Abstract—Numerous applications in the field of molecular communications (MC) such as healthcare systems are often event-driven. The conventional Shannon capacity may not be the appropriate metric for assessing performance in such cases. We propose the identification (ID) capacity as an alternative metric. Particularly, we consider randomized identification (RI) over the discrete-time Poisson channel (DTPC), which is typically used as a model for MC systems that utilize molecule-counting receivers. In the ID paradigm, the receiver's focus is not on decoding the message sent. However, he wants to determine whether a message of particular significance to him has been sent or not. In contrast to Shannon transmission codes, the size of ID codes for a Discrete Memoryless Channel (DMC) grows doubly exponentially fast with the blocklength, if randomized encoding is used. In this paper, we derive the capacity formula for RI over the DTPC subject to some peak and average power constraints. Furthermore, we analyze the case of state-dependent DTPC.

## I. INTRODUCTION

Molecular communication (MC) represents an emerging communication paradigm, using molecules or ions as the carriers of information [1], [2]. MC has arisen as a promising technique for detecting and pinpointing abnormality in diverse applications including biotechnology and medicine, such as drug delivery [3], cancer treatment [4] and health monitoring [5]. In particular, the use of MC for abnormality detection in medical applications has been extensively studied over the past decade [6], [7], [8]. In this context, by abnormality detection, we are referring to the detection of viruses, bacteria, infectious microorganisms, or tumors within the body, via either static [6], [7], [8] or mobile nanomachines [9], [10]. Once the abnormality has been detected, a suitable treatment is initiated using drug delivery, targeted therapy, nanosurgery, etc. Information-theoretical analysis of diffusion-based MC was established in [11], [12]. For diffusion-based MC, the capacity limits of molecular timing channels were investigated in [13] and lower and upper bounds on the corresponding capacity were reported.

Numerous applications in MC such as healthcare systems are often event-driven, where the conventional Shannon capacity may not be the appropriate metric for assessing performance. Especially in situations involving event detection,

where the receiver needs to make a dependable decision regarding the presence or absence of a particular event, the socalled identification (ID) capacity might be the performance metric of interest. The ID theory was first proposed by Ahlswede and Dueck in [14], [15]. They were motivated by the work [16], [17] on communication complexity. In the ID paradigm, the receiver's focus is not on decoding the message sent. However, he wants to determine whether a message of particular significance to him has been sent or not. The sender does not know about the message that piques the receiver's interest. Otherwise, this would be a trivial task. Ahlswede and Dueck [18] proved that for Discrete Memoryless Channels (DMCs) the size of ID codes grows doubly exponentially  $(2^{2^{nR}})$  fast with the blocklength, if randomized encoding is allowed. Later, ID codes have been developed [19], [20], [21]. If only deterministic encoding is allowed, the ID rate for a DMC is still more significant than the transmission rate in the exponential scale as shown in [22], [23]. The number of ID messages that can be identified over Gaussian channels [22] and Poisson channels [24], [25] scales as  $(n^{nR})$ , if no randomization is used. Lower and upper bounds on the deterministic identification (DI) capacity over the discretetime Poisson channel (DTPC) were established in [26]. In MC, a sender, such as a cell, releases molecules into the channel at a specific rate (molecules/second) over a time interval. These molecules spread in the channel by diffusion and/or advection and can even be degraded in the channel by enzymatic reactions. Decoding assumes a counting receiver (nanomachines, cells) capable of counting the number of molecules received. The molecule production/release rate of the transmitter is of course limited. Assuming that the release propagation and the reception of individual molecules are statistically similar but independent, the received signal will follow Poisson statistics if the number of molecules released is large. Therefore, it makes sense to model such channels by a DTPC. The constraints on average and peak power take into account the limited molecule production/release rate of the sender [27], [28], [29]. Furthermore, the DTPC is of significant importance in the field of optical communications, where at the transmitter, a laser emits a stream of discrete photons and the receiver consists of a photodetector, which can discern the accurate arrival times of individual photons [30].

In this work, we consider randomized identification (RI) over the DTPC. To the best of our knowledge, the RI capacity of the DTPC has not been studied so far. We derive the RI capacity of the DTPC under average and peak power constraints that account for the limited molecule production/release rate of the sender. We then extend the results to the DTPC with independent and identically distributed (i.i.d.) state sequences. The random channel state is available to neither the sender nor the receiver. We show that, in this case, the RI capacity of the state-dependent DTPC coincides with its RI capacity.

Outline: The remainder of the paper is structured as follows. In Section II, we introduce our system models, recall some basic definitions related to ID, and present the main results of the paper. In Section III, we establish the proof of the RI capacity formula of the DTPC and the state-dependent DTPC subject to some average and peak power constraints. Section IV concludes the paper.

Notation:  $\mathbb{R}_0^+$  denotes the set of nonnegative real numbers;  $\mathbb{Z}_0^+$  denotes the set of nonnegative integers; the distribution of a RV X is denoted by  $P_X$ ; for a finite set  $\mathcal{X}$ , we denote the set of probability distributions on  $\mathcal{X}$  by  $\mathcal{P}(\mathcal{X})$  and by  $|\mathcal{X}|$  the cardinality of  $\mathcal{X}$ ;  $\mathcal{X}^c$  denotes the complement of  $\mathcal{X}$ ; if X is a RV with distribution  $P_X$ , we denote the expectation of X by  $\mathbb{E}(X)$  and by  $\mathrm{Var}[X]$  the variance of X; if X and Y are two RVs with probability distributions  $P_X$  and  $P_Y$ , the mutual information between X and Y is denoted by I(X;Y); the Kullback-Leibler divergence between  $P_X$  and  $P_Y$  is denoted by  $D(P_X \parallel P_Y)$ ; all logarithms and information quantities are taken to the base 2.

## II. SYSTEM MODELS AND MAIN RESULTS

Let a memoryless DTPC  $(\mathcal{X}, \mathcal{Y}, W(y|x))$  consisting of input alphabet  $\mathcal{X} \subset \mathbb{R}_0^+$ , output alphabet  $\mathcal{Y} \subset \mathbb{Z}_0^+$  and a pmf W(y|x) on  $\mathcal{Y}$ , be given. For n channel uses, the transition probability law is given by

$$W^{n}(y^{n}|x^{n}) = \prod_{t=1}^{n} W(y_{t}|x_{t})$$

$$= \prod_{t=1}^{n} \exp\left(-(x_{t} + \lambda_{0})\right) \frac{(x_{t} + \lambda_{0})^{y_{t}}}{y_{t}!},$$

where  $\lambda_0$  is some nonnegative constant, called dark current. The dark current  $\lambda_0$ , here, represents the non-ideality of the detector. The sequences  $x^n=(x_1,x_2,\ldots,x_n)\in\mathcal{X}^n$  and  $y^n=(y_1,y_2,\ldots,y_n)\in\mathcal{Y}^n$  are the channel input and the channel output, respectively. The peak and average power constraints on the input are

$$x_t \le P_{\text{max}}, \quad \forall t = 1, \dots, n,$$
 (1)

$$\frac{1}{n} \sum_{t=1}^{n} x_t \le P_{\text{avg}},\tag{2}$$

where  $P_{\text{max}}$ ,  $P_{\text{avg}} > 0$  represent the values for peak power and average power constraints, respectively. Let  $\mathcal{X}(P_{\text{max}}, P_{\text{avg}})$ 

denote the set of all input symbols  $x \in \mathcal{X}$  such that (1) and (2) are satisfied. Let  $C(W, P_{\max}, P_{\text{avg}})$  denote the Shannon transmission capacity of the DTPC W under peak and average power constraints  $P_{\max}$  and  $P_{\text{avg}}$  as described in (1) and (2), respectively. Then  $C(W, P_{\max}, P_{\text{avg}})$  is given by [30]

$$C(W, P_{\text{max}}, P_{\text{avg}}) = \max_{\substack{P_X \in \mathcal{P}(\mathcal{X})\\X \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})}} I(X; Y). \tag{3}$$

For the sake of notational simplicity, we denote the DTPC described above by W.

In the setting depicted in Fig. 1, the sender releases molecules (ID message  $i \in \mathcal{N} := \{1,2,\ldots,N\}$ ) into the DTPC W at a specific rate over a time interval. The receiver, here, (nanomachines, cells) wants to check whether a specific pathological biomarker exists around the target or not. Assuming that the release propagation and the reception of individual molecules are statistically similar but independent, the received signal follows Poisson statistics.

In the following, we define RI codes for the DTPC introduced above.

**Definition 1.** An  $(n, N, \lambda_1, \lambda_2)$  RI code with  $\lambda_1 + \lambda_2 < 1$  for the DTPC W is a family of pairs  $\{(Q(\cdot|i), \mathcal{D}_i), i = 1, \ldots, N\}$  with

$$Q(\cdot|i) \in \mathcal{P}(\mathcal{X}^n(P_{max}, P_{avg})), \ \mathcal{D}_i \subset \mathcal{Y}^n, \ \forall i = 1, \dots, N,$$

such that the errors of the first kind and the second kind are bounded as follows.

$$\mu_{1}^{(i)} \triangleq \int_{x^{n} \in \mathcal{X}^{n}(P_{max}, P_{avg})} Q(x^{n}|i)$$

$$\cdot W^{n}(\mathcal{D}_{i}^{c}|x^{n}) dx^{n} \leq \lambda_{1}, \forall i, \qquad (4)$$

$$\mu_{2}^{(i,j)} \triangleq \int_{x^{n} \in \mathcal{X}^{n}(P_{max}, P_{avg})} Q(x^{n}|i)$$

$$\cdot W^{n}(\mathcal{D}_{j}|x^{n}) dx^{n} \leq \lambda_{2}, \forall i \neq j, \qquad (5)$$

where 
$$\mathcal{X}^n(P_{max}, P_{avg}) = \underbrace{\mathcal{X}(P_{max}, P_{avg}) \times \ldots \times \mathcal{X}(P_{max}, P_{avg})}_{n \text{ times}}$$
.

The error  $\mu_1^{(i)}$  in (4) is called the error of the first kind, which is produced by channel noise and fits the same error definition as for a transmission code. In addition, we have another kind of error  $\mu_2^{(i,j)}$  called the error of the second kind (5), which results from the ID code construction. In contrast to transmission code, we permit a degree of overlap among the decoding sets in the case of ID codes. This results in both a double exponential increase in the rate (e.g., for DMCs) and introduces another kind of error as described in (5).

In the following, we define achievable ID rate and ID capacity for our system model.

**Definition 2.** 1) The rate R of an  $(n, N, \lambda_1, \lambda_2)$  RI code for the channel W is  $R = \frac{\log \log(N)}{n}$  bits. 2) The ID rate R for W is said to be achievable if for  $\lambda \in \mathbb{R}$ 

2) The ID rate R for W is said to be achievable if for  $\lambda \in (0, \frac{1}{2})$  there exists an  $n_0(\lambda)$ , such that for all  $n \geq n_0(\lambda)$  there exists an  $(n, 2^{2^{nR}}, \lambda, \lambda)$  RI code for W.

Fig. 1: Discrete-time memoryless Poisson channel with random state

3) The RI capacity  $C_{ID}(W, P_{max}, P_{avg})$  of the channel W under the peak and average power constraints (1) and (2) is the supremum of all achievable rates.

The following Theorem characterizes the RI capacity of the DTPC W under peak and average power constraints  $P_{\rm max}$  and  $P_{\rm avg}$ , respectively.

**Theorem 3.** The RI capacity  $C_{ID}(W, P_{max}, P_{avg})$  of the channel W under peak and average power constraints  $P_{max}$  and  $P_{avg}$ , respectively, is given by

$$C_{ID}(W, P_{max}, P_{avg}) = C(W, P_{max}, P_{avg}).$$

It is to be noted that the right-hand side of (??) is a convex optimization problem. Therefore, Theorem 3 provides the formula for computing the ID capacity of the DTPC as a function of the peak power and average power values  $P_{\text{max}}$ and  $P_{\text{avg}}$ , respectively. Many studies have been dedicated to investigating the properties of the capacity-achieving distribution of the DTPC. In the absence of input constraints, the transmission capacity of the DTPC is infinite. The DTPC was addressed in [31] when only subject to peak power constraint and was shown that the support size is of an order between  $\sqrt{P_{\rm max}}$  and  $P_{\rm max} \ln^2 P_{\rm max}$ . An Analytical formulation of the transmission capacity under only average power constraints is still an open problem. However, bounds and asymptotic behaviors for the DTPC in different scenarios were established e.g., [32], [33], [34], etc. It was shown in [30] that the capacityachieving distribution for the DTPC under an average-power constraint and/or a peak power constraint is discrete. However, an analytical formula for the capacity-achieving distribution of the DTPC remains an unresolved question. In some instances, it was demonstrated that the optimal input distribution for the DTPC is not even computable [35]. All these results can be extended and applied to the RI case. Let a DTPC with random state  $(\mathcal{X} \times \mathcal{S}, W_S(y|x,s), \mathcal{Y})$  consisting of an input alphabet  $\mathcal{X}\subset\mathbb{R}^+_0$ , a discrete output alphabet  $\mathcal{Y}\subset\mathbb{Z}^+_0$ , a finite state set  $\mathcal{S}$  and a pmf W(y|x,s) on  $\mathcal{Y}$ , be given. The channel is memoryless, i.e., the probability for a sequence  $y^n \in \mathcal{Y}^n$  to be received if the input sequence  $x^n \in \mathcal{X}^n$  was sent and the sequence state is  $s^n \in \mathcal{S}^n$  is given by

$$W_S^n(y^n|x^n, s^n) = \prod_{t=1}^n W_S(y_t|x_t, s_t).$$

The state sequence  $(S_1, S_2, ..., S_n)$  is i.i.d. according to the distribution  $P_S$ . We assume that the input  $X_t$  and the state  $S_t$  are statistically independent for all  $t \in \{1, 2, ..., n\}$ . We further assume that the input satisfies the peak power and

average power constraints in (1) and (2), respectively. We further assume that the channel state is known to neither the sender nor the receiver. Now, let's define ID codes for the state-dependent DTPC  $W_S$ .

**Definition 4.** An  $(n, N, \lambda_1, \lambda_2)$  RI code with  $\lambda_1 + \lambda_2 < 1$  for the channel  $W_S$  is a family of pairs  $\{(Q(\cdot|i), \mathcal{D}_i(s^n))_{s^n \in \mathcal{S}^n}, i = 1, \dots, N\}$  with

$$Q(\cdot|i) \in \mathcal{P}(\mathcal{X}^n(P_{max}, P_{avg})), \ \mathcal{D}_i(s^n) \subset \mathcal{Y}^n$$

for all  $s^n \in S^n$  and for all i = 1, ..., N such that the errors of the first kind and the second kind are bounded as follows.

$$\sum_{s^n \in \mathcal{S}^n} P_S^n(s^n) \int_{x^n \in \mathcal{X}^n(P_{\max}, P_{avg})} Q(x^n | i)$$

$$\cdot W_S^n(\mathcal{D}_i(s^n)^c | x^n, s^n) dx^n \le \lambda_1, \forall i,$$

$$\sum_{s^n \in \mathcal{S}^n} P_S^n(s^n) \int_{x^n \in \mathcal{X}^n(P_{\max}, P_{avg})} Q(x^n | i)$$

$$\cdot W_S^n(\mathcal{D}_i(s^n) | x^n, s^n) dx^n \le \lambda_2, \forall i \ne i$$

In the following, we define achievable ID rate and ID capacity for the state-dependent DTPC  $W_S$ .

**Definition 5.** 1) The rate R of an  $(n, N, \lambda_1, \lambda_2)$  RI code for the channel  $W_S$  is  $R = \frac{\log \log(N)}{n}$  bits.

- 2) The ID rate R for  $W_S$  is said to be achievable if for  $\lambda \in (0, \frac{1}{2})$  there exists an  $n_0(\lambda)$ , such that for all  $n \geq n_0(\lambda)$  there exists an  $(n, 2^{2^{nR}}, \lambda, \lambda)$  randomized ID code for  $W_S$ .
- 3) The RI capacity  $C_{ID}(W_S, P_{max}, P_{avg})$  of the channel  $W_S$  under peak and average power constraints (1) and (2) is the supremum of all achievable rates.

The following corollary, a consequence of Theorem 3, outlines the RI capacity of the state-dependent DTPC  $W_S$ .

**Corollary 6.** The RI capacity of the state-dependent DTPC  $W_S$  under peak and average power constraints  $P_{max}$  and  $P_{avg}$ , respectively, is given by

$$C_{ID}(W_S, P_{max}, P_{avg}) = \max_{\substack{P_X \in \mathcal{P}(\mathcal{X})\\X \in \mathcal{X}(P_{max}, P_{avg})}} I(X; Y).$$

*Proof.* For the proof, we use the same idea as in [?] by averaging over the finite set of states.

Let  $W^a(y|x) = \sum_{s \in \mathcal{S}} P_S(s) W_S(y|x,s)$  be the channel obtained by averaging the state-dependent DTPCs  $W_S$  over the finite set of states  $\mathcal{S}$ . Then, it can be readily verified that the Shannon capacity of the state-dependent DTPC  $W_S$  when the state is available at neither the sender nor the receiver is given by

$$C(W_S, P_{\text{max}}, P_{\text{avg}}) = \max_{\substack{P_X \in \mathcal{P}(\mathcal{X}) \\ X \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})}} I(X; Y).$$

As the set of states S is finite, we can show that the state-dependent DTPC  $W_S$  satisfies the strong converse property as well. That means that the RI capacity of the state-dependent DTPC  $W_S$  coincides with its Shannon transmission capacity. This completes the proof of Corollary 6.

Now, we revisit the definitions of inf-mutual information rate and sup-mutual information rate defined in [36]. Those quantities will play a key role in proving Theorem 3. We first recall the definition of  $\liminf$  and  $\limsup$  in probability.

**Definition 7.** For a given sequence  $\{X^n\}_{n=1}^{\infty}$  of RVs, the lim inf and lim sup in probability are defined as

$$\begin{aligned} & \text{p-liminf } X^n := \sup \left\{ \beta \colon \lim_{n \to \infty} \Pr\{X^n < \beta\} = 0 \right\} \\ & \text{p-limsup } X^n := \inf \left\{ \alpha \colon \lim_{n \to \infty} \Pr\{X^n > \alpha\} = 0 \right\}, \end{aligned}$$

respectively. We refer the reader to [36] for more details.

The quantities mentioned above play a pivotal role in establishing information-spectrum methods.

**Definition 8.** Let  $\mathbf{X} = \{X^n\}_{n=1}^{\infty}$  be a general input process, where  $X^n$  is an arbitrary RV with probability distribution  $P_{X^n}$  on  $\mathcal{X}^n$ . Let  $\{Y^n\}_{n=1}^{\infty}$  be the output of a channel  $\mathbf{W} = \{W^n\}_{n=1}^{\infty}$  corresponding to the input X. The output  $Y^n$  is an arbitrary RV with probability distribution  $P_{Y^n}$  on  $\mathcal{Y}^n$  given by

$$P_{X^nY^n}(x^n, y^n) = P_{X^n}(x^n)W^n(y^n|x^n).$$

The spectral inf-mutual information rate and the spectral supmutual information rate defined in [36] are given by (6) and (7), respectively.

$$\underline{I}(\mathbf{X}, \mathbf{Y}) = \text{p-liminf} \frac{1}{n} \frac{W^n(Y^n | X^n)}{P_{Y^n}(Y^n)}, \tag{6}$$

$$\underline{I}(\mathbf{X}, \mathbf{Y}) = \text{p-liminf} \frac{1}{n} \frac{W^n(Y^n | X^n)}{P_{Y^n}(Y^n)},$$

$$\overline{I}(\mathbf{X}, \mathbf{Y}) = \text{p-limsup} \frac{1}{n} \frac{W^n(Y^n | X^n)}{P_{Y^n}(Y^n)},$$
(6)

where  $\frac{1}{n} \frac{W^n(Y^n|X^n)}{P_{Y^n}(Y^n)}$  is called the mutual information density rate of  $(\mathbf{X}, \mathbf{Y})$  as defined in [36].

#### III. PROOF OF THEOREM 3

In this section, we show that the RI capacity of the DTPC W coincides with its transmission capacity. Indeed, it has been shown in [36, Corollary 6.6.1] that if a channel W satisfies the strong converse property under some cost constraint, then the corresponding RI capacity and transmission capacity coincide. In the following, we prove that the DTPC under peak power constraint  $P_{\text{max}}$  and average power constraint  $P_{\text{avg}}$  satisfies the strong converse property. Let  $\mathcal{U}(P_{\max}, P_{\text{avg}})$  denote the set of all input processes  $\mathbf{X} = \{X^n\}_{n=1}^{\infty}$  satisfying

$$\Pr\{X^n \in \mathcal{X}^n(P_{\max}, P_{\text{avg}})\} = 1$$

for all  $n = 1, 2, \ldots$  Then, as stated in [36, Theorem 3.7.1], the DTPC satisfies the strong converse property under cost constraints  $P_{\text{max}}$  and  $P_{\text{avg}}$  if and only if

$$\sup_{\mathbf{X} \in \mathcal{U}(P_{\text{max}}, P_{\text{avg}})} \underline{I}(\mathbf{X}, \mathbf{Y}) = \sup_{\mathbf{X} \in \mathcal{U}(P_{\text{max}}, P_{\text{avg}})} \overline{I}(\mathbf{X}, \mathbf{Y}).$$
(8)

By applying [36, Theorem 3.6.1], the transmission capacity of the DTPC W under peak and average power constraints can be rewritten as follows:

$$C(W, P_{\text{max}}, P_{\text{avg}}) = \sup_{\mathbf{X} \in \mathcal{U}(P_{\text{max}}, P_{\text{avg}})} \underline{I}(\mathbf{X}, \mathbf{Y}).$$

Thus, in order to develop the strong converse property for the DTPC W under cost constraints  $P_{\text{max}}$  and  $P_{\text{avg}}$ , in view of [36, Theorem 3.6.1] it suffices to show

$$\sup_{\mathbf{X} \in \mathcal{U}(P_{\max}, P_{\text{avg}})} \overline{I}(\mathbf{X}, \mathbf{Y}) \leq \sup_{\substack{P_X \in \mathcal{P}(\mathcal{X}) \\ X \in \mathcal{X}(P_{\max}, P_{\text{avg}})}} I(X; Y)$$

$$= \max_{\substack{P_X \in \mathcal{P}(\mathcal{X}) \\ X \in \mathcal{X}(P_{\max}, P_{\text{avg}})}} I(X; Y)$$

$$= C(W, P_{\max}, P_{\text{avg}}). \tag{9}$$

Let  $P_X \in \mathcal{P}(\mathcal{X}(P_{\text{max}}, P_{\text{avg}}))$  an arbitray input distribution and  $P_Y \in \mathcal{P}(\mathcal{Y})$  the corresponding output distribution via the DTPC W. Then, for a fixed input sequence  $x^n = (x_1, x_2, \dots, x_n) \in \mathcal{X}^n(P_{\text{max}}, P_{\text{avg}}), \text{ we define } I(Y, x)$ as follows

$$I(Y,x) = \log \frac{W(Y|x)}{P_Y(Y)}.$$

The conditional expectation of I(Y, x) given X = x is given by

$$\mathbb{E}[I(Y,x)] = \sum_{y=0}^{\infty} W(y|x) \log \frac{W(y|x)}{P_Y(y)}$$
$$= D(W(\cdot|x) \parallel P_Y). \tag{10}$$

The mutual information induced by the input distribution  $P_X$ is given by

$$\begin{split} I(X,Y) &= \int_0^{P_{\text{max}}} P_X(x) \mathbb{E}[I(Y,x)] dx \\ &= \int_0^{P_{\text{max}}} P_X(x) D(W(\cdot|x) \parallel P_Y) dx. \end{split}$$

In the following, we define the Lagrangian function  $L(\mu, x, P_X)$  with Lagrange multiplier  $\mu \geq 0$  as

$$L(\mu, x, P_X) = I(X, Y) + \mu(x - P_{\text{avg}}) - D(W(\cdot | x) \parallel P_Y).$$
(11)

It has been shown in [30] and [37, Theorem 5] that Kuhn-Tucker conditions yield the following theorem.

**Theorem 9** ([37]). The distribution  $P_X \in \mathcal{P}(\mathcal{X}(P_{max}, P_{avg}))$  is capacity-achieving iff for some  $\mu \geq 0$ , the following conditions are satisfied

$$L(\mu, x, P_X) \ge 0, \quad x \in [0, P_{max}],$$
 (12)

$$L(\mu, x, P_X) = 0, \quad x \in \Phi_x, \tag{13}$$

where  $\Phi_x$  is the support of  $P_X$ .

It has been shown in [30] that the capacity-achieving input distribution is unique and discrete with a finite number of mass points for finite peak power and average power constraints. Let  $P_{\bar{X}}$  denote the capacity-achieving input distribution of the DTPC under peak power and average power constraints

 $P_{\text{max}}$  and  $P_{\text{avg}}$ , respectively. Therefore, as described in [37] It follows from Theorem 9 that for  $x \in [0, P_{\text{max}}]$ and w.l.o.g. the input distribution  $P_{\bar{X}}$  is given by

$$P_{\bar{X}}(x) = p_1 \delta(x - \bar{x}_1) + p_2 \delta(x - \bar{x}_2) + \dots + p_m$$
$$\cdot \delta(x - \bar{x}_m), \quad x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}}), \tag{14}$$

where  $\delta(\cdot)$  denotes the Dirac impulse function,  $\Phi_x$  $\{\bar{x}_1, \bar{x}_2, \dots, \bar{x}_m\}, \quad 0 \leq \bar{x}_1 < \bar{x}_2 < \dots < \bar{x}_m \leq P_{\max} \text{ is }$ a finite input constellation and  $\Phi_p = \{p_1, p_2, \dots, p_m\}$  is the set of the corresponding probability masses. Let  $P_{\bar{V}}$  denote the output distribution of the DTPC W corresponding to the distribution  $P_{\bar{X}}$ . For all  $y \in \mathcal{Y}$ , we have

$$P_{\bar{Y}}(y) = \int_{x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})} P_{\bar{X}}(x) W(y|x) dx$$

$$= \int_{x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})} \left( \sum_{j=1}^{m} p_{j} \delta(x - \bar{x}_{j}) \right) W(y|x) dx$$

$$= \sum_{j=1}^{m} p_{j} \int_{x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})} W(y|x) \delta(x - \bar{x}_{j}) dx$$

$$= \sum_{j=1}^{m} p_{j} W(y|\bar{x}_{j}). \tag{15}$$

Let  $\bar{X}$  and  $\bar{Y}$  be two RVs with probability distribution functions  $P_{\bar{X}}$  and  $P_{\bar{Y}}$  on  $\mathcal{X}(P_{\max}, P_{\text{avg}})$  and  $\mathcal{Y},$  respectively. In view of (10), the capacity  $C(W, P_{\text{max}}, P_{\text{avg}})$  of the DTPC W can be rewritten as follows:

$$\begin{split} &C(W, P_{\text{max}}, P_{\text{avg}}) \\ &= \max_{\substack{P_X \in \mathcal{P}(\mathcal{X}) \\ X \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})}} I(X; Y) \\ &= I(\bar{X}, \bar{Y}) \\ &= \int_{x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})} P_{\bar{X}}(x) \sum_{y=0}^{\infty} W(y|x)(y|x_i) \log \frac{W(y|x)}{P_{\bar{Y}}(y)} dx \\ &= \int_{x \in \mathcal{X}(P_{\text{max}}, P_{\text{avg}})} P_{\bar{X}}(x) D(W(\cdot|x) \parallel P_{\bar{Y}}) dx \\ &= \sum_{i=1}^{m} p_j D(W(\cdot|\bar{x}_j) \parallel P_{\bar{Y}}). \end{split}$$

It holds for each blocklength n that

$$\frac{1}{n}\log\frac{W^{n}(Y^{n}|X^{n})}{P_{\bar{Y}^{n}}(Y^{n})} = \frac{1}{n}\sum_{t=1}^{n}\log\frac{W(Y_{t}|X_{t})}{P_{\bar{Y}}(Y_{t})}.$$

For fixed  $x^n = (x_1, x_2, \dots, x_n) \in \mathcal{X}^n(P_{\text{max}}, P_{\text{avg}})$ , we define

$$I(\bar{Y}_t, x_t) = \log \frac{W(Y_t | X_t)}{P_{\bar{Y}}(Y_t)}$$

In addition, we have for all t = 1, 2, ..., n

$$\mathbb{E}[I(\bar{Y}_t, x_t)] = D(W(\cdot | x_t) \parallel P_{\bar{Y}}).$$

In order to show (9), we first prove the following inequality:

$$\mathbb{E}[\frac{1}{n}\sum_{t=1}^{n}I(\bar{Y}_{i}|x_{i})] \le C(W, P_{\max}, P_{\text{avg}}). \tag{16}$$

$$\begin{split} &L(\mu, x, P_{\bar{X}}) \\ &= I(\bar{X}, \bar{Y}) + \mu(x - P_{\text{avg}}) - D(W(\cdot|x) \parallel P_{\bar{Y}}) \\ &= C(W, P_{\text{max}}, P_{\text{avg}}) + \mu(x - P_{\text{avg}}) - D(W(\cdot|x) \parallel P_{\bar{Y}}) \\ &\geq 0. \end{split}$$

As the sequence  $x^n$  satisfies the peak power and average power constraints, we have

$$\mathbb{E}[I(\bar{Y}, x)] = D(W(\cdot | x) \parallel P_{\bar{Y}}) \le C(W, P_{\text{max}}, P_{\text{avg}}). \quad (17)$$

It yields that

$$\mathbb{E}\left[\frac{1}{n}\sum_{t=1}^{n}I(\bar{Y}_{t},x_{t})\right] \leq C(W,P_{\max},P_{\text{avg}}).$$

This completes the proof of inequality (16).

Next, we want to show that the variance of  $I(Y_t, x_t)$ , t = $1,\ldots,n$  w.r.t. the conditional probability mass function  $W(\cdot|x_t)$  for fixed  $x_t \in \mathcal{X}(P_{\max}, P_{\text{avg}})$ . For this purpose, we prove that  $\mathbb{E}[(I(\bar{Y}_t, x_t))^2], t = 1, \dots, n$  is finite. For notational simplicity, we will drop the index t. Let  $\mathcal{Y}_1$  and  $\mathcal{Y}_2$ be defined as

$$\mathcal{Y}_1 = \{ y \in \mathcal{Y} \colon \frac{P_{\bar{Y}}(y)}{W(y|x)} > 1 \},$$

$$\mathcal{Y}_2 = \{ y \in \mathcal{Y} \colon \frac{P_{\bar{Y}}(y)}{W(y|x)} \le 1 \}.$$

We have

$$\mathbb{E}\left[\left(I(\bar{Y},x)\right)^{2}\right] \tag{18}$$

$$= \sum_{y=0}^{\infty} W(y|x) \log^{2}\left(\frac{W(y|x)}{P_{\bar{Y}}(y)}\right)$$

$$= \sum_{y\in\mathcal{Y}_{1}} W(y|x) \log^{2}\left(\frac{W(y|x)}{P_{\bar{Y}}(y)}\right)$$

$$+ \sum_{y\in\mathcal{Y}_{2}} W(y|x) \log^{2}\left(\frac{W(y|x)}{P_{\bar{Y}}(y)}\right) \tag{19}$$

$$\tag{20}$$

We first establish an upper bound on the first term of the sum

in (19).

$$\begin{split} &\sum_{y \in \mathcal{Y}_{1}} W(y|x) \log^{2}\left(\frac{W(y|x)}{P_{Y}(y)}\right) \\ &= \sum_{y \in \mathcal{Y}_{1}} W(y|x) \log^{2}\left(\frac{P_{Y}(y)}{W(y|x)}\right) \\ &\stackrel{(a)}{\leq} \sum_{y \in \mathcal{Y}_{1}} W(y|x) \log\left(\frac{P_{Y}(y)}{W(y|x)}\right) \cdot \log(e) \cdot \left(\frac{P_{Y}(y)}{W(y|x)}\right) \\ &= \log(e) \sum_{y \in \mathcal{Y}_{1}} P_{Y}(y) \log\left(\frac{P_{Y}(y)}{W(y|x)}\right) \\ &\stackrel{(b)}{=} \log(e) \left(D(P_{Y}(\cdot) \parallel W(\cdot|x))\right) \\ &- \sum_{y \in \mathcal{Y}_{2}} P_{Y}(y) \log\left(\frac{P_{Y}(y)}{W(y|x)}\right)\right) \\ &\stackrel{(c)}{\leq} \log(e) \left(D(P_{Y}(\cdot) \parallel W(\cdot|x))\right) \\ &- \sum_{y \in \mathcal{Y}_{2}} P_{Y}(y) \left(1 - \frac{W(y|x)}{P_{Y}(y)}\right)\right) \\ &= \log(e) \left(D(P_{Y}(\cdot) \parallel W(\cdot|x)) + \sum_{y \in \mathcal{Y}_{2}} W(y|x) - P_{Y}(y)\right) \\ &\stackrel{(d)}{=} \log(e) \left(D(P_{Y}(\cdot) \parallel W(\cdot|x)) + \frac{1}{2} d(P_{Y}(\cdot), W(\cdot|x))\right) \\ &\stackrel{(e)}{\leq} \log(e) \left(D(P_{Y}(\cdot) \parallel W(\cdot|x)) + 1\right) \\ &\stackrel{(f)}{\leq} \log(e) \left(\sum_{j=1}^{m} p_{j} W(\cdot|\bar{x}_{j}) \parallel \sum_{j=1}^{m} p_{j} W(\cdot|x)\right) + 1\right) \\ &\stackrel{(g)}{\leq} \log(e) \left(\sum_{j=1}^{m} p_{j} D(W(\cdot|\bar{x}_{j}) \parallel W(\cdot|x)) + 1\right) \\ &\stackrel{(h)}{\leq} \log(e) \left(\sum_{j=1}^{m} p_{j} \left((\lambda + \bar{x}_{j}) \log \frac{\lambda + \bar{x}_{j}}{\lambda + x}\right) \\ &\stackrel{(\bar{x}_{j}}{=} - x)\right) + 1\right) \\ &\stackrel{(i)}{\leq} \log(e) \left(\log(e) \left(\frac{\sum_{j=1}^{m} p_{j} (\lambda + P_{\max}) \log \frac{\lambda + P_{\max}}{\lambda} + P_{\max} + 1\right) \\ &\stackrel{(j)}{\leq} \log(e) \left(\log(e) \left(\frac{(\lambda + P_{\max})^{2}}{\lambda} + P_{\max} + 1\right), \end{cases} \end{aligned} (2$$

where (a) follows because  $\log\left(\frac{P_{\bar{Y}}(y)}{W(y|x)}\right) > 0$  and  $\log(x) \leq (x-1)\log(e)$ , (b) follows from the definition of the Kullback-Leibler divergence, (c) follows because  $\log(x) \geq \log(e)(1-\frac{1}{x})$ , (d) follows from the definition of the variational distance  $d(P_{\bar{Y}}(\cdot),W(\cdot|x))$ , (e) follows because  $0 \leq d(P_{\bar{Y}}(\cdot),W(\cdot|x)) \leq 2$ , (f) follows from (15), (g) follows from the convexity of the Kullback-Leibler divergence, (h) because  $W(\cdot|\bar{x}_j)$ ,  $j=1,\ldots,m$  and  $W(\cdot|x)$  are Poisson distributed with mean  $\lambda+\bar{x}_j$  and  $\lambda+x$ , respectively, (i) follows because  $0 \leq x$ ,  $\bar{x}_j \leq P_{\max}$  and (j) follows because

 $\log(x) \le (x-1)\log(e).$ 

Now, we compute an upper bound on the second term of the sum in (19). We have

$$\sum_{y \in \mathcal{Y}_{2}} W(y|x) \log^{2} \left( \frac{W(y|x)}{P_{\bar{Y}}(y)} \right) \\
= \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \log(W(y|x)) - \log(P_{\bar{Y}}(y)) \right)^{2} \\
\stackrel{(a)}{=} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \log(W(y|x)) - \log\left(\sum_{j=1}^{m} p_{j}W(\cdot|\bar{x}_{j})\right) \right)^{2} \\
\stackrel{(b)}{\leq} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \log(W(y|x)) - \sum_{j=1}^{m} p_{j} \log\left(W(\cdot|\bar{x}_{j})\right) \right)^{2} \\
\stackrel{(c)}{=} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \left( \log(x+\lambda) - \sum_{j=1}^{m} p_{j} \log(x_{j}+\lambda) \right) y + \left(\sum_{j=1}^{m} p_{j}x_{j} - x \right) \right)^{2} \\
\stackrel{(d)}{\leq} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \alpha y + \beta \right)^{2} \\
= \alpha^{2} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \left( \alpha y + \beta \right)^{2} \\
= \alpha^{2} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \\
+ \beta^{2} \sum_{y \in \mathcal{Y}_{2}} W(y|x) \\
\leq \alpha^{2} \mathbb{E}[Y^{2}|X = x] + 2\alpha\beta \mathbb{E}[Y|X = x] + \beta^{2}(\lambda, P_{\text{max}}) \\
\stackrel{(e)}{\leq} \alpha^{2} (\lambda + P_{\text{max}})^{2} + 2\alpha\beta(\lambda + P_{\text{max}}) + \beta^{2}, \tag{22}$$

where  $d(\cdot,\cdot)$  denotes the total variational distance, (a) follows (15), (b) follows from the convexity of  $-\log(x)$ , (c) follows because  $W(\cdot|\bar{x}_j)$ ,  $j=1,\ldots,m$  and  $W(\cdot|x)$  are Poisson distributed with mean  $\lambda+\bar{x}_j$  and  $\lambda+x$ , respectively, (d) follows from (23) and (24) and (e) follows because given the input X=x, the output Y is Poisson distributed with mean  $\lambda+x$  and  $0< x \leq P_{\max}$ .

Let  $\alpha$  and  $\beta$  be defined as follows:

$$\alpha = \log(1 + \frac{P_{\text{max}}}{\lambda})$$
$$\beta = P_{\text{max}}.$$

Then, it can be easily shown that

$$\log(x+\lambda) - \sum_{i=1}^{m} p_j \log(x_j + \lambda) \le \alpha, \tag{23}$$

and

$$\sum_{j=1}^{m} p_j x_j - x \le \beta. \tag{24}$$

It follows from (21) and (22) that

$$\begin{aligned} & \operatorname{Var}[\frac{1}{n} \sum_{t=1}^{n} I(\bar{Y}_{t}, x_{t})] \\ & \leq \log(e) \bigg( \log(e) \frac{(\lambda + P_{\max})^{2}}{\lambda} + P_{\max} + 1 \bigg) \\ & + \alpha^{2} (\lambda + P_{\max})^{2} + 2\alpha\beta(\lambda + P_{\max}) + \beta^{2} \end{aligned}$$

Let  $\gamma(\lambda, P_{\text{max}})$  be defined as

$$\gamma(\lambda, P_{\text{max}}) = \log(e) \left( \log(e) \frac{(\lambda + P_{\text{max}})^2}{\lambda} + P_{\text{max}} + 1 \right)$$
$$+ \alpha^2 (\lambda + P_{\text{max}})^2 + 2\alpha\beta(\lambda + P_{\text{max}}) + \beta^2.$$

Therefore, Chebyshev's inequality implies

$$\Pr\left\{\frac{1}{n}\sum_{t=1}^{n}I(\bar{Y}_{t},x_{t}) \geq C(W,P_{\max},P_{\text{avg}}) + \nu|X^{n} = x^{n}\right\}$$

$$\leq \frac{\gamma(\lambda,P_{\max})}{n},$$
(25)

where  $\nu>0$  is an arbitrary constant. As  $\mathbf{X}=\{X^n\}_{n=1}^\infty\in\mathcal{U}(P_{\max},P_{\mathrm{avg}})$  is assumed, (25) holds for all realizations  $x^n$  of  $X^n$ . Thus, we have

$$\Pr\left\{\frac{1}{n}\sum_{t=1}^{n}I(\bar{Y}_{t},X_{t}) \geq C(W,P_{\max},P_{\text{avg}}) + \nu\right\}$$

$$\leq \frac{\gamma(\lambda,P_{\max})}{n}.$$

That means

$$\Pr\left\{\frac{1}{n}\log\frac{W^n(Y^n|X^n)}{P_{\bar{Y}^n}(Y^n)} \ge C(W, P_{\max}, P_{\text{avg}}) + \nu\right\} \le \frac{\gamma(\lambda, P_{\max})}{n}.$$

We have

$$\lim_{n \to \infty} \Pr\left\{ \frac{1}{n} \log \frac{W^n(Y^n | X^n)}{P_{\bar{Y}^n}(Y^n)} \ge C(W, P_{\text{max}}, P_{\text{avg}}) + \nu \right\}$$

$$= 0.$$

Since  $\nu > 0$  is chosen arbitrarily, we have

$$\operatorname{p-limsup}_{n \to \infty} \frac{1}{n} \log \frac{W^n(Y^n | X^n)}{P_{\bar{Y}^n}(Y^n)} \le C(W, P_{\max}, P_{\operatorname{avg}}). \tag{26}$$

It follows from (26) and [36, Lemma 3.2.1] that

$$\operatorname{p-limsup}_{n \to \infty} \frac{1}{n} \log \frac{W^n(Y^n | X^n)}{P_{Y^n}(Y^n)} \le C(W, P_{\max}, P_{\operatorname{avg}}).$$

This completes the proof of (9). Thus, (8) holds, and the strong converse property is proved for the DTPC W under peak and average power constraints  $P_{\rm max}$  and  $P_{\rm avg}$ , respectively. That means that the RI capacity of the DTPC  $C_{ID}(W, P_{\rm max}, P_{\rm avg})$  coincides with its transmission capacity  $C(W, P_{\rm max}, P_{\rm avg})$ .

### IV. CONCLUSIONS

In our work, we perform an information-theoretic analysis for event-triggered molecular communication. In the previous considerations known to us, the model was considered with deterministic encoding. We now assume in our analysis that local randomness is available at the sender. Instead of  $n^{nR_1}$ messages in the deterministic case, we get  $2^{2^{nR_2}}$  in the randomised scenario. Furthermore, we derive an exact formula for the RI capacity, whereas in the DI case, only upper and lower bounds have been established so far. Of course, one can ask how realistic it is to have randomness available at the sender. One possible scenario would be a sender outside the body (for example in a bracelet). Another scenario would be to gain randomization through resources such as feedback. Finally, we examine the scenario where the channel depends on a random state and derive the corresponding capacity. In future studies, we should investigate deterministic identification with resources (as indicated above) that allow randomized encoding. Additionally, a fundamental objective is to analyze encoding techniques with finite block lengths for this model. Our work marks the initial step in undertaking this analysis.
