(Dated: October 3, 2023)

Despite the presence of the exact solution and well-established recipe for its realization, the quest for the Kitaev spin liquid in real materials remains exceptionally challenging. Among many magnets, α -RuCl₃ emerges as a prime candidate, albeit the hallmarks of the spin liquid manifest only within the specific region where the zigzag-type antiferromagnetic order is suppressed by an applied magnetic field. Here, we propose the possibility of the Kitaev spin liquid at zero field by making van der Waals heterostructures of α -RuCl₃ and a ferromagnet CrX₃ (X=Cl and I). Using *ab initio* calculations, we find that in the case of X=Cl the zigzag order is suppressed by the proximity effect of the ferromagnetic CrCl₃ layer, while the Kitaev interaction is still relevant in the α -RuCl₃ layer. Notably, the induced Ru moment is close to the value observed in the spin liquid region of the bulk material, signifying the realization of the Kitaev spin liquid at zero field. In contrast, in the case of X=I, the system is on the verge of an insulator-metal transition by carrier doping through interlayer hybridization. Our results indicate that van der Waals heterostructures provide a new platform for studying not only magnetic but also electronic properties of the Kitaev magnets.

Introduction.— Since the successful exfoliation of graphene [1], van der Waals (vdW) materials have played a pivotal role in advancing two-dimensional physics [2–9]. The research forefront has been explosively expanded to diverse range of materials, such as elemental analogues of graphene [10–15], transition metal dichalcogenides [4, 16–19], and atomically thin magnets [9, 20–23]. Furthermore, the weak interlayer vdW force offers a wide platform for making heterostructures with emergent properties that cannot be found in individual materials [24–27]. Moiré superstructures in twisted multilayers have opened up yet another exciting avenue for manipulating electron correlation effects, exemplified by twisted bilayer graphene which realizes the Mott insulating state and superconductivity [28, 29].

Among the vdW materials, a transition metal trihalide α -RuCl₃ has garnered significant attention due to its potential to realize the quantum spin liquid predicted in the Kitaev model [30]. The model is defined on a honeycomb lattice with bond-dependent Ising-type interaction between spin-1/2 moments, and the ground state is exactly obtained as a quantum spin liquid with fractional excitations, itinerant Majorana fermions and localized Z_2 fluxes, which can be utilized for topological quantum computation [31]. Since it was pointed out that spin-orbit entangled moments can yield the Kitaev-type interaction [32], many materials with both electron correlation and spin-orbit coupling, called the spin-orbit coupled Mott insulators, have been investigated as potential candidates for the Kitaev spin liquid (KSL) [33–37]. Notably, α -RuCl₃ is a primary candidate, as it exhibits hallmarks of the KSL, as identified by several experimental techniques, such as Raman scattering [38–40], inelastic neutron scattering [41–43], and half-quantization of the thermal Hall conductivity [44, 45].

Despite the promising hallmarks, the problem is that the KSL appears to manifest only under the magnetic field at low temperatures, which hampers in-depth ex-

perimental investigations. This issue stems from the fact that, in the absence of the magnetic field, the system exhibits a zigzag-type magnetic order due to parasitic magnetic interactions beyond the Kitaev model [46–48]. The spin liquid nature is observed only in a regime where the zigzag order is destroyed by an applied magnetic field of ~ 8 T. Extensive efforts have been made to suppress the zigzag order by mitigating the parasitic interactions. For instance, theoretical research has suggested that lattice expansion can suppress the non-Kitaev interactions [49–51], stimulating the fabrication of thin films and their heterostructures [52–57]. Nonetheless, establishing a method to realize the KSL at zero field remains a challenging issue, despite its crucial significance for experimental accessibility.

In this Letter, we propose a way to achieve the KSL at zero magnetic field by employing vdW heterostructures. The key idea is to suppress the zigzag order through the proximity effect of vdW magnets, CrX₃ with X=Cl and I. CrCl₃ and CrI₃ were recently shown, respectively, to exhibit in-plane and out-of plane ferromagnetism in their monolayer form [22, 58]. Based on *ab initio* calculations, we show that an internal magnetic field and interlayer hybridization from the CrX₃ layer have a profound impact on the magnetic and electronic properties of the α -RuCl₃ layer, offering a promising route to a possible KSL at zero field.

Methods.— We consider two heterostructures: One consists of an α -RuCl₃ layer and a CrCl₃ layer (α -RuCl₃/CrCl₃) [Fig. 1(a)], and the other consists of an α -RuCl₃ layer and a CrI₃ layer (α -RuCl₃/CrI₃) [Fig. 1(b)]. For both cases, the lattice structure of each layer is taken from the bulk materials with $C2/m$ symmetry [47, 59, 60]. For α -RuCl₃/CrCl₃, because of the small lattice mismatch between α -RuCl₃ (5.97 Å) and CrCl₃ (5.96 Å), we prepare the heterostructure supercell by stacking each unit cell as is, which contains 16 atoms in total. Meanwhile, for α -RuCl₃/CrI₃, due to the large lattice mis-

TABLE I. Energy per Ru atom and magnetic moments at Ru and Cr atoms for different magnetic states in α -RuCl₃/CrCl₃ obtained by the *ab initio* calculations: “in” and “out” means that the magnetic moment is along the in-plane and out-of-plane direction, respectively, and “FM”, “Néel”, and “zigzag” denote ferromagnetic, Néel, and zigzag orders, respectively. The prime indicates that the Cr moments are antiparallel to the Ru ones (otherwise, they are parallel). The energy is measured from the most stable state where the in-plane FM order in each layer is coupled antiferromagnetically.

magnetic state		energy/Ru (meV)	moment (μ_B)	
Ru	Cr		Ru	Cr
in-FM	in-FM'	0.000	0.703	3.28
in-FM	out-FM	0.365	0.703	3.28
in-FM	in-FM	0.775	0.704	3.28
in-zigzag	in-FM	6.32	0.579	3.28
in-Néel	in-FM	16.2	0.293	3.28
out-FM	out-FM	105	0.834	3.28
out-FM	out-FM'	104	0.832	3.28

match between α -RuCl₃ (5.97 Å) and CrI₃ (6.86 Å), we prepare the heterostructure supercell by 2×2 α -RuCl₃ and $\sqrt{3} \times \sqrt{3}$ CrI₃, containing 56 atoms. We optimize the lattice structures via the nonrelativistic *ab initio* calculations described below, by relaxing the atomic positions with fixing the in-plane lattice constants of α -RuCl₃ at the bulk value. After the relaxation, the interlayer distance is optimized to 3.01 Å for α -RuCl₃/CrCl₃ and 3.22 Å for α -RuCl₃/CrI₃.

We perform the *ab initio* calculations based on the density functional theory (DFT) using the OpenMX code [61, 62]. We use the Perdew-Burke-Ernzerhof generalized gradient approximation (GGA-PBE) functional [63] including U corrections for Ru d orbitals and Cr d orbitals, as implemented in the GGA+ U method [64]; we take $U = 1.5$ eV for Ru and $U = 2.0$ eV for Cr [65, 66]. The kinetic energy cutoffs are set to be 1500 Ry. VdW corrections are also included through the DFT-D2 scheme of Grimme [67]. In the self-consistent calculation of the electron density, we take $16 \times 16 \times 1$ \mathbf{k} -point mesh for α -RuCl₃/CrCl₃ and $10 \times 10 \times 1$ \mathbf{k} -point mesh for α -RuCl₃/CrI₃. We construct maximally-localized Wannier functions [68, 69] for the electronic band structures obtained by the DFT calculation and use them to compute the partial density of states (PDOS) and effective exchange constants. For the latter, we perform the second-order perturbation for the multiorbital Hubbard model for t_{2g} orbitals of Ru atoms, following the previous studies [49, 70, 71]. In this model, we set the effective onsite Coulomb interaction \tilde{U} , the Hund’s-rule coupling J_H , and the spin-orbit coupling coefficient λ to 3.0 eV, 0.6 eV, and 0.15 eV, respectively [49].

Results.— For the optimized heterostructures, we investigate the energies of different magnetically ordered states by utilizing the constraint DFT calculation on the direction of magnetic moments. The results for α -RuCl₃/CrCl₃ are listed in Table I. We obtain seven stable

FIG. 1. Structures of the heterostructures of α -RuCl₃ and CrX₃ ($X=\text{Cl}$ and I). (a) A bird’s-eye view (upper left), side view (lower left), and top view (right) of α -RuCl₃/CrCl₃. (b) Corresponding pictures for α -RuCl₃/CrI₃. The gray, blue, green, and purple spheres represent Ru, Cr, Cl, and I atoms, respectively. The black rhombus denotes the unit cell, while the gray dashed rhombus in (a) is a 2×2 supercell used in the *ab initio* calculations.

TABLE II. Similar table for α -RuCl₃/CrI₃: “cant” means a spin canting, and the other notations are common to Table I.

magnetic state		energy/Ru (meV)	moment (μ_B)

magnetic states, and among them the most stable is the intralayer-ferromagnetic (FM) and interlayer antiferromagnetic (AFM) state with in-plane magnetic moments of $0.703 \mu_B$ for Ru and $3.28 \mu_B$ for Cr. Notably, the intralayer FM states with different Cr moment directions are obtained at slightly higher energies: the state with out-of-plane Cr moments at 0.365 meV and in-plane Cr moments parallel to the Ru ones at 0.775 meV. This suggests that the Cr layer has in-plane ferromagnetism similarly to the monolayer [58], but the magnetic anisotropy is small and the energy scale of the interlayer magnetic coupling in this heterostructure is the order of 0.1 meV (see Supplementary Material [72]). The next higher-energy state at 6.32 meV exhibits a zigzag order in the Ru layer. While the stable magnetic state for the α -RuCl₃ monolayer is still controversial [73–76], our result indicates that the heterostructure with CrCl₃ favors the FM state in the α -RuCl₃ layer, rather than the zigzag order that is stable in the bulk. We will discuss this interesting point later. The other states have much higher energies;

in particular, the states with out-of-plane Ru moments are more than 100 meV higher, indicating that the strong in-plane magnetic anisotropy in the bulk α -RuCl₃ is retained even in the heterostructure [60, 77–79].

The results for α -RuCl₃/CrI₃ are summarized in Table II. In this case also, we find that the most stable state exhibits FM ordering in each layer, whereas the Cr moments are canted about 30 degrees from the out-of-plane in the opposite direction to the Ru moments. This is understood from the fact that the monolayer CrI₃ is an out-of-plane ferromagnet [22]. Nonetheless, similarly to the case of α -RuCl₃/CrCl₃, the energy differences from the states with other Cr moment directions are rather small, while the zigzag order in the Ru layer leads to relatively higher energy (see Supplementary Material [72]).

For the most stable states obtained above, we calculate the band structures and the PDOS. For α -RuCl₃/CrCl₃ [Fig. 2(a)], we find that the low-energy state near the Fermi level is dominated by the spin-orbital coupled bands characterized by the pseudospin $j_{\text{eff}} = 1/2$ and $3/2$ hybridized with $3p$ orbitals of Cl atoms in the α -RuCl₃ layer. The system is an insulator with the energy gap of ~ 0.6 eV opening in the pseudospin bands. The situation is very similar to the bulk α -RuCl₃, where the spin-orbit coupling and electron correlation work cooperatively to realize a spin-orbital coupled Mott insulating state [30, 80, 81]. The contribution from CrCl₃ appears well below the Fermi level, and does not disturb the low-energy pseudospin bands of Ru atoms.

Meanwhile, in α -RuCl₃/CrI₃, the spin-orbital coupled features are preserved in the pseudospin bands, but the band gap is largely reduced [Fig. 2(b)]. This is due to considerable contributions from the $5p$ orbitals of I atoms, in contrast to the Cl $3p$ orbitals in the case of α -RuCl₃/CrCl₃. The enlarged plot near the Fermi level is shown in Fig. 3. We find that there still remains a small gap of ~ 0.02 eV, but the system is on the verge of an insulator-metal transition, and the $j_{\text{eff}} = 1/2$ band is slightly doped below the small gap through the hybridization with the $5p$ bands.

To understand the differences in the band structures between the two heterostructures, we compute real-space distributions of electron charges. Figure 4 displays the charge-density difference between the heterostructure and two independent monolayers, $\delta\rho(\alpha\text{-RuCl}_3/\text{CrX}_3) = \rho(\alpha\text{-RuCl}_3/\text{CrX}_3) - \rho(\alpha\text{-RuCl}_3) - \rho(\text{CrX}_3)$, with the iso-surface of $5 \times 10^{-4} e/\text{\AA}^3$. In α -RuCl₃/CrCl₃ [Fig. 4(a)], while the charge distribution in the α -RuCl₃ layer is modulated, the original symmetry is overall retained, with little changes in the interlayer region. This is consistent with the robust pseudospin bands in Fig. 2(a). In contrast, in α -RuCl₃/CrI₃ [Fig. 4(b)], the charge distributions near the Cl and I atoms at the interface are largely modulated and extended to the interlayer region. We observe that approximately $0.021e$ per unit cell of α -RuCl₃ is transferred from the CrI₃ layer. These are consistent with the large modulation of the band structure with carrier doping through the hybridization with $5p$ orbitals of

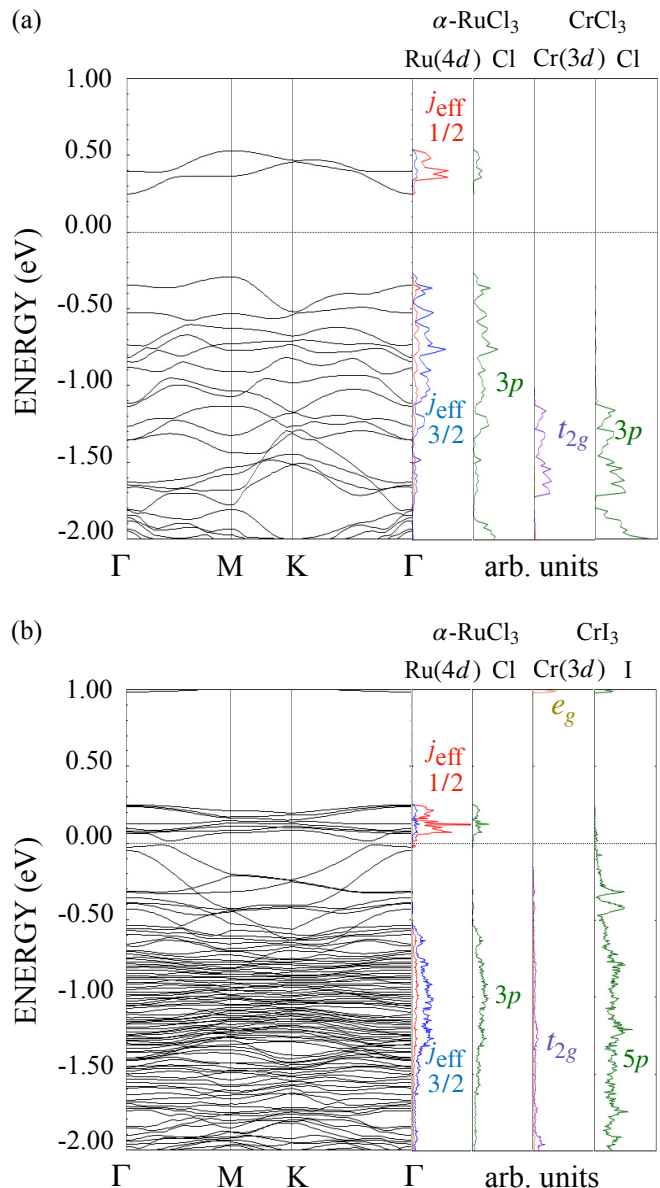

FIG. 2. Band structure and PDOS in the most stable magnetic states: (a) the Ru in-FM and Cr in FM state for α -RuCl₃/CrCl₃ and (b) the Ru in-FM and Cr cant-FM state for α -RuCl₃/CrI₃. The Fermi level is set at zero energy.

I atoms found in Figs. 2(b) and 3.

Given that the spin-orbit coupled Mott insulating nature is preserved in the α -RuCl₃ layer of α -RuCl₃/CrCl₃, we estimate effective exchange constants between the $j_{\text{eff}} = 1/2$ pseudospins, using the procedure described above. The general expression of the effective pseudospin Hamiltonian for one of three types of bonds on the honeycomb lattice is given by

$$\mathcal{H}_{ij}^z = \mathbf{S}_i^T \begin{bmatrix} J & D + \Gamma & -D' + \Gamma' \\ -D + \Gamma & J & D' + \Gamma' \\ D' + \Gamma' & -D' + \Gamma' & J + K \end{bmatrix} \mathbf{S}_j, \quad (1)$$

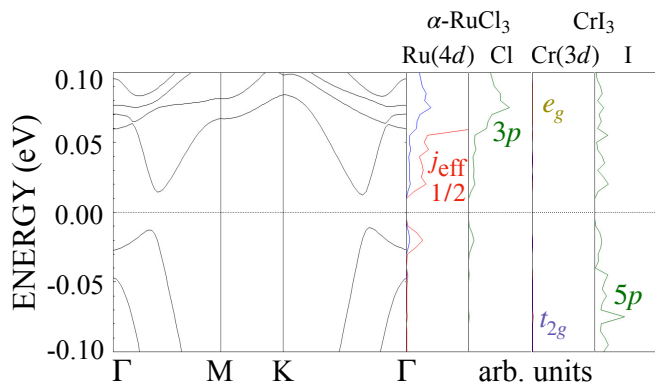

FIG. 3. Enlarged band structure and PDOS near the Fermi level for α -RuCl₃/CrI₃ in Fig. 2(b).

FIG. 4. Charge-density difference $\delta\rho$ plotted with charge isosurface $5 \times 10^{-4} e/\text{\AA}^3$ of (a) α -RuCl₃/CrCl₃ and (b) α -RuCl₃/CrI₃. Both are viewed from the a axis of the α -RuCl₃ layer. The yellow (cyan) color represents regions with charge accumulation (deficiency) compared to independent monolayers. The gray, blue, green, and purple spheres represent Ru, Cr, Cl, and I atoms, respectively.

where J and K denote the Heisenberg and Kitaev interactions, respectively, Γ and Γ' denote the symmetric off-diagonal interactions, and D and D' denote the anti-symmetric off-diagonal Dzyaloshinskii-Moriya (DM) interactions. The estimates of the exchange constants are listed in Table III, in comparison with the results for the monolayer (obtained in the present study) and bulk of α -RuCl₃ [49]. Compared to the bulk, we find that in α -RuCl₃/CrCl₃ the Heisenberg J is largely suppressed and the Kitaev K is enhanced, leading to the signifi-

TABLE III. Effective exchange constants between the $j_{\text{eff}} = 1/2$ pseudospins at the Ru sites for α -RuCl₃/CrCl₃, in comparison with those for the monolayer and bulk of α -RuCl₃. The energy unit is meV.

	J	K	Γ	Γ'	D	D'	K/J
α -RuCl ₃ /CrCl ₃	-0.9	-5.9	6.6	-1.6	-0.1	-0.1	6.6
α -RuCl ₃ (monolayer)	-1.0	-6.6	7.1	-2.0	0.0	0.0	6.6
α -RuCl ₃ (bulk) [49]	-2.2	-5.0	8.0	-1.0	0.0	0.0	2.3

cant increase of the ratio K/J . Meanwhile, the values are similar to those for the monolayer, despite the charge modulation in Fig. 4(a). This means that the suppression of the zigzag order is ascribed to the synergetic effect between the modulation of the exchange constants from the bulk to monolayer and the internal magnetic field from the ferromagnetic CrCl₃ layer in the heterostructure.

Discussion.— In α -RuCl₃/CrCl₃, the zigzag order in α -RuCl₃ is suppressed by the proximity effect of CrCl₃, and replaced by the FM state with Ru moment of $0.703 \mu_B$. Notably, this value is close to that in the spin liquid region in the bulk system where the zigzag order is destroyed by an in-plane magnetic field [47] and the half-quantization of the thermal Hall conductivity was observed [44, 45]. This, in conjunction with the dominant Kitaev interaction in Table III, suggests the possibility of KSL at zero field under the proximity effect in the vdW heterostructure.

In α -RuCl₃/CrI₃, while the spin-orbit Mott insulating nature is preserved in the Ru pseudospin bands, the band gap is almost closing and the self-doping occurs via the interlayer hybridization. A similar situation was found in the heterostructure of α -RuCl₃ and graphene [55, 56, 82, 83], where the system becomes metallic. Thus, the vdW heterostructures offer a playground for the insulator-metal transition in the spin-orbital coupled systems by carrier doping, which is expected to bring about exotic quantum phenomena such as topological superconductivity [84–87]. This is complementary to bandwidth control, which has recently been studied for the bulk materials RuX₃ (X =Cl, Br, and I) [88–91].

Summary.— We have investigated the vdW heterostructures composed of the Kitaev candidate α -RuCl₃ and the ferromagnet CrX₃ (X =Cl and I) based on the *ab initio* calculations. For α -RuCl₃/CrCl₃, we found that the zigzag order in α -RuCl₃ is replaced by an in-plane FM state with the Ru moment close to that in the region where the hallmarks of KSL were observed in the bulk material. We also showed that the Kitaev interaction between the Ru pseudospins is enhanced. These suggest that the proximity of CrCl₃ realizes the KSL in the α -RuCl₃ layer even in the absence of magnetic field. In α -RuCl₃/CrI₃, we found that the system is on the verge of insulator-metal transition due to charge transfer from CrI₃ via the strong interlayer hybridization, while the spin-orbit coupled Mott insulating nature is preserved.

Our findings unveil that the vdW heterostructures enable us to access the KSL physics at zero field, which is hard to achieve in the bulk system. The diverse range of materials and their flexible stacking control in vdW systems open up possibilities for tailoring the electronic and magnetic properties in the Kitaev magnets.

We thank S.-H. Jang, Y. Kato, S. Okumura, and Y.-

F. Zhao for fruitful discussions. This research was supported by the JSPS KAKENHI (Nos. JP19H05825 and JP20H00122) and JST CREST (No. JP-MJCR18T2). Parts of the numerical calculations were performed using the facilities of the Supercomputer Center, the Institute for Solid State Physics, the University of Tokyo.

S1. Magnetic anisotropy in α -RuCl₃/CrCl₃ and α -RuCl₃/CrI₃

We calculate the magnetic anisotropy energy for two heterostructures, α -RuCl₃/CrCl₃ and α -RuCl₃/CrI₃, by rotating the Cr moment from the most stable magnetic states obtained in the main text. The results for α -RuCl₃/CrCl₃ are shown in Fig. S1 by rotations within (a) the ab plane and (b) the ac plane. In this case, the magnetic anisotropy in the CrCl₃ layer is less than 1 meV, indicating that the AFM interlayer interaction is in the order of 0.1 meV.

FIG. S1. Magnetic anisotropy energy in the CrCl₃ layer of α -RuCl₃/CrCl₃ for the rotations of the Cr moment within (a) the ab plane and (b) the ac plane. The Ru moments are fixed along the $-a$ axis. The insets denote the definitions of the angles θ and ϕ . Schematics of the arrangements of Ru and Cr moments are shown below each panel.

Figure S2 shows the results for α -RuCl₃/CrI₃. In this case, the magnetic anisotropy in the CrI₃ layer is about 3 meV, indicating that the interlayer interaction is also AFM but the strength is one order of magnitude larger than that in α -RuCl₃/CrCl₃. Nonetheless, the most stable is not the interlayer AFM state but the state with the Cr moment canted by about 30 degrees from the c axis, presumably due to the strong out-of-plane anisotropy existing in the CrI₃ monolayer.

FIG. S2. Corresponding data for α -RuCl₃/CrI₃. The notations are common to those in Fig. S1.
