Abstract: Here, we report the development and working of a compact rubidium (Rb) atom magneto-optical trap (MOT) operated with a hollow pyramidal mirror and a single laser beam. This type of compact MOT is suitable for developing portable atom-optic devices, as it works with less number of optical components as compared to conventional MOT setup. The application of this compact MOT setup for pressure sensing has been demonstrated.

1. Introduction

A magneto-optical trap (MOT) is a work-horse setup used for generating samples of cold atoms for their applications in basic science experiments and developing various atom based quantum technologies. Using cold atoms from a MOT, several atom-optic precision measurement devices have been developed, which have shown measurement accuracy comparable or better than existing other devices. These atom-optic devices include atomic clocks [1], cold atom gravimeters [2–4], cold atom gyroscopes [5], cold atoms UHV sensors [6], etc. Besides that, MOT also serves as a source for realization of qubits, each made of single atom, for quantum information processing application [7]. World-wide, different research groups have made considerable efforts to miniaturize the MOT setup [8,9], by minimizing the number of laser sources as well minimizing the optical and mechanical components (e.g. beam splitters, retardation plates, mirrors, etc). For example, the need of two sets of frequency-stabilized lasers (called cooling and re-pumping lasers) required at different wavelengths to operate a ⁸⁷Rb-MOT, can be fulfilled by using a single laser with current modulation to simultaneously generate the cooling and re-pumping emissions from the same laser source [10, 11]. Alternatively, a single laser with an electro-optic modulator (EOM) in the output can generate the cooling and re-pumping radiation in the same beam [12, 13]. In order to minimize the number of optical and mechanical components required for MOT operation, use of some specially designed optical elements in suitable configuration have also been proposed. These include the use of a mirror surface in refection geometry [14, 15], use of a grating [16–27], and use of a pyramidal mirror [28–34] in the setup for MOT. The latter two cases use a single cooling laser beam, which provides operational ease and compactness to the setup.

Here we report the development and working of a compact and simple MOT setup for ⁸⁷Rb atoms using a pyramidal mirror. We use a single ECDL laser system with an EOM in the output to obtain both cooling and re-pumping laser emissions in a single beam. This beam (called MOT beam) when enters into a home made hollow pyramidal mirror, the required six MOT beams are generated inside the hollow region of pyramidal mirror. The fabrication of the hollow pyramidal mirror has been discussed and operation of the magneto-optical trap (MOT) using this mirror has been demonstrated. Nearly 7.9×10^{6} ⁸⁷Rb atoms have been trapped in the pyramidal-MOT. This development is important for making transportable cold atoms source.

MOT setup for sensing ultrahigh vacuum (UHV) in the chamber has been demonstrated.

2. Fabrication of hollow pyramidal mirror

The photograph of hollow pyramidal mirror (PM) is shown in Fig.1. It has the base size of 40 $mm \times 40$ mm and height of 30 mm. There is a hole of 8 mm diameter at the apex of this pyramidal mirror. It is custom-designed and fabricated in-house for our magneto-optical trap (MOT) setup. It is made of four identical triangular faces, in which adjacent faces made an angle of 120° between them and the opposite faces made an angle of 90° with each other at vertex point. These angles have been measured using laser interferometry techniques [35] and using auto-collimators [36]. Among these four faces, two opposite faces A and C are made using two right angle glass prisms, and the other two faces B and D are made using two corner cube glass prisms, Fig.1. All the four faces facing inside the pyramidal mirror were polished using the chemical-mechanical polishing process before joining them. An auto-collimator was used to align faces of the prisms before they were cemented. The accuracy of angles on joining the prisms faces was maintained at the level of 10 arc sec. After joining all the faces, a hole of 8 mm diameter at vertex of this hollow pyramid was made by applying the optical trepanning technique. In optical trepanning, a hollow cylindrical tool with required external diameter is rotated on the optical component with a downward pressure and loose abrasive (Aluminum oxide power) is fed for cutting. We have used 50 mm long trepanning tool made of brass with external diameter of 7.9 mm and wall thickness of 1 mm. The purpose of the making this hole was to allow the passage for trapped cold atoms out side the pyramidal mirror to perform further experiments. One of these experiments could be to allow fall of atoms in earth's gravitational field perform Raman pulse atom interferometry for accurate measurement of earth's gravitational acceleration (g).

Fig. 1. Photograph of the gold-coated hollow pyramidal mirror for use in compact single beam operated magneto-optical trap (MOT) setup.

Subsequent to joining of faces and cutting of hole at the apex, the inner polished surfaces of pyramidal mirror were coated for achieving reflectivity from the inner faces. For this, a 15 nm thick chromium (Cr) layer was deposited on all the four inner faces of the pyramidal element

before coating these surfaces with gold. This is necessary to improve the adhesion of gold layer on glass surface of the pyramid. Then a 200 nm thick gold (Au) layer was deposited on these chromium coated surfaces for achieving the desired high optical reflectivity of 780 nm laser beam from these surfaces. A pulsed DC magnetron sputtering system was used to deposit both the layers, chromium and gold, on the inner faces of the hollow pyramid. The finally finished pyramidal mirror (PM) was installed on a suitable mount of stainless steel (SS) before it was inserted in an ultra-high vacuum (UHV) chamber for MOT operation. The background pressure of $\approx 1 \times 10^{-8}$ Torr was generated in this chamber using a turbo molecular pump (TMP 70 L/s) and a sputter ion pump (SIP 20 L/s).

3. Pyramidal MOT setup

Fig. 2 shows an schematic of the experimental setup for magneto-optical trap (MOT) using the in-house fabricated gold coated pyramidal mirror. We need only one laser beam incident on pyramidal mirror for operation of MOT for ⁸⁷Rb atoms. From this incident single laser beam, the pyramidal mirror generates the required MOT beams for three-dimensional trapping of atoms after reflection of the incident beam from the its surfaces and from a mirror M2, as shown in Fig.2. This reduces the requirement of several optical elements, such as beam splitters and mirrors, for generating the six MOT beams required for a MOT setup.

Fig. 2. Schematic of pyramidal MOT setup. ECDL: External cavity diode laser, EOM: Electro-optic modulator, C1 and C2: quadrupole coils, M1 and M2: Mirrors, PD: Photodiode.

To generate both cooling and re-pumping radiations in the same single MOT beam, we passed the output laser beam from an ECDL through an electro-optic modulator (EOM) device. For this the ECDL output beam was locked to the cooling transition of ⁸⁷Rb atom before passing through the EOM. We have used an ECDL (Make: TOPTICA, DLC-Pro) operating at 780 nm wavelength. The maximum power of the ECDL was ~ 100 mW. We used an EOM (Make: Qubig, Germany, Model: EO-Rb87-6.6G) which was operated using rf field at frequency of $v_{RF} = 6.56$ GHz. When ECDL output was passed through the EOM, the resulting output beam had both cooling and re-pumping emissions. This output beam served as MOT beam for our experiments. In the output beam from EOM, the cooling beam at frequency v_L and re-pumping laser beam at frequency $v_L + v_{RF}$ were obtained in co-propagating geometry. In the EOM output beam, the distribution of power in cooling and re-pumping parts was distributed with ~ 60% and ~ 20% of the total output beam power. The remaining 20 % power at frequency $v_L - v_{RF}$ in the EOM

Fig. 3. (a) Photograph of cold atom cloud of ⁸⁷Rb atoms trapped in the pyramidal MOT. (b) The observed MOT loading curve which shows the temporal variation in fluorescence signal (proportional to number of atoms) from atoms in MOT.

output beam was un-utilized. In order to achieve these values, the EOM device was operated at power of ~ 32 dBm.

The output beam from EOM was expanded using a beam expander and then this linearly polarized beam was passed through a quarter-wave plate for converting its polarization to circular polarization. The diameter of beam was 20 mm after the expansion. Before entry into the UHV chamber, the power of the MOT beam was 12 mW, with 7.2 mW in cooling part and 2.4 mW in repuming part. With the use of a retro-reflecting plane mirror (M2) in the back side of the pyramidal mirror, the six MOT beams configuration was achieved with single input beam, as shown in Fig.2. Each reflection reverses the helicity of the circularly polarized beam so that the desired $\sigma^- - \sigma^+$ polarization configuration was produced along the three orthogonal axes.

The Rb-source (a combination of Rb-getter dispensers) was installed in the UHV chamber using a two-pin vacuum feed-throgh. A variable dc current, called dispenser current (I_D), was supplied to this Rb-source for generation of Rb vapor in the chamber. The dispenser source was positioned at a distance of ~ 10 cm from the MOT position. A pair of DC current carrying coils (in anti-Helmholtz like configuration) was installed out side the UHV chamber for generating the required quadrupole magnetic field for the MOT. These coils were placed such that the coils axis was parallel to the input laser beam direction. The coils were supplied a DC current of 5.3 A to produce axial magnetic field gradient of ~ 11 G/cm. Another pair of DC bias coils in Helmholtz like configuration was added in order to manipulate the zero position of the quadrupole magnetic field. This was necessary to ascertain the maximum number of atoms trapped in the MOT.

A photograph of the cloud of ⁸⁷Rb atoms trapped in pyramidal MOT is shown in Fig. 3a. Nearly 3.5×10^6 atoms have been trapped in the MOT at the dispenser current of $I_D = 4.5$ A. To study the loading behavior of the MOT, fluorescence from the atoms in the MOT was collected on a photodiode (PD). The photodiode signal was calibrated for the number of atoms using a CCD camera. The CCD camera was used to capture fluorescence image of the atom cloud and estimate the number of atoms in the MOT [37]. Fig. 3b shows the MOT loading curve at dispenser current of 4.5 A and cooling beam detuning of -15 MHz (i.e. red side of cooling transition). The red curve in Fig. 3b is the best fit of the loading equation $N(t) = N_s [1 - exp(-t/\tau_L)]$ to the experimentally observed MOT loading curve, where N(t) is number of atoms at time t and N_S is the saturated number in the MOT. From the best fit to the experimental data in Fig. 3b, we get N_S = 3.5×10^6 and $\tau_L = 0.31$ s.

4. Pyramidal MOT : Application to pressure sensing

Here, we discuss our measurements of pressure using pyramidal MOT loading characteristics. The MOT loading curve in Fig. 3b shows the observed loading behaviour of our MOT. Here we measured the variation in number of atoms in the MOT as function of time. As can be seen in the Fig. 3b, the initial rise in number of atoms is exponential before reaching to the saturated number of atoms.

The loading of a MOT, neglecting the intra-trap collisional loss rate, is governed by a rate equation,

$$\frac{dN}{dt} = R - \frac{N}{\tau_L} \tag{1}$$

where N is the number of atoms in MOT at any time t and R is the MOT loading rate from the Rb-vapour in the background. The solution of equation (1) gives the MOT loading equation as,

$$N(t) = N_s \left[1 - exp(-t/\tau_L) \right],$$
(2)

where

$$N_S = R\tau_L = \alpha P_{Rb}\tau_L. \tag{3}$$

Here, N_S represents the final saturated number of atoms in the MOT and $R=\alpha P_{Rb}$ represents the MOT loading rate. The time constant τ_L is called MOT loading time. The inverse of τ_L , i.e. $\gamma = \frac{1}{\tau_L}$, represents the loss rate of atoms in the MOT. Neglecting intra-trap collisions, the loss of atoms from the MOT is mainly due to collisions of MOT atoms with untrapped atoms and molecules present in the surroundings of MOT cloud. The partial pressure of a gas in the chamber determines the collisional loss rate of MOT atoms due to that particular gas. Therefore in a vapor loaded MOT, the MOT loss rate can be expressed as sum of loss rate due to free Rb vapor atoms and loss rate due to other gases in the chamber. Thus, we can write the total loss rate as,

$$\gamma = \frac{1}{\tau_L} = \gamma_{Rb} + \gamma_{bg} = \beta P_{Rb} + \gamma_{bg}, \tag{4}$$

where the term βP_{Rb} is the loss rate of MOT atom due to their collisions with hot Rb atoms in the vapor, with P_{Rb} being the partial pressure of Rb atomic vapor in the chamber. The term γ_{bg} represents the MOT loss rate due to collision of other atoms/molecules (excluding Rb atoms) in the chamber with Rb atoms in MOT.

After using equation (3) and (4), the relation between N_S and τ_L is given by

$$N_S = \frac{\alpha}{\beta} (1 - \gamma_{bg} \tau_L). \tag{5}$$

Thus, by measuring the variation of N_S and τ_L for different Rb pressure values (by varying the dispenser current), it is possible to estimate the Rb pressure (from α/β) as well as non-Rb gases pressure (from γ_{bg}) in the chamber.

In our experiment, the value of α/β and γ_{bg} are estimated by fitting the data points listed in Table 1. From the fit, we obtain $\gamma_{bg} = 2.6 \text{ s}^{-1}$ and $\alpha/\beta = 2.1 \times 10^7$. This value of γ_{bg} can be used to estimate the background pressure (P) due to non-Rb gases in the chamber, using the relation $\gamma_{bg}/P = 4.9 \times 10^7 \text{ Torr}^{-1} \text{ s}^{-1} [38, 39]$. Similarly, the value of α/β can be used to estimate the value of $\beta = 4.4 \times 10^7 \text{ Torr}^{-1} \text{ s}^{-1}$ available in the literature [38, 39]. After knowing the value of α , the partial pressure due to Rb vapor (P_{Rb}) can be estimated by using the relation $N_S = \alpha P_{Rb} \tau_L$. Here we obtain the value of α as $\alpha = 9.2 \times 10^{14} \text{ Torr}^{-1} \text{ s}^{-1}$ which gives

S. No.	Disp. current I_D (A)	$ au_L$ (s)	N _S	P_{Rb} (Torr)
1	4.5	0.31	3.5×10^6	1.2×10^{-8}
2	5.0	0.28	4.0×10^{6}	1.6×10^{-8}
3	5.5	0.23	7.9×10^6	3.7×10^{-8}

Table 1. The measured values of τ_L , N_S and P_{Rb} for different values of Rb-dispenser current (keeping other parameter unchanged during experiments).

partial pressure due to Rb vapor as 1.2×10^{-8} Torr at the dispenser current of 4.5 A. The value of partial pressure of Rb vapor estimated by this this method at different values of dispenser current is given in Table 1. Using the value of γ_{bg} , we estimate the background (non-Rb) pressure (P) in our chamber as $(5.3 \pm 0.9) \times 10^{-8}$ Torr, using the relation $\gamma_{bg}/P = (1/k) = 4.9 \times 10^{7}$ Torr⁻¹ s⁻¹, assuming only hydrogen (H_2) gas in the background [38,39]. This estimated non-Rb background gases pressure value is slightly higher than the value of pressure ($\approx 1 \times 10^{-8}$ Torr) read by the ion gauge in the setup. This difference could be due to the conductance of the pipe used for attaching ion gauge to the chamber. Further, the estimation of the background gases pressure from the γ_{bg} is dependent on MOT parameters and the value of k. The value of k is also dependent on the composition of the background gases, and it can be higher by a factor of 2 (or more) if other gases (He, Ar and H_2 O) are present in significant fraction in the MOT chamber [6]. Further work is in progress to ascertain the background non-Rb pressure in the chamber more accurately.

5. Conclusion

We have demonstrated the working of a magneto-optical trap with a pyramidal mirror for pressure sensing application. The pyramidal mirror was fabricated in-house using four gold-coated prism surfaces. Using this MOT setup, the background Rb and non-Rb gases pressure values were estimated from the MOT loading data. This compact MOT setup is a useful development for making field deployable cold atom based UHV pressure sensor.
