#### Abstract

For a skew polynomial ring  $R = A[X; \theta, \delta]$  where A is a commutative Frobenius ring, θ an endomorphism of A and δ a θ-derivation of A, we consider cyclic left module codes  $C = Rq/Rf \subset R/Rf$  where q is a left and right divisor of f in R. In this paper, we derive a parity check matrix when A is a finite commutative Frobenius ring using only the framework of skew polynomial rings. We consider rings  $A = B[a_1, \ldots, a_s]$  which are free B-modules where the restriction of  $\delta$  and  $\theta$  to B are polynomial maps. If a Gröbner basis can be computed over B, then we show that all Euclidean and Hermitian dual-containing codes  $C = Rg/Rf \subset R/Rf$ can be computed using a Gröbner basis. We also give an algorithm to test if the dual code is again a cyclic left module code. We illustrate our approach for rings of order 4 with non-trivial endomorphism and the Galois ring of characteristic 4.

## 1 Introduction

For a (non-commutative) skew polynomial ring  $R = A[X; \theta, \delta]$  where A is a commutative Frobenius ring,  $\theta$  an endomorphism of the ring A and  $\delta$  a  $\theta$ -derivation of A (Definition [1\)](#page-1-0), we consider codes that are cyclic left modules (i.e., generated by one element in R) of the form  $C = Rq/Rf \subset R/Rf$ with  $f = hg$  for  $g, f, h \in R$ . In order to obtain a parity check matrix for such codes we will make the additional assumption that there exists  $\hbar \in R$  such that  $f = hg = gh$  (i.e., g is a left and right divisor of f). A parity check matrix of such codes has been derived in a general approach in  $[10]$ ,

The work of H. Liu has been supported by the German Research Foundation (DFG) with a German Israeli Project Cooperation (DIP) under grants no. PE2398/1-1, KR3517/9-1. The work of F. Ulmer has been by French projects ANR-11-LABX-0020-01"Centre Henri Lebesgue".

Keywords: self-dual code, dual-containing code, skew polynomial, module code, Gröbner basis, non-zero derivation, code over rings

in [\[4,](#page-18-0) Corollary 4] for  $A = \mathbb{F}_q$  and in [\[8,](#page-18-1) [9\]](#page-19-1) and for a finite commutative Frobenius ring A. The framework of pseudo-linear transformations is used in [\[8,](#page-18-1) [9,](#page-19-1) [10\]](#page-19-0), while in this paper we only use the framework of skew polynomial rings. The entries of the parity check matrix are expressions in images under compositions of  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and g, which are difficult to solve when searching for self-dual/dual-containing codes.

If  $A = B[a_1, \ldots, a_s]$  is a free B-module and the restriction of  $\delta$  and  $\theta$  to B are polynomial maps (Definition [4\)](#page-7-0) then we can transform algebraic expressions of images under  $\theta$  and  $\delta$  into polynomial expressions over B. By representing the unknown coefficients of  $\hbar$  and g as a linear combination of the algebra basis  $B[a_1, \ldots, a_s]$ , we obtain multivariate polynomial expressions for the entries of a parity check matrix. The smallest unitary subring of a finite commutative ring A (the image of the canonical map  $\mathbb{Z} \to A$  given by  $1 \mapsto 1$ ) is either isomorphic to a finite field  $\mathbb{F}_p$  of prime order or to an integer modular ring  $\mathbb{Z}_m = \mathbb{Z}/(m)$  (note that p or m here is the characteristic of the ring A). Since θ and δ are polynomial maps over the smallest subalgebra B ⊂ A and since polynomial equations over B can be solved using a Gröbner basis  $[1, 2]$  $[1, 2]$ , our approach applies to many rings A. Within the computation complexity constraints of the Gröbner basis, we can find all dual-containing codes  $C = Rg/Rf \subset R/Rf$  over A for any given parameters [n, k]. Using this approach we can also test various properties of codes  $C = Rg/Rf \subset R/Rf$ .

- 1. In Section [4.2.1,](#page-9-0) we give an algorithm to compute, within the capability of the Gröbner basis computation, all (Hermitian-) dual-containing codes  $C = Rg/Rf \subset R/Rf$  over A for any given parameters  $[n, k]$ . Dual-containing codes play an important role in constructing quantum error-correcting codes.
- 2. In Table [8](#page-16-0) and Table [3,](#page-13-0) we give examples of Hamming weight distribution of (Hermitian-) dual-containing codes  $C = Rg/Rf \subset R/Rf$  that could not be found without considering either non-zero derivations or non-trivial endomorphisms.
- 3. In Section [5,](#page-11-0) we give an example of a generating polynomial q of a  $[6, 4]$  dual-containing code where all 8 polynomials  $f = hg = gh$  of degree 6 are non-central.
- 4. We give a procedure to decide whether the (Hermitian-) dual code  $C^{\perp}$  of a cyclic left module  $C = Rg/Rf \subset R/Rf$  is again a cyclic left module code  $Rg^{\perp}/Rf \subset R/Rf$ , i.e., generated by a single polynomial  $g^{\perp}$ .
- 5. In Section [4.2.2,](#page-10-0) we use the previous algorithm to show that many (Hermitian-) dual-containing codes  $C = Rg/Rf \subset R/Rf$  have a dual code which is not a cyclic left module code.

We apply our method to all commutative rings of order 4:  $A = \mathbb{F}_2[v]/(v^2 + v)$ ,  $A = \mathbb{F}_2[u]/(u^2)$ , and  $A = \mathbb{F}_4$ , which have a non-trivial endomorphism. We also give some examples in characteristic 4 for the Galois ring

$$
A = \text{GR}(2, 2) = \mathbb{Z}_4[X]/(X^2 + X + 1).
$$

### 2 Preliminaries

#### 2.1 Skew Polynomial Rings

<span id="page-1-0"></span>Let  $A \neq \{0\}$  be a unitary ring (i.e., there exists  $1 \in A \setminus \{0\}$ , such that  $1 \cdot a = a \cdot 1 = a, \forall a \in A$ ). We only consider **unitary endomorphisms**  $\theta$  with the property that  $\theta(1) = 1$ . The identity automorphism will be denoted by id.

**Definition 1.** Let  $A \neq \{0\}$  be a unitary ring and  $\theta$  an endomorphism of A. A  $\theta$ -derivation is a map  $\delta: A \to A$  such that, for all  $a, b \in A$ 

$$
\delta(a+b) = \delta(a) + \delta(b) \quad and \quad \delta(a b) = \delta(a) b + \theta(a) \, \delta(b).
$$

A θ-derivation δ is an **inner θ-derivation** if there exists  $\beta \in A$  with the property that  $\delta(x) =$  $\beta x - \theta(x)\beta$  for all  $x \in A$ . For  $\beta = 0$  we obtain the zero derivation which we denote 0.

We also use the exponential notation  $\theta(a) = a^{\theta}$  and  $\delta(a) = a^{\delta}$  throughout the paper. Skew polynomial rings have been introduced and studied by Ore in [\[14\]](#page-19-2). A skew polynomial ring  $R$  is defined as a set of (left) polynomials  $R = A[X; \theta, \delta] = \left\{ \sum_{i=0}^{n} a_i X^i \mid a_i \in A, n \in \mathbb{N} \right\}$  with coefficients in the ring A. The addition in R is the usual polynomial addition and the multiplication is defined using the rule  $Xa = a^{\theta}X + a^{\delta}$  which is extended using associativity and distributivity.

If the leading coefficient of  $g \in R$  is invertible, then  $\deg(hg) = \deg(h) + \deg(g)$  for all  $h \in$ R. In the case of a non-division ring A, if  $\theta$  is an automorphism and the leading coefficient of  $g \in R$  is invertible, then for any  $f \in R$ , we can perform a right (resp. left) division of f by g and we obtain a unique right (resp. left) remainder of degree  $\langle \deg(q) \rangle$ . To see this, let  $g = \sum_{i=0}^{m} g_i X^i$ ,  $f = \sum_{i=0}^{n} f_i X^i$  and  $m \leq n$ . Then for the right (resp. left) division, the degree of  $f - \overline{(f_n \theta^{n-m}(g_m^{-1})X^{n-m})g}$  (resp.  $f - g \cdot (\theta^{-m}(g_m^{-1}f_n)X^{n-m})$ ) is less than the degree of f. To show that the right<sup>[1](#page-2-0)</sup> division of  $f \in R$  by a fixed  $g \in R$  is unique, suppose that  $f = hg + r = \tilde{h}g + \tilde{r}$ . This implies that  $(h - \tilde{h})g = \tilde{r} - r$ . If  $h - \tilde{h} = c_s X^s + ...$  is non-zero, then the leading monomial in  $(h - \tilde{h})g$  is  $c_s\theta^s(g_m)X^{s+m}$ . A unitary automorphism maps 1 to 1 and invertible elements to invertible elements, so that  $c_s\theta^s(g_m)$  is non-zero. Since the right side of  $(h-\tilde{h})g = \tilde{r}-r$  is of degree  $\langle m \rangle$  we obtain  $h = \tilde{h}$  and  $r = \tilde{r}$ . Note that a unique right division of any  $f \in R$  by a polynomial g with invertible leading coefficient exists even if  $\theta$  is just an endomorphism.

### 2.2 Cyclic Left Module  $(\theta, \delta)$ -Codes  $Rq/Rf \subset R/Rf$

**Definition 2.** Let A be a finite ring,  $\theta$  an endomorphism of A,  $\delta$  a  $\theta$ -derivation of A and R =  $A[X;\theta,\delta]$  the corresponding skew polynomial ring. Let  $f \in R$  be a **monic** skew polynomial of degree n and  $g \in R$  be a right divisor of f. A **cyclic left module**  $(\theta, \delta)$ -code (in short  $(\theta, \delta)$ -code) is defined as  $C = \frac{Rg}{Rf} \subset \frac{R}{Rf}$  in the polynomial representation, and as

$$
C = \{ \mathbf{c} = (c_0, c_1, \dots, c_{n-1}) \mid c_0 + c_1 X + \dots + c_{n-1} X^{n-1} \in Rg/Rf \}
$$

in the vector representation.

Note that  $(\theta, \delta)$ -codes with endomorphism and derivation have been studied in [\[7,](#page-18-4) [8,](#page-18-1) [9,](#page-19-1) [15\]](#page-19-3). For  $\delta = 0$  and  $f = X^n - 1$  we obtain  $\theta$ -cyclic codes characterized by

$$
(a_0, a_1, \ldots, a_{n-2}, a_{n-1}) \in C \implies (\theta(a_{n-1}), \theta(a_0), \theta(a_1), \ldots, \theta(a_{n-2})) \in C
$$

<span id="page-2-1"></span>while the classical cyclic code correspond to  $f = X^n - 1$ ,  $\theta = id$  and  $\delta = 0$  (in this case R is a commutative univariate ring).

**Proposition 1.** Let  $g \in R = A[X; \theta, \delta]$  of degree  $n-k$  be a right divisor of a monic skew polynomial  $f \in R$  of degree n. A cyclic left module  $(\theta, \delta)$ -code  $C = Rg/Rf \subset R/Rf$  has the following properties:

<span id="page-2-0"></span><sup>&</sup>lt;sup>1</sup>The uniqueness of the left division can be shown in the similar manner.

- The left R-module  $R/Rf$  is also a free A-module isomorphic to  $A^n$  with A-basis  $(1, X, \ldots, X^{n-1})$ .
- Rg/Rf is a left R-submodule of  $R/Rf$ .
- Rg/Rf is also a free left A-submodule of  $R/Rf \cong A^n$  of dimension  $k = \deg(f) \deg(g)$  (i.e. a linear code of length n and dimension k over the alphabet A).
- If g is a left and right divisor of  $f = hg = gh$ , then we can assume that all the three polynomials in f = hg for a cyclic left module  $(\theta, \delta)$ -code  $Rg/Rf \subset R/Rf$  are monic (i.e. have leading coefficient 1). The monic generator polynomial g of a cyclic left module  $(\theta, \delta)$ -code Rg/Rf ⊂ R/Rf is unique.
- If g is a left and right divisor of  $f = hg = gh$  and  $\theta$  is an automorphism, then we can assume that all the four polynomials in  $f = hg = gh$  for a cyclic left module  $(\theta, \delta)$ -code  $Rg/Rf \subset R/Rf$  are monic.

PROOF. Since f is monic we can perform a right division of any element of R by f and produce a unique remainder of degree  $\langle n.$  Therefore any element of the R-module  $R/Rf$  has a unique representation (the remainder of the division) of degree  $\langle n \rangle$  in  $R/Rf$ . Viewed as an A-module,  $R/Rf$  is a free A-module with basis  $1, X, \ldots, X^{n-1}$  (i.e. every element in  $R/Rf$  is a unique linear combination of those elements).

For  $g \in R$  we have  $Rf \subset Rg$  if and only if g is a right factor of f and in this case  $Rg/Rf$  is a cyclic left R-submodule of  $R/Rf$  generated by  $g + Rf$ . The leading coefficient  $g_{n-k}$  of  $g = \sum_{i=0}^{n-k} g_i X^i$ is a right divisor of 1 and is therefore invertible. This shows that  $\deg(hg) = \deg(h) + \deg(g)$  for all  $h \in R$  and implies that the R-module  $Rg/Rf$  is a free A-module of rank k of  $A^n$  with basis  $g, Xg, \ldots, X^{k-1}g.$ 

We now prove the fourth statement for  $g = g_{n-k}X^{n-k} + \cdots + g_0$  and  $h = h_kX^k + \cdots + h_0$ . If  $f = hg = gh$ , since f is monic, the leading coefficient of  $f = hg$  is  $h_k\theta^k(g_{n-k}) = 1$ , showing that  $h_k$ and  $\theta^k(g_{n-k})$  are invertible. We obtain

$$
f = \underbrace{(h_k X^k + \dots + h_0)}_h \cdot \underbrace{(g_{n-k} X^{n-k} + \dots + g_0)}_g
$$
  
= 
$$
\underbrace{(h_k X^k + \dots + h_0) \cdot g_{n-k}}_h \cdot \underbrace{g_{n-k}^{-1} \cdot (g_{n-k} X^{n-k} + \dots + g_0)}_g
$$

In this representation  $\tilde{g}$  is a monic polynomial. Since the endomorphism  $\theta$  maps 1 to 1, the product rule of  $A[X;\theta,\delta]$  shows that the leading coefficient of  $\tilde{h}\tilde{g}$  is the leading coefficient of  $\tilde{h}$ . Because  $h\tilde{g} = f$  is monic, we obtain that h is also a monic polynomial. The polynomials g and  $\tilde{g}$  differ by an invertible element. Using the above equations in both directions we see that any multiple of g by a polynomial of degree  $\leq k-1$  is also a multiple of  $\tilde{g}$  by a polynomial of degree  $\leq k-1$  and vice versa. Therefore  $Rg/Rf = R\tilde{q}/Rf$ , showing that g and  $\tilde{q}$  generate the same codes. Hence, without loss of generality, we can assume that  $f, h$  and  $g$  are monic. If C is a cyclic left module  $(\theta, \delta)$ -code with parameters  $[n, k]$  and monic generator polynomial g, then any codeword is of the form  $c = m \cdot g$  with  $\deg(g) = n - k$  and  $\deg(m) < k$ . In particular the only monic polynomial of degree  $n - k$  in C is  $g = 1 \cdot g$ .

<span id="page-3-0"></span>We now show that  $\hbar = \hbar_k X^k + \cdots + \hbar_0$  is monic if  $\theta$  is an automorphism. According to the above we can assume that f and g are monic, so that the leading coefficient  $\theta^{n-k}(\hbar_k)$  in  $g\hbar = f$ must be 1. Since  $\theta^{n-k}$  is an automorphism, we obtain that  $\hbar_k = 1$ .

**Example 1.** The Frobenius chain ring  $A = \mathbb{F}_2[u]/(u^2)$  is a free  $\mathbb{F}_2$ -module  $\mathbb{F}_2[u]$  with  $\mathbb{F}_2$  basis  $[1, u]$ . The only automorphism of A is the identity  $\theta_1 : x \mapsto x$ . There is a unique endomorphism defined by  $\theta_2(u) = 0$  (note that  $\theta_2(1) = 1$ ) which is a polynomial map on  $\mathbb{F}_2$  and on A itself  $\theta_2: x \mapsto x^2$ . Any θ-derivation  $\delta$  is determined by  $\delta(u)$  (note that  $\delta(1) = \delta(0) = 0$ ). The list of  $\theta$ -derivation is:

		$Automorphism \parallel Endomorphism \parallel$
	$\theta_1 = \mathrm{id}$	$\theta_2: u \mapsto 0$
$\delta_1=0$	$u \mapsto 0$	$u \mapsto 0$
$\delta_2$	$u \mapsto 1$	
$\mathfrak{d}_3$	$u \mapsto u$	$u \mapsto u$
	$u \mapsto u+1$	

We marked the inner  $\theta$ -derivation by a gray cell.

In Proposition [1](#page-2-1) we showed that all the three polynomials in  $f = hg$  for a cyclic left module  $(\theta, \delta)$ -code Rg/Rf  $\subset R/Rf$  can be chosen to be monic. If  $\theta$  is a non-trivial endomorphism, i.e., not an automorphism, the  $\hbar$  in the decomposition  $f = g\hbar$  is not necessarily monic. To see this, consider the ring  $R = A[X; \theta_2(u) = 0, \delta_3(u) = u]$  and the code Rg/Rf with  $g = X^2 + uX + u + 1$ and  $f = X^4 + (u+1)X^3 + X + u + 1$ . It can be found that  $f = hg$  with  $h = X^2 + (u+1)X + 1$ , and  $f = gh$  with  $\hbar = (u + 1)X^2 + (u + 1)X + u + 1$  or  $\hbar = (u + 1)X^2 + X + u + 1$ .

The **encoding** of the information  $(b_0, b_1, \ldots, b_{k-1}) \in A^k$  in a cyclic left module  $(\theta, \delta)$ -code  $C = Rg/Rf \subset R/Rf$  is given by the coefficients of  $\left(\sum_{i=0}^{k-1} b_i X^i\right)g \in R$ . A generator matrix of the code is of the following form:

$$
G = \begin{pmatrix} g_0 & g_1 & \cdots & g_{n-k} & 0 & \cdots \\ g_0^{\delta} & g_1^{\delta} + g_0^{\theta} & g_2^{\delta} + g_1^{\theta} & \cdots & g_{n-k}^{\theta} & 0 & \cdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\ g_0^{\delta^{k-1}} & \cdots & \cdots & \cdots & g_{n-k}^{\theta^{k-1}} \end{pmatrix}
$$

The rows are given by the coefficients of  $g, X \cdot g, \ldots, X^{k-1} \cdot g$  and can be computed using the rule  $Xa = a^{\theta} X + a^{\delta}$  for  $a \in A$ . In particular, the code is completely determined by  $g, \theta$  and  $\delta$ .

**Example 2.** In the notations of the above definition, consider a unitary polynomial  $f = hg$  in  $R = \overline{A}[X; \theta, \delta]$  of degree 4 with  $g = g_1 X + g_0$ ,  $h = \sum_{i=0}^{3} h_i X^i$  and  $h_3 g_1 = 1$ . The code  $\mathcal{C} =$  $Rg/Rf \subset R/Rf$  is a  $[4,3]_A$  code whose generating matrix is

$$
G = \begin{pmatrix} g_0 & g_1 & 0 & 0 \\ g_0^{\delta} & g_1^{\delta} + g_0^{\theta} & g_1^{\theta} & 0 \\ g_0^{\delta^2} & g_0^{\delta \theta} + g_0^{\theta \delta} + g_1^{\delta^2} & g_0^{\theta^2} + g_1^{\delta \theta} + g_1^{\theta \delta} & g_1^{\theta^2} \end{pmatrix}.
$$

If  $\theta$  is of the form  $a \mapsto a^{p^m}$  and  $\delta$  is an inner  $\theta$ -derivation  $a \mapsto \beta a - \theta(a)\beta$  (those are the only possibilities if A is a finite field  $\mathbb{F}_q$ , then the entries of the above matrix become polynomials in the coefficients of  $g$  and allow sophisticated computations. This is the reason why almost all known examples of self dual  $(\theta, \delta)$ -code consider A to be a finite field.

**Definition 3** (Hermitian Inner Product and Hermitian Dual). Let  $\sigma$  be an automorphism of A whose order divides 2. The  $\sigma$ -**Hermitian inner product** of  $x, y \in A^n$  is defined as  $\langle x, y \rangle_{\sigma} =$  $\sum_{i=1}^{n} x_i \sigma(y_i)$ . The (σ-**Hermitian) dual code** of a code C is defined as

$$
C^{\perp_{\sigma}}=\{\boldsymbol{v} \mid \langle \boldsymbol{v}, \boldsymbol{c} \rangle_{\sigma}=0, \,\, \forall \boldsymbol{c} \in C\}\,\,.
$$

A code is  $\sigma$ -dual-containing if  $C^{\perp_{\sigma}} \subset C$  and  $\sigma$ -self dual if  $C = C^{\perp_{\sigma}}$ .

<span id="page-5-1"></span>If  $\sigma = id$ , the identity automorphism, we obtain the Euclidean inner product over  $A^k$  and the Euclidean dual. In this case, we omit the  $\sigma$  in the notation.

**Lemma 1.** ([\[16\]](#page-19-4)) Let A be a commutative Frobenius ring and C be a linear code over A. Then for the (Hermitian) dual code  $C^{\perp_{\sigma}}$  we have  $|C| \cdot |C^{\perp_{\sigma}}| = |A|^n$ .

## 3 Parity Check Matrix and Generating Matrix of the Euclidean and Hermitian Dual Code

A parity check matrix of a cyclic left module  $(\theta, \delta)$ -code  $\mathcal{C} = Rg/Rf \subset R/Rf$  over a field  $\mathbb{F}_q$  (where all derivations must be inner) is given in [\[4,](#page-18-0) Corollary 4] and over a commutative Frobenius ring in [\[8,](#page-18-1) [9\]](#page-19-1). In [\[15\]](#page-19-3) a parity check matrix for a cyclic left module  $(\theta, \delta)$ -code  $\mathcal{C} = Rq/Rf \subset R/Rf$  over the ring  $A = (\mathbb{Z}/4\mathbb{Z})[X]/(X^2 - 1)$  is studied when  $f = hg$  is a central polynomial. Our approach is similar to [\[4\]](#page-18-0) and [\[15\]](#page-19-3). In this case  $Rg/Rf$  is an ideal in  $R/Rf$ . In the next theorem we follow the assumption in [\[4,](#page-18-0) [6,](#page-18-5) [8\]](#page-18-1) that g is both a right and a left divisor of f, i.e.,  $f = hg = g\hbar$ , in which case  $Rg/Rf$  is usually only a submodule of  $R/Rf$ . The assumption that  $f = hg = gh$  is much weaker than the assumption that  $f$  is central (see the  $[6, 4]$  example in Section [5\)](#page-11-0).

<span id="page-5-0"></span>**Lemma 2.** Let  $\theta$  be an endomorphism of the finite ring A,  $\delta$  a  $\theta$ -derivation on A,  $R = A[X; \theta, \delta]$ ,  $f \in R$  a monic polynomial having both a right and a left divisor g (i.e.  $f = hg = gh$ ) and  $C =$  $Rg/Rf \subset R/Rf$  a cyclic left module  $(\theta, \delta)$ -code. A word in  $A^n$  corresponding to an element  $w \in R$ of degree  $\lt n$  is a codeword of C if and only if (the coset of)  $w \cdot \hbar = 0$  in R/Rf. We obtain an  $n \times n$ matrix M such that the vector representation of C is  $C = \{w \in A^n | wM = 0\}$  (i.e.  $C = \text{lker}(M)$ is a left kernel of M), where the entries of M are images under compositions of  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and g. The i-th row of M corresponds to the coefficients of  $X^{i-1}\hbar$  mod f, for  $i=1,\ldots,n$ .

PROOF. Since f is monic, an element of  $A^n \cong R/Rf$  has a unique representation as a remainder of the right division by f, which corresponds to a polynomial  $w \in R$  of degree  $\lt n$ . Following [\[5,](#page-18-6) Lemma 8] we now show that w corresponds to a codeword if and only if (the coset of)  $w \cdot \hbar = 0$  in  $R/Rf$ . If  $w \in \mathcal{C}$ , then  $w = \tilde{w}g$  for some  $\tilde{w} \in R$ . Therefore  $w\hbar = \tilde{w}gh = \tilde{w}(h \cdot g)$  showing that  $w\hbar = 0$ in  $R/Rf = R/R(h \cdot g)$ . Conversely, if  $w\hbar = 0$  in  $R/Rf = R/R(h \cdot g)$ , then  $w\hbar = \tilde{w}(h \cdot g) = \tilde{w}(gh)$ for some  $\tilde{w} \in R$ . Since  $\hbar$  is not a zero divisor in R we obtain  $w = \tilde{w}g$ , showing that  $w \in C$ .

Since f is monic, a word in  $A^n$  corresponds to a coset  $w = \sum_{i=0}^{n-1} a_i X^i \in R/Rf$ . Such a coset  $w = \sum_{i=0}^{n-1} c_i$  belongs to C if and only if  $w\hbar = 0$  in  $R/Rf$ . The coefficients of

$$
w\hbar \mod f = \left(\sum_{i=0}^{n-1} c_i X^i\right) \left(\sum_{i=0}^k \hbar_i X^i\right) \mod f
$$

<span id="page-5-2"></span>are obtained by bringing the coefficients  $h_i$  to the left side and performing the right division of f. The code C corresponds to the left kernel of this linear system and can therefore be represented as the left kernel of a matrix M, i.e.,  $\sum_{i=0}^{n-1} c_i M_{i,j} X^j = 0$ ,  $\forall j \in [0, n-1]$ . The entries  $M_{ij} \in A$  are the images under  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and f. Since  $f = g\hbar$ , the entries  $M_{ij} \in A$  are images under  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and g. The *i*-the row of M corresponds to the contribution of  $c_i X^i \cdot \hbar \mod f$  in the product  $w\hbar = 0 \mod f$ .

**Example 3** (A toy example for  $n = 3, k = 1$ ). Consider a ring A, a skew polynomial ring R =  $A[X;\theta,\delta]$  and  $f = X^3 + \sum_{i=0}^{2} f_i X^i \in R$  such that  $f = g\hbar$  in  $A[X;\theta,\delta]$  for  $g = g_2 X^2 + g_1 X + g_0$ and  $\hbar = \hbar_1 X + \hbar_0$ . According to Lemma [2,](#page-5-0)  $w = c_0 + c_1 X + c_2 X^2$  belongs to  $C = Rg/Rf \subset R/Rf$ if and only if  $w\hbar = 0$  in  $R/Rf$ , i.e.  $w\hbar \equiv 0 \mod f$ . Since

$$
w\hbar \mod f = \left(c_2(\hbar_1^{\theta\delta} + \hbar_1^{\delta\theta} + \hbar_0^{\theta^2} - \hbar_1^{\theta^2} f_2) + c_1 \hbar_1^{\theta}\right) X^2 + \left(c_2(\hbar_1^{\delta^2} + \hbar_0^{\theta\delta} + \hbar_0^{\delta\theta} - \hbar_1^{\theta^2} f_1) + c_1(\hbar_1^{\delta} + \hbar_0^{\theta}) + c_0 \hbar_1\right) X + c_2(\hbar_0^{\delta^2} - \hbar_1^{\theta^2} f_0) + c_1 \hbar_0^{\delta} + c_0 \hbar_0
$$

we obtain the condition  $w \in \mathcal{C} \Leftrightarrow w \cdot M = 0$  where  $w = (c_0, c_1, c_2)$  and

<span id="page-6-0"></span>
$$
M = \begin{pmatrix} \hbar_0 & \hbar_1 & 0 \\ \hbar_0^{\delta} & \hbar_1^{\delta} + \hbar_0^{\theta} & \hbar_1^{\beta} \\ \hbar_0^{\delta^2} - \hbar_1^{\theta^2} f_0 & \hbar_1^{\delta^2} + \hbar_0^{\theta\delta} + \hbar_0^{\delta\theta} - \hbar_1^{\theta^2} f_1 & \hbar_1^{\theta\delta} + \hbar_0^{\delta\theta} + \hbar_0^{\theta^2} - \hbar_1^{\theta^2} f_2 \end{pmatrix}.
$$
 (1)

Note that the entry  $M_{ij}$  corresponds to the coefficient of the term  $c_i X^j$  in the polynomial  $w\hbar$  mod f.

The following result is contained in [\[8,](#page-18-1) [9\]](#page-19-1) where the result is proven using pseudo-linear transformation or Matrix-Product Codes, while we give a proof within the setting of skew polynomial rings.

<span id="page-6-2"></span>**Theorem 1.** (cf. [\[8,](#page-18-1) [15\]](#page-19-3)) Let  $\theta$  be an endomorphism of the finite Frobenius commutative ring A, δ a θ-derivation on A, R = A[X; θ, δ] a skew polynomial ring, f ∈ R a monic polynomial having a right and left divisor g (i.e.  $f = hg = gh$ ) and  $C = Rg/Rf \subset R/Rf$  a cyclic left module  $(\theta, \delta)$ code. Let C be the vector representation of C. The dual code  $C^{\perp}$  is a free A-module code and  $|C| \cdot |C^{\perp}| = |A|^n$ . There exists a parity check matrix H for the code C such that it is a generator matrix of the dual code  $C^{\perp}$ . The entries of the matrix H are images under compositions of  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and q.

**PROOF.** We denote by  $\hat{C}$  the code generated by the columns of the  $n \times n$  matrix M in Lemma [2](#page-5-0) whose left kernel is exactly the code C. Then the columns of M form a generating set of  $\tilde{C}$ . By construction we have that  $\tilde{C} \subset C^{\perp}$ . Note that  $\mathbf{w} \in C$  if and only if  $\mathbf{w}M = \mathbf{0}$ , which is equivalent to w is orthogonal to all generators of  $\tilde{C}$ . Therefore  $C = \tilde{C}^{\perp}$ . By Lemma [1](#page-5-1) we have that  $|\tilde{C}^{\perp}| \cdot |\tilde{C}| = |A|^n$ . From  $C = \tilde{C}^{\perp}$  and  $|C| = |A|^k$  we then get  $|\tilde{C}| = |A|^{n-k}$ . By Lemma [1](#page-5-1) we also have that  $|C^{\perp}| \cdot |C| = |A|^n$ , which implies that  $|C^{\perp}| = |A|^{n-k}$ . Since  $\tilde{C} \subset C^{\perp}$  and both codes have the same number of elements we get  $\tilde{C} = C^{\perp}$ .

It is shown in Lemma [2](#page-5-0) that for  $i = 1, \ldots, n - k$ , the *i*-th row of M corresponds to  $X^{i-1}$   $\hbar$ (e.g. the gray part in [\(1\)](#page-6-0)). This shows that the right-upper  $(n - k) \times (n - k)$  submatrix of M is lower triangular with invertible diagonal elements  $\hbar_k, \theta(\hbar_k), \ldots, \theta^{n-k-1}(\hbar_k)$  and the right-most  $n - k$  columns of M are therefore linearly independent. Hence, the A-submodule generated by the right-most  $n - k$  columns of M contains  $|A|^{n-k}$  elements. This shows that  $C^{\perp}$  is a free A-module generated by the right-most  $n - k$  columns of M which (after transposing) form a parity check matrix of C (see [\(2\)](#page-6-1) for an example).  $\blacksquare$ 

<span id="page-6-3"></span>Example 4. According to Theorem [1,](#page-6-2) the dual of the code in Example [3](#page-5-2) is generated by the rightmost two columns M in  $(1)$  which (after transposing) form a parity check matrix of C,

<span id="page-6-1"></span>
$$
H = \begin{pmatrix} \hbar_1 & \hbar_1^{\delta} + \hbar_0^{\theta} & \hbar_1^{\delta^2} + \hbar_0^{\theta\delta} + \hbar_0^{\delta\theta} - \hbar_1^{\theta^2} f_1 \\ 0 & \hbar_1^{\theta} & \hbar_1^{\theta\delta} + \hbar_1^{\delta\theta} + \hbar_0^{\theta^2} - \hbar_1^{\theta^2} f_2 \end{pmatrix}.
$$
 (2)

**Theorem 2.** Let  $\sigma$  be an automorphism of order 2 of A,  $\theta$  be an endomorphism of the finite Frobenius commutative ring A,  $\delta$  be a  $\theta$ -derivation on A,  $R = A[X; \theta, \delta]$  a skew polynomial ring,  $f \in R$  a monic polynomial having a right and left divisor g (i.e.  $f = hg = gh$ ) and  $C = Rg/Rf \subset$  $R/Rf$  a cyclic left module  $(\theta, \delta)$ -code. Let C be the vector representation of C and  $C^{\perp}$  the dual code of C. If we apply  $\sigma$  to all entries of the generator matrix  $G^{\perp} := H$  of the dual code  $C^{\perp}$ , then we obtain a generator matrix  $G^{\perp_{\sigma}}$  of the  $\sigma$ -Hermitian dual code  $C^{\perp_{\sigma}}$  of C. The coefficients of the matrix  $\sigma(H)$  are expressions in images under compositions of  $\theta$ ,  $\delta$  and  $\sigma$  of the coefficients of  $\hbar$  and g.

PROOF. For each row  $g_s, s \in \{1, ..., k\}$  of a generating matrix G of C and each row  $g_t^{\perp}, t \in$  $\{1,\ldots,n-k\}$  of a generating matrix of  $G^{\perp}$  of  $C^{\perp}$  we have  $\langle g_s, g_t^{\perp} \rangle = \sum_{i=1}^n g_{s,i} g_{t,i}^{\perp} = 0$ . Therefore

$$
\langle g_s, \sigma(g_t^{\perp}) \rangle_{\sigma} = \sum_{i=1}^n g_{s,i} \, \sigma(\sigma(g_{t,i}^{\perp})) = \sum_{i=1}^n g_{s,i} \, g_{t,i}^{\perp} = 0.
$$

Since the  $n - k$  rows of  $G^{\perp}$  generate a free code of dimension  $|A|^{n-k}$  and  $\sigma$  is an automorphism, the  $n - k$  rows of  $\sigma(G^{\perp})$  also generate a free code of dimension  $|A|^{n-k}$ . Lemma [1](#page-5-1) implies that they generate  $C^{\perp_{\sigma}}$ .

## 4 Computing all Dual-Containing  $(\theta, \delta)$ -Codes

For the case  $\delta = 0$  and  $A = \mathbb{F}_q$ , the generators of the dual code have been derived in [\[3,](#page-18-7) [5,](#page-18-6) [6,](#page-18-5) [8,](#page-18-1) [9\]](#page-19-1). For an arbitrary Frobenius ring A or  $\delta \neq 0$ , the dual code is much less studied. The algorithms in this section will allow us to show that the dual of a cyclic left module  $(\theta, \delta)$ -code is in general not a cyclic left module (θ, δ)-code.

#### 4.1 Polynomial Maps

<span id="page-7-0"></span>Our first goal is to transform algebraic expressions in the images under  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and g (cf. M in [\(1\)](#page-6-0) above), into multivariate polynomials over some subalgebra of A.

**Definition 4.** A polynomial map on a ring B is a map  $f : B \to B; x \mapsto \sum_{i=0}^{s} b_i x^i$ , where  $s \in \mathbb{N}$ and  $b_i \in B$ .

<span id="page-7-1"></span>**Lemma 3.** Let  $\theta$  be an endomorphism of the finite ring A,  $\delta$  a  $\theta$ -derivation of A and  $B \subset A$  a subring. Let  $\mathcal E$  be a system of finitely many equations over A that are polynomial expressions in the images under  $\theta$  and  $\delta$  of a finite set of variables  $y_1, \ldots, y_m$ . If  $A = B[a_1, \ldots, a_s]$  ( $s \in \mathbb{N}$ ) is a free B-module and the restriction of  $\delta$  and  $\theta$  to B are polynomial maps, then all solutions in  $A^m$ of the system  $\mathcal E$  correspond to the solutions in  $B^{ms}$  of a system of polynomial equations over  $B$  in the variables  $y_{1,1}, \ldots, y_{1,s}, \ldots, y_{m,1}, \ldots, y_{m,s}$  where  $y_i = y_{i,1}a_1 + \cdots + y_{i,s}a_s$ .

**PROOF.** The image of the B-basis  $a_1, \ldots, a_s$  of A under  $\delta$  and  $\theta$  are expressions of the form  $\theta(a_i) = \gamma_{i,1}a_1 + \cdots + \gamma_{i,s}a_s$  and  $\delta(a_i) = \beta_{i,1}a_1 + \cdots + \beta_{i,s}a_s$  for some given  $\gamma_{i,j}$  and  $\beta_{i,j}$  in B:

$$
y_i^{\theta} = (y_{i,1}a_1 + \dots + y_{i,s}a_s)^{\theta}
$$
  
\n
$$
= y_{i,1}^{\theta}a_1^{\theta} + \dots + y_{i,s}^{\theta}a_s^{\theta}
$$
  
\n
$$
= y_{i,1}^{\theta}(\gamma_{1,1}a_1 + \dots + \gamma_{1,s}a_s) + \dots + y_{i,s}^{\theta}(\gamma_{s,1}a_1 + \dots + \gamma_{s,s}a_s)
$$
  
\n
$$
y_i^{\delta} = (y_{i,1}a_1 + \dots + y_{i,s}a_s)^{\delta} = (y_{i,1}a_1)^{\delta} + \dots + (y_{i,s}a_s)^{\delta}
$$
  
\n
$$
= y_{i,1}^{\delta}a_1 + y_{i,1}^{\theta}a_1^{\delta} + \dots + y_{i,s}^{\delta}a_s + y_{i,s}^{\theta}a_s^{\delta}
$$
  
\n
$$
= y_{i,1}^{\delta}a_1 + y_{i,1}^{\theta}(\beta_{1,1}a_1 + \dots + \beta_{1,s}a_s) + \dots + y_{i,s}^{\delta}a_s + y_{i,s}^{\theta}(\beta_{s,1}a_1 + \dots + \beta_{s,s}a_s)
$$

Using

- 1. the algebra relations  $a_i a_j = \mu_{i,j,1} a_1 + \ldots + \mu_{i,j,s} a_s$  (where  $\mu_{i,j,s} \in B$  are given),
- 2. the additive and multiplicative properties of  $\theta$  and  $\delta$ ,
- 3. the fact that the restriction of  $\delta$  and  $\theta$  to B are polynomial maps on B (so that  $y_{i,j}^{\theta}$  and  $y_{i,j}^{\delta}$ are polynomials in  $y_{i,j}$  over  $B$ ),

we can recursively transform any system of polynomial equations in the variables  $y_1, \ldots, y_m$ , whose solutions are in  $A^m$ , into a system of polynomial equations in the variables  $y_{1,1}, \ldots, y_{1,s}, \ldots, y_{m,1}, \ldots$ ,  $y_{m,s}$ , whose solutions are in  $B^{ms}$ .

<span id="page-8-0"></span>The following two examples show that there are endomorphism  $\theta$  and  $\theta$ -derivation  $\delta$  of a ring A which are not polynomial maps over A, but only polynomial maps over a subring B.

**Example 5.** Consider the Frobenius ring  $A = \mathbb{F}_2[v]/(v^2 + v)$  of order 4. There are two automorphisms  $\theta_1 = id$  and  $\theta_2$  of order two, and two non-trivial endomorphisms  $\theta_3$  and  $\theta_4$ . Any  $\theta$ -derivation δ is determined by  $δ(v)$  (note that  $δ(1) = δ(0) = 0$ ). All the θ-derivations are listed below:

		Automorphism	Endomorphism		
	$\theta_1 = id \mid \theta_2(v) = v + 1$		$\theta_3(v) = 0 \mid \theta_4(v) = 1$		
$\delta_1=0$	$v \mapsto 0$	$v \mapsto 0$	$v \mapsto 0$	$v \mapsto 0$	
$\delta_2$		$v \mapsto 1$			
$\delta_3$		$v \mapsto v$	$v \mapsto v$		
		$v \mapsto v+1$		$v \mapsto v+1$	

The inner θ-derivations are marked by a gray cell. Here all θ-derivations are inner. Suppose that the automorphism  $\theta_2$  is a polynomial map on A of the form

$$
f: x \mapsto \sum_{i \in \mathbb{N}_0} (\alpha_{i,1}v + \alpha_{i,0})x^i = \sum_{i \in \mathbb{N}_0} \alpha_{i,1}vx^i + \sum_{i \in \mathbb{N}_0} \alpha_{i,0}x^i \qquad (\alpha_{i,j} \in \mathbb{F}_2).
$$

Then  $\theta_2(0) = 0 \Rightarrow \alpha_{0,0} = 0$ . Since  $\alpha_{i,j} \in \{0,1\}$ ,  $f(v)$  is a multiple of positive powers of v. Since  $v^2 = v$  we get that  $f(v)$  is a sum of v, which is either v or 0 in this ring. Since  $\theta_2(v) = v + 1$ , we obtain that  $\theta_2$  is not a polynomial map on A.

**Example 6.** We keep the notation of Example [1](#page-3-0) for the ring  $A = \mathbb{F}_2[u]/(u^2)$ . The only automorphism of A is the identity  $\theta_1: x \mapsto x$  which is a polynomial map. Suppose that a derivation  $\delta$  of A is given by a polynomial map  $\delta: x \mapsto \sum_{i=0}^{t} b_i x^i$  over A (where  $b_i \in A$ ). Since  $\delta(1) = 0$ , we must have  $b_0 = 0$  in the polynomial map. From  $u^2 = 0$ , we obtain  $\delta : u \mapsto \sum_{i=1}^t b_i u^i = b_1 u$ . Write  $b_1 = \beta_{1,1}u + \beta_{1,0} \in A$  for some  $\beta_{1,1}, \beta_{1,0} \in \mathbb{F}_2$ , then  $\delta(u) = \beta_{1,1}u^2 + \beta_{1,0}u = \overline{\beta_{1,0}u}$ , which can never be  $u + 1$  or 1. Hence,  $\delta_2(u) = 1$  and  $\delta_4(u) = u + 1$  are not polynomial maps on A. For this ring we will always work over  $B = \mathbb{F}_2$  even for  $\delta_1$  and  $\delta_3$ . Codes of small length over A are classified in  $[11, 12]$  $[11, 12]$ .

<span id="page-9-1"></span>Lemma 4. Automorphisms and derivations of a finite Frobenius ring A are polynomial maps over the smallest unitary subring B of A.

PROOF. The smallest unitary subring B of A is the image of the canonical map  $\mathbb{Z} \to A$  given by  $1 \mapsto 1$  and is either isomorphic to a finite field  $\mathbb{F}_p$  of prime order or to an integer modular ring  $\mathbb{Z}_m = \mathbb{Z}/(m)$  (here p or m is the characteristic of the ring A). Since any automorphism  $\theta$  is given by  $x \mapsto x$  and  $\theta$ -derivation  $\delta$  is given by  $x \mapsto 0$  on B, they are both polynomial maps on B.

#### 4.2 Computations via Gröbner Basis over  $B \subset A$

In this section we assume that  $\theta$  and  $\delta$  are polynomial maps over a subalgebra  $B \subset A$  (this is always the case for the smallest unitary subring B of A by Lemma [4\)](#page-9-1) and that  $A = B[a_1, \ldots, a_s]$  is a free B-module. This will enable us to transform any expression in  $\theta$  and  $\delta$  over A into a polynomial expression over  $B$  (Lemma [3\)](#page-7-1). The classical algorithm to solve systems of polynomial equations in a multivariate polynomial commutative ring  $B[y_{1,1}, \ldots, y_{1,s}, \ldots, y_{m,1}, \ldots, y_{m,s}]$  is via Gröbner **basis**. This algorithm exists in particular if B is a field or an integer quotient ring  $([1, 2])$  $([1, 2])$  $([1, 2])$  $([1, 2])$ , and therefore always over the smallest unitary subring  $B$  of the finite unitary ring  $A$  (Lemma [4\)](#page-9-1).

#### <span id="page-9-0"></span>4.2.1 An Algorithm to Compute All Dual-Containing  $(\theta, \delta)$ -Codes

We first express the unknown coefficients in A of g and  $\hbar$  as linear combinations in a given B-basis of A over B with unknown coefficients  $x_i$  in B. The expressions in images under compositions of  $\theta$  and  $\delta$  of the coefficients of  $\hbar$  and g then become polynomials in the variables  $x_i$  in  $B$ . We then obtain a parity check matrix whose coefficients are polynomials in the variables  $x_i$ . We can impose that q divides  $q\hbar$  on the right by imposing that all the coefficients of the remainder, whose entries are polynomials in the unknown  $x_i$ , to be zero. We can also impose  $C^{\perp} \subset C$  by imposing all the entries  $M^{\top} \cdot M$ , which are also polynomials in the unknown  $x_i$ , to be zero. All these conditions lead to a multivariate polynomial system in the unknowns  $x_i$  with coefficients in B. If a Gröbner basis algorithm exists for the ring  $B$ , then we can compute all dual-containing cyclic left module  $(\theta, \delta)$ -codes  $\mathcal{C} = Rg/Rf \subset R/Rf$  for the fixed parameters  $[n, k]$ . Note that  $\mathcal{C}^{\perp} \subset \mathcal{C}$  is a property of the code C and is therefore independent of the choice of  $h, f, h$ . In other words, if  $C^{\perp} \subset C$  holds for some valid solution of  $h, f, \hbar$ , then this will hold for any valid solution of  $h, f, \hbar$ . We therefore simply have to compute an elimination basis for the possible polynomials  $g$  and keep those skew polynomials g that can be extended to a solution of the whole system.

<span id="page-10-1"></span>**Algorithm 1:** Computing all *dual-containing* cyclic module  $(\theta, \delta)$ -codes for given [n, k].

**Input:** A,  $\theta$ ,  $\delta$ , a subalgebra  $B \subset A$  over which  $A = B[a_1, \ldots, a_s]$  is free and over which  $\theta$ ,  $\delta$  are polynomial maps and the Gröbner basis can be computed, code parameters  $n, k.$ **Output:** A set of solutions  $P = \{g, h, f \mid C = Rg/Rf \text{ is dual-containing}\}\$ 1  $P_1 \leftarrow B[g_{0,1}, \ldots, g_{0,s}, \ldots, g_{n-k-1,1}, \ldots, g_{n-k-1,s}, \hbar_{0,1}, \ldots, \hbar_{0,s}, \ldots, \hbar_{k-1,1}, \ldots, \hbar_{k-1,s}]$ ; /\* multivariate ring over  $B *$ /  $2~\mathcal{P} \leftarrow \{\}\; ; \qquad \qquad \text{/* Initialize a set to collect } g, \hbar \text{ of self-dual codes } *\mathcal{P}$ 3 foreach  $\hbar_k = \sum_{j=1}^s \hbar_{k,j} a_j \in \{invertible \ element \ of \ A\}$  do 4 LSEs  $\leftarrow$  {Constraints such that  $g_{i,j}, \hbar_{i,j} \in B$ }; /\*  $g_{i,j}^p = g_{i,j}, \hbar_{i,j}^p = \hbar_{i,j}$  if  $B = \mathbb{F}_p$  \*/ 5  $g \leftarrow \sum_{i=0}^{n-k-1} (\sum_{j=1}^{s} g_{i,j} a_j) X^i + X^{n-k}$ /\*  $q \in P_1[X; \theta, \delta]$  \*/ 6  $\hat{h} \leftarrow \sum_{i=0}^{k-1} (\sum_{j=1}^{s} \hbar_{i,j} a_j) X^i + (\sum_{j=1}^{s} \hbar_{k,j} a_j) X^k$ /\*  $\hbar \in P_1[X; \theta, \delta]$  \*/  $7 \mid f \leftarrow g \cdot \hbar;$  /\*  $LC(f)$  may not be monic but does not contain variable \*/ 8 h, r ← quotient, remainder of g right dividing f;  $\forall * h, r \in P_1[X; \theta, \delta] * \ell$ 9 LSEs  $\overset{\text{Append}}{\longleftarrow}$  {All coefficients of r are 0 }; /\* implies  $g \mid r f \cdot \frac{f}{f}$ 10  $\mathbf{G} \leftarrow$  a generator matrix constructed from q; 11  $M \leftarrow$  the matrix constructed from  $\hbar$  according to Example [3;](#page-5-2) 12 LSEs  $\overset{\text{Append}}{\longleftarrow}$  {All entries in  $\boldsymbol{M}^\top\cdot\boldsymbol{M}$  are  $0\}$  ;  $\hspace{1.5cm}\text{\hspace{0.5cm}}\prime\ast\text{ implies}\hspace{0.1cm}C$  $\mathcal{U}^*$  implies  $C^\perp \subseteq C \,\, * \mathcal{U}$ 13  $S \leftarrow \{\text{solutions of } g_{0,1}, \ldots, g_{n-k-1,s}, h_{0,1}, \ldots, h_{k-1,s} \text{ from the Groebner basis of LSEs}\};$ 14  $\mathcal{P} \overset{\text{Append}}{\longleftarrow} \{g, \hbar, f \in A[X; \theta, \delta] : \forall \text{ solution in } \mathcal{S}\};$  $/ * g, \hbar \in A[X; \theta, \delta]$  are reconstructed by evaluating coefficients of  $g, \hbar \in P_1[X; \theta, \delta]$  for each solution in S; f is reconstructed by  $f = g \cdot \hbar$ \*/ <sup>15</sup> end

#### <span id="page-10-0"></span>4.2.2 Is the Dual  $C^{\perp_{\sigma}}$  of a Cyclic Module  $(\theta, \delta)$ -Code Again a Cyclic Module  $(\theta, \delta)$ -Code ?

In the following let  $\sigma$  be the identity or an automorphism of order 2 of A. Note that the rows of the generator matrix  $G^{\perp_{\sigma}} = \sigma(H)$  in Theorem [2](#page-6-3) correspond to skew polynomials  $p_1, \ldots, p_k$  in  $R/Rf$  which form an A-basis of the free code  $C^{\perp_{\sigma}}$ . If the (Hermitian-) dual code  $C^{\perp_{\sigma}}$  is a cyclic module code  $Rg^{\perp_{\sigma}}/R\tilde{f} \subset R/R\tilde{f}$  generated by some monic skew polynomial  $g^{\perp_{\sigma}}$  of degree k, then this monic polynomial  $g^{\perp_{\sigma}}$  is a left divisor of all the polynomials  $p_1, \ldots, p_k$ .

We follow the notations in Algorithm [1.](#page-10-1) We first set up a monic polynomial

$$
g^{\perp_{\sigma}} = \sum_{i=0}^{k-1} (\sum_{j=1}^s g_{i,j}^{\perp_{\sigma}} a_j) X^i + X^k \in R
$$

in the unknowns  $g_{0,1}^{\perp_{\sigma}}, \ldots, g_{b,s}^{\perp_{\sigma}}, \ldots, g_{k-1,s}^{\perp_{\sigma}}$  over B. Then we perform a right division of all polynomials  $p_1, \ldots, p_{n-k}$  by  $g^{\perp_{\sigma}}$  and set the remainders  $r_1, \ldots, r_{n-k}$  to zero. Note that the coefficients of all  $r_1, \ldots, r_{n-k}$  are polynomials in  $B[g_{0,1}^{\perp_{\sigma}}, \ldots, g_{k-1,s}^{\perp_{\sigma}}]$  and must all be zero. This leads to a polynomial system over B that can be solved by an algorithm via Gröbner basis. If the Gröbner basis is  $\{1\}$ then  $C^{\perp_{\sigma}}$  is not a cyclic module code in  $R/Rf$  for any  $f \in R$ . Otherwise the Gröbner basis gives the generator polynomial  $g^{\perp_{\sigma}}$  of degree k of the cyclic module code  $C^{\perp_{\sigma}}$ .

# <span id="page-11-0"></span>5 Computational Results for  $A = \mathbb{F}_2[v]/(v^2 + v)$

We keep the notation used in Example [5](#page-8-0) and compute the dual-containing cyclic left module  $(\theta, \delta)$ code over the ring  $A = \mathbb{F}_2[v]/(v^2 + v)$  using the algorithm given in Section [4.2.1.](#page-9-0) Lemma [4](#page-9-1) shows that we can use the subalgebra  $B = \mathbb{F}_2 \subset A$  for the algorithm. Codes of small length over A are classified in [\[12\]](#page-19-6). We follow [\[11\]](#page-19-5) and define the Lee weight of  $0, 1, v, v + 1$  respectively as  $0, 2, 1, 1$  $0, 2, 1, 1$  $0, 2, 1, 1$  and the Bachoc weight respectively as  $0, 1, 2, 2$ . Table [1a](#page-12-0) and Table 2 give an overview of the best Euclidean and Hermitian dual-containing codes  $C = Rg/Rf \subset R/Rf$  (the algorithm found all such codes). The empty set indicates that the approach shows that no dual-containing code  $Rg/Rf \subset R/Rf$  exists for the parameter  $[n, k]$ . A question mark indicates that such dualcontaining codes exist, but we did not compute the minimal distance. The codes that could not have been found without considering non-zero derivations are marked in gray; the codes that only can be found by a non-zero derivation and an endomorphism which is not an automorphism are marked in dark gray. Examples of such codes are the three weight distributions of the [6, 4] codes in Table [3.](#page-13-0) Table [3](#page-13-0) and [4](#page-13-2) show more precisely which Hamming weight enumerators could only be found by using specific  $(\theta, \delta)$  combinations.

Besides the complexity of a Gröbner basis, the complexity of our approach is also linked to the fact that many decompositions  $f = hg = g\hbar$  can exist for a fixed g, and that all combinations lead to the same code whose generating matrix is constructed only from  $q$  and the corresponding  $A[X;\theta,\delta]$ . To illustrate this we present in more detail the results for the [6,4] code with Hamming weight enumerator  $1+13w^2+24w^3+\ldots$ . There are four possible generator polynomials g presented in Table [5.](#page-14-0) Note that given g and  $A[X; \theta, \delta]$  one can compute a generating matrix immediately. We consider the first polynomial  $g = X^2 + X + v + 1 \in (\mathbb{F}_2[v]/[v^2 + v]) [X; \theta_3, \delta_3]$  of Table [5.](#page-14-0) There exist 8 non-central polynomials f for which there are polynomials h,  $\hbar$  such that  $f = hg = g\hbar$ , i.e.,  $g$  is a left and right divisor of  $f$ :

$$
f_1 = X^6 + vX^4 + vX^3 + vX + v + 1 = (X^4 + X^3 + vX^2 + X + v + 1) \cdot g
$$
  
\n
$$
f_2 = X^6 + X^5 + (v + 1)X^4 + X^3 + vX + v + 1
$$
  
\n
$$
= (X^4 + vX^2 + (v + 1)X + 1) \cdot g
$$
  
\n
$$
f_3 = X^6 + (v + 1)X^4 + vX^3 + vX^2 + X + v + 1
$$
  
\n
$$
= (X^4 + X^3 + (v + 1)X^2 + 1) \cdot g
$$
  
\n
$$
f_4 = X^6 + X^5 + vX^4 + X^3 + vX^2 + X + v + 1
$$
  
\n
$$
= (X^4 + (v + 1)X^2 + vX + v + 1) \cdot g
$$
  
\n
$$
f_5 = X^6 + vX^4 + vX^3 + X^2 + (v + 1)X = (X^4 + X^3 + vX^2 + X + v) \cdot g
$$
  
\n
$$
f_6 = X^6 + X^5 + (v + 1)X^4 + X^3 + X^2 + (v + 1)X
$$
  
\n
$$
= (X^4 + vX^2 + (v + 1)X) \cdot g
$$
  
\n
$$
f_7 = X^6 + (v + 1)X^4 + vX^3 + (v + 1)X^2 = (X^4 + X^3 + (v + 1)X^2) \cdot g
$$
  
\n
$$
f_8 = X^6 + X^5 + vX^4 + X^3 + (v + 1)X^2 = (X^4 + (v + 1)X^2 + vX + v) \cdot g
$$

For each f, there is a unique h corresponding to  $f = hg$  and 16 distinct  $\hbar$  such that  $f = g\hbar$ , where

$$
  
\n
$$
= g \cdot (X^4 + X^3 + vX^2 + X + 1) = g \cdot (X^4 + (v+1)X^3 + X + 1)
$$
  
\n
$$
= g \cdot (X^4 + X^3 + X + 1)
$$

The  $[8, 4, d_H = 5]$  code in Table [2](#page-13-1) that achieves the Singleton bound in Hamming metric are obtained with  $g = X^4 + (v+1)X^3 + X^2 + vX + 1$  and  $g = X^4 + vX^3 + X^2 + (v+1)X + 1$  in  $(\mathbb{F}_2[v]/[v^2+v])$  [X; id,  $\theta_2$ ].

We apply the algorithm presented in Section [4.2.2](#page-10-0) to verify for which dual-containing codes  $C = Rg/Rf \subset R/Rf$  the dual code  $C^{\perp}$  is again a cyclic module  $(\theta, \delta)$ -code. See in Table [1b](#page-12-0) and Table [1c](#page-12-0) for an overview. We list two examples below which show that the dual of a dual-containing cyclic module  $(θ, δ)$ -code is not always a cyclic module  $(θ, δ)$ -code:

• For  $[n = 4, k = 3]$ , we found three  $g \in A[X; \theta_2, \delta_2]$  that generate dual-containing cyclic module codes:  $g_1 = X + v + 1$ ,  $g_2 = X + 1$ ,  $g_3 = X + v$  where only the dual of  $g_2 = X + 1$  is a cyclic module code, with  $g_2^{\perp} = X^3 + X^2 + X + 1$ .

• For  $[n = 6, k = 4]$ , we found four  $g \in A[X; \theta_3, \delta_3]$  that generate dual-containing cyclic module codes:  $g_1 = X^2 + (v+1)X + v+1$ ,  $g_2 = X^2 + X + 1$ ,  $g_3 = X^2 + X + v+1$ ,  $g_4 = X^2 + (v+1)X + 1$ . Only the dual of  $g_2$  and  $g_4$  are cyclic module codes, with  $g_2^{\perp} = X^4 + X^3 + X + 1$  and  $g_4^{\perp} = X^4 + (v+1)X^3 + X + v + 1$ , respectively.

# 6 Computational Results for  $A = \mathbb{F}_2[u]/(u^2)$

We keep the notations of Example [1](#page-10-1) for the ring  $A = \mathbb{F}_2[u]/(u^2)$ . Lemma [4](#page-9-1) and Algorithm 1 show that we can search dual-containing cyclic left module  $(\theta, \delta)$ -code  $\mathcal{C} = Rg/Rf \subset R/Rf$  over the subalgebra  $B = \mathbb{F}_2 \subset A$  using a Gröbner basis approach. We follow [\[11\]](#page-19-5) and define the Lee weight of  $0, 1, u, u + 1$  respectively as  $0, 1, 2, 1$  and the Euclidean weight respectively as  $0, 1, 4, 1$ . Table [6](#page-15-0) give an overview of the best dual-containing codes  $C = Rq/Rf \subset R/Rf$  (the algorithm found all such codes). For the cell marked in gray, the dual-containing cyclic module codes are only found from the maps (id,  $\delta_2$ ) and (id,  $\delta_4$ ).

<span id="page-15-0"></span>Table 6: Best Hamming, Lee, and Euclidean distances of dual-containing cyclic module  $(\theta, \delta)$ -codes over  $\mathbb{F}_2[u]/(u^2)$ .

Table [7](#page-16-1) gives an overview whether the dual codes  $C^{\perp}$  of the dual-containing codes found by Algorithm [1](#page-10-1) are again cyclic module  $(\theta, \delta)$ -codes.

Table [8](#page-16-0) shows examples for which Hamming weight enumerators could only be found using specific  $(\theta, \delta)$  combinations. In particular the gray cells indicate those that can only be obtained using a non-zero derivation.

## 7 Computational Results for  $A = \mathbb{F}_4$

Consider the field  $\mathbb{F}_4 = \mathbb{F}_2(\alpha)$  where  $\alpha^2 = \alpha + 1$ . There are two automorphisms:  $\theta_1 = id$  and the Frobenius automorphism  $\theta_2: x \mapsto x^2$ .  $\theta_2$  is of order 2 and is a polynomial map on both  $\mathbb{F}_4$  and  $\mathbb{F}_2$ . All the θ-derivations are inner derivations and are marked in gray in the list below:

	Automorphism				
		$\theta_1 = \mathrm{id} \mid \theta_2(\alpha) = \alpha + 1$			
$\delta_1=0$	$\alpha \mapsto 0$	$\alpha \mapsto 0$			
ბი		$\alpha \mapsto 1$			
92		$\alpha \mapsto \alpha$			
		$\alpha \mapsto \alpha + 1$

6		All	All	All				
			All		All			
8			All	All	All	All		
9							(id, $\delta_2$ ): None (id, $\delta_4$ ): Some	
$10\,$				All	All			All

<span id="page-16-1"></span>Table 7: For which dual-containing cyclic module codes C is the dual  $C^{\perp}$  again a cyclic module code, according to Section [4.2.2?](#page-10-0)

<span id="page-16-0"></span>Table 8: Hamming weight enumerator of dual-containing  $(\theta, \delta)$ -codes over  $\mathbb{F}_2[u]/[u^2]$ .

n,k	Hamming Weight	Constructed with $(\theta, \delta)$
[4,2]	$1 + 2w^2 + 8w^3 + 5w^4$	$(id, 0), (id, \delta_2), (id, \delta_3), (\theta_2, \delta_2)$
	$1+6w^2+9w^4$	all maps
	$1 + 4w^2 + 30w^4 + \dots$	$(id,0), (\theta_2,\delta_2)$
	$1 + 4w^2 + 46w^4 + \dots$	(id, 0)
[8,4]	$1 + 4w^2 + 16w^3 + \dots$	(id,0)
	$1 + 12w^2 + 54w^4 + \dots$	all maps
	$1 + 26w^4 + 64w^5 + \dots$	$(\mathrm{id}, \delta_2)$
	$1 + 4w^2 + 16w^3 + 94w^4 + \dots$	$(id, 0), (id, \delta_2)$
	$1 + 4w^2 + 16w^3 + 110w^4 + \dots$	(id, 0)
[8,5]	$1 + 12w^2 + 102w^4 + \dots$	all maps
	$1 + 16w^2 + 8w^3 + 114w^4 + \dots$	$(\mathrm{id}, \delta_2)$

Following [\[11\]](#page-19-5) we define the Lee weight of  $0, 1, \alpha, \alpha + 1$  respectively as  $0, 2, 1, 1$  and following [\[13\]](#page-19-7) we define the Euclidean weight respectively as 0, 1, 2, 1.

Table [9](#page-17-0) shows the existence and the best Hamming, Lee and Euclidean distance of the  $\theta_{2}$ -Hermitian dual-containing cyclic module  $(\theta, \delta)$ -codes  $\mathcal{C} = Rg/Rf \subset R/Rf$  over  $\mathbb{F}_4$ . The gray cells indicate the codes that can only be obtained using a non-zero derivation.

<span id="page-17-0"></span>Table 9: The best Hamming, Lee and Euclidean  $d_H, d_L, d_E$  distance of  $\theta_2$ -Hermitian dual-containing codes  $Rg/Rf \subset R/Rf$  over  $\mathbb{F}_4$ .

$\boldsymbol{n}$ $\kappa$								
	2, 2, 2	2, 2, 2						
$\overline{5}$		3, 3, 3	1, 1, 1					
6		4, 4, 4	2, 2, 2	2, 2, 2				
			3, 3, 3		1, 1, 1			
8			2, 2, 2	2, 2, 2	2, 2, 2	2, 2, 2		
9							1, 1, 1	
10				4, 4, 4	3, 3, 3	2, 2, 2	2, 2, 2	2, 2, 2

<span id="page-17-1"></span>Table [10](#page-17-1) provides some examples of the Hamming weight distributions. This shows that in Table 10: Weight enumerator of  $\theta_2$ -Hermitian dual-containing cyclic module  $(\theta, \delta)$  codes over  $\mathbb{F}_4$ .

Hermitian case, non-zero derivation does produce other code than in the  $\delta = 0$  case. In the  $\delta = 0$ case we could not exhibit new codes.

## 8 Computation Results for the Galois Ring  $A = \mathbb{G}R(4,2)$

The galois ring  $A = \overline{GR(4, 2)} = Z_4[u] = (\mathbb{Z}/4\mathbb{Z})[u]/(u^2 + u + 1)$  is a Frobenius ring of order 16. This ring has two automorphisms:  $\theta_1 = id$  and  $\theta_2(u) = 3u + 3$  of order 2. The zero derivation is the only id-derivation. The  $\theta_2$ -derivations are all inner (i.e.  $\delta: a \mapsto \beta a - \theta_2(a)\beta, \forall \beta \in A$ ):  $\delta_1(u) = 0, \delta_2(u) = 0$ 

 $u, \delta_3(u) = 2u, \delta_4(u) = 3u, \delta_5(u) = 1, \delta_6(u) = u + 1, \delta_7(u) = 2u + 1, \delta_8(u) = 3u + 1, \delta_9(u) = 2,$  $\delta_{10}(u) = u + 2, \, \delta_{11}(u) = 2u + 2, \, \delta_{12}(u) = 3u + 2, \, \delta_{13}(u) = 3, \, \delta_{14}(u) = u + 3, \, \delta_{16}(u) = 3u + 3.$ 

We computed all [4, 2] self-dual and [4, 3] dual-containing cyclic left module  $(\theta, \delta)$ -codes over  $A = GR(4, 2)$  by Algorithm [1.](#page-10-1) For the [4, 2] codes, there are 8 g's given by each map in Table [11.](#page-18-8) They generate [4, 2,  $d_H = 3$ ] codes with distinct codebooks (i.e. the codewords in the codes are not all equal), however, with the same weight enumerator  $1 + 60w^3 + 195w^4$ . For each g there are 16 f's which are all central and including one in the form of  $X^n - a$  for some  $a \in \mathbb{Z}_4$ . The [4, 3] codes can be obtained from all maps. From each map, there are four unique  $g$ 's. For each  $g$  there are more than 1000 f's which include at least one central f and an f in the form of  $X^n - a$  for some  $a \in \mathbb{Z}_4$ . All the codes have the same weight enumerator given in Table [11.](#page-18-8)

<span id="page-18-8"></span>Table 11: The best Hamming distance  $d_H$  of dual-containing codes  $Rg/Rf \subset R/Rf$  over  $GR(4, 2)$ .
