We describe a quantum error-detecting and error-correcting code embedded within irreducible representations of SU(3). These logical quartity inherit the He(3) symmetries induced by the representation, while protecting against small SU(3) displacements. We explore the general methodology for finding codes from structure-inducing representations of groups, together with symmetries inherited from finite subgroups, extending the case of spin representations of SU(2) [1].

I. INTRODUCTION

Quantum error correction is essential to realizing large-scale quantum computation. To distinguish errors from computation, one must embed the logical quantum state space in a larger physical state space. The most widely used strategy for doing this is to encode a small number of logical systems in a large number of physical systems, such as encoding a single logical qubit in a collection of many physical qubits.

However, depending on the types of errors one wants to correct, the large physical state space need not decompose into multiple subsystems. Gottesman-Kitaev-Preskill (GKP) codes [2], cat codes [3], binomial codes [4], and other variants [5, 6] all encode logical qubits in the infinite-dimensional Hilbert space of a bosonic mode. While multi-system codes are designed to protect against errors restricted to a few subsystems, these bosonic codes are designed to protect against dominant errors in oscillator systems, such as photon loss, dephasing, thermalization, and displacement [7–9]. Because harmonic oscillators are ubiquitous, these codes have enjoyed a great deal of experimental attention [10-16].

Of course, there are many monolithic state spaces other than bosonic modes. Qubits have also been encoded in large angular-momentum state spaces [1, 17–20] and abstract finitedimensional systems [21, 22]. In these cases, the relevant errors are given by some extra structure on the Hilbert space. For bosonic modes, the relevant Gaussian errors correspond to a representation of $SL(2, \mathbf{R})$ on the Hilbert space. For angular-momentum systems, there is a natural representation of SU(2) or SO(3), and more abstract systems are generally associated with a representation of a discrete group, such as a cyclic group [21] or finite Heisenberg group [22].

The present work is a natural extension of the approach followed in [1], where we take the physical state space to be an irreducible representation of SU(3). In addition to defining relevant errors, the structure-inducing representation also defines the simplest controls available over the physical system. We therefore desire to find codes that not only correct small SU(3)displacements, but also allow certain logical operations to be performed using large SU(3) displacements. This is analogous to transversal gates in multi-system codes, which allow logical operations when acting on many of the subsystems, as well as the GKP code, which allows logical operations via large displacements. The authors of [23, 24] have extensively studied the relationship between these different notions of transversality. In the case of SU(2) codes, narrowing the search by restricting to highly symmetric codespaces - namely those endowed with "natural" logical operators - proved fruitful for efficiently protecting against errors, and we find the same true for SU(3). In this work, we focus on enforcing He(3) symmetry, endowing our codes with the analogue of logical Pauli operators.

The paper is organized as follows. We begin with a brief introduction in Section II, including the Knill-Laflamme conditions for quantum error-correction and the relevant representation theory of $\text{He}(3) \subseteq \text{SU}(3)$. In Section III, we discuss using the imposed He(3) symmetry to simplify the detection and correction conditions. In Section IV, we present a 15-dimensional quantum error-detecting code which supports logical Pauli operators. We also use this simpler example to build intuition for tools that will as-

^{*} xzavier.herbert@gmail.com

sist our search for a quantum error-correcting code. Finally, in Section V we present a much larger quantum error-correcting code along with a proof of correctability against small SU(3) displacements. We conclude in Section VI with thoughts on how to find smaller codes, codes with more symmetries, and plausible physical instantiations of such codes. For convenience, Python code verifying correctability may be found at [25].

II. BACKGROUND

A. Error correction conditions

We begin with the group SU(3), generalizing the "spin code" case of SU(2). Our aim is to find a special subspace of a monolithic state space \mathcal{H} presented as an irreducible representation of SU(3). The representation imbues \mathcal{H} with distinguished error operators - those generated by $\mathfrak{su}(3)$. Correcting such error operators are relevant e.g. to number-preserving operations on collections of harmonic oscillators [26].

The Knill-Laflamme quantum error correction conditions determine whether particular error can be corrected. Given a code spanned by an orthonormal basis $\{|\bar{i}\rangle\}$, we say the code detects a set of errors $\{E_a\}$ if

$$\langle \overline{i} | E_a | \overline{j} \rangle = C_a \delta_{ij}$$

and corrects them if

$$\langle \overline{i} | E_b^{\dagger} E_a | \overline{j} \rangle = C_{ab} \delta_{ij}.$$

It suffices to satisfy these conditions on a basis for a set of errors. For $\mathfrak{su}(3)$, we consider representatives for the basis

$$\lambda_{1} = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \qquad \lambda_{2} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}$$
$$\lambda_{3} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \qquad \lambda_{4} = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$
$$\lambda_{5} = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \qquad \lambda_{6} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}$$
$$H_{1} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \qquad H_{2} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

.

B. Irreducible representations of SU(3)

We briefly review the representation theory of SU(3) - see [27] for further details. The irreducible representations of SU(3) are classified in terms of their highest weights, which are determined by vectors in the associated complexified Lie algebra $\mathfrak{su}(3)_{\mathbb{C}} \cong \mathfrak{sl}(3;\mathbb{C})$. For any representation (π, V) of $\mathfrak{sl}(3;\mathbb{C})$, a weight for π is an ordered pair $\mu = (\mu_1, \mu_2) \in \mathbb{Z}^2_{\geq 0}$ such that there is some nonzero $v \in V$ such that

$$\pi(H_1)v = \mu_1 v$$

$$\pi(H_2)v = \mu_2 v.$$

A root is defined similarly as a nontrivial weight of the adjoint representation, i.e. an ordered pair $\alpha = (\alpha_1, \alpha_2) \in \mathbb{C}^2$ such that $(\alpha_1, \alpha_2) \neq 0$ and there exists $Z \in \mathfrak{sl}(3; \mathbb{C})$ such that

$$[H_1, Z] = \alpha_1 Z$$
$$[H_2, Z] = \alpha_2 Z$$

The ordering on weights is defined using the respective roots of the raising operators $|1\rangle \langle 0|$ and $|2\rangle \langle 1|$,

$$\alpha = (2, -1)$$

 $\beta = (-1, 2).$

The partial ordering is then defined as $\mu_1 \succeq \mu_2$ if there exist $a, b \ge 0$ such that

$$\mu_1 - \mu_2 = a\alpha + b\beta.$$

Each irreducible representation of SU(3) has a unique highest weight under this ordering, and so we refer to the irreducible representations using these highest weights (p, q).

C. (p,0) representations

The standard prescription for constructing (p,q) representations is to identify them within the combined p- and q-fold tensor product of the (1,0) and (0,1) representations, respectively. The (1,0) representation corresponds to the standard representation, with highest weight vector $|0\rangle$, and (0,1) its dual, with highest weight vector $|2\rangle$. One can repeatedly apply sequences of lowering operators Y_1 and Y_2 to the highest (p,q)-weight vector $|0\rangle^{\otimes p} \otimes |2\rangle^{\otimes q}$ (under the product rule action by $\mathfrak{sl}(3;\mathbb{C})$) to explicitly

construct the (p, q) representation. In general, it has dimension

$$\frac{1}{2}(p+1)(q+1)(p+q+2).$$

To assist our search, we focus on (p, 0) representations of SU(3), which follow a simple pattern. The (p, 0) representations are generated by symmetric vectors, taking the form

$$[a_1 a_2 \dots a_p] := \sum_{\sigma \in \operatorname{orb}_{S_3}[a_1 a_2 \dots a_p]} \sigma$$

Note that (as expected) the number of symmetric vectors $\binom{p+2}{2}$ matches the dimension formula.

D. Representations of He(3)

Of similar importance to protecting encoded information is to be able to deliberately manipulate it. Consequently, we will focus on quantum codes which are endowed with logical He(3) actions inherited from the SU(3) representation. Importantly, He(3) is a finite group, so we can distinguish different logical operations from unintended infinitesimal transformations [28]. Being a finite group, He(3) has finitely many irreducible representations. These representations are given in Table I.

To obtain a faithful representation of He(3), the representative of Z must apply the appropriate phases on the logical states. Since $\omega Z = \exp\left[-i2\pi(H_1 + H_2)/3\right]$, the weight vectors are also eigenvectors of Z. This means we can make diagrams of the weight vectors forming the supports of various logical states, as in Figure 1. These diagrams also let us easily see what happens when we apply the X operator it simply rotates the triangle counter clockwise. From this, we observe that faithful representations of He(3) are only possible when $p \neq 0$ mod 3. In fact, we focus on $p \equiv 1 \mod 3$ to obtain standard He(3) actions. In particular, the $\chi_{(p,0)}$ irreducible representations of SU(3) restrict to $\chi_{std}^{\oplus \frac{1}{6}(p+1)(p+2)}$ reducible representations of He(3).

III. CONSTRAINT REDUCTION

Not only does embedding within faithful He(3) representations imbue the codespace with

(a) For $p \equiv 1 \mod 3$ we can obtain standard representations of He(3), since the rotations made by X permute the eigenstates of the Z representative in the ordinary direction.

(b) For $p \equiv 2 \mod 3$ we can obtain dual representations of He(3), since the rotations made by X permute the eigenstates of the Z representative in the opposite direction.

(c) For $p \equiv 0 \mod 3$ we can't obtain faithful representations of He(3), since the rotations made by X do not permute all three of the Z-eigenstates.

FIG. 1: Candidates for faithful representations of He(3) within (p, 0) representations of SU(3).

desirable logical operators - it places structural

TABLE I: Character table of He(3).

constraints on the codespace. This helps simplify the system of equations required to satisfy the Knill-Laflamme conditions.

Focusing on error detection for example, suppose we find a codespace on which He(3) is represented faithfully and satisfies the identical expectation condition

$$\langle \overline{0} | \lambda_1 | \overline{0} \rangle = \langle \overline{1} | \lambda_1 | \overline{1} \rangle = \langle \overline{2} | \lambda_1 | \overline{2} \rangle = C_{\lambda_1}.$$

Then, noting that

$$X^{\dagger}\lambda_1 X = \lambda_2, \ (X^2)^{\dagger}\lambda_1 X^2 = \lambda_3,$$

we simultaneously obtain

$$C_{\lambda_1} = \langle \overline{0} | X^{\dagger} \lambda_1 X | \overline{0} \rangle = \langle \overline{0} | \lambda_2 | 0 \rangle = C_{\lambda_2}$$

$$C_{\lambda_1} = \langle \overline{0} | (X^2)^{\dagger} \lambda_1 X^2 | \overline{0} \rangle = \langle \overline{0} | \lambda_3 | \overline{0} \rangle = C_{\lambda_3}.$$

because of the logical action of X on the logical qutrits. Furthermore,

$$\begin{split} C_{\lambda_1} &= \langle \overline{2} | \lambda_1 | \overline{2} \rangle = \langle \overline{1} | X^{\dagger} \lambda_1 X | \overline{1} \rangle = \langle \overline{1} | \lambda_2 | \overline{1} \rangle \\ C_{\lambda_1} &= \langle \overline{0} | \lambda_1 | \overline{0} \rangle = \langle \overline{2} | X^{\dagger} \lambda_1 X | \overline{2} \rangle = \langle \overline{2} | \lambda_2 | \overline{2} \rangle \\ C_{\lambda_1} &= \langle \overline{2} | \lambda_2 | \overline{2} \rangle = \langle \overline{1} | X^{\dagger} \lambda_2 X | \overline{1} \rangle = \langle \overline{1} | \lambda_3 | \overline{1} \rangle \\ C_{\lambda_1} &= \langle \overline{0} | \lambda_2 | \overline{0} \rangle = \langle \overline{2} | X^{\dagger} \lambda_2 X | \overline{2} \rangle = \langle \overline{2} | \lambda_3 | \overline{2} \rangle . \end{split}$$

Using a similar argument, we can show that if $\langle \bar{i} | \lambda_1 | \bar{j} \rangle = 0$, then this condition will hold for λ_2 and λ_3 as well. In summary, if we have a code that detects some error λ_i for $1 \leq i \leq 3$, then it detects any error λ_j for $1 \leq j \leq 3$.

Next, we observe that a code that detects λ_1 errors must also detect λ_4 errors. First, we find that

$$Z^{\dagger}\lambda_1 Z = -\frac{1}{2}\lambda_1 - \frac{\sqrt{3}}{2}\lambda_4.$$

So, we can replace

$$C_{\lambda_1} = \langle \overline{0} | Z^{\dagger} \lambda_1 Z | \overline{0} \rangle = \langle \overline{0} | \left(-\frac{1}{2} \lambda_1 - \frac{\sqrt{3}}{2} \lambda_4 \right) | \overline{0} \rangle$$

noting that $|\overline{0}\rangle$ must be a +1-eigenvector of Z. Simplifying, we see

$$\langle \overline{0} | \lambda_4 | \overline{0} \rangle = -\sqrt{3} C_{\lambda_1}.$$

Next, $X^{\dagger}Z^{\dagger}\lambda_1 Z X = -\frac{1}{2}\lambda_2 - \frac{\sqrt{3}}{2}\lambda_5$ and recalling that the expectation of a codeword under λ_2 is the same as under λ_1 ,

$$\langle \overline{0} | \lambda_5 | \overline{0} \rangle = -\sqrt{3} C_{\lambda_1}.$$

Using a similar argument, we find that $\langle \overline{0} | \lambda_6 | \overline{0} \rangle = -\sqrt{3}C_{\lambda_1}$. Applying the same strategy as before, we conclude that if the code detects some error λ_i , then it detects any error λ_j .

It follows similarly that a code that detects H_i also detects H_j . Furthermore, because codewords are eigenvectors of the H_k operators,

$$\langle \overline{i} | H_k | \overline{j} \rangle = 0$$

for $i \neq j$. Consequently, for H_k operators, we are only left to satisfy the identical expectation condition. We will show later that this reduces down to 2 constraints. It follows that in order to find an error detecting code, there are only 8 conditions to satisfy, reduced from a naive count of 40 (noting Hermicity of the error basis). This gives a flavor of how symmetry simplifies our search, and we will observe similar reductions can be made for error correction.

IV. FINDING AN ERROR-DETECTING CODE

As we've observed, symmetries significantly reduce the set of error-detection constraints we must satisfy. In particular, it suffices to show

$$\langle \overline{i} | \lambda_1 | \overline{j} \rangle = C_{\lambda_1} \delta_{ij} \text{ and } \langle \overline{i} | H_1 | \overline{i} \rangle = C_{H_1}.$$

Such a code can be found in a space as small as the (4,0) representation. We start by restricting the support of $|\overline{0}\rangle$ to

$$\begin{split} |\overline{0}\rangle &= \alpha \left[0000 \right] + \beta \left[1110 \right] + \gamma \left[2220 \right] + \delta \left[1122 \right] \\ &+ \epsilon \left[0012 \right] \end{split}$$

with $|\overline{1}\rangle = X |\overline{0}\rangle$ and $|\overline{2}\rangle = X |\overline{1}\rangle$.

We first tackle the λ_1 constraints. To do so, we compute the λ_1 action on the basis vectors, noting that

$$\pi_{(4,0)}\lambda_1(v) = \left(\sum_{i=0}^3 I^{\otimes i} \otimes \lambda_1 \otimes I^{\otimes 3-i}\right)(v),$$

$$\begin{split} \lambda_1 \ &|\overline{0}\rangle = \alpha \left[0001\right] + 4\beta \left[1111\right] + 2\beta \left[0110\right] \\ &+ \gamma \left[2221\right] + \delta \left[0122\right] + 2\epsilon \left[1022\right] \\ &+ 3\epsilon \left[0002\right] \\ \lambda_1 \ &|\overline{1}\rangle = \alpha \left[1110\right] + \beta \left[2220\right] + 2\gamma \left[0011\right] \\ &+ 4\gamma \left[0000\right] + \delta \left[2210\right] + 3\epsilon \left[1112\right] \\ &+ 2\epsilon \left[0012\right] \\ \lambda_1 \ &|\overline{2}\rangle = \beta \left[0012\right] + \gamma \left[0112\right] + 3\delta \left[0001\right] \\ &+ 3\delta \left[1110\right] + 2\epsilon \left[1122\right] + 2\epsilon \left[2200\right]. \end{split}$$

Note that $\lambda_1 |\overline{0}\rangle$ does not contain any +1eigenvectors of Z. Similarly, $\lambda_1 |\overline{1}\rangle$ and $\lambda_1 |\overline{2}\rangle$ do not contain any of their respective Z-operator eigenstates as well. Therefore, we obtain

$$\begin{split} & \langle \overline{0} | \lambda_1 | \overline{0} \rangle = C_{\lambda_1} = 0 \\ & \langle \overline{1} | \lambda_1 | \overline{1} \rangle = C_{\lambda_1} = 0 \\ & \langle \overline{2} | \lambda_1 | \overline{2} \rangle = C_{\lambda_1} = 0. \end{split}$$

Next, we must evaluate $\langle \overline{i} | \lambda_1 | \overline{j} \rangle$, for $i \neq j$. We observe the constraints

$$\begin{split} \langle \overline{0} | \lambda_1 | \overline{1} \rangle &= 4\alpha \overline{\gamma} + 4\beta \overline{\alpha} + 4\gamma \overline{\beta} + 24 |\epsilon|^2 = 0\\ \langle \overline{0} | \lambda_1 | \overline{2} \rangle &= 12\beta \overline{\delta} + 12\delta \overline{\epsilon} + 12\epsilon \overline{\beta} = 0\\ \langle \overline{1} | \lambda_1 | \overline{2} \rangle &= 12\delta \overline{\gamma} + 12\gamma \overline{\epsilon} + 12\epsilon \overline{\delta} = 0 \end{split}$$

and note $\langle \overline{i} | \lambda_1 | \overline{j} \rangle = \langle \overline{j} | \lambda_1 | \overline{i} \rangle$. Next, we compute the H_1 determined by the action

$$\begin{split} H_1 \left| \overline{0} \right\rangle &= 4\alpha \left[0000 \right] - 2\beta \left[1110 \right] \\ &+ \gamma \left[2220 \right] - 2\delta \left[1122 \right] + \epsilon \left[0012 \right] \\ H_1 \left| \overline{1} \right\rangle &= -4\alpha \left[1111 \right] - \beta \left[2221 \right] \\ &+ 2\gamma \left[0001 \right] + 2\delta \left[2200 \right] - \epsilon \left[1120 \right] \\ H_1 \left| \overline{2} \right\rangle &= 3\beta \left[0002 \right] - 3\gamma \left[1112 \right] . \end{split}$$

yielding expectations

$$\begin{split} \langle \overline{0} | \, H_1 \, | \overline{0} \rangle &= 4 \, |\alpha|^2 - 8 \, |\beta|^2 + 4 \, |\gamma|^2 \\ &- 12 \, |\delta|^2 + 12 \, |\epsilon|^2 \\ \langle \overline{1} | \, H_1 \, | \overline{1} \rangle &= -4 \, |\alpha|^2 - 4 \, |\beta|^2 + 8 \, |\gamma|^2 \\ &+ 12 \, |\delta|^2 - 12 \, |\epsilon|^2 \\ \langle \overline{2} | \, H_1 \, | \overline{2} \rangle &= 12 \, |\beta|^2 - 12 \, |\gamma|^2 \, . \end{split}$$

Note that $\langle \overline{0} | H_1 | \overline{0} \rangle + \langle \overline{1} | H_1 | \overline{1} \rangle + \langle \overline{2} | H_1 | \overline{2} \rangle = 0$. Imposing the Knill-Laflamme conditions we see that

$$3C_{H_1} = 0 \Rightarrow C_{H_1} = 0.$$

Hence, $\langle \overline{0} | H_1 | \overline{0} \rangle = \langle \overline{1} | H_1 | \overline{1} \rangle = \langle \overline{2} | H_1 | \overline{2} \rangle$ must all be identically zero. Therefore, we must have $|\beta|^2 = |\gamma|^2$ and the remaining constraint

$$\langle \overline{0} | H_1 | \overline{0} \rangle = 4 | \alpha |^2 - 4 | \beta |^2 - 12 | \delta |^2 + 12 | \epsilon |^2 = 0.$$

Assembling the remaining constraints, we obtain the system of equations

$$\begin{split} \langle \overline{1} | \lambda_1 | \overline{0} \rangle &= 4\alpha \overline{\gamma} + 4\beta \overline{\alpha} + 4\gamma \overline{\beta} + 24 |\epsilon|^2 = 0 \\ \langle \overline{2} | \lambda_1 | \overline{0} \rangle &= 12\beta \overline{\delta} + 12\delta \overline{\epsilon} + 12\epsilon \overline{\beta} = 0 \\ \langle \overline{1} | \lambda_1 | \overline{2} \rangle &= 12\delta \overline{\gamma} + 12\gamma \overline{\epsilon} + 12\epsilon \overline{\delta} = 0 \\ \langle \overline{0} | H_1 | \overline{0} \rangle &= 4 |\alpha|^2 - 4 |\beta|^2 - 12 |\delta|^2 + 12 |\epsilon|^2 = 0. \end{split}$$

To solve this system, we start by setting $\beta = \gamma = 0$, with the topmost equation forcing $\epsilon = 0$. With this, it follows that $\langle \overline{1} | \lambda_1 | \overline{2} \rangle = 0$ as desired. Consequently, we are left with a family of solutions

$$4 |\alpha|^2 - 12 |\delta|^2 = 0 \Rightarrow |\delta| = \pm \frac{1}{\sqrt{3}} |\alpha|$$

with e.g. one possible choice $\alpha = \sqrt{3}$ and $\delta = 1$. The resulting codespace is given by

$$\begin{split} |\overline{0}\rangle &= \frac{1}{3} \left(\sqrt{3} \left[0000 \right] + \left[1122 \right] \right) \\ |\overline{1}\rangle &= \frac{1}{3} \left(\sqrt{3} \left[1111 \right] + \left[2200 \right] \right) \\ |\overline{2}\rangle &= \frac{1}{3} \left(\sqrt{3} \left[2222 \right] + \left[0011 \right] \right). \end{split}$$

FIG. 2: Visualizing the support of the error-detecting code. Necessary conditions for detecting the X_j and Y_j errors are manifest in the spacing on the triangular lattice, since these errors only move states to the adjacent weights.

Note that the logical basis is expressed in terms of symmetric orbits, so that it is indeed normalized. We visualize the code support in Figure 2, which conveys it's ability to detect bit shifts.

With the help of symmetries simplifying the error-detection conditions, a solution - defining a quantum error-detecting code - can be found in a relatively small 15-dimensional representation. However, the error-correction conditions introduce substantially more constraints, resulting in a blowup of the dimension of the representation.

V. FINDING AN ERROR-CORRECTING CODE

For finding an error correction code, we use various techniques to reduce the complexity of the system of equations induced by the Knill-Laflamme conditions. A key technique we employ is choosing a large enough irrep of SU(3) so that the predictable action of the operators can help us choose a manageable codespace. From there, we can set certain degrees of freedom equal to zero to automatically satisfy many constraints.

A. Satisfying λ_i Constraints

In this section, we aim to highlight strategies that will make satisfying the error detecting and correcting conditions introduced by the λ_i operators easier. Throughout this section, we will assume that $p \equiv 1 \mod 3$. This is so that the Z operator's action is equivalent its standard representation action. Define $[s_{\ell,y,t}]$ such that

$$[s_{\ell,y,t}] = \left[0^{\ell} \otimes 1^{y} \otimes 2^{t}\right].$$

We will use this notation for the rest of the paper. Note that

$$[s_{\ell,y,t}] = 0$$

if ℓ, y , or t is less than 0. One convenient fact to note is that the length of $[s_{\ell,y,t}]$ denoted by $|[s_{\ell,y,t}]|$ is given by

$$|[s_{\ell,y,t}]| = \sqrt{\frac{(\ell+y+t)!}{\ell!y!t!}}.$$

Let us consider the action of λ_1 on the symmetric vector $[s_{\ell,y,t}]$. Letting $y \equiv t \mod 3$, from the previous section, we see that

$$\begin{split} [s_{\ell,y,t}] &\xrightarrow{\lambda_1} (\ell+1) \left[s_{\ell+1,y-1,t} \right] \\ &+ (y+1) \left[s_{\ell-1,y+1,t} \right]. \end{split}$$

Notice that λ_1 sends a vector in the +1 eigenspace of the Z operator to the sum of vectors in the ω and ω^2 eigenspaces of Z. Hence,

$$C_{\lambda_1} = \langle \overline{0} | \lambda_1 | \overline{0} \rangle = 0.$$

Because λ_1 sends $|\overline{0}\rangle$ to the ω and ω^2 eigenspaces of the Z operator, there is a possibility that $\langle \overline{1} | \lambda_1 | \overline{0} \rangle \neq 0$ and $\langle \overline{2} | \lambda_1 | \overline{0} \rangle \neq 0$. We can force these force these equations to be 0 by taking advantage of large SU(3) irreps.

There are an unlimited number of SU(3) irreps to work with, and looking in exceptionally large representations is advantageous. However, in doing so, we expose ourselves to a headacheinducing number of degrees of freedom. For instance, in Section VC we find an error correction code in the (37,0) representation. The number of degrees of freedom in this representation is $\frac{1}{2}(37+1)(37+2) \cdot \frac{1}{3} = 247$. If we considered all of the degrees of freedom, we would have a system of many equations with 247 unknowns. Using simplification techniques, we can simply set 243 of the unknowns to be zero! When choosing which degrees of freedom are zero, understanding the images of symmetric vectors under λ_i gives us helpful insight. To start, we will work with the λ_1 operator. First, we will define some notation. Suppose we are given a codespace in the (p, 0) irrep, and let $[s_{\ell,y,t}]$ be a summand of the $|\overline{0}\rangle$ codeword. Define the coefficient of $[s_{\ell,y,t}]$ by $c_{\ell,y,t}$ and define the sets $S_{|\overline{i}\rangle}$ as the following

$$\begin{split} S_{|\overline{0}\rangle} &= \left\{ [s_{q,p,r}] \in V_{(p,0)} \mid c_{q,p,r} \neq 0 \right\} \\ S_{|\overline{1}\rangle} &= \left\{ [s_{q,p,r}] \in V_{(p,0)} \mid c_{p,r,q} \neq 0 \right\} \\ S_{|\overline{2}\rangle} &= \left\{ [s_{q,p,r}] \in V_{(p,0)} \mid c_{r,q,p} \neq 0 \right\}, \end{split}$$

where $V_{(p,0)}$ is the irreducible representation corresponding to the (p,0) irrep. The $S_{|\bar{i}\rangle}$ tells us what symmetric vectors appear as nonzero summands of the $|\bar{i}\rangle$ codeword. For the following example, suppose that $\ell, y, t \geq 2$. We make the assumption that $\ell, y, t \geq 2$ for simplicity. Under the image of λ_1 , $[s_{\ell,y,t}]$ maps to a vector that contains $(\ell + 1) [s_{\ell+1,y-1,t}]$ and $(y+1) [s_{\ell-1,y+1,t}]$ as a summands, which are in the ω^2 and ω codespaces, respectively.

Now, we restrict our attention to $(y + 1) [s_{\ell-1,y+1,t}]$. By definition, $|\overline{1}\rangle$ contains symmetric vectors that are in the ω eigenspace of the Z operator. As a consequence, $|\overline{1}\rangle = X |\overline{0}\rangle$. Our aim is to find coefficient of the vector in $S_{|\overline{0}\rangle}$ that maps to the vector $[s_{\ell-1,y+1,t}]$ under the X operator. We have the following,

$$X^{-1}[s_{\ell-1,y+1,t}] = [s_{y+1,t,\ell-1}].$$

Hence, if $[s_{y+1,t,\ell-1}] \in S_{|\overline{0}\rangle}$, meaning that its coefficient $c_{y+1,t,\ell-1} \neq 0$, then $c_{y+1,t,\ell-1} [s_{\ell-1,y+1,t}]$ is a summand of the $|\overline{1}\rangle$ codeword as desired.

Next, restricting our attention to $(\ell + 1) [s_{\ell+1,y-1,t}]$, we can repeat a similar process noting that $|\overline{2}\rangle$ is a sum of of ω^2 eigenvectors of the Z operator and $|\overline{2}\rangle = X^2 |\overline{0}\rangle$. We find that if $[s_{t,\ell+1,y-1}] \in S_{|\overline{0}\rangle}$, its coefficient $c_{t,\ell+1,y-1} \neq 0$, and thus, $c_{t,\ell+1,y-1} [s_{\ell+1,y-1,t}]$ is a summand of the $|\overline{2}\rangle$ codeword.

Now, we observe that

$$\overline{\langle \overline{1} | \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = \overline{c_{y+1,t,\ell-1}} \cdot d_1 \cdot |[s_{\ell-1,y+1,t}]|^2 } \\ \overline{\langle \overline{2} | \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = \overline{c_{t,\ell+1,y-1}} \cdot d_2 \cdot |[s_{t,\ell+1,y-1}]|^2 }$$

where $d_1 = c_{\ell,y,t}(y+1), d_2 = (\ell+1)c_{\ell,y,t}$. One easy way to force these quantities to be zero, is to state that $c_{y+1,t,\ell-1}, c_{t,\ell+1,y-1} =$ 0. This condition is true if and only if $[s_{y+1,t\ell-1}], [s_{t,\ell+1,y-1}] \notin S_{|\overline{0}\rangle}$. In other words, we do not want to include these vectors in the $|\overline{0}\rangle$ codeword.

What we have just demonstrated is that if we have some $[s_{\ell,y,t}] \in S_{|\overline{0}\rangle}$, then $[s_{y+1,t,\ell-1}], [s_{t,\ell+1,y-1}] \notin S_{|\overline{0}\rangle}$ implies

$$\langle \overline{1} | \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = \langle \overline{2} | \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = 0.$$

In this case, λ_1 introduced 2 symmetric vectors that we want to avoid including as summands in the $|\overline{0}\rangle$ codeword. It turns out that λ_4 tells us that we want to avoid the same vectors that λ_1 tells us to avoid.

Given that $[s_{\ell,y,t}] \in S_{|\overline{0}\rangle}$, $\lambda_1, \lambda_2, \lambda_3$ give us 6 vectors total that should not be in $S_{|\overline{0}\rangle}$, namely

$$\begin{bmatrix} s_{y+1,t,\ell-1} \end{bmatrix}, \begin{bmatrix} s_{y,t-1,\ell+1} \end{bmatrix}, \begin{bmatrix} s_{y-1,t+1,\ell} \end{bmatrix}, \\ \begin{bmatrix} s_{t,\ell+1,y-1} \end{bmatrix}, \begin{bmatrix} s_{t+1,\ell-1,y} \end{bmatrix}, \begin{bmatrix} s_{t-1,\ell,y+1} \end{bmatrix}.$$

Note that the *i*-th column corresponds to the vectors that λ_i tell us to avoid. To derive these, we would simply to the exact same procedure as before. We apply λ_i to $[s_{\ell,y,t}]$. The image vector will be the sum of two vectors. We then find which eigenspaces of the Z operator the summands lie in. From there, we apply the appropriate power of the X operator that would send the summands to the +1 eigenspace. The vectors in the +1 eigenspace are precisely the vectors that we do not want to include in $S_{|\overline{0}\rangle}$.

What we have just demonstrated is that we can methodically choose the vectors in $S_{|\overline{0}\rangle}$ such that

$$\langle \overline{i} | \lambda_i | \overline{0} \rangle = 0.$$

Using similar techniques as in Section III, we find that

$$\langle \overline{i} | \lambda_j | \overline{k} \rangle = 0,$$

for all $0 \le i, k \le 2$ and $1 \le j \le 6$.

While we can force the Knill-Laflamme conditions to be zero for error detection using the aforementioned method, we are not able to do this for error correction. For example, λ_1^2 acts in the following way

$$\begin{split} & [s_{\ell,y,t}] \xrightarrow{\lambda_1} \\ & (\ell+1) \left[s_{\ell+1,y-1,t} \right] + (y+1) \left[s_{\ell-1,y+1,t} \right] \xrightarrow{\lambda_1} \\ & (\ell+2)(\ell+1) \left[s_{\ell+2,y-2,t} \right] + y(\ell+1) \left[s_{\ell,y,t} \right] \\ & + \ell(y+1) \left[s_{\ell,y,t} \right] \\ & + (y+2)(y+1) \left[s_{\ell-2,y+2,t} \right]. \end{split}$$

For the following example, we will analyze the image of $\lambda_2 \lambda_1$. We see that the action of $\lambda_2 \lambda_1$ is given by

$$\begin{split} & [s_{\ell,y,t}] \xrightarrow{\lambda_1} \\ & (\ell+1) \left[s_{\ell+1,y-1,t} \right] + (y+1) \left[s_{\ell-1,y+1,t} \right] \xrightarrow{\lambda_2} \\ & (t+1)(\ell+1) \left[s_{\ell,y-1,t+1} \right] \\ & + (\ell+2)(\ell+1) \left[s_{\ell+2,y-1,t-1} \right] \\ & + \ell(y+1) \left[s_{\ell,y+1,t-1} \right] \\ & + (t+1)(y+1) \left[s_{\ell-2,y+1,t+1} \right]. \end{split}$$

Note that there are 4 summands in the image, namely

$$\begin{bmatrix} s_{\ell,y-1,t+1} \end{bmatrix}, \begin{bmatrix} s_{\ell+2,y-1,t-1} \end{bmatrix}, \\ \begin{bmatrix} s_{\ell,y+1,t-1} \end{bmatrix}, \begin{bmatrix} s_{\ell-2,y+1,t+1} \end{bmatrix}.$$

Note that because $y \equiv t \mod 3$, we have that $y \pm 1 \equiv t \pm 1 \mod 3$ and thus $[s_{\ell+2,y-1,t-1}]$ and $[s_{\ell-2,y+1,t+1}]$ are in the +1 eigenspace of the Z operator. Using similar logic as before, if $[s_{\ell+2,y-1,t-1}], [s_{\ell-2,y+1,t+1}] \notin S_{|\overline{0}\rangle}$, in other words $c_{\ell+2,y-1,t+1} = c_{\ell-2,y+1,t+1} = 0$, then it follows that

$$\langle \overline{0} | \lambda_2 \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = 0.$$

Next, we note that $[s_{\ell,y-1,t+1}]$ is a vector in the ω eigenspace of Z. From this, we assert that $X^{-1}[s_{\ell,y-1,t+1}] = [s_{y-1,t+1,\ell}] \notin S_{|\overline{0}\rangle}$ so that

$$\langle \overline{1} | \lambda_2 \lambda_1(c_{\ell,y,t} [s_{\ell,y,t}]) = 0.$$

Finally, we note that $[s_{\ell,y+1,t-1}]$ is in the ω^2 eigenspace of the Z operator. Therefore, we assert that $X^{-2}[s_{\ell,y+1,t-1}] = [s_{t-1,\ell,y+1}] \notin S_{|\overline{0}\rangle}$. Hence,

$$\langle \overline{2} | \lambda_2 \lambda_1 (c_{\ell,y,t} [s_{\ell,y,t}]) = 0$$

In conclusion, if we assert that $[s_{\ell,y,t}] \in S_{|\overline{0}\rangle}$, then $\lambda_2 \lambda_1$ tells us that we should avoid including the following vectors in $S_{|\overline{0}\rangle}$:

$$\begin{bmatrix} s_{\ell+2,y-1,t-1} \end{bmatrix}, \begin{bmatrix} s_{\ell-2,y+1,t+1} \end{bmatrix}, \\ \begin{bmatrix} s_{\ell,y-1,t+1} \end{bmatrix}, \begin{bmatrix} s_{t-1,\ell,y+1} \end{bmatrix}.$$

Notice that we already knew to avoid $[s_{\ell,y-1,t+1}], [s_{t-1,\ell,y+1}]$ because they are summands of the image of $[s_{\ell,y,t}]$ under λ_2 , which

we handled previously. The new vectors that $\lambda_2 \lambda_1$ tells us to avoid are the vectors that are two operations away from $[s_{\ell,y,t}]$.

Repeating a similar process for $\lambda_q \lambda_p$, we find that we should avoid including the following vectors in $S_{|\overline{0}\rangle}$:

$$\begin{bmatrix} s_{y-1,t+1,\ell} \end{bmatrix}, & \begin{bmatrix} s_{y+1,t,\ell-1} \end{bmatrix}, & \begin{bmatrix} s_{y,t-1,\ell+1} \end{bmatrix} \\ \begin{bmatrix} s_{t-1,\ell,y+1} \end{bmatrix}, & \begin{bmatrix} s_{t,\ell+1,y-1} \end{bmatrix}, & \begin{bmatrix} s_{t+1,\ell-1,y} \end{bmatrix} \\ \begin{bmatrix} s_{y-2,t,\ell+2} \end{bmatrix}, & \begin{bmatrix} s_{y,t+2,\ell-2} \end{bmatrix}, & \begin{bmatrix} s_{y+2,t-2,\ell} \end{bmatrix} \\ \begin{bmatrix} s_{t-2,\ell+2,y} \end{bmatrix}, & \begin{bmatrix} s_{t+2,\ell,y-2} \end{bmatrix}, & \begin{bmatrix} s_{t,\ell-2,y+2} \end{bmatrix} \\ \begin{bmatrix} s_{\ell-2,y+1,t+1} \end{bmatrix}, & \begin{bmatrix} s_{\ell+1,y+1,t-2} \end{bmatrix}, & \begin{bmatrix} s_{\ell+1,y-2,t+1} \end{bmatrix}, \\ & & (V.1) \end{bmatrix}$$

Next, we define what it means for a codespace to be *properly spaced*. Let $[s_{\ell,y,t}]$ be a member of the +1 eigenspace of the Z operator. Define the set $A_{\ell,y,t}$ as the following set

$$A_{\ell,y,t} = \begin{cases} [s_{y-1,t+1,\ell}], & [s_{y+1,t,\ell-1}], & [s_{y,t-1,\ell+1}] \\ [s_{t-1,\ell,y+1}], & [s_{t,\ell+1,y-1}], & [s_{t+1,\ell-1,y}] \\ [s_{y-2,t,\ell+2}], & [s_{y,t+2,\ell-2}], & [s_{y+2,t-2,\ell}] \\ [s_{t-2,\ell+2,y}], & [s_{t+2,\ell,y-2}], & [s_{t,\ell-2,y+2}] \\ [s_{\ell-2,y+1,t+1}], & [s_{\ell+1,y+1,t-2}], & [s_{\ell+1,y-2,t+1}] \end{cases}$$

We say that a codespace is properly spaced if for all $[s_{\ell,y,t}] \in S_{|\overline{0}\rangle}, S_{|\overline{0}\rangle} \cap A_{\ell,y,t} = \emptyset$. One consequence of a codespace being properly spaced is that it follows that the following conditions are satisfied

$$\langle i | \lambda_k | j \rangle = 0 \langle \overline{i} | \lambda_q \lambda_p | \overline{j} \rangle = 0,$$

for $p \neq q, 0 \leq i, j \leq 2$, and $1 \leq j \leq 6$.

When working in large enough representations, we have more than enough degrees of freedom to concoct properly spaced codespaces. For example, consider the codespace in the (37, 0)irrep given by

$$\begin{split} |\overline{0}\rangle &= a_0 \left[s_{35,1,1} \right] + a_1 \left[s_{11,1,25} \right] \\ &+ b_1 \left[s_{11,25,1} \right] + c_0 \left[s_{9,14,14} \right] \\ |\overline{1}\rangle &= X \left| \overline{0} \right\rangle = a_0 \left[s_{1,35,1} \right] + a_1 \left[s_{25,11,1} \right] \\ &+ b_1 \left[s_{1,11,25} \right] + c_0 \left[s_{14,9,14} \right] \\ |\overline{2}\rangle &= X \left| \overline{1} \right\rangle = a_0 \left[s_{1,1,35} \right] + a_1 \left[s_{1,25,11} \right] \\ &+ b_1 \left[s_{25,1,11} \right] + c_0 \left[s_{14,14,9} \right]. \end{split}$$

We observe that $\lambda_2 \lambda_1 [s_{35,1,1}]$ given by

$$\lambda_2 \lambda_1 [s_{35,1,1}] = 2 \cdot 36 [s_{35,0,2}] + 37 \cdot 36 [s_{37,0,0}] + 35 \cdot 2 [s_{35,2,0}] + 2 \cdot 2 [s_{34,2,2}].$$

By construction, one can check that $[s_{35,0,2}] \notin S_{|\overline{1}\rangle}$, $[s_{37,0,0}], [s_{34,2,2}], \notin S_{|\overline{0}\rangle}$, and $[s_{35,2,0}] \notin S_{|\overline{2}\rangle}$, and hence

$$\langle \bar{i} | \lambda_2 \lambda_1 a_0 [s_{35,1,1}] = 0,$$

for i = 0, 1, 2. The reader can check that this code detects λ_i errors, and we will give a specific code in Section V C that has the same $S_{|\overline{0}\rangle}$ and corrects λ_i errors.

In conclusion, we can satisfy most of the λ_i Knill-Laflamme conditions by constructing a properly spaced codespace. Once we have a properly spaced codespace, the only nontrivial constraints introduced by the λ_i operators are introduced by $\langle \bar{i} | \lambda_p^2 | \bar{j} \rangle$.

B. Satisfying H_i Constraints

The H_i constraints play a huge role in determining whether or not our system of equations can be solved. First off, we note that the H_i operators preserve the eigenspaces of the Z operator. Therefore, if we have a codespace that satisfies $\langle \bar{i} | \lambda_q | \bar{j} \rangle = 0$, then $H_p \lambda_q | \bar{j} \rangle = c_2 \lambda_q | \bar{j} \rangle$, and thus $\langle \bar{i} | H_p \lambda_q | \bar{j} \rangle = c_2 \cdot 0 = 0$. Consequently, if we want to find a code that corrects λ_i and H_j errors, as long as the λ_i conditions are satisfied, we just need to worry about the $\langle \bar{i} | H_k | \bar{j} \rangle$ and $\langle \bar{i} | H_k^2 | \bar{j} \rangle$ constraints.

To apply some clever tricks to simplifying the H_i constraints, it's helpful to understand some special relationships between vectors. One special relationship exists between the vectors $[s_{\ell,y,t}]$ and $[s_{\ell,t,y}]$, where $y \equiv t \mod 3$. Denote by v the symmetric vector given by

$$v = X^{2} \left(c_{\ell,y,t} \left[s_{\ell,y,t} \right] + c_{\ell,t,y} \left[s_{\ell,t,y} \right] \right)$$

Observe the following

$$v^{\dagger}H_1v = p \cdot (y-t)^2 (|c_{\ell,y,t}|^2 - |c_{\ell,t,y}|^2),$$

where $p = \frac{(\ell + y + t)!}{\ell! y! t!}$. Therefore, if

$$|c_{\ell,y,t}|^2 - |c_{\ell,t,y}|^2 = 0,$$

this would imply that $|c_{\ell,y,t}| = \pm |c_{\ell,t,y}|$. One simplification that we make is the simplification that $c_{\ell,y,t} = c_{\ell,t,y}$. In other words, if we include $[s_{\ell,y,t}]$ in the codeword $|\overline{0}\rangle$, we want to include $[s_{\ell,t,y}]$ in $|\overline{0}\rangle$ as well because it makes solving the equations easier. In general, $|\overline{0}\rangle$ may contain the following superposition of basis vectors

$$\sum_{i} (\alpha_i [s_{\ell_i, t_i, y_i}] + \beta_i [s_{\ell_i, y_i, t_i}]),$$

and the following contribution of these vectors to $\langle \overline{2} | H_1 | \overline{2} \rangle$ is given by

$$\sum_{i} p_i (y_i - t_i)^2 \left(|\alpha_i|^2 - |\beta_i|^2 \right),$$

where $p_i = \frac{(\ell_i + t_i + y_i)!}{\ell_i ! y_i ! t_i !}$. As we can see, setting $\alpha_i = \beta_i$ in most cases will make $\langle \overline{2} | H_1 | \overline{2} \rangle = 0$. We should note that we want to make sure that $[s_{\ell,y,t}]$ is not within 2 operations of $[s_{\ell,t,y}]$ because then the λ_k conditions may no longer be satisfied.

The next type of special vector is the vector of the type $[s_{\ell,y,y}]$. This is because

$$H_1\left(X^2(\alpha\left[s_{\ell,y,y}\right])\right) = 0.$$

Hence, these vectors have no contribution in the equation $\langle \overline{2} | H_1 | \overline{2} \rangle = C_{H_1}$. However, the contributions that these vectors make to the other equations allow for us to manipulate the system of equations so that the system has a solution.

C. Finding a Code in (37,0)

Next, we will go through the process of finding an error correction code in the (37, 0) irrep of SU(3).

First, we start by presenting the following properly spaced codespace,

$$\overline{0}
angle = a_0 \left[s_{35,1,1}
ight] + a_1 \left[s_{11,1,25}
ight] \ + b_1 \left[s_{11,25,1}
ight] + c_0 \left[s_{9,14,14}
ight].$$

It follows that

$$\langle \overline{i} | \lambda_q \lambda_p | \overline{j} \rangle = 0 \langle \overline{i} | \lambda_q | \overline{j} \rangle = 0$$

for $q \neq p$. From the previous section, we also know that

$$\langle \overline{i} | H_q \lambda_p | \overline{j} \rangle = 0.$$

Furthermore, we know that

$$\langle \overline{i} | H_1 | \overline{j} \rangle = 0,$$

for $i \neq j$ because the codewords are orthogonal to each other.

Next, we analyze the constraints that are not satisfied trivially. We will analyze the constraints introduced by H_i errors first. We begin by observing the following

$$\begin{split} \langle \overline{0} | \, H_1 \, | \overline{0} \rangle &= 34 p_1 \, |a_0|^2 + 10 p_2 \, |a_1|^2 \\ &- 14 p_2 \, |b_1|^2 - 5 p_3 \, |c_0|^2 \\ \langle \overline{1} | \, H_1 \, | \overline{1} \rangle &= -34 p_1 \, |a_0|^2 + 14 p_2 \, |a_1|^2 \\ &- 10 p_2 \, |b_1|^2 + 5 p_3 \, |c_0|^2 \\ \langle \overline{2} | \, H_1 \, | \overline{2} \rangle &= 34 p_2 \, |b_1|^2 - 34 p_2 \, |a_1|^2 \,. \end{split}$$

where p_i are the dot product multiplicities and

$$p_1 = \frac{37!}{35!}, \ p_2 = \frac{37!}{25! \cdot 11!}, \ p_3 = \frac{37!}{14! \cdot 14! \cdot 9!}$$

As mentioned earlier, we can make the assumption that $|b_1| = |a_1|$ to make the equations simpler. When doing this we get,

$$- \langle \overline{1} | H_1 | \overline{1} \rangle = \langle \overline{0} | H_1 | \overline{0} \rangle$$

= $34p_1 |a_0|^2 - 4p_2 |a_1|^2$
 $- 5p_3 |c_0|^2$
= 0
 $\langle \overline{2} | H_1 | \overline{2} \rangle = 0.$

One thing to note here is that many times, in this step, we get a quadratic equation similar to the one in the above equations. However, we can determine whether or not the system is solvable if there are a mix of positive and negative coefficients. For instance, if we would have chosen $|\overline{0}\rangle$ to be

$$\overline{0} \rangle = p [s_{35,1,1}] + q_1 [s_{23,1,13}] + q_1 [s_{23,13,1}] + r [s_{17,10,10}]$$

then we would have had the following equation

$$\langle \overline{0} | H_1 | \overline{0} \rangle = 34 p_1 | p |^2 + 32 c_1 | q_1 |^2$$

+ 7 c_2 | r | ²
= 0,

with $c_1, c_2 > 0$. As one can see, this equation has no non-trivial solution. Therefore, we want to choose our codespace such that in $|\overline{0}\rangle$, the tensor power of 0 is greater than the tensor power of 1 in some basis vectors and less than the tensor power of 1 in other basis vectors. This will ensure that $\langle \overline{0}| H_1 |\overline{0} \rangle = 0$ has nontrivial solutions.

Next, we compute the second order H_i constraints. Note that we did not compute $\langle \overline{i} | H_2 | \overline{j} \rangle$ because we are using the assumption that if the H_1 conditions for error detection are satisfied, then the H_2 conditions will be satisfied as well. For error correction, however, we have to check the second order H_2 conditions as well. We begin by observing the following

$$\begin{split} \langle \overline{0} | \, H_1^2 \, | \overline{0} \rangle &= 34^2 p_1 \, | a_0 |^2 + 10^2 p_2 \, | a_1 |^2 \\ &+ 14^2 p_2 \, | b_1 |^2 + 25 p_3 \, | c_0 |^2 \\ \langle \overline{1} | \, H_1^2 \, | \overline{1} \rangle &= 34^2 p_1 \, | a_0 |^2 + 10^2 p_2 \, | a_1 |^2 \\ &+ 14^2 p_2 \, | b_1 |^2 + 25 p_3 \, | c_0 |^2 \\ \langle \overline{2} | \, H_1^2 \, | \overline{2} \rangle &= 34^2 p_2 \, | b_1 |^2 + 34^2 p_2 \, | a_1 |^2 \,. \end{split}$$

Next, we use the assumption that $|a_1| = |b_1|$, to conclude that

$$\begin{split} \langle \overline{1} | H_1^2 | \overline{1} \rangle &= \langle \overline{0} | H_1^2 | \overline{0} \rangle \\ &= 34^2 p_1 |a_0|^2 + 25 p_3 |c_0|^2 \\ &+ (10^2 + 14^2) p_2 |a_1|^2 \\ \langle \overline{2} | H_1^2 | \overline{2} \rangle &= 2 \cdot 34^2 p_2 |a_1|^2 \,. \end{split}$$

The error correction conditions tells us that all the quantities must be the same, therefore, it follows that

$$\begin{aligned} 34^2 p_1 \left| a_0 \right|^2 + 25 p_3 \left| c_0 \right|^2 \\ + \left(10^2 + 14^2 \right) p_2 \left| a_1 \right|^2 \\ = 2 \cdot 34^2 p_2 \left| a_1 \right|^2 \end{aligned}$$

Note again that because $10^2 + 14^2 < 2 \cdot 34^2$, the equation has a chance of having nontrivial solutions.

Next, we check the H_1H_2 conditions. Note that $H_1H_2 = H_2H_1$, therefore, we only need to check $\langle \overline{i} | H_1H_2 | \overline{j} \rangle = C$. The process is similar to the other processes, so we get the following

$$\begin{split} \langle \overline{2} | H_1 H_2 | \overline{2} \rangle &= \langle \overline{0} | H_1 H_2 | \overline{0} \rangle \\ &= -(576) p_2 | a_1 |^2 \\ \langle \overline{1} | H_1 H_2 | \overline{1} \rangle &= -34^2 p_1 | a_0 |^2 \\ &+ 280 p_2 | a_1 |^2 - 5^2 p_3 | c_0 |^2 \,, \end{split}$$

and hence

$$-34^{2}p_{1}|a_{0}|^{2} - 5^{2}p_{3}|c_{0}|^{2} + 280p_{2}|a_{1}|^{2}$$
$$= -(576)p_{2}|a_{1}|^{2}.$$

By construction, we see that this equation will also have non-trivial solutions because there is a mixture of positive and negative coefficients. In summary, the ${\cal H}_i$ constraints for error correction are given by

$$\begin{aligned} 34p_1 |a_0|^2 - 4p_2 |a_1|^2 - 5p_3 |c_0|^2 &= 0\\ 34^2p_1 |a_0|^2 + 296p_2 |a_1|^2 + 25p_3 |c_0|^2\\ &= 2 \cdot 34^2p_2 |a_1|^2\\ &- 34^2p_1 |a_0|^2 + 280p_2 |a_1|^2 - 25p_3 |c_0|^2\\ &= -(576)p_2 |a_1|^2. \end{aligned}$$

Next, we compute the non-trivial λ_i conditions. Note that $X^{\dagger}\lambda_1^2 X = \lambda_2^2$. Therefore, using the same logic as before, we only need to check $\langle \bar{i} | \lambda_1^2 | \bar{i} \rangle$. The equations that we get for λ_1^2 are

$$\begin{split} \langle \overline{1} | \lambda_1^2 | \overline{1} \rangle &= \langle \overline{0} | \lambda_1^2 | \overline{0} \rangle \\ &= (106) p_1 | a_0 |^2 \\ &+ (620) p_2 | a_1 |^2 \\ &+ (275) p_3 | c_0 |^2 \\ \langle \overline{2} | \lambda_1^2 | \overline{2} \rangle &= 4 p_1 | a_0 |^2 + 152 p_2 | a_1 |^2 \\ &+ 420 p_3 | c_0 |^2 \,, \end{split}$$

thus, we have the following result

$$(106)p_1 |a_0|^2 + (620)p_2 |a_1|^2 + (275)p_3 |c_0|^2 = 4p_1 |a_0|^2 + 152p_2 |a_1|^2 + 420p_3 |c_0|^2.$$

Putting everything together, we get

$$\begin{aligned} & 34p_1 \left| a_0 \right|^2 - 4p_2 \left| a_1 \right|^2 - 5p_3 \left| c_0 \right|^2 \\ &= 0 \\ & 1156p_1 \left| a_0 \right|^2 + 296p_2 \left| a_1 \right|^2 \\ &+ 25p_3 \left| c_0 \right|^2 \\ &= 2312p_2 \left| a_1 \right|^2 - 1156p_1 \left| a_0 \right|^2 \\ &+ 280p_2 \left| a_1 \right|^2 - 25p_3 \left| c_0 \right|^2 \\ &= -576p_2 \left| a_1 \right|^2 \\ & 106p_1 \left| a_0 \right|^2 + 359p_2 \left| a_1 \right|^2 \\ &+ 275p_3 \left| c_0 \right|^2 \\ &= 4p_1 \left| a_0 \right|^2 + 152p_2 \left| a_1 \right|^2 \\ &+ 420p_3 \left| c_0 \right|^2 . \end{aligned}$$

A solution to the system of equations yields the

following codewords,

$$\begin{split} |\overline{0}\rangle &= \frac{1}{d} \begin{pmatrix} \sqrt{670371601625} \left[s_{35,1,1}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{11,1,25}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{11,25,1}\right] \\ &+ \left[s_{9,14,14}\right] \end{pmatrix} \\ |\overline{1}\rangle &= \frac{1}{d} \begin{pmatrix} \sqrt{670371601625} \left[s_{1,35,1}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{25,11,1}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{1,11,25}\right] \\ &+ \left[s_{14,9,14}\right] \end{pmatrix} \\ |\overline{2}\rangle &= \frac{1}{d} \begin{pmatrix} \sqrt{670371601625} \left[s_{1,1,35}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{1,25,11}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{25,1,11}\right] \\ &+ \sqrt{\frac{10214875}{168}} \left[s_{25,1,11}\right] \\ &+ \left[s_{14,14,9}\right] \end{pmatrix} , \end{split}$$

where $d = \sqrt{8586854127423000}$.

VI. CONCLUSION AND FUTURE WORK

We have found that there exists an error correction code in the (37,0) irrep of SU(3); however, there is reason to believe that this is not the smallest possible representation that has an error correction code. One possible extension of this project is to find a lower bound on the dimension of the space that contains an error correcting code. Another possible extension is to find a recipe for generating error correction codes in SU(n) for $n \ge 4$. SU(3) just so happend to be fairly similar to SU(2), but as nincreases, things may potentially become more complicated.

A natural question to ask is whether SU(3)representations correspond to "physical" state spaces. Harmonic oscillators, molecules, and large nuclear spins all give relevant examples of $SL(2, \mathbf{R})$, SO(3), and SU(2) representations. Within physics, SU(3) is famous for its role in the standard model, but we're hardly advocating for building a quantum computer out of individually addressable quarks! However, one can look to the Schwinger representation to provide a motivating physical instantiation. This useful representation of SU(2) [26], which uses number-preserving operations on a collection of harmonic oscillators, also provides a means of realizing SU(3) symmetry via linear optics (beamsplitters and phase shifters) [29]. Encoding logical qutrits can also yield computational advantages [30].

Designing codes using SU(3) is also a natural step towards building a general prescription for constructing quantum codes from higher dimensional unitary group representations, showcasing some of the complexities hidden in the special case of SU(2) [1]. The result of our labor is the discovery of new codes embedding threedimensional logical quantum systems in physical state spaces given by SU(3) irreps.

Appendix A: Structural Proof of (p, 0) Irrep

First, we will show that the action of the Y_1 operator preserves symmetric vectors. We wish to show that

$$\begin{bmatrix} 0^{\ell} \otimes 1^{y} \otimes 2^{t} \end{bmatrix} \xrightarrow{Y_{1}} (y+1) \begin{bmatrix} 0^{\ell-1} \otimes 1^{y+1} \otimes 2^{t} \end{bmatrix}.$$

To show this, we will first show that any permutation of the vector $|0^{\ell-1} \otimes 1^{y+1} \otimes 2^t\rangle$ is the image of some permutation of $|0^{\ell} \otimes 1^{y} \otimes 2^t\rangle$ under Y_1 . For the rest of this section define $|s_{\ell,y,t}\rangle$ as the following

$$|s_{\ell,y,t}\rangle = |0^{\ell} \otimes 1^{y} \otimes 2^{t}\rangle.$$

Given any permutation $|r\rangle$ of $|s_{\ell-1,y+1,t}\rangle$, we know that there exists some permutation σ such that

$$|r\rangle = \sigma |s_{\ell-1,y+1,t}\rangle.$$

Hence, we see that $\sigma |s_{\ell y,t}\rangle$ will have nearly the same tensor product decomposition as $|r\rangle$, the only difference is that $|r\rangle$ has a 1 in a spot where $\sigma |s_{\ell,y,t}\rangle$ has a 0. Suppose $\sigma |s_{\ell,y,t}\rangle$ differs from $|r\rangle$ at the *i*th tensor product. Therefore, we see that

$$\left(I^{\otimes i-1} \otimes Y_1 \otimes I^{\otimes n-i}\right) \sigma \left|s_{\ell,y,t}\right\rangle = \left|r\right\rangle,$$

where $n = k + \ell + t$. We have shown that there exists some permutation of $\sigma |s_{\ell,y,t}\rangle$ that maps to $|r\rangle$. In other words, there exists some vector in the class $[0^{\ell} \otimes 1^{y} \otimes 2^{t}]$ that maps to $|r\rangle$. Hence, every vector in the class $[0^{\ell-1} \otimes 1^{y+1} \otimes 2^{t}]$ is reached. A similar argument can be made for Y_{2} to show that

$$\begin{bmatrix} 0^{\ell} \otimes 1^{y} \otimes 2^{t} \end{bmatrix} \xrightarrow{Y_{2}} (t+1) \begin{bmatrix} 0^{\ell} \otimes 1^{y-1} \otimes 2^{t+1} \end{bmatrix}$$

To see why the multiplicity is y + 1, we begin by denoting the transposition $\tau_{(i,j)}$ as the permutation that swaps the *i*th and *j*th letter. We claim that

$$(I^{\otimes \ell+j-1} \otimes Y_1 \otimes I^{n-y}) \tau_{(\ell,\ell+j)} | s_{\ell,y,t} \rangle$$

= $(I^{\otimes \ell-1} \otimes Y_1 \otimes I^{n-\ell}) | s_{\ell,y,t} \rangle,$

for $0 \leq j \leq y$. Indeed, we have

$$\begin{split} & \left(I^{\otimes \ell+j-1} \otimes Y_1 \otimes I^{\otimes (n-y)}\right) \tau_{(\ell,\ell+j)} \left|s_{\ell,y,t}\right\rangle \\ &= \left(I^{\otimes \ell+j-1} \otimes Y_1 \otimes I^{\otimes (n-y)}\right) \left|w\right\rangle \\ &= \left|s_{\ell-1,y+1,t}\right\rangle \\ &= \left(I^{\otimes \ell-1} \otimes Y_1 \otimes I^{n-\ell}\right) \left|s_{\ell,y,t}\right\rangle, \end{split}$$

where $|w\rangle$ is the following vector

$$|w\rangle = |0^{\ell-1} \otimes 1^j \otimes 0 \otimes 1^{y-j} \otimes 2^t\rangle.$$

Because there are y+1 different transpositions that map to the same image, we see that the image multiplier is y + 1, as desired.

As a consequence of the above results, we have that for $y \equiv t \mod 3$,

$$\begin{bmatrix} 0^{\ell} \otimes 1^{y} \otimes 2^{t} \end{bmatrix} \xrightarrow{Y_{1}Y_{2}Y_{1}} \\ (y+1)(t+1)(y+1) \begin{bmatrix} 0^{\ell-2} \otimes 1^{y+1} \otimes 2^{t+1} \end{bmatrix},$$

therefore, it follows that $[0^{\ell-2} \otimes 1^{y+1} \otimes 2^{t+1}]$ is a member of the irrep. Consequentially, if we start of with $[0^n]$, we can repeatedly apply the family of operators Y_1^{3r} , $(Y_1Y_2Y_1)^w$, and Y_2^{3q} to generate all of the classes of vectors that correspond to the +1 eigenspace of the Z operator.

We have shown that the symmetric vectors are a subspace of the irrep, now it is time to show that there are $\frac{1}{2}(p+1)(p+2)$ symmetric vectors. To prove this, the problem reduces down to showing that there are $\frac{1}{2}(p+1)(p+2)$ ways of summing 3 non-negative numbers to p.

First, we show that there are p + 1 ways of summing up to p using 2 non-negative numbers. Note that $p \ge p - x_0 \ge 0$ for $0 \le x_0 \le p$. Therefore, there are $p+1 x_0$ that satisfy the inequality, which proves that there are p+1 ways to sum

up two non-negative integers to p. Next, if we want to find the number of ways to sum of 3 non-negative integers to p, we can do the following. Note note that there are p+1 solutions to $p \ge p - 0 + x_0 + x_1 \ge 0$. Similarly, there are p solutions to $p - 1 \ge (p - 1) + x_0 + x_1 \ge 0$. In general, there are p + 1 - q solutions to

$$x_0 + x_1 = p - q.$$

Therefore, if we let q range from 0 to p, this gives us the number of ways to sum up 3 numbers to p. Consequently, summing up the number of solutions, we have

$$\sum_{j=0}^{p} (p+1-j) = \sum_{i=1}^{p+1} i$$
$$= \frac{1}{2} (p+1)(p+2)$$

Hence, we know that there exists a bijection between solutions of the equation

$$\ell + y + t = p,$$

and symmetric vectors

$$\left[0^{\ell}\otimes 1^{y}\otimes 2^{t}\right]$$

which proves that the symmetric vectors are a basis for the (p, 0) irrep.
