sqrt{\mu}}{|q|}, \frac{\mu}{T} \right\} \right) \chi_{2 < \min\{\mu/T, \sqrt{\mu}/|q|\}} + C(\mu, V). \quad (3.12)$$

In combination, we have for $\lambda \rightarrow 0$

$$e_\mu \ln \mu/T_c^1(\lambda) \leq \int_{|q_1| < \sqrt{\mu}/2} \langle F_2\Psi_\lambda(\cdot, q_1), O_\mu F_2\Psi_\lambda(\cdot, q_1) \rangle \ln \left(\min \left\{ \frac{\sqrt{\mu}}{\sqrt{q_1^2 + \eta(\lambda)^2}}, \frac{\mu}{T_c^1(\lambda)} \right\} \right) dq_1 + O(1) \quad (3.13)$$

We will use this to prove the three parts of the claim.

(i) By definition of e_μ , we can bound $\langle F_2\Psi_\lambda(\cdot, q_1), O_\mu F_2\Psi_\lambda(\cdot, q_1) \rangle \leq e_\mu \|F_2\Psi_\lambda(\cdot, q_1)\|_2^2$. Moreover, clearly $\ln\left(\min\left\{\frac{\sqrt{\mu}}{\sqrt{q_1^2 + \eta(\lambda)^2}}, \frac{\mu}{T_c^1(\lambda)}\right\}\right) \leq \ln(\sqrt{\mu}/\eta(\lambda))$. By (3.13) and since $\|F_2\Psi_\lambda\|_2 = 1$, there is a constant c such that $e_\mu \ln(\mu/T_c^1(\lambda)) \leq e_\mu \ln(\sqrt{\mu}/\eta(\lambda)) + c$ for small λ . In particular, $|\eta(T)| \leq \frac{\exp(c/e_\mu)}{\sqrt{\mu}} T_c^1(\lambda)$, i.e. $\eta(\lambda) = O(T_c^1(\lambda))$.

(ii) Denote the ratio of the second highest and the highest eigenvalue of O_μ by α , where $\alpha < 1$ by Assumption 1.2(v). Then

$$\begin{aligned} \int_{\mathbb{R}} \langle F_2\Psi_\lambda(\cdot, q_1), O_\mu F_2\Psi_\lambda(\cdot, q_1) \rangle dq_1 &\leq e_\mu (\|\mathbb{P}F_2\Psi_\lambda\|^2 + \alpha\|\mathbb{P}^\perp F_2\Psi_\lambda\|^2) \\ &= e_\mu (\|F_2\Psi_\lambda\|^2 - (1-\alpha)\|\mathbb{P}^\perp F_2\Psi_\lambda\|^2) \end{aligned} \quad (3.14)$$

Therefore, by (3.13)

$$\ln \mu/T_c^1(\lambda) \leq (1 - (1 - \alpha)\|\mathbb{P}^\perp F_2\Psi_\lambda\|^2) \ln \mu/T_c^1(\lambda) + O(1) \quad (3.15)$$

for $\lambda \rightarrow 0$. This means that $\|\mathbb{P}^\perp F_2\Psi_\lambda\|^2 = O(1/\ln \mu/T_c^1(\lambda))$. According to Remark 3.1, $\lim_{\lambda \rightarrow 0} \lambda \ln \mu/T_c^1(\lambda) = e_\mu^{-1}$ and thus $\|\mathbb{P}^\perp F_2\Psi_\lambda\|^2 = O(\lambda)$.

(iii) Let $\epsilon(\lambda) = \|\mathbb{Q}_\beta^\perp F_2\Psi_\lambda\|^2 = \int_{\mathbb{R}^3} |F_2\Psi_\lambda(r, q_1)|^2 \chi_{|q_1| > \sqrt{\mu} \left(\frac{T_c^1(\lambda)}{\mu}\right)^\beta} dr dq_1$. By (3.13), we have for small λ

$$e_\mu \ln \mu/T_c^1(\lambda) \leq (1 - \epsilon(\lambda))e_\mu \ln \mu/T_c^1(\lambda) + \epsilon(\lambda)e_\mu \ln \frac{\mu^\beta}{T_c^1(\lambda)^\beta} + C \quad (3.16)$$

for some constant C . Hence

$$\epsilon(\lambda) \leq \frac{C}{(1 - \beta)e_\mu \ln \mu/T_c^1(\lambda)} = O(\lambda) \quad (3.17)$$

where we used Remark 3.1 in the last step. \square

3.2 Proof of Lemma 3.4

Proof of Lemma 3.4. If we show $\|\Phi_\lambda^d\|_{L_1^\infty(\mathbb{R}^2)L_2^2(\mathbb{R})} < \infty$ and $\|\Phi_\lambda^{ex}\|_{L_1^\infty(\mathbb{R}^2)L_2^2(\mathbb{R})} < \infty$, the Schwarz inequality implies $\|\Phi_\lambda\|_{L_1^\infty(\mathbb{R}^2)L_2^2(\mathbb{R})} < \infty$.

We shall first prove that $\|\Phi_\lambda^d\|_{L_1^\infty L_2^2}$ is finite and of order $O(1)$ for $\lambda \rightarrow 0$. Using (3.6) we have

$$\begin{aligned} &\|\Phi_\lambda^d(r, \cdot)\|_2^2 \\ &= 2\lambda^2 \int_{\mathbb{R}^5} \widehat{V^{1/2}\Psi_\lambda(p', q_1)} B_{T_c^1}(p', (q_1, \eta)) \frac{e^{i(p-p')\cdot r}}{(2\pi)^2} B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\Psi_\lambda}(p, q_1) dp dp' dq_1 \\ &\leq 2\lambda^2 \sup_{q_1 \in \mathbb{R}} \sup_{\psi \in L^2(\mathbb{R}^2), \|\psi\|_2=1} \int_{\mathbb{R}^4} \widehat{V^{1/2}\psi}(p') B_{T_c^1}(p', (q_1, \eta)) \frac{e^{i(p-p')\cdot r}}{(2\pi)^2} B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\psi}(p) dp dp' \end{aligned} \quad (3.18)$$

The latter integral is the quadratic form corresponding to the projection onto the function $\phi_{q_1}(r') = \frac{1}{2\pi} F_1 B_{T_c^1}(r - r', (q_1, \eta)) V^{1/2}(r')$. Hence, taking the supremum over ψ , (3.18) equals

$$2\lambda^2 \sup_{q_1 \in \mathbb{R}} \|\phi_{q_1}\|_2^2 = 2\lambda^2 \sup_{q_1 \in \mathbb{R}} \int_{\mathbb{R}^4} \frac{e^{i(p-p')\cdot r}}{(2\pi)^3} B_{T_c^1}(p, (q_1, \eta)) \widehat{V}(p-p') B_{T_c^1}(p', (q_1, \eta)) dp dp'. \quad (3.19)$$

We split the integration into $p^2 > 2\mu, p^2 < 2\mu$ and $p'^2 > 2\mu, p'^2 < 2\mu$. Using (2.2) leads to the bound

$$\begin{aligned} \|\Phi_\lambda^d(r, \cdot)\|_2^2 &\leq \frac{2\lambda^2}{(2\pi)^3} \left[\|\widehat{V}\|_\infty \sup_{q_1} \left(\int_{\mathbb{R}^2} B_{T_c^1}(p, (q_1, \eta)) \chi_{p^2 < 2\mu} dp \right)^2 \right. \\ &\quad + 2 \sup_{q_1} \int_{\mathbb{R}^4} B_{T_c^1}(p, (q_1, \eta)) \chi_{p^2 < 2\mu} |\widehat{V}(p-p')| \frac{C}{1+p'^2} dp dp' \\ &\quad \left. + \int_{\mathbb{R}^4} \frac{C}{1+p^2} |\widehat{V}(p-p')| \frac{C}{1+p'^2} dp dp' \right] \quad (3.20) \end{aligned}$$

for a constant C independent of λ . We start by considering the first term in the square bracket. Note that $\|\widehat{V}\|_\infty < \frac{\|V\|_1}{2\pi} < \infty$. For fixed $T > 0$, the function $B_T(p, q)$ is bounded, hence the term is finite for fixed λ . For $T \rightarrow 0$ we have $\sup_{q \in \mathbb{R}^2} \int_{\mathbb{R}^2} B_T(p, q) \chi_{p^2 < 2\mu} dp = O(\ln \mu/T)$. To see this, we first apply the inequality [5, (6.1)]

$$B_T(p, q) \leq \frac{1}{2} (B_T(p+q, 0) + B_T(p-q, 0)). \quad (3.21)$$

This gives the upper bound $\sup_{q \in \mathbb{R}^2} \int_{\mathbb{R}^2} B_T(p, 0) \chi_{(p-q)^2 < 2\mu} dp$. The vector q shifts the disk-shaped domain of integration, but does not change its size. In particular, the contribution with $p^2 < 2\mu$ is bounded above by $\int_{\mathbb{R}^2} B_T(p, 0) \chi_{p^2 < 2\mu} dp = O(\ln \mu/T)$ [7, Proposition 3.1] while the contribution with $p^2 > 2\mu$ is uniformly bounded in T since by (2.2) the integrand is uniformly bounded. Since for $\lambda \rightarrow 0$ we have $\ln \mu/T_c^1(\lambda) = O(1/\lambda)$ by Remark 3.1, the first term in the square bracket in (3.20) is of order $1/\lambda^2$ as $\lambda \rightarrow 0$. For the second term in the square bracket we use Hölder's inequality in p' . Since $V \in L^t$ for some $t > 0$, by the Hausdorff-Young inequality we have $\widehat{V} \in L^{t'}$ where $1 = 1/t' + 1/t$. Hence, the second term is bounded by

$$2 \sup_{q_1} \int_{\mathbb{R}^4} B_{T_c^1}(p, (q_1, \eta)) \chi_{p^2 < 2\mu} dp \|\widehat{V}\|_{t'} \left\| \frac{C}{1+|\cdot|^2} \right\|_{L^t(\mathbb{R}^2)}, \quad (3.22)$$

which is finite for fixed λ and of order $O(1/\lambda)$ for $\lambda \rightarrow 0$. Using Young's inequality, one sees that the third term in the square bracket is bounded. Taking into account the factor λ^2 in front of the square bracket, we conclude that $\|\Phi_\lambda^d(r, \cdot)\|_2^2 = O(1)$ uniformly in r .

We shall now show that for fixed λ , $\|\Phi_\lambda^{ex}\|_{L_1^\infty L_2^2} < \infty$ and $\|\Phi_\lambda^{ex, >}\|_{L_1^\infty L_2^2} = O(\lambda)$ as $\lambda \rightarrow 0$. We have

$$\begin{aligned} \|\Phi_\lambda^{ex}(r, \cdot)\|_2^2 &= 2\lambda^2 \int_{\mathbb{R}^{2d+1}} \overline{\widehat{V^{1/2}\Psi_\lambda((q_1, p'_2), p'_1)} B_{T_c^1}(p', (q_1, \eta))} \frac{e^{i(p-p') \cdot r}}{(2\pi)^d} B_{T_c^1}(p, (q_1, \eta)) \\ &\quad \times \widehat{V^{1/2}\Psi_\lambda((q_1, p_2), p_1)} dp dp' dq_1 \quad (3.23) \end{aligned}$$

Similarly, we get an expression for $\|\Phi_\lambda^{ex, >}(r, \cdot)\|_2^2$ if we multiply the above integrand by the characteristic functions $\chi_{p^2+q_1^2 > 2\mu} \chi_{p'^2+q_1^2 > 2\mu}$. Using (2.2), we bound $\|\Phi_\lambda^{ex}\|_{L_1^\infty L_2^2}^2$ and $\|\Phi_\lambda^{ex, >}\|_{L_1^\infty L_2^2}^2$ above by

$$C\lambda^2 \int_{\mathbb{R}^{2d+1}} |\widehat{V^{1/2}\Psi_\lambda((q_1, p'_2), p'_1)}| \frac{1}{1+p'^2+q_1^2} \frac{1}{1+p^2+q_1^2} |\widehat{V^{1/2}\Psi_\lambda((q_1, p_2), p_1)}| dp dp' dq_1 \quad (3.24)$$

where the constant C depends on μ and λ for the bound on $\|\Phi_\lambda^{ex}\|_{L_1^\infty L_2^2}^2$, but is independent of λ for the bound on $\|\Phi_\lambda^{ex, >}\|_{L_1^\infty L_2^2}^2$. Using the Schwarz inequality in p_1 and p'_1 and then Lemma 3.3 we get the upper bound

$$\begin{aligned} C\lambda^2 \|\widehat{V^{1/2}\Psi_\lambda}\|_{L_1^\infty L_2^2}^2 \int_{\mathbb{R}^{2d+1}} \left(\int_{\mathbb{R}} \frac{1}{(1+p'^2+q_1^2)^2} dp'_1 \right)^{1/2} \left(\int_{\mathbb{R}} \frac{1}{(1+p^2+q_1^2)^2} dp_1 \right)^{1/2} dp_2 dp'_2 dq_1 \\ \leq \tilde{C}\lambda^2 \|V\|_1 \|\Psi_\lambda\|_2^2 \quad (3.25) \end{aligned}$$

Therefore, $\|\Phi_\lambda^{ex}\|_{L_1^\infty L_2^2}$ is finite and $\|\Phi_\lambda^{ex, >}\|_{L_1^\infty L_2^2} = O(\lambda)$. \square

3.3 Proof of Lemma 3.5

Proof of Lemma 3.5. By the Schwarz inequality, it suffices to prove that for $j \in \{d, ex\}$ and $\# \in \{<, >\}$ the integrals $\int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{j,\#}(r_1, z_2, z_1)|^2 dr dz$ are finite for all $\lambda_0 \geq \lambda > 0$ and that as $\lambda \rightarrow 0$ we have $\int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{j,>}(r_1, z_2, z_1)|^2 dr dz = O(\lambda^2)$ for $j \in \{d, ex\}$, $\int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{d,<}(r_1, z_2, z_1)|^2 dr dz = O(\lambda^{-1})$ and $\int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{ex,<}(r_1, z_2, z_1)|^2 dr dz = O(\lambda)$.

Using the definitions (see (3.6) and (3.7)) one can rewrite for $\# \in \{<, >\}$

$$\begin{aligned} \int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{d,\#}(r_1, z_2, z_1)|^2 dr dz &= 2\lambda^2 \int_{\mathbb{R}^4} \widehat{V}(p_1 - p'_1, 0) B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \overline{\widehat{V^{1/2}\Psi_\lambda(p'_1, p_2, q_1)}} \\ &\quad \times B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\Psi_\lambda}(p, q_1) \chi_{p^2+q_1^2 \# 2\mu} \chi_{p_1'^2+p_2^2+q_1^2 \# 2\mu} dp_1 dp'_1 dp_2 dq_1 \end{aligned} \quad (3.26)$$

and

$$\begin{aligned} \int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{ex,\#}(r_1, z_2, z_1)|^2 dr dz &= 2\lambda^2 \int_{\mathbb{R}^4} \widehat{V}(p_1 - p'_1, 0) B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \overline{\widehat{V^{1/2}\Psi_\lambda(q_1, p_2, p'_1)}} \\ &\quad \times B_{T_c^1}(p, (q_1, \eta)) \widehat{V^{1/2}\Psi_\lambda}(q_1, p_2, p_1) \chi_{p^2+q_1^2 \# 2\mu} \chi_{p_1'^2+p_2^2+q_1^2 \# 2\mu} dp_1 dp'_1 dp_2 dq_1. \end{aligned} \quad (3.27)$$

For $\Phi_\lambda^{d,>}$, with the aid of (2.2) and Lemma 3.3 the expression is bounded by

$$\begin{aligned} C\lambda^2 \|V\|_1 \int_{\mathbb{R}^4} \frac{1}{1+p_1'^2+p_2^2} \frac{1}{1+p_1^2+p_2^2} \|\widehat{V^{1/2}\Psi_\lambda}(\cdot, q_1)\|_\infty^2 dq_1 dp'_1 dp_1 dp_2 \\ \leq \tilde{C}\lambda^2 \|V\|_1^2 \|\Psi_\lambda\|_2^2 < \infty \end{aligned} \quad (3.28)$$

where the constants C, \tilde{C} depend only on μ . For $\Phi_\lambda^{ex,>}$ we use (2.2) and the Schwarz inequality in p_1 and p'_1 to bound (3.27) by

$$C\lambda^2 \|V\|_1 \int_{\mathbb{R}^2} \left\| \frac{1}{1+|\cdot|^2+p_2^2+q_1^2} \right\|_{L^2(\mathbb{R})}^2 dp_2 dq_1 \|\widehat{V^{1/2}\Psi_\lambda}\|_{L_p^\infty L_q^2}^2 \leq \tilde{C}\lambda^2 \|V\|_1^2 \|\Psi_\lambda\|_2^2 \quad (3.29)$$

where we used Lemma 3.3 in the second step. Again, the constants C, \tilde{C} depend only on μ .

For $\Phi_\lambda^{d,<}$ we bound (3.26) above by

$$\begin{aligned} \frac{\|V\|_1}{\pi} \lambda^2 \int_{\mathbb{R}^4} B_{T_c^1}(p, (q_1, \eta)) B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \|\widehat{V^{1/2}\Psi_\lambda}(\cdot, q_1)\|_\infty^2 \chi_{p^2+q_1^2 < 2\mu} \chi_{p_1'^2+p_2^2+q_1^2 < 2\mu} dp dp'_1 dq_1 \\ \leq \frac{\|V\|_1^2}{4\pi^3} \lambda^2 \sup_{q_1 \in \mathbb{R}} \int_{\mathbb{R}^3} B_{T_c^1}(p, (q_1, \eta)) B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \chi_{p^2+q_1^2 < 2\mu} \chi_{p_1'^2+p_2^2+q_1^2 < 2\mu} dp dp'_1 \end{aligned} \quad (3.30)$$

where we used Lemma 3.3 and $\|\Psi_\lambda\|_2 = 1$ in the second step. For fixed λ this is finite because $B_{T_c^1}$ is a bounded function. For $\lambda \rightarrow 0$ the following Lemma together with Remark 3.1 imply that this is of order $O(\lambda^{-1})$.

Lemma 3.7. *Let $\mu, C > 0$. For $T \rightarrow 0$ we have*

$$\sup_{q, q' \in \mathbb{R}^2} \int_{\mathbb{R}^3} B_T(p, q) B_T((p'_1, p_2), q') dp_1 dp'_1 dp_2 = O(\ln \mu / T)^3. \quad (3.31)$$

Furthermore, for every $0 < \delta_1 < \mu$ there is a $\delta_2 > 0$ such that for $T \rightarrow 0$

$$\begin{aligned} \sup_{|q|, |q'| < \delta_2} \int_{\mathbb{R}^3} (1 - \chi_{\mu - \delta_1 < p_2^2 < \mu + \delta_1} \chi_{p_1^2 < 4\delta_1} \chi_{p_1'^2 < 4\delta_1}) B_T(p, q) B_T((p'_1, p_2), q') dp_1 dp'_1 dp_2 \\ = O(\ln \mu / T)^{5/2}. \end{aligned} \quad (3.32)$$

The second part of this Lemma will be used in the proof of Lemma 1.9 to compute the asymptotics of L_2 . The proof of Lemma 3.7 can be found in Section 7.2.

For $\Phi_\lambda^{ex, <}$ we bound (3.27) above using Lemma 3.3 and $\|\Psi_\lambda\|_2 = 1$, which gives

$$\frac{\lambda^2}{2\pi^2} \|V\|_1^2 \|B_{T_c^1}^{ex, 2}(\eta)\| \quad (3.33)$$

where $B_T^{ex, 2}(\xi)$ is the operator acting on $L^2(-\sqrt{2\mu}, \sqrt{2\mu})$ with integral kernel

$$B_T^{ex, 2}(\xi)(p'_1, p_1) = \int_{\mathbb{R}^2} B_T((p'_1, p_2), (q_1, \xi)) B_T(p, (q_1, \xi)) \chi_{q_1^2 + p_2^2 < 2\mu} dq_1 dp_2. \quad (3.34)$$

The superscript 2 indicates that there are two factors of B_T , as opposed to B_T^{ex} which is defined later in (5.7). The following Lemma together with Remark 3.1 and Lemma 3.2(i) implies that (3.33) is bounded for fixed λ and of order $O(\lambda)$ for $\lambda \rightarrow 0$.

Lemma 3.8. *Let $c, \mu > 0$. Then $\sup_{|\xi| < cT} \|B_T^{ex, 2}(\xi)\|$ is finite for all $T > 0$ and of order $O(\ln \mu/T)$ as $T \rightarrow 0$.*

The proof of Lemma 3.8 is given in Section 7.3. □

3.4 Proof of Lemma 3.6

Proof of Lemma 3.6. For functions ψ on \mathbb{R}^3 let $S\psi(p_1, p_2, q_1) = \psi(p, q_1) + \psi(-p_1, p_2, -q_1) \mp \psi(q_1, p_2, p_1) \mp \psi(-q_1, p_2, -p_1)$. For $p, q \in \mathbb{R}^2$ let

$$L^0(p, q) := \lambda B_{T_c^1}(p, (q_1, \eta)), \quad (3.35)$$

$$L^\pm(p, q) := \lambda^2 B_{T_c^1}(p, (q_1, \eta)) \left[B_{T_c^1}^{-1}(p, q) - B_{T_c^1}^{-1}(p, (q_1, \eta)) \right] B_{T_c^1}((p_1, \pm q_2), (q_1, \eta)) \quad (3.36)$$

Using (3.5) we have

$$g_0(p_2, q_2) = \int_{\mathbb{R}^2} \overline{SV\widehat{\chi_{\Omega_1}}\Phi_\lambda(p, q_1)} L^0(p, q) V\widehat{\chi_{\Omega_1}}\Phi_\lambda(p_1, q_2, q_1) dp_1 dq_1 \quad (3.37)$$

and

$$g_\pm(p_2, q_2) = \int_{\mathbb{R}^2} \overline{SV\widehat{\chi_{\Omega_1}}\Phi_\lambda(p, q_1)} L^\pm(p, q) SV\widehat{\chi_{\Omega_1}}\Phi_\lambda(p_1, \pm q_2, q_1) dp_1 dq_1. \quad (3.38)$$

Note that $g_\pm(p_2, \eta) = 0$ since $L^\pm(p, (q_1, \eta)) = 0$. For measurable functions ψ_1, ψ_2 on \mathbb{R}^3 and $p_2, q_2 \in \mathbb{R}$ we obtain using the Schwarz inequality in q_1

$$\begin{aligned} \int_{\mathbb{R}^2} |\psi_1(p_1, p_2, q_1)| \frac{1}{1+p_1^2} |\psi_2(p_1, q_2, q_1)| dp_1 dq_1 \\ \leq \int_{\mathbb{R}} \frac{1}{1+p_1^2} dp_1 \sup_{p \in \mathbb{R}^2} \|\psi_1(p, \cdot)\|_{L^2(\mathbb{R})} \sup_{p \in \mathbb{R}^2} \|\psi_2(p, \cdot)\|_{L^2(\mathbb{R})} \end{aligned} \quad (3.39)$$

and using the Schwarz inequality in q_1, p_1

$$\begin{aligned} \int_{\mathbb{R}^2} |\psi_1(p_1, p_2, q_1)| \frac{1}{1+p_1^2+q_1^2} |\psi_2(q_1, q_2, p_1)| dp_1 dq_1 \\ \leq \int_{\mathbb{R}} \frac{1}{1+p_1^2} dp_1 \sup_{p \in \mathbb{R}^2} \|\psi_1(p, \cdot)\|_{L^2(\mathbb{R})} \sup_{p \in \mathbb{R}^2} \|\psi_2(p, \cdot)\|_{L^2(\mathbb{R})}. \end{aligned} \quad (3.40)$$

By (2.2) there is a constant C independent of p, q (but dependent on λ) such that $L^0(p, q) \leq \frac{C}{1+p_1^2+q_1^2}$. Similarly, by (2.2) and Lemma 2.1 there is a constant C independent of p, q but dependent on λ such that

$$L^\pm(p, q) \leq \frac{C(1+p^2+q^2)}{(1+p^2+q_1^2)(1+p_1^2+q^2)} \leq \frac{2C}{1+p_1^2+q_1^2} \quad (3.41)$$

It follows from (3.39) and (3.40) that there is a constant C such that for all measurable functions ψ_1, ψ_2 on \mathbb{R}^3 and $p_2, p'_2, q_2, q'_2 \in \mathbb{R}$

$$\left| \int_{\mathbb{R}^2} \overline{S\psi_1(p, q_1)} L^0(p_1, p'_2, q_1, q'_2) \psi_2(p_1, q_2, q_1) dp_1 dq_1 \right| \leq C \sup_{p \in \mathbb{R}^2} \|\psi_1(p, \cdot)\|_{L^2(\mathbb{R})} \sup_{p \in \mathbb{R}^2} \|\psi_2(p, \cdot)\|_{L^2(\mathbb{R})}, \quad (3.42)$$

and similarly

$$\left| \int_{\mathbb{R}^2} \overline{S\psi_1(p, q_1)} L^\pm(p_1, p'_2, q_1, q'_2) S\psi_2(p_1, \pm q_2, q_1) dp_1 dq_1 \right| \leq C \sup_{p \in \mathbb{R}^2} \|\psi_1(p, \cdot)\|_{L^2(\mathbb{R})} \sup_{p \in \mathbb{R}^2} \|\psi_2(p, \cdot)\|_{L^2(\mathbb{R})}. \quad (3.43)$$

In particular it follows from (3.37) and (3.38) with Lemma 3.3 and the normalization $\|V^{1/2}\chi_{\tilde{\Omega}_1}\Phi_\lambda\|_2 = 1$ that g_0 and g_\pm are bounded.

To prove continuity, first note that

$$\widehat{V\chi_{\tilde{\Omega}_1}\Phi_\lambda}(p_1, p_2 + \epsilon, q_1) - \widehat{V\chi_{\tilde{\Omega}_1}\Phi_\lambda}(p, q_1) = \widehat{W_\epsilon\chi_{\tilde{\Omega}_1}\Phi_\lambda}(p, q_1) \quad (3.44)$$

where $W_\epsilon(r) = V(r)(e^{-i\epsilon r} - 1)$. We only spell out the proof for g_\pm , the argument for g_0 is analogous. For all $p_2, q_2 \in \mathbb{R}$ we have

$$\begin{aligned} & g_\pm(p_2 + \epsilon, q_2 + \epsilon') - g_\pm(p_2, q_2) \\ &= \int_{\mathbb{R}^2} \overline{SV\chi_{\tilde{\Omega}_1}\Phi_\lambda(p_1, p_2 + \epsilon, q_1)} L^\pm(p_1, p_2 + \epsilon, q_1, q_2 + \epsilon') SW_\epsilon\chi_{\tilde{\Omega}_1}\Phi_\lambda(p_1, \pm q_2, q_1) dp_1 dq_1 \\ & \quad + \int_{\mathbb{R}^2} \overline{SW_\epsilon\chi_{\tilde{\Omega}_1}\Phi_\lambda(p, q_1)} L^\pm(p_1, p_2 + \epsilon, q_1, q_2 + \epsilon') SV\chi_{\tilde{\Omega}_1}\Phi_\lambda(p_1, \pm q_2, q_1) dp_1 dq_1 \\ & \quad + \int_{\mathbb{R}^2} \overline{SV\chi_{\tilde{\Omega}_1}\Phi_\lambda(p, q_1)} (L^\pm(p_1, p_2 + \epsilon, q_1, q_2 + \epsilon') - L^\pm(p, q_1, q_2, q_2)) SV\chi_{\tilde{\Omega}_1}\Phi_\lambda(p_1, \pm q_2, q_1) dp_1 dq_1 \end{aligned} \quad (3.45)$$

Using (3.41) it follows by dominated convergence that the last line vanishes as $\epsilon, \epsilon' \rightarrow 0$. Furthermore, note that by Lemma 3.3

$$\|\widehat{W_\epsilon\chi_{\tilde{\Omega}_1}\Phi_\lambda}\|_{L_p^\infty L_{q_1}^2} \leq \frac{\|W_\epsilon\|_1^{1/2}}{2\pi} \|W_\epsilon^{1/2}\chi_{\tilde{\Omega}_1}\Phi_\lambda\|_2 \leq \frac{\|W_\epsilon\|_1}{2\pi} \|\Phi_\lambda\|_{L_r^\infty L_{z_1}^2} \quad (3.46)$$

where $\|\Phi_\lambda\|_{L_r^\infty L_{z_1}^2} < \infty$ by Lemma 3.4. Since $\|W_\epsilon\|_1 \leq |\epsilon| \cdot \|V\|_1$ it follows from (3.43) that the first two lines in (3.45) vanish as $\epsilon, \epsilon' \rightarrow 0$. In particular, g_\pm are continuous. \square

4 Proof of Lemma 1.8

This section contains the proof of Lemma 1.8. Recall the definition of t from (2.5) and let $\tilde{t}(p_1, q_1, r_1, z_1) = t((p_1, 0), q_1, (r_1, 0), z_1)$. Let $\tilde{\Omega}_2 = \{(r, z) \in \mathbb{R}^2 \times \mathbb{R}^2 \mid |r_1| < z_1, |r_2| < z_2\}$. Analogously to (2.7) we have

$$\begin{aligned} \langle \psi_\lambda^\epsilon, UH_T^{\Omega_2} U^\dagger \psi_\lambda^\epsilon \rangle &= \int_{\mathbb{R}^4} B_T(p, q)^{-1} \left| \int_{\tilde{\Omega}_2} \frac{1}{(2\pi)^2} \tilde{t}(p_1, q_1, r_1, z_1) \tilde{t}(p_2, q_2, r_2, z_2) \psi_\lambda^\epsilon(r, z) dr dz \right|^2 dp dq \\ & \quad - \lambda \int_{\tilde{\Omega}_2} V(r) |\psi_\lambda^\epsilon(r, z)|^2 dr dz. \end{aligned} \quad (4.1)$$

Since the function ψ_λ^ϵ defined in (1.5) is symmetric under $(r_2, z_2) \rightarrow -(r_2, z_2)$ and (anti)symmetric under $(r_2, z_2) \rightarrow (z_2, r_2)$, we have

$$\int_{|r_2| < z_2} \tilde{t}(p_2, q_2, r_2, z_2) \psi_\lambda^\epsilon(r, z) dr_2 dz_2 = \frac{1}{2} \int_{\mathbb{R}^2} e^{-ip_2 r_2 - iq_2 z_2} \psi_\lambda^\epsilon(r, z) dr_2 dz_2 \quad (4.2)$$

and

$$\int_{|r_2| < z_2} V(r) |\psi_\lambda^\epsilon(r, z)|^2 dr_2 dz_2 = \frac{1}{4} \int_{\mathbb{R}^2} (V(r) \chi_{|r_2| < |z_2|} + V(r_1, z_2) \chi_{|z_2| < |r_2|}) |\psi_\lambda^\epsilon(r, z)|^2 dr_2 dz_2. \quad (4.3)$$

Together with (2.7) we obtain $\langle \psi_\lambda^\epsilon, UH_{T_c^1}^{\Omega_2} U^\dagger \psi_\lambda^\epsilon \rangle = \frac{1}{4} \langle \psi_\lambda^\epsilon, H_{T_c^1}^2 \psi_\lambda^\epsilon \rangle$, where the operator H_T^2 is given by

$$H_T^2 = UK_T^{\Omega_1} U^\dagger - \lambda V(r) \chi_{|r_2| < |z_2|} - \lambda V(r_1, z_2) \chi_{|z_2| < |r_2|} \quad (4.4)$$

acting on $L^2(\tilde{\Omega}_1 \times \mathbb{R})$ functions symmetric in r and antisymmetric/symmetric under swapping $r_2 \leftrightarrow z_2$ for Dirichlet/Neumann boundary conditions, respectively. Let us define $K_T^2 := UK_T^{\Omega_1} U^\dagger$.

The trial state ψ_λ^ϵ has four summands, which we number from one to four in the order they appear in (1.5) and refer to as $|j\rangle$ for $j \in \{1, 2, 3, 4\}$. By symmetry under $(z_2, r_2) \rightarrow -(z_2, r_2)$ and $(r_2, z_2) \rightarrow (z_2, r_2)$ we have

$$\langle \psi_\lambda^\epsilon, H_{T_c^1}^2 \psi_\lambda^\epsilon \rangle = 4 \sum_{j=1}^4 \langle 1, H_{T_c^1}^2 j \rangle \quad (4.5)$$

For each $j \in \{1, 2, 3, 4\}$ we write

$$\langle 1, H_{T_c^1}^2 j \rangle = \langle 1, (K_{T_c^1}^2 - \lambda V(r)) j \rangle + \langle 1, (\lambda V(r) \chi_{|z_2| < |r_2|} + \lambda V(r_1, z_2) \chi_{|r_2| < |z_2|}) j \rangle - \langle 1, \lambda V(r_1, z_2) j \rangle \quad (4.6)$$

We shall prove that

$$\lim_{\epsilon \rightarrow 0} \sum_{j=1}^4 \langle 1, (K_{T_c^1}^2 - \lambda V(r)) j \rangle = 0, \quad (4.7)$$

$$L_1 = \lim_{\epsilon \rightarrow 0} \sum_{j=1}^4 \langle 1, (V(r) \chi_{|z_2| < |r_2|} + V(r_1, z_2) \chi_{|r_2| < |z_2|}) j \rangle, \quad (4.8)$$

and

$$L_2 = - \lim_{\epsilon \rightarrow 0} \sum_{j=1}^4 \langle 1, V(r_1, z_2) j \rangle. \quad (4.9)$$

In particular, it follows that $\lim_{\epsilon \rightarrow 0} \langle \psi_\lambda^\epsilon, UH_{T_c^1}^{\Omega_2} U^\dagger \psi_\lambda^\epsilon \rangle = \lambda(L_1 + L_2)$.

4.1 Proof of (4.7):

We argue that all summands vanish as $\epsilon \rightarrow 0$.

j=1: We first show that

$$\langle 1, (K_{T_c^1}^2 - \lambda V(r)) 1 \rangle = \frac{1}{2\pi} \int_{\mathbb{R}^4} \left[B_{T_c^1}^{-1}(p, (q_1, q_2 + \eta)) - B_{T_c^1}^{-1}(p, (q_1, \eta)) \right] \frac{\epsilon^2}{(\epsilon^2 + q_2^2)^2} |\widehat{\Phi}_\lambda(p, q_1)|^2 dp dq \quad (4.10)$$

Using eigenvalue equation $K_{T_c^1}^1(\eta) \chi_{\tilde{\Omega}_1} \Phi_\lambda = \lambda V \chi_{\tilde{\Omega}_1} \Phi_\lambda$ together with the expressions (2.7) and (2.9) for $K_T^{\Omega_1}$ and $K_T^1(q_2)$, respectively, we observe that

$$\begin{aligned} & \langle 1, (K_{T_c^1}^2 - \lambda V(r)) 1 \rangle \\ &= \frac{1}{(2\pi)^4} \int_{(\tilde{\Omega}_1 \times \mathbb{R})^2 \times \mathbb{R}^3} \overline{\Phi_\lambda(r, z_1)} \overline{t(p, q_1, r, z_1)} \left[\int_{\mathbb{R}} B_{T_c^1}^{-1}(p, q) e^{i(\eta - q_2)(z'_2 - z_2) - \epsilon(|z_2| + |z'_2|)} dq \right. \\ & \quad \left. - B_{T_c^1}^{-1}(p, (q_1, \eta)) e^{-2\epsilon|z_2|} 2\pi \delta(z_2 - z'_2) \right] t(p, q_1, r', z'_1) \Phi_\lambda(r', z'_1) dr dz dr' dz' dp dq_1 \quad (4.11) \end{aligned}$$

We shall carry out the r, r', z, z' integrations. With $\int_{\mathbb{R}} e^{i(\eta-q_2)z_2 - \epsilon|z_2|} dz_2 = \frac{2\epsilon}{\epsilon^2 + (\eta - q_2)^2}$, $2\pi \int_{\mathbb{R}} e^{-2\epsilon|z_2|} = 2\pi\epsilon^{-1} = \int_{\mathbb{R}} \frac{4\epsilon^2}{(\epsilon^2 + (\eta - q_2)^2)^2} dq_2$ and (3.4) we obtain

$$\langle 1, (K_{T_c^1}^2 - \lambda V(r))1 \rangle = \frac{1}{2\pi} \int_{\mathbb{R}^4} \left[B_{T_c^1}^{-1}(p, q) - B_{T_c^1}^{-1}(p, (q_1, \eta)) \right] \frac{\epsilon^2}{(\epsilon^2 + (\eta - q_2)^2)^2} |\widehat{\Phi}_\lambda(p, q_1)|^2 dpdq \quad (4.12)$$

and substituting $q_2 \rightarrow q_2 + \eta$ we arrive at (4.10).

For $|q_2| > 1$, we bound the integrand in (4.10) by $\frac{C\epsilon^2(1+p^2+q_1^2)}{q_2^2} |\widehat{\Phi}_\lambda(p, q_1)|^2$ using Lemma 2.1. Since $\widehat{\Phi}_\lambda \in H^1(\mathbb{R}^3)$, the integral vanishes as $\epsilon \rightarrow 0$. For $|q_2| < 1$ substitute $q_2 \rightarrow \epsilon q_2$ and use that $q_2^{-1}(B_{T_c^1}^{-1}(p, (q_1, q_2 + \eta)) - B_{T_c^1}^{-1}(p, (q_1, \eta))) = -f(p, (q_1, \eta), q_2) B_{T_c^1}^{-1}(p, (q_1, q_2 + \eta)) B_{T_c^1}^{-1}(p, (q_1, \eta))$ where f is defined as in Lemma 2.2. The integral then equals

$$-\frac{1}{2\pi} \int_{\mathbb{R}^4} \chi_{|q_2| < \epsilon^{-1}} f(p, (q_1, \eta), \epsilon q_2) B_{T_c^1}^{-1}(p, (q_1, \epsilon q_2 + \eta)) B_{T_c^1}^{-1}(p, (q_1, \eta)) \frac{q_2}{(1 + q_2^2)^2} |\widehat{\Phi}_\lambda(p, q_1)|^2 dpdq. \quad (4.13)$$

By Lemma 2.2 and Lemma 2.1 the integrand is bounded above by the integrable function

$$C(1 + p^2 + q_1^2) \frac{|q_2|}{(1 + q_2^2)^2} |\widehat{\Phi}_\lambda(p, q_1)|^2. \quad (4.14)$$

Thus by dominated convergence, continuity of f and B_T and since $\int_{\mathbb{R}} \frac{q_2}{(1+q_2^2)^2} dq_2 = 0$ we have $\lim_{\epsilon \rightarrow 0} \langle 1, K_{T_c^1}^2 - \lambda V(r)1 \rangle = 0$.

j=2: We distinguish the cases $\eta(\lambda) = 0$ and $\eta(\lambda) \neq 0$. If $\eta(\lambda) = 0$, $\widehat{\Phi}_\lambda(r, z_1)$ is either even or odd in r_2 . The term for $j = 2$ hence agrees with the term for $j = 1$ or its negative and hence vanishes in the limit. For $\eta(\lambda) \neq 0$, the intuition is that integration over z_2, z_2' approximately gives a product of delta functions $\delta(q_2 - \eta)\delta(q_2 + \eta) = 0$. Using (3.4) and $t(p, q_1, (r_1, -r_2), z_1) = t((p_1, -p_2), q_1, r, z_1)$ we have

$$\begin{aligned} \langle 1, (K_{T_c^1}^2 - \lambda V(r))2 \rangle &= \frac{1}{8\pi} \int_{\mathbb{R}^6} \overline{\widehat{\Phi}_\lambda(p, q_1)} B_{T_c^1}^{-1}(p, q) e^{-i(\eta-q_2)z_2 - i(\eta+q_2)z_2' - \epsilon(|z_2| + |z_2'|)} \widehat{\Phi}_\lambda((p_1, -p_2), q_1) dz_2 dz_2' dpdq \\ &\quad - \int_{\widehat{\Omega}_1 \times \mathbb{R}} \overline{\widehat{\Phi}_\lambda(r, z_1)} \lambda V(r) \widehat{\Phi}_\lambda(r_1, -r_2, z_1) e^{-2i\eta z_2 - 2\epsilon|z_2|} dr dz \quad (4.15) \end{aligned}$$

Carrying out the z_2 and z_2' integrations gives

$$\begin{aligned} \langle 1, (K_{T_c^1}^2 - \lambda V(r))2 \rangle &= \frac{1}{2\pi} \int_{\mathbb{R}^4} \overline{\widehat{\Phi}_\lambda(p, q_1)} B_{T_c^1}^{-1}(p, q) \frac{\epsilon^2}{(\epsilon^2 + (\eta - q_2)^2)(\epsilon^2 + (\eta + q_2)^2)} \widehat{\Phi}_\lambda((p_1, -p_2), q_1) dpdq \\ &\quad - \int_{\widehat{\Omega}_1} \overline{\widehat{\Phi}_\lambda(r, z_1)} \lambda V(r) \widehat{\Phi}_\lambda(r_1, -r_2, z_1) \frac{\epsilon}{\epsilon^2 + \eta^2} dr dz_1 \quad (4.16) \end{aligned}$$

Using the Schwarz inequality in the r_2 variable, we bound the absolute value of the second term by $\frac{\epsilon\lambda}{\eta^2} \int_{\widehat{\Omega}_1} V(r) |\widehat{\Phi}_\lambda(r, z_1)|^2 dr dz_1 \leq \frac{\epsilon\lambda}{\eta^2} \|V\|_1 \|\widehat{\Phi}_\lambda\|_{L_1^\infty L_2^2}^2$. According to Lemma 3.4, $\|\widehat{\Phi}_\lambda\|_{L_1^\infty L_2^2} < \infty$ and hence the term vanishes for $\epsilon \rightarrow 0$. To bound the absolute value of the first term in (4.16), we first use Lemma 2.1 and the Schwarz inequality in the p_2 variable, and then use symmetry to restrict to $q_2 > 0$ and distinguish the cases $|q_2 - \eta| \leq \epsilon$:

$$\begin{aligned} C \int_{\mathbb{R}^4} \frac{\epsilon^2(1 + p^2 + q^2)}{(\epsilon^2 + (\eta - q_2)^2)(\epsilon^2 + (\eta + q_2)^2)} |\widehat{\Phi}_\lambda(p, q_1)|^2 dpdq \\ \leq 2C \int_{\mathbb{R}^3} \left(\int_0^\infty \left[\frac{\chi_{|q_2 - \eta| < \epsilon} (1 + p^2 + q^2)}{(\eta - q_2)^2 + (\eta + q_2)^2} + \frac{\chi_{|q_2 - \eta| > \epsilon} \epsilon^2 (1 + p^2 + q^2)}{(\eta - q_2)^2 (\eta + q_2)^2} \right] dq_2 \right) |\widehat{\Phi}_\lambda(p, q_1)|^2 dpdq_1. \quad (4.17) \end{aligned}$$

There is a constant $C(\eta)$ such that the first term in the square brackets is bounded above by $C(\eta)\chi_{|q_2-\eta|<\epsilon}(1+p^2+q_1^2)$, and the second term is bounded by $C(\eta)\frac{\chi_{|q_2-\eta|>\epsilon\epsilon^2(1+p^2+q_1^2)}}{(\eta-q_2)^2}$. This gives the upper bound

$$\tilde{C}\left(\int_0^\infty\left[\chi_{|q_2-\eta|<\epsilon}+\frac{\chi_{|q_2-\eta|>\epsilon\epsilon^2}}{(\eta-q_2)^2}\right]dq_2\right)\|\Phi_\lambda\|_{H^1(\mathbb{R}^3)}^2 \quad (4.18)$$

The remaining integral is of order $O(\epsilon)$ as $\epsilon \rightarrow 0$, and thus the term vanishes in the limit $\epsilon \rightarrow 0$.

j=3,4: Using the eigenvalue equation $K_{T_c^1}^1(\lambda)\chi_{\tilde{\Omega}_1}\Phi_\lambda=\lambda V\chi_{\tilde{\Omega}_1}\Phi_\lambda$ and (3.4) we have

$$\begin{aligned} &|\langle 1, (K_{T_c^1}^2 - \lambda V(r))j \rangle| \\ &= \left| \frac{1}{8\pi} \int_{\mathbb{R}^6} \overline{\widehat{\Phi}_\lambda(p, q_1)} \left(B_{T_c^1}^{-1}(p, q) - B_{T_c^1}^{-1}(p, (q_1, \eta)) \right) e^{-i(\eta-q_2)z_2 - i(\mp\eta+p_2)r'_2 - \epsilon(|z_2|+|r'_2|)} \right. \\ &\quad \left. \times \widehat{\Phi}_\lambda((p_1, \pm q_2), q_1) dz_2 dr'_2 dp dq \right| \quad (4.19) \end{aligned}$$

where the upper signs correspond to $j=3$ and the lower ones to $j=4$, respectively. Carrying out the integration over r'_2 and z_2 and substituting $q_2 \rightarrow \epsilon q_2 + \eta, p_2 \rightarrow \epsilon p_2 \pm \eta$ we obtain

$$\begin{aligned} &|\langle 1, (K_{T_c^1}^2 - \lambda V(r))j \rangle| \\ &= \left| \frac{1}{2\pi} \int_{\mathbb{R}^4} \overline{\widehat{\Phi}_\lambda((p_1, \epsilon p_2 \pm \eta), q_1)} \frac{1}{1+p_2^2} \frac{1}{1+q_2^2} \left[B_{T_c^1}^{-1}((p_1, \epsilon p_2 \pm \eta), (q_1, \epsilon q_2 + \eta)) \right. \right. \\ &\quad \left. \left. - B_{T_c^1}^{-1}((p_1, \epsilon p_2 \pm \eta), (q_1, \eta)) \right] \widehat{\Phi}_\lambda((p_1, \pm(\epsilon q_2 + \eta)), q_1) dp dq \right| \quad (4.20) \end{aligned}$$

With the definition of g_\pm as in Lemma 3.6, the latter equals

$$\left| \frac{1}{2\pi} \int_{\mathbb{R}^2} \frac{g_\pm(\epsilon p_2 \pm \eta, \epsilon q_2 + \eta)}{(1+p_2^2)(1+q_2^2)} dp_2 dq_2 \right| \quad (4.21)$$

With Lemma 3.6 it follows by dominated convergence that $\lim_{\epsilon \rightarrow 0} \langle 1, (K_{T_c^1}^2 - \lambda V(r))j \rangle = 0$.

4.2 Proof of (4.8):

We have

$$\begin{aligned} &\sum_{j=1}^4 \langle 1, (V(r)\chi_{|z_2|<|r_2|} + V(r_1, z_2)\chi_{|r_2|<|z_2|})j \rangle = \int_{\tilde{\Omega}_1 \times \mathbb{R}} (V(r)\chi_{|z_2|<|r_2|} + V(r_1, z_2)\chi_{|r_2|<|z_2|}) \overline{\Phi_\lambda(r, z_1)} \\ &\quad \times \left(\Phi_\lambda(r, z_1)e^{-2\epsilon|z_2|} + \Phi_\lambda(r_1, -r_2, z_1)e^{-2\epsilon|z_2|-2i\eta z_2} \mp \Phi_\lambda(r_1, z_2, z_1)e^{-\epsilon(|r_2|+|z_2|)-i\eta(z_2-r_2)} \right. \\ &\quad \left. \mp \Phi_\lambda(r_1, -z_2, z_1)e^{-\epsilon(|r_2|+|z_2|)-i\eta(z_2+r_2)} \right) dr dz \quad (4.22) \end{aligned}$$

The claim follows from dominated convergence provided that

$$\begin{aligned} &\int_{\mathbb{R}^4} (V(r)\chi_{|z_2|<|r_2|} + V(r_1, z_2)\chi_{|r_2|<|z_2|}) |\Phi_\lambda(r, z_1)| \left(|\Phi_\lambda(r, z_1)| + |\Phi_\lambda(r_1, -r_2, z_1)| \right. \\ &\quad \left. + |\Phi_\lambda(r_1, z_2, z_1)| + |\Phi_\lambda(r_1, -z_2, z_1)| \right) dr dz \quad (4.23) \end{aligned}$$

is finite. Using the Schwarz inequality in z_1 and carrying out the integration over z_2 , this is bounded above by

$$4 \int_{\mathbb{R}^3} (V(r)\chi_{|z_2|<|r_2|} + V(r_1, z_2)\chi_{|r_2|<|z_2|}) \|\Phi_\lambda\|_{L_1^\infty L_2^2} dr dz_2 \leq 16 \int_{\mathbb{R}^2} V(r)|r_2| dr \|\Phi_\lambda\|_{L_1^\infty L_2^2} \quad (4.24)$$

This is finite by Lemma 3.4 and since $|\cdot|V \in L^1$ by assumption.

4.3 Proof of (4.9):

j=1,2: We have

$$\langle 1, V(r_1, z_2)1 \rangle = \int_{\tilde{\Omega}_1 \times \mathbb{R}} V(r_1, z_2) |\Phi_\lambda(r, z_1)|^2 e^{-2\epsilon|z_2|} dr dz \quad (4.25)$$

and

$$\langle 1, V(r_1, z_2)2 \rangle = \int_{\tilde{\Omega}_1 \times \mathbb{R}} V(r_1, z_2) \overline{\Phi_\lambda(r, z_1)} \Phi_\lambda(r_1, -r_2, z_1) e^{-2\epsilon|z_2| - 2i\eta z_2} dr dz \quad (4.26)$$

In both cases we can apply dominated convergence by Lemma 3.5 (and the Schwarz inequality in the second case) and obtain the first two terms in L_2 .

j=3,4: We start with the case of Neumann boundary conditions. Rewriting the expression in momentum space we have

$$\begin{aligned} \langle 1, V(r_1, z_2)j \rangle &= \int_{\mathbb{R}^4} V(r_1, z_2) \chi_{\tilde{\Omega}_1} \overline{\Phi_\lambda(r, z_1)} \Phi_\lambda(r_1, \pm z_2, z_1) e^{-\epsilon|z_2| - i\eta z_2} e^{-\epsilon|r_2| \pm i\eta r_2} dr dz \\ &= \frac{2}{\pi} \int_{\mathbb{R}^4} \overline{\widehat{\Phi}_\lambda(p, q_1)} V \widehat{\chi_{\tilde{\Omega}_1} \Phi_\lambda}(p_1, p'_2, q_1) \frac{\epsilon^2}{(\epsilon^2 + (p_2 \mp \eta)^2)(\epsilon^2 + (p'_2 \mp \eta)^2)} dp_1 dp_2 dp'_2 dq_1 \\ &= \frac{2}{\pi} \int_{\mathbb{R}^2} g_0(\epsilon p_2 \pm \eta, \epsilon p'_2 \pm \eta) \frac{1}{(1 + p_2^2)(1 + p_2'^2)} dp_2 dp_2' \end{aligned} \quad (4.27)$$

where the upper/lower signs correspond to $j = 3$ and $j = 4$, respectively, and g_0 is defined as in Lemma 3.6. It follows from Lemma 3.6, dominated convergence and $\int_{\mathbb{R}} \frac{1}{1+x^2} dx = \pi$ that

$$\lim_{\epsilon \rightarrow 0} \langle 1, V(r_1, z_2)j \rangle = 2\pi g_0(\pm\eta, \pm\eta) \quad (4.28)$$

For Dirichlet boundary conditions this comes with a minus sign.

5 Weak coupling asymptotics

In this section we shall prove Lemma 1.9. We prove the desired asymptotic bounds for L_1 and L_2 in Sections 5.1 and 5.2, respectively.

5.1 Asymptotics of L_1

The goal is to show that L_1 defined in (1.7) is of order $O(1)$ as $\lambda \rightarrow 0$. By the Schwarz inequality, it suffices to prove that $\int_{\tilde{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) (|\Phi_\lambda(r_1, r_2, z_1)|^2 + |\Phi_\lambda(r_1, z_2, z_1)|^2) dr dz = O(1)$. Furthermore, since $\Phi_\lambda = \Phi_\lambda^d \mp \Phi_\lambda^{ex, <} \mp \Phi_\lambda^{ex, >}$ (see (3.6) and (3.7) for the definitions), again by the Schwarz inequality it suffices to prove

$$\int_{\tilde{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) |\Phi_\lambda^j(r_1, r_2, z_1)|^2 dr dz = O(1) \quad (5.1)$$

and

$$\int_{\tilde{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) |\Phi_\lambda^j(r_1, z_2, z_1)|^2 dr dz = O(1) \quad (5.2)$$

for $j \in \{d, (ex, <), (ex, >)\}$.

Case $j \in \{d, (ex, >)\}$: According to Lemma 3.4, $\sup_{r \in \mathbb{R}^2} \int_{\mathbb{R}} |\Phi_\lambda^j(r, z_1)|^2 dz_1 = O(1)$. Both (5.1) and (5.2) follow since $|\cdot| V \in L^1$.

Case $j = (ex, <)$: Let $W_1(r) := 2|r_2|V(r)$ and $W_2(r) := \int_{\mathbb{R}} V(r_1, z_2) \chi_{|r_2| < |z_2|} dz_2$. We have $W_1, W_2 \in L^1(\mathbb{R}^2)$. Note that

$$\int_{\tilde{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) |\Phi_\lambda^{ex, <}(r_1, r_2, z_1)|^2 dr dz = \int_{\tilde{\Omega}_1} W_1(r) |\Phi_\lambda^{ex, <}(r_1, r_2, z_1)|^2 dr dz_1 \quad (5.3)$$

and

$$\int_{\widehat{\Omega}_1 \times \mathbb{R}} \chi_{|z_2| < |r_2|} V(r) |\Phi_\lambda^{ex, <}(r_1, z_2, z_1)|^2 dr dz = \int_{\widehat{\Omega}_1} W_2(r) |\Phi_\lambda^{ex, <}(r_1, r_2, z_1)|^2 dr dz_1, \quad (5.4)$$

where we renamed $z_2 \leftrightarrow r_2$. For any L^1 -function $W \geq 0$ we have

$$\begin{aligned} \left(\int_{\widehat{\Omega}_1} W(r) |\Phi_\lambda^{ex, <}(r_1, r_2, z_1)|^2 dr dz_1 \right)^{1/2} &= \|W^{1/2} \Phi_\lambda^{ex, <}\|_2 = \sup_{\psi \in L^2(\widehat{\Omega}_1), \|\psi\|_2=1} |\langle \psi, W^{1/2} \Phi_\lambda^{ex, <} \rangle| \\ &\leq \sqrt{2} \lambda \sup_{\psi_1, \psi_2 \in L^2(\mathbb{R}^3), \|\psi_1\| = \|\psi_2\| = 1} \int_{\mathbb{R}^3} |\widehat{W^{1/2} \psi_1}(p, q_1) B_{T_c^1}(p, (q_1, \eta)) \chi_{p_2^2 < 2\mu} \\ &\quad \times \widehat{V^{1/2} \psi_2}((q_1, p_2), p_1)| dp dq_1 \end{aligned} \quad (5.5)$$

where we used (3.7) and the normalization $\|\widehat{\Psi_\lambda}\| = 1$ in the last step. We bound $|\widehat{W^{1/2} \psi_1}(p, q_1)| \leq \|W\|_1^{1/2} \|F_2 \psi_1(\cdot, q_1)\|_2$, and similarly for $|\widehat{V^{1/2} \psi_2}(p, q_1)|$. Thus (5.5) is bounded above by

$$\sqrt{2} \lambda \|W\|_1^{1/2} \|V\|_1^{1/2} \|B_T^{ex}(\eta)\| \quad (5.6)$$

where $B_T^{ex}(q_2)$ is the operator on $L^2(\mathbb{R})$ with integral kernel

$$B_T^{ex}(q_2)(p_1, q_1) = \int_{\mathbb{R}} B_T(p, q) \chi_{p_2^2 < 2\mu} dp_2. \quad (5.7)$$

It was shown in [9, Proof of Lemma 6.1] (see Eq. (6.16) and rest of argument), that

$$\sup_T \sup_{q_2} \|B_T^{ex}(q_2)\| < \infty. \quad (5.8)$$

In particular, we conclude that $\int_{\widehat{\Omega}_1} W_k(r) |\Phi_\lambda^{ex, <}(r_1, r_2, z_1)|^2 dr dz_1 = O(\lambda^2)$ for $k \in \{1, 2\}$.

5.2 Asymptotics of L_2

The goal is to prove that L_2 defined in (1.8) diverges like $-\lambda^{-1}$ to negative infinity as $\lambda \rightarrow 0$. We shall prove that the second line in (1.8) is of order $O(1)$ as $\lambda \rightarrow 0$. For the first line in (1.8) we shall prove that it is bounded above by $-c\lambda^{-1}$ for some $c > 0$ as $\lambda \rightarrow 0$.

Second line of (1.8): Let $\xi \in \{\eta, -\eta\}$. Combining (3.8), (3.37) and the definitions of L^0 and S at the beginning of Section 3.4 we have

$$\begin{aligned} \left| \int_{\mathbb{R}^2} \widehat{\Phi_\lambda}(p_1, \xi, q_1) \widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(p_1, \xi, q_1) dp_1 dq_1 \right| &\leq \lambda \int_{\mathbb{R}^2} (|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(p_1, \xi, q_1)| + |\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(-p_1, \xi, -q_1)| \\ &\quad + |\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(q_1, \xi, p_1)|) + |\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(-q_1, \xi, -p_1)|) B_{T_c^1}((p_1, \xi), (q_1, \eta)) |\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(p_1, \xi, q_1)| dp_1 dq_1 \end{aligned} \quad (5.9)$$

Using the Schwarz inequality and $|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(p_1, \xi, q_1)| \leq \|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(\cdot, q_1)\|_\infty$ this is bounded above by

$$\begin{aligned} 4\lambda \int_{\mathbb{R}^2} B_{T_c^1}((p_1, \xi), (q_1, \eta)) \|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(\cdot, q_1)\|_\infty^2 dp_1 dq_1 \\ \leq 4\lambda \sup_{q_1 \in \mathbb{R}} \int_{\mathbb{R}} B_{T_c^1}((p_1, \xi), (q_1, \eta)) dp_1 \|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}\|_{L^2(\mathbb{R}) L^1_\infty(\mathbb{R}^2)}^2, \end{aligned} \quad (5.10)$$

where in the second step we used that $\int_{\mathbb{R}} B_{T_c^1}((p_1, \xi), (q_1, \eta)) dp_1$ acts as multiplication operator on $\|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}(\cdot, q_1)\|_\infty$. By Lemma 3.3 and since $\|V^{1/2} \chi_{\widehat{\Omega}_1} \Phi_\lambda\|_2 = 1$ we have $\|\widehat{V \chi_{\widehat{\Omega}_1} \Phi_\lambda}\|_{L^2(\mathbb{R}) L^1_\infty(\mathbb{R}^2)}^2 \leq \|V\|_1$. The following Lemma together with Remark 3.1 and Lemma 3.2(i) implies that (5.10) is of order $O(1)$.

Lemma 5.1. *Let $\xi(T), \xi'(T)$ be functions of T with $\lim_{T \rightarrow 0} \xi(T) = \lim_{T \rightarrow 0} \xi'(T) = 0$. Then as $T \rightarrow 0$,*

$$\sup_{q_1} \int_{\mathbb{R}} B_T((p_1, \xi(T)), (q_1, \xi'(T))) dp_1 = O(\ln \mu/T). \quad (5.11)$$

The proof can be found in Section 7.4.

First line of (1.8): Recall from Section 3 that $\Phi_\lambda = \Phi_\lambda^> + \Phi_\lambda^{d,<} \mp \Phi_\lambda^{ex,<}$. By Lemma 3.5 the L^2 -norms of $V^{1/2}(r)\Phi_\lambda^>(r_1, z_2, z_1)$, $V^{1/2}(r)\Phi_\lambda^{d,<}(r_1, z_2, z_1)$, and $V^{1/2}(r)\Phi_\lambda^{ex,<}(r_1, z_2, z_1)$ are of order $O(\lambda)$, $O(\lambda^{-1/2})$, and $O(\lambda^{1/2})$, respectively. It follows with the Schwarz inequality that the first line of L_2 in (1.8) equals

$$- \int_{\tilde{\Omega}_1 \times \mathbb{R}} V(r) \left(|\Phi_\lambda^{d,<}(r_1, z_2, z_1)|^2 + \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) dr dz + O(1) \quad (5.12)$$

Note that $\Phi_\lambda^{d,<}(r_1, z_2, z_1) = \Phi_\lambda^{d,<}(-r_1, z_2, -z_1)$. We rewrite the expression in (5.12) as

$$\begin{aligned} & - \frac{1}{2} \int_{\mathbb{R}^4} V(r) \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \left(\Phi_\lambda^{d,<}(r_1, z_2, z_1) + \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) \chi_{|r_1| < |z_1|} dr dz \\ & = - \frac{1}{2} \int_{\mathbb{R}^4} V(r) \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \left(\Phi_\lambda^{d,<}(r_1, z_2, z_1) + \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) dr dz \\ & + \frac{1}{2} \int_{\mathbb{R}^4} V(r) \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \left(\Phi_\lambda^{d,<}(r_1, z_2, z_1) + \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) \chi_{|z_1| < |r_1|} dr dz \quad (5.13) \end{aligned}$$

We first consider the last line in (5.13) with the restriction to $|z_1| < |r_1|$. We prove that this term is of order $O(1)$ as $\lambda \rightarrow 0$. Second, we will prove that the expression on the second line in (5.13) is bounded above by $-c\lambda^{-1}$ for some constant $c > 0$ as $\lambda \rightarrow 0$.

Asymptotics of third line in (5.13): Define $W \in L^1(\mathbb{R}^3)$ by $W(r, z_1) := V(r)\chi_{|z_1| < |r_1|}$. By the Schwarz inequality it suffices to prove that $\int_{\mathbb{R}^4} W(r, z_1) |\Phi_\lambda^{d,<}(r_1, z_2, z_1)|^2 dr dz = O(1)$ for $\lambda \rightarrow 0$. Using the definition of $\Phi_\lambda^{d,<}$ we have

$$\begin{aligned} \int_{\mathbb{R}^4} W(r, z_1) |\Phi_\lambda^{d,<}(r_1, z_2, z_1)|^2 dr dz & = \frac{2\lambda^2}{(2\pi)^{1/2}} \int_{\mathbb{R}^5} \widehat{W}((p_1 - p'_1, 0), q_1 - q'_1) B_{T_c^1}(p, (q_1, \eta)) \\ & \times \overline{V^{1/2}\Psi_\lambda(p, q_1) B_{T_c^1}((p'_1, p_2), (q'_1, \eta))} V^{1/2}\Psi_\lambda(p'_1, p_2, q'_1) \chi_{p^2+q_1^2 < 2\mu} \chi_{p_1'^2+p_2^2+q_1'^2 < 2\mu} dp dp'_1 dq_1 dq'_1 \quad (5.14) \end{aligned}$$

Using $|\widehat{W}(p, q_1)| \leq \frac{\|W\|_1}{(2\pi)^{3/2}}$ and $\|\widehat{V^{1/2}\Psi_\lambda(\cdot, q_1)}\|_\infty \leq \|V\|_1^{1/2} \|F_2\Psi_\lambda(\cdot, q_1)\|_2$ we bound this from above by

$$\begin{aligned} & \frac{\lambda^2}{2\pi^2} \|W\|_1 \|V\|_1 \int_{\mathbb{R}^5} B_{T_c^1}(p, (q_1, \eta)) B_{T_c^1}((p'_1, p_2), (q'_1, \eta)) \chi_{p^2+q_1^2 < 2\mu} \chi_{p_1'^2+p_2^2+q_1'^2 < 2\mu} \\ & \quad \times \|F_2\Psi_\lambda(\cdot, q_1)\|_2 \|F_2\Psi_\lambda(\cdot, q'_1)\|_2 dp dp'_1 dq_1 dq'_1 \\ & \leq \frac{\lambda^2}{2\pi^2} \|W\|_1 \|V\|_1 \left[\sup_{q_1, q'_1 \in \mathbb{R}} \int_{\mathbb{R}^3} B_{T_c^1}(p, (q_1, \eta)) B_{T_c^1}((p'_1, p_2), (q'_1, \eta)) \chi_{p_1'^2+q_1'^2+p_2^2 < 2\mu} \chi_{p^2+q_1^2 < 2\mu} dp dp'_1 \right] \\ & \quad \times \left(\int_{\mathbb{R}} \|F_2\Psi_\lambda(\cdot, q_1)\|_2 \chi_{q_1^2 < 2\mu} dq_1 \right)^2 \quad (5.15) \end{aligned}$$

By Lemma 3.7 and Remark 3.1, the term in the square bracket in (5.15) is of order $O(\lambda^{-3})$. Splitting the domain of integration into $|q_1|/\sqrt{\mu} \geq (T_c^1/\mu)^\beta$ for some $0 < \beta < 1$ and using the

Schwarz inequality we observe that

$$\int_{\mathbb{R}} \|F_2 \Psi_\lambda(\cdot, q_1)\|_2 \chi_{q_1^2 < 2\mu} dq_1 \leq (2\sqrt{\mu}(T_c^1/\mu)^\beta)^{1/2} \|\Psi_\lambda\|_2 + (2\sqrt{2\mu})^{1/2} \|F_2 \Psi_\lambda \chi_{|q_1|/\sqrt{\mu} > (T_c^1/\mu)^\beta}\|_2 \quad (5.16)$$

By Lemma 3.2(iii), $\|F_2 \Psi_\lambda \chi_{|q_1|/\sqrt{\mu} > (T_c^1/\mu)^\beta}\|_2 = O(\lambda^{1/2})$ and by Remark 3.1 we have $(T_c^1/\mu)^{\beta/2} \leq O((\ln \mu/T_c^1)^{-1}) = O(\lambda)$. Thus, $\left(\int_{\mathbb{R}} \|F_2 \Psi_\lambda(\cdot, q_1)\|_2 \chi_{q_1^2 < 2\mu} dq_1\right)^2 = O(\lambda)$ and (5.15) is of order $O(1)$.

Asymptotics of second line in (5.13): Analogously to (3.26) we have

$$\int_{\mathbb{R}^4} V(r) \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} dr dz = 2\lambda^2 \int_{\mathbb{R}^4} \widehat{V}(p_1 + p'_1, 2\eta) B_{T_c^1}(p, (q_1, \eta)) \times \overline{V^{1/2} \Psi_\lambda(p, q_1)} B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \widehat{V^{1/2} \Psi_\lambda}(p'_1, p_2, q_1) \chi_{p^2 + q_1^2 < 2\mu} \chi_{p_1'^2 + p_2^2 + q_1^2 < 2\mu} dp dp'_1 dq_1 \quad (5.17)$$

We can thus write

$$\frac{1}{2} \int_{\mathbb{R}^4} V(r) \overline{\Phi_\lambda^{d,<}(r_1, z_2, z_1)} \left(\Phi_\lambda^{d,<}(r_1, z_2, z_1) + \Phi_\lambda^{d,<}(r_1, -z_2, z_1) e^{-2i\eta(\lambda)r_2} \right) dr dz = \langle F_2 \Psi_\lambda, M_\lambda F_2 \Psi_\lambda \rangle, \quad (5.18)$$

where M_λ is the operator acting on $L^2(\mathbb{R}^3)$ given by

$$\langle \psi, M_\lambda \psi \rangle = \lambda^2 \int_{\mathbb{R}^4} \left(\widehat{V}(p_1 - p'_1, 0) + \widehat{V}(p_1 + p'_1, 2\eta) \right) B_{T_c^1}(p, (q_1, \eta)) \overline{F_1 V^{1/2} \psi(p, q_1)} \chi_{p^2 + q_1^2 < 2\mu} \times B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \chi_{p_1'^2 + p_2^2 + q_1^2 < 2\mu} F_1 V^{1/2} \psi(p'_1, p_2, q_1) dp dp'_1 dq_1 \quad (5.19)$$

By the same argument as in the proof of $\int_{\mathbb{R}^4} V(r) |\Phi_\lambda^{d,<}(r_1, z_2, z_1)|^2 dr dz = O(\lambda^{-1})$ in Lemma 3.5 (see (3.30)) we have $\|M_\lambda\| = O(\lambda^{-1})$. Recall the projections \mathbb{P} and \mathbb{Q}_β from Section 3. Let \mathbb{T} be the projection $\mathbb{T} = \mathbb{P}\mathbb{Q}_\beta$ for some $0 < \beta < 1$ and $\mathbb{T}^\perp = 1 - \mathbb{T}$. We have

$$\langle F_2 \Psi_\lambda, M_\lambda F_2 \Psi_\lambda \rangle = \langle \mathbb{T} F_2 \Psi_\lambda, M_\lambda \mathbb{T} F_2 \Psi_\lambda \rangle + \langle \mathbb{T} F_2 \Psi_\lambda, M_\lambda \mathbb{T}^\perp F_2 \Psi_\lambda \rangle + \langle \mathbb{T}^\perp F_2 \Psi_\lambda, M_\lambda F_2 \Psi_\lambda \rangle \quad (5.20)$$

Since \mathbb{P} and \mathbb{Q}_β commute, we have $\|\mathbb{T}^\perp F_2 \Psi_\lambda\| = \|\mathbb{Q}_\beta^\perp F_2 \Psi_\lambda + \mathbb{Q}_\beta \mathbb{P}^\perp F_2 \Psi_\lambda\| = O(\lambda^{1/2})$ according to Lemma 3.2(ii) and (iii). In particular, the last two terms in (5.20) are of order $O(\lambda^{-1/2})$. The remaining term in (5.20) is bounded below by

$$\langle \mathbb{T} F_2 \Psi_\lambda, M_\lambda \mathbb{T} F_2 \Psi_\lambda \rangle \geq \inf_{|q_1|/\sqrt{\mu} < (T_c^1/\mu)^\beta} \lambda^2 \int_{\mathbb{R}^3} \left(\widehat{V}(p_1 - p'_1, 0) + \widehat{V}(p_1 + p'_1, 2\eta) \right) B_{T_c^1}((p_1, p_2), (q_1, \eta)) \widehat{V} j_2(p) \chi_{p^2 + q_1^2 < 2\mu} \times B_{T_c^1}((p'_1, p_2), (q_1, \eta)) \chi_{p_1'^2 + p_2^2 + q_1^2 < 2\mu} \widehat{V} j_2(p'_1, p_2) dp dp'_1 \|\mathbb{T} F_2 \Psi_\lambda\|_2^2 \|V^{1/2} j_2\|_2^{-2} \quad (5.21)$$

The remainder of the proof follows the same ideas as the proof of [9, Lemma 4.11]. Since $V \geq 0$ we have $\widehat{V}(0) > 0$. Furthermore, the eigenvalue equation $e_\mu V^{1/2} j_2 = O_\mu V^{1/2} j_2 = \widehat{V} j_2(|p| = \sqrt{\mu}) V^{1/2} j_2$ implies that $\widehat{V} j_2(|p| = \sqrt{\mu}) = e_\mu > 0$. By continuity of \widehat{V} and $\widehat{V} j_2$ and Lemma 3.2(i), there exist $\tilde{\lambda} > 0$, $0 < \delta < \mu$ and $c_1 > 0$ such that for all $\sqrt{\mu - \delta} < p_2 < \sqrt{\mu + \delta}$, $p_1^2 < 4\delta$, $p_1'^2 < 4\delta$ and $\lambda < \tilde{\lambda}$ we have

$$\left(\widehat{V}(p_1 - p'_1, 0) + \widehat{V}(p_1 + p'_1, 2\eta) \right) \widehat{V} j_2(p) \widehat{V} j_2(p'_1, p_2) \chi_{p^2 + q_1^2 < 2\mu} \chi_{p_1'^2 + p_2^2 + q_1^2 < 2\mu} \|V^{1/2} j_2\|_2^{-2} > c_1. \quad (5.22)$$

Using the second part of Lemma 3.7, Lemma 3.2(i) and the boundedness of \widehat{V} , $\widehat{V} j_2$, it follows that up to an error of order $O(\lambda^2 (\ln \mu/T_c^1)^{5/2}) = O(\lambda^{-1/2})$ we may restrict the domain of

integration in (5.21) to $\sqrt{\mu - \delta} < p_2 < \sqrt{\mu + \delta}, p_1^2 < 4\delta, p_1'^2 < 4\delta$. Since $\|\mathbb{T}F_2\Psi_\lambda\|_2^2 = 1 - O(\lambda) \geq \frac{1}{2}$ for small λ , we obtain

$$\begin{aligned} \langle \mathbb{T}F_2\Psi_\lambda, M_\lambda \mathbb{T}F_2\Psi_\lambda \rangle &\geq \frac{c_1}{2} \inf_{|q_1|/\sqrt{\mu} < (T_c^1/\mu)^\beta} \lambda^2 \int_{\mathbb{R}^3} B_{T_c^1}((p_1, p_2), (q_1, \eta)) \\ &\quad \times B_{T_c^1}((p_1', p_2), (q_1, \eta)) \chi_{\mu - \delta < p_2^2 < \mu + \delta} \chi_{p_1^2 < 4\delta} \chi_{p_1'^2 < 4\delta} dp dp_1' + O(\lambda^{-1/2}) \end{aligned} \quad (5.23)$$

Using Lemma 3.7 once more, we may leave away the characteristic functions at the expense of an error of order $O(\lambda^{-1/2})$. Since $\eta(\lambda) = O(T_c^1(\lambda))$, there is a $c_2 > 0$ such that $\eta^2 + (\sqrt{\mu}(T_c^1/\mu)^\beta)^2 \leq c_2^2 \mu (T_c^1/\mu)^{2\beta}$ for $T_c^1 < \mu$. The following Lemma, whose proof is given in Section 7.5, thus concludes the proof of Lemma 1.9.

Lemma 5.2. *Let $\mu, c_2 > 0$, $0 < \beta < 1$ and $\epsilon := c_2 \sqrt{\mu}(T/\mu)^\beta$ for $T > 0$. Then there are constants $T_0, C > 0$ such that*

$$\inf_{|q| < \epsilon} \int_{\mathbb{R}} \left(\int_{\mathbb{R}} B_T(p, q) dp_1 \right)^2 dp_2 \geq C (\ln \mu/T)^3 \quad (5.24)$$

for all $0 < T < T_0$.

6 Proof of Theorem 1.5

This Section is dedicated to the proof of Theorem 1.5, which states that the relative difference of T_c^2 and T_c^0 vanishes in the weak coupling limit. It has been shown in [9, Theorem 1.7] that the relative difference of T_c^1 and T_c^0 vanishes in the weak coupling limit and we follow the same proof strategy here. We first switch to the Birman-Schwinger picture. Recall the Birman-Schwinger operator A_T^0 corresponding to $H_T^{\Omega_0}$ defined in (2.10). Furthermore, recall the notation \tilde{t} , $\tilde{\Omega}_2$ and the representation of $UH_T^{\Omega_2}U^\dagger$ in (4.1) from Section 4. The corresponding Birman-Schwinger operator $A_T^2 : L^2(\tilde{\Omega}_2) \rightarrow L^2(\tilde{\Omega}_2)$ is given by

$$\langle \psi, A_T^2 \psi \rangle = \int_{\mathbb{R}^4} B_T(p, q) \left| \int_{\tilde{\Omega}_2} \frac{1}{(2\pi)^2} \tilde{t}(p_1, q_1, r_1, z_1) \tilde{t}(p_2, q_2, r_2, z_2) V^{1/2}(r) \psi(r, z) dr dz \right|^2 dp dq \quad (6.1)$$

and it follows from the Birman-Schwinger principle that $\text{sgn} \inf \sigma(H_T^{\Omega_2}) = \text{sgn}(1/\lambda - \sup \sigma(A_T^2))$. Let $a_T^j = \sup \sigma(A_T^j)$. It is a straightforward generalization of [5, Lemma 4.1] that the claim (1.4) is equivalent to

$$\lim_{T \rightarrow 0} (a_T^0 - a_T^2) = 0 \quad (6.2)$$

and we refer to [5] for the proof.

To verify (6.2), the first step is to argue that $a_T^2 \geq a_T^0$ for all $T > 0$. Lemma 1.1 together with [9, Lemma 2.3] imply that $\inf \sigma(H_T^{\Omega_2}) \leq \inf \sigma(H_T^{\Omega_0})$ for all $\lambda, T > 0$. Using the Birman-Schwinger principle, it follows that $a_T^2 \geq a_T^0$ for all $T > 0$. For details we refer to the proof of [9, Theorem 1.7].

It remains to show that $\lim_{T \rightarrow 0} (a_T^0 - a_T^2) \geq 0$. We decompose A_T^2 in the same spirit as we decomposed $A_T^1(q_2)$ in (2.16). For A_T^1 , the decomposition consisted of the ‘‘unperturbed’’ term A_T^0 and the ‘‘perturbation term’’ G_T , where the first components of the momentum variables were swapped. For A_T^2 we additionally get the terms arising from swapping the variables in the second component, which leads to four terms in total. Let $\tilde{t} : L^2(\tilde{\Omega}_2) \rightarrow L^2(\mathbb{R}^4)$ be the isometry

$$\begin{aligned} \tilde{t}\psi(r, z) &= \frac{1}{2} \left(\psi(r, z) \chi_{\tilde{\Omega}_2}(r, z) + \psi(-r_1, r_2, -z_1, z_2) \chi_{\tilde{\Omega}_2}(-r_1, r_2, -z_1, z_2) \right. \\ &\quad \left. + \psi(r_1, -r_2, z_1, -z_2) \chi_{\tilde{\Omega}_2}(r_1, -r_2, z_1, -z_2) + \psi(-r, -z) \chi_{\tilde{\Omega}_2}(-r, -z) \right). \end{aligned} \quad (6.3)$$

Using the definition of \tilde{t} and evenness of V in r_1 and r_2 we rewrite (6.1) as

$$\langle \psi, A_T^2 \psi \rangle = \int_{\mathbb{R}^4} B_T(p, q) \left| \frac{1}{2} (\widehat{V^{1/2} \tilde{t} \psi}(p, q) \mp \widehat{V^{1/2} \tilde{t} \psi}((q_1, p_2), (p_1, q_2))) \mp \widehat{V^{1/2} \tilde{t} \psi}((p_1, q_2), (q_1, p_2)) + \widehat{V^{1/2} \tilde{t} \psi}(q, p) \right|^2 dpdq \quad (6.4)$$

Define the self-adjoint operators G_T^1, G_T^2 , and N_T on $L^2(\mathbb{R}^4)$ through

$$\langle \psi, G_T^1 \psi \rangle = \int_{\mathbb{R}^4} \overline{F_1 V^{1/2} \psi((q_1, p_2), (p_1, q_2))} B_T(p, q) F_1 V^{1/2} \psi(p, q) dpdq, \quad (6.5)$$

$$\langle \psi, G_T^2 \psi \rangle = \int_{\mathbb{R}^4} \overline{F_1 V^{1/2} \psi((p_1, q_2), (q_1, p_2))} B_T(p, q) F_1 V^{1/2} \psi(p, q) dpdq, \quad \text{and} \quad (6.6)$$

$$\langle \psi, N_T \psi \rangle = \int_{\mathbb{R}^4} \overline{F_1 V^{1/2} \psi(q, p)} B_T(p, q) F_1 V^{1/2} \psi(p, q) dpdq. \quad (6.7)$$

We slightly abuse notation and write F_2 for the Fourier transform in the second variable also when the second variable has two components, i.e. $F_2 \psi(r, q) = \frac{1}{2\pi} \int_{\mathbb{R}^2} e^{-iq \cdot z} \psi(r, z) dz$. It follows from (6.4) and $B_T(p, q) = B_T((q_1, p_2), (p_1, q_2)) = B_T(q, p)$ that

$$A_T^2 = \tilde{t}^\dagger (A_T^0 - F_2^\dagger R_T F_2) \tilde{t}, \quad (6.8)$$

where $R_T = \pm G_T^1 \pm G_T^2 - N_T$. Let $B_T(\cdot, q) : L^2(\mathbb{R}^2) \rightarrow L^2(\mathbb{R}^2)$ denote multiplication by $B_T(p, q)$ in momentum space and define the function $E_T(q)$ on \mathbb{R}^2 through

$$E_T(q) := a_T^0 - \|V^{1/2} B_T(\cdot, q) V^{1/2}\|. \quad (6.9)$$

Note that $a_T^0 = \sup_{q \in \mathbb{R}^2} \|V^{1/2} B_T(\cdot, q) V^{1/2}\|$ and therefore $E_T(q) \geq 0$. For $\psi \in L^2(\mathbb{R}^4)$ let $E_T \psi(r, q) = E_T(q) \psi(r, q)$. We get the operator inequality $a_T^0 \mathbb{I} - A_T^0 \geq F_2^\dagger E_T F_2$, where \mathbb{I} denotes the identity operator on $L^2(\mathbb{R}^4)$. Using (6.8), the above inequality and that $\|F_2 \tilde{t} \psi\|_2 = \|\psi\|_2$ we obtain

$$a_T^0 - a_T^2 \geq \inf_{\psi \in L^2(\tilde{\Omega}_2), \|\psi\|_2=1} \langle F_2 \tilde{t} \psi, (E_T + R_T) F_2 \tilde{t} \psi \rangle \geq \inf_{\psi \in L^2(\mathbb{R}^4), \|\psi\|_2=1} \langle \psi, (E_T + R_T) \psi \rangle. \quad (6.10)$$

Therefore, it suffices to show that $\lim_{T \rightarrow 0} \inf \sigma(E_T + R_T) \geq 0$. The proof relies on the following three Lemmas.

Lemma 6.1. *Let $\mu > 0$ and let V satisfy Assumption 1.2. Then $\sup_{T > 0} \|R_T\| < \infty$.*

Lemma 6.2. *Let $\mu > 0$ and let V satisfy Assumption 1.2. Let $\mathbb{I}_{\leq \epsilon}$ act on $L^2(\mathbb{R}^4)$ as $\mathbb{I}_{\leq \epsilon} \psi(r, q) = \psi(r, q) \chi_{|q| \leq \epsilon}$. Then $\lim_{\epsilon \rightarrow 0} \sup_{T > 0} \|\mathbb{I}_{\leq \epsilon} R_T \mathbb{I}_{\leq \epsilon}\| = 0$.*

Lemma 6.3. *Let $\mu > 0$ and let V satisfy Assumption 1.2. Let $0 < \epsilon < \sqrt{\mu}$. There are constants $c_1, c_2, T_0 > 0$ such that for $0 < T < T_0$ and $|q| > \epsilon$ we have $E_T(q) > c_1 |\ln(c_2/T)|$.*

The first two Lemmas are extensions of [9, Lemma 6.1 and Lemma 6.2] and proved in Sections 7.6 and 7.7, respectively. The third Lemma is contained in [9, Lemma 6.3].

With these Lemmas, the claim follows completely analogously to the proof of [5, Theorem 1.2 (ii)] and we provide a sketch for completeness. Using that $E_T(q) \geq 0$, we write

$$E_T + R_T + \delta = \sqrt{E_T + \delta} \left(\mathbb{I} + \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \right) \sqrt{E_T + \delta} \quad (6.11)$$

for any $\delta > 0$. It suffices to prove that for all $\delta > 0$ the norm of the second term in the bracket vanishes in the limit $T \rightarrow 0$. With the notation from Lemma 6.2 we estimate for all $0 < \epsilon < \sqrt{\mu}$

$$\begin{aligned} \left\| \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \right\| &\leq \left\| \mathbb{I}_{\leq \epsilon} \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \mathbb{I}_{\leq \epsilon} \right\| \\ &+ \left\| \mathbb{I}_{\leq \epsilon} \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \mathbb{I}_{> \epsilon} \right\| + \left\| \mathbb{I}_{> \epsilon} \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \right\|. \end{aligned} \quad (6.12)$$

Lemma 6.3 and $E_T \geq 0$ imply

$$\lim_{T \rightarrow 0} \left\| \frac{1}{\sqrt{E_T + \delta}} R_T \frac{1}{\sqrt{E_T + \delta}} \right\| \leq \sup_{T > 0} \frac{1}{\delta} \left\| \mathbb{I}_{\leq \epsilon} R_T \mathbb{I}_{\leq \epsilon} \right\| + \lim_{T \rightarrow 0} \frac{2}{(\delta c_1 |\ln(c_2/T)|)^{1/2}} \|R_T\|. \quad (6.13)$$

The first term can be made arbitrarily small by Lemma 6.2 and the second term vanishes by Lemma 6.1. Hence, Theorem 1.5 follows.

7 Proofs of Auxiliary Lemmas

7.1 Proof of Lemma 2.2

Proof of Lemma 2.2. Using the Mittag-Leffler series (as in [5, (2.1)]) one can write

$$\begin{aligned} f(p, q, x) = 2T \sum_{n \in \mathbb{Z}} \Xi_n^{-1} &\left[(2q_2 + x)(2\mu - 2q^2 - 2p^2 - x^2 + 2(p_2 - q_2)x) \right. \\ &\left. + 2p_2(4p \cdot q - 2iw_n + 2(p_2 - q_2)x - x^2) \right] \end{aligned} \quad (7.1)$$

where

$$\begin{aligned} \Xi_n = &\left((p + q + (0, x))^2 - \mu - iw_n \right) \left((p - q - (0, x))^2 - \mu + iw_n \right) \\ &\times \left((p + q)^2 - \mu - iw_n \right) \left((p - q)^2 - \mu + iw_n \right) \end{aligned} \quad (7.2)$$

and $w_n = (2n + 1)\pi T$. Continuity of f follows from dominated convergence. For $x > \sqrt{\mu}/4$ the bound on f follows from (2.2). Let $Q_2 = Q_1 + \sqrt{\mu}/4$. For $x < \sqrt{\mu}/4$ we have

$$|f(p, q, x)| \leq \sup_{|q_2| \leq Q_2} \left| \frac{\partial}{\partial q_2} B_T(p, q) \right| = \sup_{|q_2| \leq Q_2} |f(p, q, 0)|. \quad (7.3)$$

To bound $|f(p, q, 0)|$, first note that for $x = 0$ with the notation $y = (p + q)^2 - \mu$, $z = (p - q)^2 - \mu$ and $v = \max\{(|p_1| + |q_1|)^2 + (|p_2| - |q_2|)^2 - \mu, 0\}$,

$$|\Xi_n| = (y^2 + w_n^2)(z^2 + w_n^2) \geq (v^2 + w_n^2) \left(\max\{(|p_2| - |q_2|)^2 - \mu, 0\}^2 + w_n^2 \right). \quad (7.4)$$

Furthermore,

$$\begin{aligned} \sup_{(p, q) \in \mathbb{R}^4, |q_2| \leq Q_2} &\left| \frac{4iw_n p_2}{\max\{(|p_2| - |q_2|)^2 - \mu, 0\}^2 + w_n^2} \right| \\ &\leq \sup_{(p, q) \in \mathbb{R}^4, |q_2| < Q_2} \frac{4|p_2|}{\sqrt{\max\{(|p_2| - |q_2|)^2 - \mu, 0\}^2 + w_n^2}} =: c_1 < \infty \end{aligned} \quad (7.5)$$

There is a constant $c_2 > \mu$ depending only on μ and Q_2 such that $|p_2|^2 \leq 4(\min\{y, z\} + c_2)$ for $|q_2| \leq Q_2$ and all $p_1, q_1 \in \mathbb{R}$. One obtains that for $|q_2| \leq Q_2$

$$|f(p, q, 0)| \leq 2T \sum_{n \in \mathbb{Z}} \frac{2Q_2|y + z| + 4\sqrt{\min\{y, z\} + c_2}|y - z|}{(y^2 + w_n^2)(z^2 + w_n^2)} + 2T \sum_{n \in \mathbb{Z}} \frac{c_1}{v^2 + w_n^2} \quad (7.6)$$

Since the summands are decreasing in n , we can estimate the sums by integrals. The second term is bounded by

$$4Tc_1 \left[\frac{1}{v^2 + w_0^2} + \int_{1/2}^{\infty} \frac{1}{v^2 + 4\pi^2 T^2 x^2} dx \right] = 4Tc_1 \left[\frac{1}{v^2 + w_0^2} + \frac{\arctan\left(\frac{v}{\pi T}\right)}{2\pi T v} \right] < \frac{C}{1 + p_1^2 + q_1^2 + p_2^2} \quad (7.7)$$

for some constant C independent of p and q_1 , since $\sup_{(p,q) \in \mathbb{R}^4, |q_2| \leq Q_2} \frac{1+p_1^2+q_1^2+p_2^2}{1+v} < \infty$. The first term in (7.6) is bounded by

$$16T(Q_2 + 2\sqrt{\min\{|y|, |z|\} + c_2}) \max\{|y|, |z|\} \left[\frac{1}{(y^2 + w_0^2)(z^2 + w_0^2)} + \int_{1/2}^{\infty} \frac{1}{(y^2 + 4\pi^2 T^2 x^2)(z^2 + 4\pi^2 T^2 x^2)} dx \right] \quad (7.8)$$

Note that $y + z + 2\mu + 1 = 1 + 2p^2 + 2q^2$. The claim thus follows if we prove that for $c_3 > 0$

$$\sup_{y>z>0} (1 + y + z)(1 + \sqrt{z + 1})y \left[\frac{1}{(y^2 + 1)(z^2 + 1)} + \int_{c_3}^{\infty} \frac{1}{(y^2 + x^2)(z^2 + x^2)} dx \right] < \infty \quad (7.9)$$

The supremum over the first summand is obviously finite. The supremum over the second summand is bounded by

$$\sup_{y>z>0} \frac{(1 + 2y)y}{y^2 + c_3^2} \frac{1 + \sqrt{z + 1}}{(z^2 + c_3^2)^{1/4}} \int_{c_3}^{\infty} \frac{1}{x^{3/2}} dx < \infty. \quad (7.10)$$

□

7.2 Proof of Lemma 3.7

Proof of Lemma 3.7. Using (3.21) and substituting $p_1 \pm q_1 \rightarrow p_1, p'_1 \pm q'_1 \rightarrow p'_1$, we have

$$\int_{\mathbb{R}^3} B_T(p, q) B_T((p'_1, p_2), q') dp_1 dp'_1 dp_2 \leq \frac{1}{4} \int_{\mathbb{R}^3} (B_T((p_1, p_2 + q_2), 0) + B_T((p_1, p_2 - q_2), 0)) \times (B_T((p'_1, p_2 + q'_2), 0) + B_T((p'_1, p_2 - q'_2), 0)) dp_1 dp'_1 dp_2 \quad (7.11)$$

One can bound this from above by

$$\begin{aligned} & \sup_{q_2, q'_2 \in \mathbb{R}} \int_{\mathbb{R}} \left(\int_{\mathbb{R}} B_T((p_1, p_2 + q_2), 0) dp_1 \right) \left(\int_{\mathbb{R}} B_T((p'_1, p_2 + q'_2), 0) dp'_1 \right) dp_2 \\ & \leq \sup_{q_2 \in \mathbb{R}} \int_{\mathbb{R}^3} B_T((p_1, p_2 + q_2), 0) B_T((p'_1, p_2 + q_2), 0) dp_1 dp'_1 dp_2 \\ & = \int_{\mathbb{R}^3} B_T((p_1, p_2), 0) B_T((p'_1, p_2), 0) dp_1 dp'_1 dp_2 \quad (7.12) \end{aligned}$$

where in the second step we used the Schwarz inequality in p_2 . The latter expression is of order $O(\ln(\mu/T)^3)$ for $T \rightarrow 0$, as was shown in the proof of [9, Lemma 4.10].

To prove the second statement, we shall use that for fixed $0 < \delta < \mu$

$$\int_{\mathbb{R}^3} (1 - \chi_{\mu-\delta < p_2^2 < \mu} \chi_{p_1^2 < 2\delta} \chi_{p_1'^2 < 2\delta}) B_T(p, 0) B_T((p'_1, p_2), 0) dp_1 dp'_1 dp_2 = O((\ln \mu/T)^2) \quad (7.13)$$

for $T \rightarrow 0$ as was shown in the proof of [9, Lemma 4.10]. We choose δ_2 and δ small enough, such that for all $q^2 < \delta_2$, if $p_1^2 > 4\delta_1$ we have $(p_1 + q_1)^2 > 2\delta$ and if $p_2^2 < \mu - \delta_1$ or $p_2^2 > \mu + \delta_1$ we have $(p_2 + q_2)^2 < \mu - \delta$ or $(p_2 + q_2)^2 > \mu$, respectively. Using (3.21) as above, we have

$$\begin{aligned} & \sup_{q^2, q'^2 < \delta_2} \int_{\mathbb{R}^3} (1 - \chi_{\mu - \delta_1 < p_2^2 < \mu + \delta_1} \chi_{p_1^2 < 4\delta_1} \chi_{p_1'^2 < 4\delta_1}) B_T(p, q) B_T((p'_1, p_2), q') dp_1 dp'_1 dp_2 \\ & \leq \sup_{q^2, q'^2 < \delta_2} \int_{\mathbb{R}^3} (1 - \chi_{\mu - \delta_1 < p_2^2 < \mu + \delta_1} \chi_{p_1^2 < 4\delta_1} \chi_{p_1'^2 < 4\delta_1}) B_T(p + q, 0) B_T((p'_1, p_2) + q', 0) dp_1 dp'_1 dp_2 \end{aligned} \quad (7.14)$$

Note that $1 - \chi_{\mu - \delta_1 < p_2^2 < \mu + \delta_1} \chi_{p_1^2 < 4\delta_1} \chi_{p_1'^2 < 4\delta_1} \leq \chi_{\mu - \delta_1 > p_2^2} + \chi_{\mu + \delta_1 < p_2^2} + \chi_{p_1^2 > 4\delta_1} + \chi_{p_1'^2 > 4\delta_1}$. Using the Schwarz inequality in p_2 we bound (7.14) above by

$$\begin{aligned} & \sup_{q^2 < \delta_2} \int_{\mathbb{R}^3} (\chi_{\mu - \delta_1 > p_2^2} + \chi_{\mu + \delta_1 < p_2^2}) B_T((p_1 + q_1, p_2 + q_2), 0) B_T((p'_1 + q_1, p_2 + q_2), 0) dp_1 dp'_1 dp_2 \\ & + 2 \sup_{q^2, q'^2 < \delta_2} \left(\int_{\mathbb{R}^3} B_T((p_1 + q_1, p_2 + q_2), 0) B_T((p'_1 + q_1, p_2 + q_2), 0) \chi_{p_1^2 > 4\delta_1} \chi_{p_1'^2 > 4\delta_1} dp_1 dp'_1 dp_2 \right)^{1/2} \\ & \quad \times \left(\int_{\mathbb{R}^3} B_T((p_1, p_2 + q_2), 0) B_T((p'_1, p_2 + q_2), 0) dp_1 dp'_1 dp_2 \right)^{1/2} \end{aligned} \quad (7.15)$$

Substituting $p_j + q_j \rightarrow p_j$ and by choice of δ_2 and δ , this is bounded above by

$$\begin{aligned} & \int_{\mathbb{R}^3} (\chi_{\mu - \delta > p_2^2} + \chi_{\mu < p_2^2}) B_T(p, 0) B_T((p'_1, p_2), 0) dp_1 dp'_1 dp_2 \\ & \quad + 2 \left(\int_{\mathbb{R}^3} B_T(p, 0) B_T((p'_1, p_2), 0) \chi_{p_1^2 > 2\delta} \chi_{p_1'^2 > 2\delta} dp_1 dp'_1 dp_2 \right)^{1/2} \\ & \quad \times \left(\int_{\mathbb{R}^3} B_T(p, 0) B_T((p'_1, p_2), 0) dp_1 dp'_1 dp_2 \right)^{1/2} \end{aligned} \quad (7.16)$$

By (7.13) and the first part of this Lemma, this is of order $O((\ln \mu/T)^2) + O((\ln \mu/T)(\ln \mu/T)^{3/2}) = O((\ln \mu/T)^{5/2})$. \square

7.3 Proof of Lemma 3.8

Proof of Lemma 3.8. For $p_2, q_2 \in \mathbb{R}$ let $B_T((\cdot, p_2), (\cdot, q_2))$ denote the self-adjoint operator on $L^2((-\sqrt{2\mu}, \sqrt{2\mu}))$ acting as $\langle \psi, B_T((\cdot, p_2), (\cdot, q_2)) \psi \rangle = \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \overline{\psi(p_1)} B_T(p, q) \psi(q_1) dp_1 dq_1$. Enlarging the domain of integration for (q_1, p_2) from a disk to square we have

$$\begin{aligned} \|B_T^{ex,2}(\xi)\| & \leq \sup_{\|\psi\|_2=1} \int_{(-\sqrt{2\mu}, \sqrt{2\mu})^4} \overline{\psi(p'_1)} B_T((p'_1, p_2), (q_1, \xi)) B_T(p, (q_1, \xi)) \psi(p_1) dp_1 dp'_1 dq_1 dp_2 \\ & = \sup_{\|\psi\|_2=1} \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \langle \psi, B_T((\cdot, p_2), (\cdot, \xi))^2 \psi \rangle dp_2. \end{aligned} \quad (7.17)$$

By the triangle inequality,

$$\|B_T^{ex,2}(\xi)\| \leq \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \|B_T((\cdot, \xi), (\cdot, p_2))\|^2 dp_2. \quad (7.18)$$

For fixed p_2, q_2 we derive two bounds on $\|B_T((\cdot, p_2), (\cdot, q_2))\|^2$. For the first bound we estimate the Hilbert-Schmidt norm using (2.2):

$$\begin{aligned} \|B_T((\cdot, p_2), (\cdot, q_2))\|^2 &\leq \|B_{T,\mu}((\cdot, p_2), (\cdot, q_2))\|_{\text{HS}}^2 \\ &\leq \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \frac{1}{\max\{|p_1^2 + q_1^2 + p_2^2 + q_2^2 - \mu|^2, T^2\}} dp_1 dq_1 \\ &\leq 2\pi \int_0^{2\sqrt{\mu}} \frac{r}{\max\{|r^2 + p_2^2 + q_2^2 - \mu|^2, T^2\}} dr \leq \pi \int_{\mathbb{R}} \frac{1}{\max\{x^2, T^2\}} dx = \frac{4\pi}{T} \end{aligned} \quad (7.19)$$

where we first switched to angular coordinates and then substituted $x = r^2 + p_2^2 + q_2^2 - \mu$.

For the second bound the idea is to apply [9, Lemma 6.5]. For $\mu_1, \mu_2 \in \mathbb{R}$ let D_{μ_1, μ_2} be the operator on $L^2(\mathbb{R})$ with integral kernel

$$D_{\mu_1, \mu_2}(p_1, q_1) = \frac{2}{|(p_1 + q_1)^2 - \mu_1| + |(p_1 - q_1)^2 - \mu_2|}. \quad (7.20)$$

It was shown in [5, Lemma 4.6] that

$$B_T(p, q) \leq \frac{2}{|(p + q)^2 - \mu| + |(p - q)^2 - \mu|}. \quad (7.21)$$

In particular, we have $\|B_T((\cdot, p_2), (\cdot, q_2))\| \leq \|D_{\mu - (p_2 + q_2)^2, \mu - (p_2 - q_2)^2}\|$ and

$$\|B_T^{ex,2}(\xi)\| \leq \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \min\left\{\frac{4\pi}{T}, \|D_{\mu - (\xi + q_2)^2, \mu - (\xi - q_2)^2}\|^2\right\} dq_2 \quad (7.22)$$

According to [9, Lemma 6.5], for $\mu_1, \mu_2 \leq \mu$ there is a constant $C > 0$ such that

$$\|D_{\mu_1, \mu_2}\| \leq C + \frac{C\mu^{1/2}}{|\min\{\mu_1, \mu_2\}|^{1/2}} \left[1 + \chi_{\min\{\mu_1, \mu_2\} < 0 < \max\{\mu_1, \mu_2\}} \ln \left(1 + \frac{\max\{\mu_1, \mu_2\}}{|\min\{\mu_1, \mu_2\}|} \right) \right] \quad (7.23)$$

The condition $\mu - (|q_2| + |\xi|)^2 < 0 < \mu - (|q_2| - |\xi|)^2$ can only be satisfied for $\sqrt{\mu} - |\xi| \leq |q_2| \leq \sqrt{\mu} + |\xi|$. We get the bound

$$\begin{aligned} \sup_{|\xi| < cT} \|B_T^{ex,2}(\xi)\| &\leq C \left(\int_{||q_2| - \sqrt{\mu}| < 2cT} \frac{1}{T} dq_2 \right. \\ &\quad \left. + \sup_{|\xi| < cT} \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} \chi_{||q_2| - \sqrt{\mu}| > 2cT} \left[1 + \frac{1}{|\mu - (|q_2| + |\xi|)^2|^{1/2}} \right]^2 dq_2 \right) \leq \tilde{C}(1 + \ln \mu/T) \end{aligned} \quad (7.24)$$

□

7.4 Proof of Lemma 5.1

Proof of Lemma 5.1. Applying (3.21), we have

$$\begin{aligned} &\sup_{q_1} \int_{\mathbb{R}} B_{T,\mu}((p_1, \xi(T)), (q_1, \xi'(T))) dp_1 \\ &\leq \frac{1}{2} \left[\int_{\mathbb{R}} B_{T,\mu}((p_1, \xi(T) + \xi'(T)), 0) dp_1 + \int_{\mathbb{R}} B_{T,\mu}((p_1, \xi(T) - \xi'(T)), 0) dp_1 \right] \end{aligned} \quad (7.25)$$

The first integral equals

$$\int_{\mathbb{R}} B_{T,\mu - (\xi(T) + \xi'(T))^2}(p_1, 0) dp_1, \quad (7.26)$$

where here $B_{T,\mu}$ is understood as the function defined through (2.1) on $\mathbb{R} \times \mathbb{R}$ instead of $\mathbb{R}^2 \times \mathbb{R}^2$. For the second integral replace $\xi'(T)$ by $-\xi'(T)$. The claim follows from the asymptotics

$$\int_{\mathbb{R}} B_{T,\mu}(p_1, 0) dp_1 = \frac{2}{\sqrt{\mu}} (\ln(\mu/T) + O(1)) \quad (7.27)$$

for $T/\mu \rightarrow 0$, see e.g. [5, Lemma 3.5]. \square

7.5 Proof of Lemma 5.2

Proof of Lemma 5.2. Let $\gamma = \mu(T/\mu)^{\beta/2}$. By invariance of $B_T(p, q)$ under $(p_j, q_j) \rightarrow -(p_j, q_j)$ for $j \in \{1, 2\}$, we may assume without loss of generality that $q \in [0, \infty)^2$. For a lower bound, we restrict the integration to $p_1, p_2 > 0$, $p_2^2 < \mu - \epsilon^2 - \gamma$ and $p_1^2 > (\sqrt{\mu} + \epsilon)^2 + T - p_2^2$. For $p, q \in [0, \infty)^2$ with $|q| < \epsilon$ and $p^2 > (\sqrt{\mu} + \epsilon)^2 + T$, we have $(p - q)^2 - \mu \geq \|p\| - |q|^2 - \mu \geq 0$ and $(p + q)^2 - \mu \geq p^2 + q^2 - \mu \geq T$. Therefore, in this regime

$$B_T(p, q) \geq \frac{1}{2} \frac{\tanh(1/2)}{p^2 + q^2 - \mu}. \quad (7.28)$$

This is minimal if $|q| = \epsilon$. Since $\int_a^\infty \frac{1}{p_1^2 - b^2} dp_1 = \frac{\operatorname{artanh}(b/a)}{b} = \frac{1}{b} \operatorname{artanh}\left(\sqrt{1 - (a^2 - b^2)/a^2}\right)$ for $a > b > 0$, the left hand side of (5.24) is bounded below by

$$\frac{\tanh(1/2)^2}{4} \int_{\sqrt{\mu - \delta}}^{\sqrt{\mu - \epsilon^2 - \gamma}} \frac{\operatorname{artanh}\left(\sqrt{1 - \frac{2\sqrt{\mu}\epsilon + 2\epsilon^2 + T}{(\sqrt{\mu} + \epsilon)^2 + T - p_2^2}}\right)^2}{\mu - \epsilon^2 - p_2^2} dp_2 \quad (7.29)$$

By monotonicity of artanh , the artanh term in the integrand is minimal for $p_2 = \sqrt{\mu - \epsilon^2 - \gamma}$. Since $\int_{\sqrt{\mu - \delta}}^{\sqrt{\mu - \epsilon^2 - \gamma}} \frac{1}{\mu - \epsilon^2 - p_2^2} dp_2 = \frac{1}{\mu - \epsilon^2} (\operatorname{artanh}(\sqrt{1 - (\epsilon^2 + \gamma)/\mu}) - \operatorname{artanh}(\sqrt{1 - \delta/\mu}))$, the left hand side of (5.24) is bounded below by

$$\frac{\tanh(1/2)^2}{4(\mu - \epsilon^2)} \operatorname{artanh}\left(\sqrt{1 - \frac{2\sqrt{\mu}\epsilon + 2\epsilon^2 + T}{2\sqrt{\mu}\epsilon + 2\epsilon^2 + T + \gamma}}\right)^2 \left[\operatorname{artanh}\left(\sqrt{1 - \frac{\epsilon^2 + \gamma}{\mu}}\right) - \operatorname{artanh}\left(\sqrt{1 - \frac{\delta}{\mu}}\right) \right] \quad (7.30)$$

With $\operatorname{artanh}(\sqrt{1 - x}) = \frac{1}{2} \ln(4/x) + o(1)$ as $x \rightarrow 0$, we have for $T \rightarrow 0$

$$\operatorname{artanh}\left(\sqrt{1 - \frac{2\sqrt{\mu}\epsilon + 2\epsilon^2 + T}{2\sqrt{\mu}\epsilon + 2\epsilon^2 + T + \gamma}}\right) = \frac{\beta}{4} \ln(\mu/T) + O(1) \quad (7.31)$$

and

$$\operatorname{artanh}\left(\sqrt{1 - \frac{\epsilon^2 + \gamma}{\mu}}\right) = \frac{\beta}{4} \ln(\mu/T) + O(1). \quad (7.32)$$

Hence, the left hand side of (5.24) is bounded below by $\frac{\tanh(1/2)^2}{4^3} \frac{\beta^3}{\mu} (\ln \mu/T)^3 + O(\ln \mu/T)^2$, and the claim follows. \square

7.6 Proof of Lemma 6.1

Proof of Lemma 6.1. According to [9, Lemma 6.1], $\sup_T \|G_T^j\| < \infty$ for $j \in \{1, 2\}$ and it suffices to prove $\sup_T \|N_T\| < \infty$. We have $\|N_T\| \leq \|N_T^<\| + \|N_T^>\|$, where

$$\langle \psi, N_T^<\psi \rangle = \int_{\mathbb{R}^4} \overline{F_1 V^{1/2} \psi(q, p)} B_T(p, q) \chi_{p^2, q^2 < 2\mu} F_1 V^{1/2} \psi(p, q) dp dq \quad (7.33)$$

and for $N_T^>$ replace the characteristic function by $1 - \chi_{p^2, q^2 < 2\mu}$.

To bound $\|N_T^>\|$, we first use the Schwarz inequality to obtain

$$\|N_T^>\| \leq \sup_{\psi \in L^2(\mathbb{R}^4), \|\psi\|_2=1} \int_{\mathbb{R}^4} B_T(p, q) (1 - \chi_{p^2, q^2 < 2\mu}) |F_1 V^{1/2} \psi(p, q)|^2 dp dq \quad (7.34)$$

By (2.2), there is a constant $C > 0$ independent of T such that $\|N_T^>\| \leq C\|M\|$, where $M := V^{1/2} \frac{1}{1-\Delta} V^{1/2}$ on $L^2(\mathbb{R}^2)$. The Young and Hölder inequalities imply that M is a bounded operator [8].

To bound $\|N_T^<\|$, we use that $\|F_1 V^{1/2} \psi(\cdot, q)\|_\infty \leq \|V\|_1^{1/2} \|\psi(\cdot, q)\|_2$ by the Schwarz inequality and (7.21) to obtain

$$\langle \psi, N_T^< \psi \rangle \leq 2\|V\|_1 \int_{\mathbb{R}^4} \frac{\|\psi(\cdot, q)\|_2 \|\psi(\cdot, p)\|_2}{|(p+q)^2 - \mu| + |(p-q)^2 - \mu|} \chi_{p^2, q^2 < 2\mu} dp dq \quad (7.35)$$

Recalling the definition of the operator D_{μ_1, μ_2} from (7.20), this is further bounded by

$$2\|V\|_1 \int_{\mathbb{R}^2} \|\psi(\cdot, (\cdot, q_2))\|_2 \|D_{\mu - (p_2 + q_2)^2, \mu - (p_2 - q_2)^2}\| \|\psi(\cdot, (\cdot, p_2))\|_2 \chi_{p_2^2, q_2^2 < 2\mu} dp dq \quad (7.36)$$

It follows from (7.23) that for any $\alpha > 0$ there is a constant C_α independent of p_2, q_2 such that $\|D_{\mu - (p_2 + q_2)^2, \mu - (p_2 - q_2)^2}\| \leq C_\alpha (1 + |\mu - (|p_2| + |q_2|)^2|^{-1/2-\alpha})$. Let \tilde{D}_α denote the operator on $L^2((-\sqrt{2\mu}, \sqrt{2\mu}))$ with integral kernel $\tilde{D}_\alpha(q_2, p_2) = (1 + |\mu - (|p_2| + |q_2|)^2|^{-1/2-\alpha})$. Then we have $\|N_T^<\| \leq 2C_\alpha \|V\|_1 \|\tilde{D}_\alpha\|$ and it remains to prove that $\|\tilde{D}_\alpha\| < \infty$ for a suitable choice of α . Applying the Schur test with constant test function gives

$$\|\tilde{D}_\alpha\| \leq \sup_{|q_2| < \sqrt{2\mu}} \int_{-\sqrt{2\mu}}^{\sqrt{2\mu}} (1 + |\mu - (|p_2| + |q_2|)^2|^{-1/2-\alpha}) dp_2, \quad (7.37)$$

which is finite for $\alpha < 1/2$. □

7.7 Proof of Lemma 6.2

Proof of Lemma 6.2. It was shown in [9, Lemma 6.2] that $\lim_{\epsilon \rightarrow 0} \sup_{T > 0} \|\mathbb{I}_{\leq \epsilon} G_T^j \mathbb{I}_{\leq \epsilon}\| = 0$ for $j \in \{1, 2\}$ and it remains to prove $\lim_{\epsilon \rightarrow 0} \sup_{T > 0} \|\mathbb{I}_{\leq \epsilon} N_T \mathbb{I}_{\leq \epsilon}\| = 0$. We use the Schwarz inequality twice to bound

$$\begin{aligned} \|\mathbb{I}_{\leq \epsilon} N_T \mathbb{I}_{\leq \epsilon}\| &\leq \|V\|_1 \sup_{\psi \in L^2(\mathbb{R}^4), \|\psi\|_2=1} \int_{\mathbb{R}^4} \|\psi(\cdot, p)\|_2 B_T(p, q) \chi_{|p|, |q| \leq \epsilon} \|\psi(\cdot, q)\|_2 dp dq \\ &\leq \|V\|_1 \sup_{\psi \in L^2(\mathbb{R}^4), \|\psi\|_2=1} \int_{\mathbb{R}^4} B_T(p, q) \chi_{|p|, |q| \leq \epsilon} \|\psi(\cdot, q)\|_2^2 dp dq \leq \|V\|_1 \sup_{|q| \leq \epsilon} \int_{|p| \leq \epsilon} B_T(p, q) dp. \end{aligned} \quad (7.38)$$

Applying (2.2), for $\epsilon < \sqrt{\mu/2}$ one can bound the right hand side uniformly in T by

$$\|V\|_1 \sup_{|q| \leq \epsilon} \int_{|p| \leq \epsilon} \frac{1}{\mu - p^2 - q^2} dp, \quad (7.39)$$

which vanishes as $\epsilon \rightarrow 0$. The claim follows. □
