We study the topological properties of the Haldane and modified Haldane models in α - T_3 lattice. The band structures and phase diagrams of the system are investigated. Individually, each model undergoes a distinct phase transition: (i) The Haldane-only model experiences a topological phase transition from the Chern insulator ($\mathcal{C}=1$) phase to the higher Chern insulator ($\mathcal{C}=2$) phase; while (ii) the modified-Haldane-only model experiences a phase transition from the topological metal ($\mathcal{C}=2$) phase to the higher Chern insulator ($\mathcal{C}=2$) phase and we show that \mathcal{C} is insufficient to characterize this system because \mathcal{C} remains unchanged before and after the phase transition. By plotting the Chern number and \mathcal{C} phase diagram, we show that in the presence of both Haldane and modified Haldane models in the α - T_3 lattice, the interplay between the two models manifests three distinct topological phases, namely the $\mathcal{C}=1$ Chern insulator (CI) phase, $\mathcal{C}=2$ higher Chern insulator (HCI) phase and $\mathcal{C}=2$ topological metal (TM) phase. These results are further supported by the α - T_3 zigzag edge states calculations.

I. INTRODUCTION

Nontrivial topological states of matter in twodimensional (2D) systems have garnered an enormous amount of research interest since the experimental observation of the integer quantum Hall effect (IQHE) in 1980 [1]. This was followed by the proposal of the quantum anomalous Hall effect (QAHE) by the Haldane model [2] in 1988 describing the mechanism through which the quantized Hall conductance can be realized without an external magnetic field which was later experimentally observed [3–10]. Quantum anomalous Hall insulators (QAHIs) belong to a class of topological insulators [11, 12] known as the Chern insulators (CIs) because they are characterized by a topological invariant called the Chern number, C otherwise known as the Thouless-Kohmoto-Nightingale-Nijs (TKNN) number [13]. Subsequently, a subclass of CIs which have C > 2 known as the higher Chern insulators (HCIs) was proposed and experimentally realized [14, 15].

QAHIs host chiral edge states - unidirectional propagating states along an edge due to the breaking of time-reversal symmetry. The Haldane model can be generalized to spinful systems, giving rise to the quantum spin Hall insulators (QSHIs) as proposed by the Kane-Mele model [11, 16, 17] which host time-reversal-invariant helical edge states - pairs of counterpropagating states with opposite spins along an edge. Like QAHIs, QSHIs have also been experimentally demonstrated [18–20].

Recently, another variant of the edge states is proposed by the modified Haldane model [21], namely the antichiral edge states. They are co-propagating edge states accompanied by counterpropagating bulk states as required by the law of energy conservation. As such, they can be realized in topological metals (TMs), conducting materials with gapless band structures and localized edge states [22]. Various experimental platforms have been proposed [23–27] to realize the antichiral edge states. To date, the antichiral edge states have been experimentally observed in a microwave-scale gyromagnetic photonic crystal [28], topological circuit [29] and a 3D layer-stacked photonic metacrystal [30].

Concurrently, there is a great deal of undergoing interest in studying topological phases in different lattice systems. For instance, the QAHE is studied in the Lieb [31–33], dice [34], checkerboard [35], Kagomé [36, 37] and honeycomb Kagomé lattices [38]. Similarly, the QSHE is studied in the honeycomb [16, 39], checkerboard [35], Kagomé [40, 41], square [42], Lieb [43, 44], diamond [45] and α - T_3 lattices [46].

The α - T_3 lattice [47] is a well-known platform for realizing the pseudospin-1 2D Dirac fermions. It is an extension of the graphene honeycomb lattice, that is it has the conventional honeycomb A and B sites as well as an additional C site introduced in the center of each hexagon. The C sublattice is coupled to either the A or B sublattice via the coupling strength, αt where α $(0 \le \alpha \le 1)$ acts as a tuning parameter and t is the A-B hopping term. As such, the α - T_3 lattice serves as an interpolation between the graphene honeycomb ($\alpha = 0$) and dice or T_3 ($\alpha = 1$) lattices. Such a lattice structure manifests a low-energy dispersion made of a Dirac cone and a dispersionless zero-energy flat band. It has been shown that at a critical doping, $\operatorname{Hg}_{1-x}\operatorname{Cd}_{\underline{x}}\operatorname{Te}$ can be mapped onto the α - T_3 lattice with $\alpha = 1/\sqrt{3}$ [48] and that the lattice can be realized on optical platforms [47, 49] too. Various aspects of the α - T_3 lattice have been studied such as electro-magnetotransport properties [50–52], thermoelectric properties [53, 54], super-Klein tunneling [55, 56], Andreev reflection [57], Josephson effect [57], Floquet states [58–60] and the effect of Rashba spin-orbit coupling (RSOC) [61].

Specifically, both the Haldane and modified Haldane models have yet to be investigated in the α - T_3 lattice.

In this work, we study the possible topological phases in the α - T_3 lattice that could emerge from the interplay between the Haldane and modified Haldane terms. We first demonstrate the topological phases of the individual cases by determining the Chern number (\mathcal{C}), direct (ΔE_{Direct}), and indirect ($\Delta E_{Indirect}$) band gaps. In particular, we argue that \mathcal{C} is insufficient to characterize the modified Haldane model by showing that \mathcal{C} remains unchanged before and after it undergoes a phase transition. Next, by plotting the Chern number, \mathcal{C} phase diagram and α - T_3 zigzag edge states, we show that the interplay between the two models in the α - T_3 lattice manifests three distinct topological phases, namely the $\mathcal{C}=1$ Chern insulator (CI) phase, $\mathcal{C}=2$ higher Chern insulator (HCI) phase and $\mathcal{C}=2$ topological metal (TM) phase.

The remainder of this paper is organized as follows. In Sec. II, the formulation is presented which includes the protocols of the Haldane and modified Haldane models in the α - T_3 lattice, Hamiltonian and topological invariant. In Sec. III, the results are presented which include the bulk band structures, phase diagrams and edge states. Lastly, in Sec. IV, this paper is concluded with a brief summary of our results.

II. MODEL AND FORMALISM

A. Model

The α - T_3 lattice with both Haldane and modified Haldane terms as illustrated schematically in Fig. 1 is described by the following Hamiltonian:

$$\mathcal{H} = \mathcal{H}_0 + \mathcal{H}_H + \mathcal{H}_{MH},\tag{1}$$

where the first term

$$\mathcal{H}_0 = -\sum_{\langle ij \rangle} t c_i^{\dagger} c_j - \sum_{\langle jk \rangle} \alpha t c_j^{\dagger} c_k + H.c., \tag{2}$$

describes the nearest-neighbour (NN) hoppings between the B and A (C) sites with strength t (αt). The second

TABLE II. Definitions of the next-nearest-neighbour (NNN) vectors pointing from the B sites

NNN Vector	Definition
δ_1'	$(\sqrt{3}a,0)$
δ_2'	$\left(rac{\sqrt{3}}{2}a,rac{3}{2}a ight)$
δ_3'	$\left(-\frac{\sqrt{3}}{2}a, \frac{3}{2}a\right)$
δ_4'	$\left(-\sqrt{3}a,0\right)$
δ_5'	$\left(-rac{\sqrt{3}}{2}a,-rac{3}{2}a ight)$
δ_6'	$\left(\frac{\sqrt{3}}{2}a, -\frac{3}{2}a\right)$

and third terms

$$\mathcal{H}_{H} = \frac{t_{H}}{3\sqrt{3}} \left[\sum_{\langle \langle ij \rangle \rangle} e^{-iv_{ij}\phi} c_{i}^{\dagger} c_{j} + \alpha \sum_{\langle \langle jk \rangle \rangle} e^{-iv_{jk}\phi} c_{j}^{\dagger} c_{k} \right] + H.c., \tag{3}$$

and

$$\mathcal{H}_{MH} = \frac{t_{MH}}{3\sqrt{3}} \left[\sum_{\langle\langle ij\rangle\rangle} e^{-i\mu_i v_{ij}\phi'} c_i^{\dagger} c_j + \alpha \sum_{\langle\langle jk\rangle\rangle} e^{-i\mu_j v_{jk}\phi'} c_j^{\dagger} c_k \right] + H.c., \tag{4}$$

are the Haldane and modified Haldane terms with strengths t_H and t_{MH} as well as phases ϕ and ϕ' respectively. Here, $c_i^{\dagger}(c_i)$ is the spinless fermionic creation (annihilation) operator acting at the *i*th site, the summation of $\langle ij \rangle (\langle \langle ij \rangle \rangle)$ runs over all the nearest (next-nearest)-neighbour sites, H.c. denotes the Hermitian conjugate, $v_{ij} = +1$ (-1) denotes the anticlockwise (clockwise) hopping and $\mu_i = +1$ (-1) denotes the next-nearest-neighbour (NNN) hoppings between A/C (B) sites.

In contrast to the honeycomb lattice where an electron crosses from one sublattice to the other to hop to an NNN site (e.g., the path undertaken by an electron hopping from a B site to another B site is B-A-B), there are instead two possible paths for an electron to hop from a B site to another B site in the $\alpha-T_3$ lattice (i.e., B-A-B and B-C-B with hopping strengths t_H and αt_{MH} respectively). All possible Haldane and modified Haldane NNN hopping paths are illustrated in Figs. 1(b) and (c) respectively.

The resulting k-space Hamiltonian in the sublattice basis, $(|A_k\rangle, |B_k\rangle, |C_k\rangle)^{\top}$ obtained via the Fourier transformation of Eq. (1) is presented as follows:

$$\hat{\mathcal{H}}(\mathbf{k}) = \begin{bmatrix} G_{--} & f^{\dagger}(\mathbf{k}) & 0\\ f(\mathbf{k}) & G_{+-} + \alpha G_{-+} & \alpha f^{\dagger}(\mathbf{k})\\ 0 & \alpha f(\mathbf{k}) & \alpha G_{++} \end{bmatrix}, \quad (5)$$

where

$$f(\mathbf{k}) = -t \sum_{n=1.3}^{5} e^{i\mathbf{k}\cdot\boldsymbol{\delta}_n},$$
 (6)

FIG. 1. (a) Schematic of the α - T_3 lattice with zigzag edges. δ_n and δ'_n (n=1,2,3,4,5,6) denote the nearest-neighbour (NN) and next-nearest-neighbour (NNN) vectors pointing from the B sites respectively as defined in Tables I and II. Schematic of the (b) Haldane and (c) modified Haldane NNN hoppings. The A, B and C sites are coloured in red, blue and green respectively.

results from the conventional B-A NN hopping whereas

$$G_{\gamma\beta} = \frac{1}{3\sqrt{3}} \left[t_H g\left(\mathbf{k}, \gamma\phi\right) + t_{MH} g\left(\mathbf{k}, \beta\phi'\right) \right], \qquad (7)$$

$$g(\mathbf{k},\zeta) = \sum_{n=1}^{6} e^{i[(-1)^{n}\zeta + \mathbf{k}\cdot\boldsymbol{\delta}'_{n}]},$$
 (8)

results from the Haldane and modified Haldane NNN hopping terms with $\zeta = \phi$ or ϕ' , $\mathbf{k} = (k_x, k_y)$ and indices γ , $\beta = \pm 1$. The competition between the terms shall govern the possible phases of the system which are revealed directly by the bulk band structure obtained by solving the eigenvalue problem of Eq. (5) numerically.

On the other hand, as to be demonstrated in Sec. IIB, the physics around the $\mathbf{K}' = (-4\pi/3\sqrt{3}a, 0)$ and $\mathbf{K} = (4\pi/3\sqrt{3}a, 0)$ points is also focused on where the states are described by the following Dirac-like Hamiltonian:

$$\mathcal{H}_{\eta}\left(\boldsymbol{q}\right) = \begin{bmatrix} L_{++}^{\eta} & \tilde{q} & 0\\ \tilde{q}^{\dagger} & L_{-+}^{\eta} + \alpha L_{+-}^{\eta} & \alpha \tilde{q}\\ 0 & \alpha \tilde{q}^{\dagger} & \alpha L_{--}^{\eta} \end{bmatrix}, \quad (9)$$

where $\eta = +1$ (-1) represents the K (K') valley with $\mathbf{q} = (q_x, q_y) = \mathbf{k} - \mathbf{K}$ ($\mathbf{k} - \mathbf{K}'$), $\tilde{q} = \hbar v_f (\eta q_x - i q_y)$, $\hbar v_f = 3at/2$ and

$$L_{\gamma\beta}^{\eta} = \frac{t_H}{\sqrt{3}} \left[-\cos\phi + \eta\sqrt{3}\sin(\gamma\phi) \right] + \frac{t_{MH}}{\sqrt{3}} \left[-\cos\phi' + \eta\sqrt{3}\sin(\beta\phi') \right], \quad (10)$$

serves as the Dirac mass term determining the bulk spectral gap.

The low-energy dispersion of Eq. (9) can be solved for analytically via the secular equation, $\det(\mathcal{H}_{\eta}(\mathbf{q}) - E_{\eta}(\mathbf{q})I) = 0$ which is, however, too complex to be presented in its full form here. For convenience, the three bands and their corresponding wavefunctions are labeled as $E_m^{\eta}(\mathbf{q})$ and ψ_m^{η} respectively. The subscript, m = -1, 0, and +1 denotes the valence, middle, and conduction bands respectively. For our work, we let $\phi = \phi' = \pi/2$ to ensure the Haldane and modified Haldane NNN hoppings are purely imaginary [34].

At the K' and K points ($\tilde{q} = 0$), Eq. (9) becomes a diagonal matrix. Since a topological phase transition is usually related to a band gap closing-reopening process, we can define both the direct and indirect band gaps of our system in terms of the diagonal elements as follows:

$$\Delta E_{Direct} = |(L_{-+}^{\eta} + \alpha L_{+-}^{\eta}) - \alpha L_{--}^{\eta}|, \qquad (11)$$

and

$$\Delta E_{Indirect} = |(L_{-+}^{+1} + \alpha L_{+-}^{+1}) - \alpha L_{--}^{-1}|.$$
 (12)

B. Topological Invariant

Typically, topological phases are associated with topological invariants in which for our system is characterized by the Chern number, \mathcal{C} of the valence band defined as follows:

$$C = C_K + C_{K'}, \tag{13}$$

where $\mathcal{C}_{K(K')}$ is the so-called valley Chern number defined as

$$C_{\eta} = \frac{1}{2\pi} \iint_{BZ} \Omega_{\eta} (\mathbf{q}) d\mathbf{q}, \qquad (14)$$

and

$$\Omega_{\eta}(\mathbf{q}) = i \operatorname{Im} \sum_{m=0,1} \frac{\langle \psi_{-1}^{\eta} | v_x | \psi_m^{\eta} \rangle \langle \psi_m^{\eta} | v_y | \psi_{-1}^{\eta} \rangle}{(E_{-1}^{\eta} - E_m^{\eta})^2}, \quad (15)$$

is the Berry curvature of the occupied band at the η -valley and $\mathbf{v} = \partial \mathcal{H}_{\eta}(\mathbf{q})/\partial \mathbf{q}$. It is assumed that only the valence band (m = -1) is occupied.

III. RESULTS AND DISCUSSION

Hereafter, the NN hopping strength, t serves as the energy unit (t=1) and the phases of the NNN hoppings, ϕ and ϕ' are fixed at $\pi/2$ [34]. Each bulk band structure is plotted along the k_x axis at $k_y=0$, that is along the path joining the high-symmetry K', M and K points. The unit of k_x is $k_0=4\pi/\sqrt{3}a$ where a is the graphene lattice constant taken to be 1.

A. Bulk Spectral and Topological Properties

By setting the NNN hopping strengths, $(t_{MH}, t_H) =$ (0,0.2)t and solving the eigenvalue problem of Eq. (5) numerically, we obtain the Haldane bulk band structure comprising three bands, namely the conduction, middle and valence bands. Figure 2(a) depicts its evolution with respect to α where it experiences a direct band gap opening-closing-reopening process. At $\alpha = 0$, akin to the graphene case, spectral gaps open at the K' and K points due to the Haldane NNN hopping term, t_H but the middle band remains flat owing to the presence of localized electrons at the C sites. The middle band then becomes dispersive when $\alpha \neq 0$ due to the interaction between the B and C sublattices which causes the spectral gaps to shrink. As the value of α increases, the dispersive nature of the middle band becomes more prominent until it closes the spectral gaps at $\alpha = 0.5$. By further increasing α to 1, the middle band returns to being dispersionless and the spectral gaps are recovered.

The plot of the Chern number, \mathcal{C} and direct band gap, ΔE_{Direct} against α is depicted in Fig. 2(b). Here, the blue and red regions represent the $\mathcal{C}=1$ and $\mathcal{C}=2$ topological phases respectively. Both a jump from $\mathcal{C}=1$ (CI) to $\mathcal{C}=2$ (HCI) and $\Delta E_{Direct}=0$ at $\alpha=0.5$ are observed, indicating that the topological phase transition corresponds to the closing of the direct band gap at $\alpha=0.5$.

Similarly, by setting $(t_{MH}, t_H) = (0.2, 0)t$, we obtain the modified Haldane bulk band structure. Figure 2(c) depicts its evolution with respect to α where it experiences an indirect band gap opening-closing-reopening process. At $\alpha = 0$, the bulk band structure is gapless and the band-touching points are shifted vertically in opposite directions due to the presence of the modified Haldane NNN hopping term, t_{MH} . The middle band becomes dispersive and spectral gaps open at the K' and

K points when $\alpha \neq 0$ as a result of the interaction between the B and C sublattices. In contrast to the Haldane model, the middle band becomes less dispersive as the value of α increases and it shrinks the indirect spectral gaps until they are closed at $\alpha = 0.5$. Again, the middle band returns to being dispersionless and the spectral gaps are recovered when $\alpha = 1$.

The plot of the Chern number, \mathcal{C} and indirect band gap, $\Delta E_{Indirect}$ against α is depicted in Fig. 2(d). Unlike the previous case, no jump in the value of \mathcal{C} is observed. Instead, for infinitesimal values of α ($\alpha \to 0$) \mathcal{C} is illdefined due to the gapless spectrum. The sharp increase is not captured perfectly by Fig. 2(d) for want of computational accuracy. As α continues to increase, \mathcal{C} attains a definite value of 2. This shows that the Chern number is insufficient to characterize this particular system. On the other hand, $\Delta E_{Indirect}$ indeed becomes zero at $\alpha = 0.5$. Therefore, this system only experiences a phase transition from $\mathcal{C} = 2$ (TM) to $\mathcal{C} = 2$ (HCI) at $\alpha = 0.5$ as represented by the green and red regions of Fig. 2(d) respectively. Its topology remains unchanged.

Next, we consider three cases for the combined Haldane models in the α - T_3 lattice: (i) Case I - $t_H > t_{MH}$, (ii) Case II - $t_H = t_{MH}$ and (iii) Case III - $t_H < t_{MH}$ where $(t_{MH}, t_H) = (0.1, 0.2)t$, (0.2, 0.2)t and (0.2, 0.1)trespectively. They are shown in Figs. 3(a), (b) and (c) accordingly. In Case I, we do not only obtain spectral gaps at the K' and K points due to t_H but also their opposite vertical shifts due to t_{MH} as shown in Fig. 3(a) at $\alpha = 0$. Moreover, the presence of t_{MH} leads to the system experiencing a topological phase transition from $\mathcal{C} = 1$ (CI) to $\mathcal{C} = 2$ (HCI) at $\alpha = 0.25$ instead of 0.5 [Fig. 2(a)]. The opposite manner occurs for Case III. Here, we do not only obtain the shifts at the K' and K points due to t_{MH} but also the spectral gaps due to t_H as shown in Fig. 3(c) at $\alpha = 0$. Similarly, the presence of t_H causes the system to experience a phase transition from C=2(TM) to $\mathcal{C}=2$ (HCI) at $\alpha=0.25$ instead of 0.5 [Fig. 2(c)]. On the other hand, as exemplified by Case II [Fig. 3(b)], the system is gapless (remains at C = 2 (HCI)) at $\alpha = 0 \ (\alpha \neq 0)$ whenever $t_H = t_{MH}$. At $\alpha = 1$, Figs. 3(a), (b) and (c) appear similar which can be explained by solving the eigenvalue problem of Eq. (9) as follows:

$$\mathcal{H}_{\eta}^{\alpha=1}\left(\boldsymbol{q}\right) = \begin{bmatrix} \Delta & \tilde{q} & 0\\ \tilde{q}^{\dagger} & 0 & \tilde{q}\\ 0 & \tilde{q}^{\dagger} & -\Delta \end{bmatrix},\tag{16}$$

where $\Delta = \eta(t_H + t_{MH})$ and the resulting eigenvalues are

$$E_0 = 0; \quad E_{\pm 1}^{\eta} = \pm \sqrt{|\tilde{q}|^2 + \Delta}.$$
 (17)

The Chern number, \mathcal{C} phase diagram further demonstrates the interplay between t_H , t_{MH} and α as depicted in Fig. 4(a) for the specific case of $\alpha=0.2$. Here, the combined Haldane models in the α - T_3 lattice manifests a total of three phases, namely the $\mathcal{C}=1$ (CI) phase, $\mathcal{C}=2$ (HCI) phase and $\mathcal{C}=2$ (TM) phase. For instance,

Haldane Model in the $\alpha-T_3$ lattice

Modified Haldane Model in the $\alpha-T_3$ lattice

FIG. 2. Evolution of the bulk band structures of the (a) Haldane and (c) modified Haldane models in the α - T_3 lattice with respect to α . The conduction, middle and valence bands are coloured in red, green and blue respectively. (b) Chern number, \mathcal{C} and direct band gap, ΔE_{Direct} vs α . (d) Chern number, \mathcal{C} and indirect band gap, $\Delta E_{\text{Indirect}}$ vs α . The yellow dots denote the values of \mathcal{C} , ΔE_{Direct} and $\Delta E_{\text{Indirect}}$ at $\alpha = 0$, 0.4, 0.5, 0.6 and 1. For (a) and (b), $(t_{MH}, t_H) = (0, 0.2)t$ and $\phi = \phi' = \pi/2$. For (c) and (d), $(t_{MH}, t_H) = (0.2, 0)t$ and $\phi = \phi' = \pi/2$.

at $t_H = 0.2t$, increasing t_{MH} from 0.05t to 0.4t [going from the left to right in Fig. 4(a)] causes the system to first experience the CI phase, followed by the HCI phase and finally the TM phase. The CI-HCI and HCI-TM phase boundaries are determined by the closing of the direct and indirect band gaps respectively. Figure 4(a) exhibits fluctuations at the lower left region, indicating \mathcal{C} is ill-defined due to the system being gapless.

The variation of the CI-HCI and HCI-TM phase boundaries with respect to α is depicted in Fig. 4(b)

which satisfy the following relations:

$$t_H = \frac{t_{MH}}{1 - 2\alpha},\tag{18}$$

and

$$t_H = (1 - 2\alpha)t_{MH},\tag{19}$$

respectively. The relations are derived by equating Eqs. (11) and (12) to zero. As a result, at $\alpha = 0$, the phase boundaries are degenerate, restoring the graphene case

FIG. 3. Evolution of the bulk band structure of the combined Haldane models in the α - T_3 lattice with respect to α for (a) Case I - t_H > t_{MH} , (b) Case II - t_H = t_{MH} and (c) Case III - t_H < t_{MH} . The values of the parameters are $(t_{MH}, t_H) = (0.1, 0.2)t$ for Case I, $(t_{MH}, t_H) = (0.2, 0.2)t$ for Case II, $(t_{MH}, t_H) = (0.2, 0.1)t$ for Case III and $\phi = \phi' = \pi/2$ for all three cases. Each panel is labeled with its respective Chern number, \mathcal{C} . The conduction, middle and valence bands are coloured in red, green and blue respectively.

[21]. As α increases, the slopes of the CI-HCI and HCI-TM phase boundaries increases and decreases respectively, opening the $\mathcal{C}=2$ HCI phase regime which eventually dominates the entire phase diagram when $\alpha \geq 0.5$.

B. Edge States

The concept of the bulk-edge correspondence (BEC) states that topological phases possess localized edge states protected by non-trivial bulk topological invariants [62–64]. Therefore, the evolutions of the Chern numbers as well as the phases correspond to that of the edge states of the system.

To plot the edge states, the band structure of the α - T_3 zigzag nanoribbon [65, 66] is obtained by considering open boundary condition along the y-direction and periodic boundary condition along the x-direction with zigzag edges. The sites along the y-direction are labelled as A_1 , B_1 , C_1 , A_2 , B_2 , C_2 ,..., A_N , B_N , C_N , etc. A schematic of the α - T_3 nanoribbon is illustrated in Fig.

FIG. 4. (a) Chern number, \mathcal{C} phase diagram with respect to t_H and t_{MH} at $\alpha=0.2$ and $\phi=\phi'=\pi/2$. Here, CI, HCI and TM denote the terms Chern insulator, higher Chern insulator and topological metal respectively. The three yellow dots denote the values of \mathcal{C} at $(t_{MH},t_H)=(0.05,0.2)t, (0.25,0.2)t$ and (0.4,0.2)t. (b) The variation of the CI-HCI (dashed blue) and HCI-TM (solid red) phase boundaries with respect to α for $\alpha=0,0.2,0.4$ and 0.5.

1(a).

Figure 5 depicts the crossings of the zigzag edge states with the Fermi level. For the case of the Haldane model in the α - T_3 lattice, initially, there is one edge state in each edge propagating in opposite directions [Fig. 5(a)] which is consistent with $\mathcal{C}=1$ (one chiral edge state), signifying the Chern insulator (CI) phase. After the critical point ($\alpha=0.5$), there are two edge states in each edge propagating in opposite directions [Fig. 5(b)] which is consistent with $\mathcal{C}=2$ (two chiral edge states), signifying the higher Chern insulator (HCI) phase.

For the case of the modified Haldane model in the α - T_3 lattice, before $\alpha=0.5$, there are two edge states in each edge propagating in opposite directions accompanied by bulk states [Fig. 5(c)], indicating the topological metal (TM) phase. $\mathcal{C}=2$ (two chiral edge states) does not encode information regarding the bulk states. After $\alpha=0.5$, the Fermi level does not cross the bulk states and only the two chiral edge states remain ($\mathcal{C}=2$) [Fig. 5(d)], indicating the higher Chern insulator (HCI) phase.

Figures 5(e) to (g) visualize the topological phases manifested by the combined Haldane models as the \mathcal{C} phase diagram of Fig. 4(a) is traversed horizontally to the right. At (0.05,0.2)t, we first obtain one edge state in each edge propagating in opposite directions corresponding to $\mathcal{C}=1$ (one chiral edge state) [Fig. 5(e)], indicating the CI phase. Next, at (0.25,0.2)t, we obtain two edge states in each edge propagating in opposite directions corresponding to $\mathcal{C}=2$ (two chiral edge states) [Fig. 5(f)], indicating the HCI phase. Finally, at (0.4,0.2)t, we obtain two chiral edge states ($\mathcal{C}=2$) and bulk states, indicating the TM phase.

FIG. 5. The band structure of the Haldane model applied to the α - T_3 zigzag nanoribbon at (a) $\alpha = 0.4$ and (b) $\alpha = 0.6$. The values of the parameters are $(t_{MH}, t_H) = (0, 0.2)t$ and $\phi = \phi' = \pi/2$. The band structure of the modified Haldane model applied to the α - T_3 zigzag nanoribbon at (c) $\alpha = 0.4$ and (d) $\alpha = 0.6$. The values of the parameters are $(t_{MH}, t_H) = (0.2, 0)t$ and $\phi = \phi' = \pi/2$. (e) to (g) The band structures of the combined Haldane models applied to the α - T_3 zigzag nanoribbon corresponding to the three yellow dots in Fig. 4(a). The zigzag chain along the y-axis contains N = 50 AB sites.

IV. CONCLUSION

In summary, we study the topological properties of the Haldane and modified Haldane models in the α - T_3 lattice, both individually and collectively. Firstly, we demonstrate that each model manifests a distinct phase transition. The Haldane model experiences a topological phase transition at $\alpha = 0.5$ from the Chern insulator $(\mathcal{C}=1)$ phase to the higher Chern insulator $(\mathcal{C}=2)$ phase. For the modified Haldane model, it experiences a phase transition from the topological metal ($\mathcal{C}=2$) phase to the higher Chern insulator (C = 2) phase at $\alpha = 0.5$. The fact that \mathcal{C} remains 2 indicates that the Chern number is insufficient to characterize the modified Haldane model. By plotting the Chern number, \mathcal{C} phase diagram, we show that the interaction between the Haldane and modified Haldane parameters realizes three distinct topological phases, namely the C = 1 Chern insulator (CI) phase, C = 2 higher Chern insulator (HCI) phase and $\mathcal{C}=2$ topological metal (TM) phase. Furthermore, we

investigate how the tuning parameter, α influences the phases. At $\alpha=0$, the system only has the CI and TM phase regimes which is the graphene case. As α increases, the HCI phase regime is created and dominates the entire phase diagram at $\alpha \geq 0.5$. The Chern numbers and phases of the aforementioned cases are corroborated by plotting the zigzag edge states. Finally, we remark that we can include more effects into our current model such as the intrinsic [46] and Rashba [61] spin-orbit couplings (SOCs) as well as circularly polarized radiation [58, 60] in order to potentially realize new possible topological phases.
