(Dated: July 18, 2024)

We study shot noise in a two-dimensional, disordered marginal Fermi liquid (MFL) driven out of equilibrium. We consider electrons with Planckian dissipation on the Fermi surface coupled to quantum-critical bosons in the presence of disorder. In the non-interacting and strong electron-boson drag limits, MFL effects disappear and our theory reproduces known results. For the case where the bosons remain in equilibrium, inelastic scattering strongly suppresses the noise by dissipating the injected energy. Interestingly, we find that MFL effects do play a role in this regime, and give a weak *enhancement* on top of the otherwise strong suppression. Our results suggest that shot noise can be strongly suppressed in quantum-critical systems, and this scenario may be relevant to recent measurements in a heavy-fermion strange metal.

Introduction.—Shot noise in electronic transport measures the correlation of current fluctuations

$$S_{\text{shot}} = \int dt \left\langle \delta \hat{I}(t) \,\delta \hat{I}(0) + \delta \hat{I}(0) \,\delta \hat{I}(t) \right\rangle \tag{1}$$

when the system is driven out-of-equilibrium by a voltage V [1, 2], where $\delta \hat{I}(t) = \hat{I}(t) - \langle I \rangle$ is the current fluctuation and t is time. The associated Fano factor $\mathsf{F} = S_{\mathsf{shot}}/(2 e I)$ (e is electric charge, $I = \langle I \rangle$ is electric current) offers a unique way to probe the effective charge of carriers in mesoscopic systems, such as superconductor tunneling junctions [3], fractional quantum Hall devices [4, 5] and quantum-dot Kondo systems [6, 7].

Shot noise in a diffusive wire has been widely studied [1, 2, 8–16]. In the non-interacting limit, $\mathsf{F} = 1/3$ due to the Dorokhov statistics [1, 10, 11, 14, 15]. In the presence of electron-electron interactions, F acquires a non-universal enhancement at weak coupling [14] and becomes universal $\mathsf{F} = \sqrt{3}/4$ at T = 0 (*T* is temperature) in the strongly interacting hydrodynamic limit [13, 14]. Meanwhile, inelastic electron-phonon scattering suppresses F in a non-universal manner [10, 16].

In a recent experiment, shot noise measurements on a heavy-fermion strange metal YbRh₂Si₂ reveal a strongly suppressed Fano factor F [17]. Experimental determination of the electron-phonon coupling seemingly rules out electron-phonon scattering as the mechanism [10, 16]. This intriguing result calls for a new theoretical description of shot noise in quantum-critical systems without well-defined quasiparticles.

In this Letter, we investigate the shot noise in a two-dimensional (2D), disordered marginal Fermi liquid (MFL) [18, 19]. In this model, electrons are strongly coupled to quantum-relaxational bosons in the presence of quenched disorder, leading to electronic Planckian dissipation. Our main physical result is that the *adjusted* Fano factor

$$\mathsf{F}_{\mathsf{adj}}(T,V) \equiv \left(S_{\mathsf{shot}} - S_{\mathsf{JN}}\right) / \left(2\sigma_D eV\right),\tag{2}$$

which characterizes the excess noise, is strongly suppressed when the quantum-critical bosons remain in equilibrium. Here $S_{\rm JN} = 4T\sigma_D$ denotes the equilibrium Johnson-Nyquist noise and $\sigma_{\rm D}$ is the Drude conductivity.

Plot of the adjusted Fano factor F_{adj} [Eq. (2)] FIG. 1. (a,b) and the marginal-Fermi-liquid (MFL) correction factor \mathcal{R} [Eq. (25)] (c,d). The latter arises due to the combination of Planckian dissipation (the MFL self-energy) and the Maki-Thompson diagram shown in Fig. 3(b). All results are plotted as a function of eV/T, where V is the voltage and T is the boson temperature, based on Eqs. (24) and (25) in the equilibrium boson regime. Here the parameter $a \equiv \alpha/\alpha_m$ is inversely proportional to the bosonic thermal mass $m_b^2 = \alpha_m T$ [see Eq. (6)]; \bar{g}^2 denotes the reduced squared Yukawa coupling. F_{adi} is suppressed as the interaction strength \bar{g}^2 increases (black to yellow). The parameters are $\gamma_{\rm el} = 10$, T = 0.05, and $E_{\rm Th} = 2 \times 10^{-3}$. Our plotted results for $F_{\rm adj}$ artificially approach $\sqrt{3}/4$ for $\bar{g}^2 = 0$ and $eV \gg T$ because of the assumed Fermi-Dirac distribution, Eq. (17). For $\bar{g}^2 > 0$, the device length L is always taken to be much longer than the electron-boson scattering length at the wire center. Panels (c,d) indicate that the lack of well-defined quasiparticles gives a *weak enhancement* of the noise, on top of the main effect of dissipative suppression by the boson bath.

FIG. 2. Power-law dependence of T_e/T on $b \equiv (eV)^2 E_{\mathsf{Th}}/(8T^3\bar{g}^2)$ for different *a*, see Eqs. (3) and (4).

Throughout this work, we adopt the units $k_B = \hbar = 1$.

A regime wherein bosons remain in equilibrium can arise when interactions amongst critical fluctuations dominate the boson kinetics, instead of boson-fermion The corresponding F_{adi} as a function of scattering. eV/T is illustrated in Figs. 1(a,b) for different values of the dimensionless squared boson-fermion coupling $\bar{g}^2 =$ $g^2/(4\pi^2\gamma_{\rm el})$. Here $\gamma_{\rm el}$ is the impurity scattering rate. Excess noise is determined by the critical interaction through the electron temperature T_{e} [Eq. (3), below] and the MFL correction to the shot noise. The former is suppressed by the rate of inelastic electron-boson scattering [10, 16], while the latter slightly enhances the Fano factor due to non-equilibrium effects. We quantify the MFL correction through the ratio \mathcal{R} illustrated in Figs. 1(c,d). The parameter $a \equiv \alpha / \alpha_m$ labeling these plots is inversely proportional to the thermal mass $m_{\rm b}^2$ of the bosons, see Eq. (6). Overall, a lighter thermal mass (larger a) screens the quantum-critical interaction less and thus boosts the suppression. Notably, we find that F_{adj} can fall well below 1/3.

In the crossover regime where $eV \gtrsim T$, $\mathsf{F}_{\mathsf{adj}}$ decreases as T increases [Figs. 1(a,b)], in agreement with the recent experimental observation [17]. We find an effective electron temperature that is spatially homogeneous except near the contacts (see Fig. 4), given by

$$T_{\rm e} \simeq \left[\theta_{\bar{g}} D(eE)^2 + T^3\right]^{1/3},$$
 (3)

where $\theta_{\bar{g}}^{-1} \equiv 2\pi\zeta(3)\bar{g}^2$, *D* is the diffusion constant and *E* is the applied electric field. As the interaction strength \bar{g}^2 increases, energy is transferred more rapidly from the electrons to the bosons, which serve as a heat sink, resulting in a more suppressed $T_{\rm e}$. Eq. (3) holds for $a \gtrsim 1$. For $a \ll 1$, a weaker (roughly 1/4) power-law is instead obtained,

$$T_{\rm e}(a \ll 1) \sim \left[(c/a\bar{g}^2) T D(eE)^2 + T^4 \right]^{1/4}$$
 (4)

where c is a constant, see Fig. 2. Our results in Eqs. (3) and (4) are reminiscent of a holographic prediction [20].

The field appears through the combination $(eV)^2 E_{\text{Th}}$ in Eqs. (3) and (4), relevant in the diffusive regime; here $E_{\text{Th}} = D/L^2$ is the Thouless energy and L is the device length. The power law in Eq. (4) is consistent with the experimental data in Ref. [17], although we do not expect our 2D theory to apply directly to a bulk heavyfermion material (see [21] for a more detailed analysis). The power in Eq. (3) differs from the electron-phonon result [14] because the latter depends upon the Debye energy; for the 2D MFL, only the dimensionless \bar{g}^2 enters.

When the bosons and leads reside at T = 0, we find

$$\mathsf{F}_{\mathsf{adj}}(T=0) = \mathsf{F} \simeq \frac{2T_{\mathsf{eff}}}{eV} \,\mathcal{J}_0\left(\frac{\bar{g}^2 \pi \,T_{\mathsf{eff}}}{\gamma_{\mathsf{el}}}\right),\tag{5}$$

where $\mathcal{J}_0(y) = (1+y)/(1+y\ln 2)$ and the effective electronic temperature $T_{\text{eff}} = T_{\text{e}}(T=0)$ in Eq. (3).

We focus here on the dirty MFL because recent theoretical studies suggest that disorder is crucial for strange metallicity observed in many quantum materials [18, 22– 24]. The interplay of disorder, Planckian dissipation, and quantum effects results in interesting consequences for transport [18, 22–24] and superconductivity [19, 25]. Due to disorder smearing, the critical bosonic propagator acquires a quantum relaxational form, with the retarded component being [18, 23, 24, 26]

$$D_{\omega,\mathbf{q}}^{R} = -\left[2(q^{2} - i\,\alpha\,\omega \,+\,m_{b}^{2})\right]^{-1}.$$
 (6)

Here, q is momentum, ω is frequency, $m_{\rm b}^2 = \alpha_m T$ is the thermal mass arising due to quartic self-interactions amongst the bosons [18, 23, 24, 27], while α and α_m are model-specific parameters. The quantum relaxational bosons give arise to a MFL self-energy [18, 22–24, 28] for electrons at equilibrium. The fermionic and bosonic propagators are in sharp contrast with their counterparts in the clean limit [29–31], and offer possible sources for the linear-T resistivity observed in strange metals [18, 22–24].

We investigate the shot noise using the Keldysh formalism [1, 32]. We evaluate the interaction corrections via the bubble [Fig. 3(a)] and Maki-Thompson diagrams (MT) [Fig. 3(b)] using the non-equilibrium electron distribution function. The latter is governed by the kinetic equation derived from the MFL-Finkel'stein non-linear sigma model (MFL-FNLsM) [1, 18]. For bosons staying in equilibrium, we will show that the excess noise is strongly suppressed by the dissipation. On the other hand, in the limit of strong electron-boson drag, contributions from the MFL self-energy and MT diagram cancel and we recover $\mathsf{F} = \sqrt{3}/4$ at T = 0 [13, 14].

Model.—We consider a 2D system with N flavors of spinless, disordered electrons at finite density coupled to SU(N) matrix quantum-critical bosons with a Yukawa coupling strength g [18, 19, 31, 33] (formally

in the unitary class [34, 35]). We restrict our attention to onsite impurity potential disorder and ignore the Sachdev–Ye–Kitaev (SYK)-type randomness in g [36].

We focus on a wire geometry with a potential difference V applied across the sample along \hat{x} . We evaluate the shot noise in Eq. (1) by computing the the Keldysh component of the current-current correlator, which describes the correlation of the stochastic fluctuations of the electric current [1].

At the semiclassical level, we focus on the contribution due to the bubble [Fig. 3(a)] and MT diagrams [Fig. 3(b)]:

$$S_{\text{shot}} = S_{\text{B}} + S_{\text{MT}}.$$
 (7)

The bold lines in the diagrams represent the fermionic Green's function at the saddle-point level [18], encoding the elastic scattering rate due to disorder and the MFL self-energy. We ignore the weak-localization [1, 37] and the Altshuler-Aronov quantum corrections [18, 38] arising from the interplay between the diffusive collective modes and the quantum-critical bosons.

The shot noise due to the bubble diagram is

$$S_{\mathsf{B}} = \sigma_{\mathsf{D}} \int_{0}^{L} \frac{dx}{L} \int \frac{d\omega}{1 - \operatorname{Im} \Sigma_{\omega}^{R}(x)/\gamma_{\mathsf{el}}} \left[1 - F_{\omega}^{2}(x) \right], \quad (8)$$

where $\sigma_{\rm D} = Ne^2\nu_0 D$ is the Drude conductivity, ν_0 is the density of states, L is the length of the wire, and the imaginary part of the non-equilibrium fermionic selfenergy is [18]

$$\operatorname{Im} \Sigma_{\omega}^{R}(x) = \frac{\bar{g}^{2}}{2} \int_{-\infty}^{\infty} d\nu \, \tan^{-1}\left(\frac{\alpha\nu}{m_{b}^{2}}\right) \left[F_{\omega+\nu}(x) - F_{B,\nu}(x)\right],\tag{9}$$

where $F_{\varepsilon}(x)$ and $F_{B,\varepsilon}(x)$ are respectively the generalized fermionic and bosonic distribution functions, which are governed by the kinetic equation discussed below. The center-of-mass position x dependence arises from the potential gradient applied across the wire. In the diffusive limit, the momentum dependence of the distribution functions is very weak and can be ignored. The corresponding equilibrium versions are $F_{\varepsilon}^{\text{eq}} = \tanh(\varepsilon/2T)$ and $F_{B,\varepsilon}^{\text{eq}} = \coth(\varepsilon/2T)$ [1, 18, 32, 37]. In this case, Eq. (9) reduces to the MFL form [18].

On the other hand, the contribution from the MT diagram is [21]

$$S_{\mathsf{MT}} = \frac{i N e^2}{2d} \int_0^L \frac{dx}{L} I_{\mathsf{MT}}(x), \qquad (10)$$

where d = 2 is the dimension, and

$$I_{\mathsf{MT}}(x) \simeq 2i \, g^2 \, v_F^2 \int_{\mathbf{k}, \mathbf{q}, \omega, \nu} 2 \, \operatorname{Im} D_{-\nu, -\mathbf{q}}^R$$

$$\times G_{\omega, \mathbf{k}}^R G_{\omega, \mathbf{k}}^A G_{\omega+\nu, \mathbf{k}+\mathbf{q}}^R G_{\omega+\nu, \mathbf{k}+\mathbf{q}}^A \mathcal{F}(\omega, \nu),$$
(11)

FIG. 3. Feynman diagrams for the Keldysh current-current correlation function: (a) the bubble diagram [Eq. (8)] and (b) the Maki-Thompson (MT) diagram [Eq. (10)]. Here, the black line is the fermion Green's function incorporating the MFL self-energy and disorder scattering, while the red wavy line represents the quantum relaxational bosonic propagator.

the thermal factor

$$\mathcal{F}(\omega,\nu) = F_{B,-\nu} \left(F_{\omega} F_{\omega+\nu} - F_{\omega+\nu}^2 + 1 - F_{\omega}^2 \right) + F_{\omega} F_{\omega+\nu} \left(F_{\omega+\nu} - F_{\omega} \right),$$
(12)

and $G_{\omega,\mathbf{k}}^{R/A}$ is the retarded/advanced fermionic propagator. In the above expression, we have dropped terms that vanish by causality and ignored finite angle scattering terms. We explicitly check that S_{B} and S_{MT} reduce to the Johnson–Nyquist noise at equilibrium [21], as expected by the fluctuation-dissipation theorem [1, 2].

It now remains to determine the distribution functions in order to compute the interaction corrections to the shot noise. The kinetic equation governing F_{ω} in the diffusive regime can be derived based on the saddle point of the MFL-FNLsM [1, 18, 21]. The result is

$$-D\nabla_x^2 F_\omega(x) = \mathfrak{St}_{\mathsf{eb}}[F], \tag{13}$$

where $D = v_F^2/4\gamma_{el}$ is the diffusion constant and the electron-boson collision integral is given by

$$\mathfrak{St}_{\mathsf{eb}}[F] = 4g^2 \int_{\Omega,\mathbf{q}} \operatorname{Im} G^R_{\omega+\Omega,\mathbf{p}+\mathbf{q}} \operatorname{Im} D^R_{\Omega,\mathbf{q}} \times \left\{ F_{B,\Omega}(x) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x)F_{\omega}(x)] \right\}.$$
(14)

In equilibrium, $\mathfrak{St}_{\mathsf{eb}}[F] = 0$. $F_{\omega}(x)$ satisfies the boundary conditions

$$F_{\omega}(0) = \tanh\left(\frac{\omega}{2T}\right), \ F_{\omega}(L) = \tanh\left(\frac{\omega - eV}{2T}\right).$$
 (15)

Results.—In the absence of interactions, $\mathfrak{St}_{\mathsf{eb}}[F] = \operatorname{Im} \Sigma^R_{\omega}(x) = 0$ and Eq. (13) has the standard solution

$$F_{\omega}^{\mathsf{NI}}(x) = (1 - \bar{x}) \tanh\left(\frac{\omega}{2T}\right) + \bar{x} \tanh\left(\frac{\omega - eV}{2T}\right), \ (16)$$

where $\bar{x} = x/L$. Plugging Eq. (16) into Eq. (8) yields the Fano factor F = 1/3.

With interactions, we focus on the kinetic regime $l_{\rm el} \ll l_{\rm eb} \ll L$, where $l_{\rm el} (l_{\rm eb})$ is the elastic (inelastic) scattering length due to impurities (electron-boson collisions). In this "hydrodynamic" limit, both the fermion and boson distribution functions are expected to reflect local

FIG. 4. Plot of the electron temperature profile $T_{\rm e}(\bar{x})$ obtained by solving Eq. (19). As the interaction coupling strength \bar{g}^2 increases, $T_{\rm e}$ decreases, which suppresses the shot noise as a result. With a larger bosonic thermal mass (smaller a), the suppression to $T_{\rm e}$ is weakened due to thermal screening. In the long wire limit with a finite \bar{g}^2 , $T_{\rm e}$ is essentially a constant except in proximity to the contacts. Here, $\gamma_{\rm el} = 10$, T = 0.05, $E_{\rm Th} = 2 \times 10^{-3}$ and V = 1.

equilibration throughout the bulk of the wire, although deviations can occur near the contacts. Even with this constraint, however, different limits are possible, depending upon the relationship between the local electron and boson temperatures.

If electron-boson collisions occur much more frequently than boson-boson scattering, then the bosons are driven away from equilibrium with the electrons and share a common local temperature (electron-boson drag regime). The distribution function F_{ω} acquires a local Fermi-Dirac form

$$F_{\omega}^{\mathsf{hydro}}(x) = \tanh\left[\frac{\omega - e\,V\,\bar{x}}{2T_{\mathsf{e}}(\bar{x})}\right] \tag{17}$$

and $F_{B,\Omega}$ acquires a local Bose form

$$F_{B,\omega}^{\text{hydro}}(x) = \coth\left[\frac{\omega}{2T_{\text{e}}(\bar{x})}\right],$$
 (18)

nullifying the collision integral in Eq. (14). The local temperature profile $T_{\rm e}(\bar{x})$ can be determined using Eq. (13) subjected to the boundary conditions $T_{\rm e}(0) = T_{\rm e}(1) = T$ [14]. In this limit, the self-energy term $\Sigma_{\omega}^{R}(x)$ in $S_{\rm B}$ [Eq. (8)] is canceled by $S_{\rm MT}$ [Eq. (10)] [21], as also occurs in the dc conductivity calculation [18, 23, 24]. As a result, $\mathsf{F} = \sqrt{3}/4$ for $T \to 0$ [14].

The physics is more interesting if we assume that the fermions acquire a hydrodynamic distribution function [Eq. (17)] while the bosons remain at equilibrium, i.e. $F_{B,\omega} = F_{B,\omega}^{\text{eq}}$, which can happen due to the boson-boson self-interactions, boson-impurity collisions, and other sources of scattering. In this regime, we can integrate both sides of Eq. (13) to obtain a diffusion equation for the electron temperature profile T_{e} [14]:

$$\frac{\pi^2}{6}\nabla_{\bar{x}}^2 T_{\mathsf{e}}^2(\bar{x}) = -(eV)^2 + \frac{1}{2E_{\mathsf{Th}}} \int_{-\infty}^{\infty} d\omega \,\omega \,\mathfrak{St}_{\mathsf{eb}}[F], \quad (19)$$

where $E_{\rm Th} = D/L^2$ is the Thouless energy. We numerically solve for $T_{\rm e}$ using Eq. (19) and the results are shown in Fig. 4. In the long-wire limit $(L \to \infty)$, the Laplacian term in Eq. (19) can be dismissed and $T_{\rm e}$ remains constant except in proximity to the contacts. At low T, $T_{\rm e}$ can be solved approximately to give Eq. (3) [21], which is consistent with the numerics.

Evaluating the shot noise using Eqs. (7), (8), (10) and (17), we have

$$S_{\mathsf{shot}} = 4\,\sigma_{\mathsf{D}}\,\int_0^1 d\bar{x}\,T_{\mathsf{e}}(\bar{x})\,\mathcal{J}(\bar{x},\bar{g}^2,T),\tag{20}$$

where

$$\mathcal{J}(\bar{x}, \bar{g}^2, T) = \frac{1}{2} \int_{-\infty}^{\infty} d\bar{\omega} \, \frac{\mathcal{I}_{\mathsf{B}}(\bar{x}, \bar{\omega}) + \mathcal{I}_{\mathsf{MT}}(\bar{x}, \bar{\omega})}{1 - \operatorname{Im} \Sigma^R_{2T_{\mathsf{e}}\bar{\omega}}(\bar{x})/\gamma_{\mathsf{e}}}, \, (21)$$
$$\mathcal{I}_{\mathsf{B}}(\bar{x}, \bar{\omega}) = 1 - \tanh^2 \left(\bar{\omega} - e \, V \, \bar{x}/2T_{\mathsf{e}} \right), \quad (22)$$

and

$$\mathcal{I}_{\mathsf{MT}}(\bar{x},\bar{\omega}) = -\frac{\bar{g}^2 T_{\mathsf{e}}}{\gamma_{\mathsf{e}\mathsf{l}}} \int_{-\infty}^{\infty} d\bar{\nu} \tan^{-1}\left(\frac{2a T_{\mathsf{e}}\bar{\nu}}{T}\right) \times \mathcal{F}(2T_{\mathsf{e}}\bar{\omega},2T_{\mathsf{e}}\bar{\nu}).$$
(23)

Here, the parameter $a = \alpha/\alpha_m$ and the position dependence on T_e is implicit. The corresponding formal Fano factor (defined here for general eV/T) is

$$\mathsf{F} = \frac{2}{eV} \int_0^1 d\bar{x} \, T_{\mathsf{e}}(\bar{x}) \, \mathcal{J}(\bar{x}, \bar{g}^2, T).$$
(24)

In the integrand, $T_{e}(\bar{x})$ arises from the solution to the kinetic equation, as occurs for electron-phonon scattering [16], while $\mathcal{J}(\bar{x}, \bar{g}^2, T)$ [Eq. (21)] encodes MFL corrections that slightly enhance F. Despite its complicated form, S_{shot} can be evaluated analytically at T = 0, resulting in Eq. (5) [21]. Numerical results for T > 0 are shown in Figs. 1(a,b).

We quantify the effects of the MFL self-energy and the Maki-Thompson (MT) diagram through the ratio

$$\mathcal{R}(\bar{g},T) = \int_0^1 d\bar{x} \, T_e(\bar{x}) \, \mathcal{J}(\bar{x},T,\bar{g}^2) \left[\int_0^1 d\bar{x} \, T_e(\bar{x}) \right]^{-1},$$
(25)

which is illustrated in Figs. 1(c,d). Since the bosons and fermions do not share the same temperature, i.e. $T \neq T_{\rm e}(0 < \bar{x} < 1)$, the contribution from $\Sigma^R_\omega(x)$ is not canceled, in contrast with the boson-fermion drag and linear response regimes. Similar to the phonon suppression mechanism, $\mathsf{F}_{\mathsf{adj}}$ decreases as the wire length L and the coupling strength \bar{g}^2 increase. The MFL effects encoded in \mathcal{J} and $\mathcal{R}(\bar{g},T)$ produce a weak enhancement to the noise.

Conclusion.—We have developed a theory for the suppression of shot noise in a 2D disordered MFL at the semiclassical level using the Keldysh frame-

work. Our theory reproduces known results in the non-interacting and electron-boson drag limits. If the quantum-relaxational bosons remain in equilibrium, shot noise is strongly suppressed in the non-universal manner described by Eq. (24). This scenario may be relevant to the recent experiment [17, 21].

Our theory features a power-law temperature dependence in the shot noise [Eqs. (3) and (4)], with an exponent that can differentiate noise suppression mechanisms due to quantum-critical bosons versus phonons [14, 16]. Our results imply that the suppression of shot noise does not necessarily correlate to the absence of quasiparticles [17]. In fact, we find that the non-equilibrium MFL selfenergy and vertex correction instead *weakly boost* the shot noise on top of the dissipative suppression due to the bosons [Figs. 1(c,d)].

Our results contrast with a recent theory proposed in Ref. [42], where a universal Fano factor of 1/6 is obtained in the large-interaction variance limit $q^{\prime 2} \rightarrow \infty$ using the SYK-type model with spatially random Yukawa couplings at T = 0. The differences arise from the form of the electron distribution function used; both calculations consider bosons in equilibrium. We focus on the kinetic regime where $l_{\rm el} \ll l_{\rm eb} \ll L$, which generically admits electron and boson distribution functions of local equilibrium form [16]. Moreover, for a fixed voltage V, the Fano factor in Ref. [42] is independent of L whereas our result vanishes as $L \to \infty$ (for either fixed voltage V or electric field strength V/L). Physically, as the length of the nanowire increases, we expect the shot noise to be further suppressed due to additional dissipation, consistent with the case of electron-phonon interactions [16].

There are numerous intriguing avenues that merit further investigations. From a theoretical perspective, it would be interesting to explore the weak-localization [1, 37] and Altshuler-Aronov [18, 38] quantum corrections to shot noise. It would also be valuable to explore the effects of other impurity distributions and the consequences a non-equilibrium bosonic temperature by solving a separate kinetic equation for the bosons. On the experimental front, it would be captivating to measure the shot noise in other quantum-critical systems to determine the universality of the results and to test the predicted power-law temperature dependence. On the other hand, it is worthwhile to explore the local temperature profile of the nanowire, which can offer valuable insights into unveiling the physical distribution function.

Acknowledgments.—We thank Maxim Dzero, Alex Kamenev, Alex Levchenko, Doug Natelson, and Yiming Wang for useful discussions. We are grateful to Doug Natelson and Liyang Chen for sending us the experimental data. This work was supported by the Welch Foundation Grant No. C-1809 (T.C.W. and M.S.F.).

I. EVALUATION OF THE BUBBLE AND MAKI-THOMPSON DIAGRAMS FOR SHOT NOISE

In this section, we derive the shot noise contributed by the bubble and Maki-Thompson (MT) diagrams (Fig. 3) using the Keldysh path integral formalism. Our conventions closely follow our previous works in Refs. [S1–S3]. The partition function Z[A] in this work is essentially Eq. (26) in Ref. [S2]. However, instead of introducing source field V that couples with the fermionic density operator, we introduce a quantum component of the vector potential source field A^{q} that couples with the classical component of the electric current operator [S1, S4].

The shot noise can be evaluated by computing the Keldysh component of the current-current correlator [S4]:

$$S_{\text{shot}} = -\frac{e^2}{2} \frac{\delta^2 \ln Z[A]}{\delta A^{\mathsf{q}}_{\Omega} \delta A^{\mathsf{q}}_{-\Omega}} \bigg|_{A^{\mathsf{q}}=0,\Omega\to0} = S_{\mathsf{B}} + S_{\mathsf{MT}} + \text{quantum corrections}, \tag{S1}$$

which generates the bubble and MT diagrams at the semiclassical level. We leave the quantum interference corrections arising from weak localization [S4, S5] and Altshuler-Aronov contributions [S2, S6] for further studies.

A. Bubble diagram

The bubble diagram is given by

$$S_{\mathsf{B}} = \lim_{\Omega \to 0} \frac{Ne^2 v_F^2}{2d} \int_0^L \frac{dx}{L} \int_{\omega, \mathbf{k}} \mathsf{Tr} \left[\hat{G}_{\omega+\Omega}(\mathbf{k}) \hat{\gamma}_{\omega+\Omega,\omega}^{\mathsf{q}} \hat{G}_{\omega}(\mathbf{k}) \hat{\gamma}_{\omega,\omega+\Omega}^{\mathsf{q}} \right], \tag{S2}$$

where $\int_{\omega} = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi}$, $\int_{\mathbf{k}} = \int \frac{d^2 \mathbf{k}}{(2\pi)^2}$, the dimension d = 2, and v_F is the Fermi velocity, and the Green's function is

$$\hat{G}_{\omega,\mathbf{k}} = \begin{bmatrix} G_{\omega,\mathbf{k}}^{R} & 0\\ 0 & G_{\omega,\mathbf{k}}^{A} \end{bmatrix}_{\tau},$$
(S3)

with $G_{\omega,\mathbf{k}}^{R/A}$ being the retarded/advanced Green's function. The subscript τ indicates that the matrix is expressed in the Keldysh τ space. At the saddle point level [S2],

$$G^{R}_{\omega,\mathbf{k}} = \frac{1}{\omega + i\gamma_{\mathsf{el}} - \tilde{\varepsilon}_{\mathbf{k}} - \Sigma^{R}_{\omega}},\tag{S4}$$

where $\tilde{\varepsilon}_{\mathbf{k}} = \mathbf{k}^2/2m - \mu$, *m* is the electron mass, μ is the chemical potential, and Σ^R_{ω} is the retarded MFL self-energy [S2]. The trace runs over the Keldysh space τ , $\hat{\gamma}^{\mathsf{cl}}_{\omega,\omega'} = \hat{M}_{F,\omega}\hat{M}_{F,\omega'}$, $\hat{\gamma}^{\mathsf{q}}_{\omega,\omega'} = \hat{M}_{F,\omega}\hat{\tau}^1\hat{M}_{F,\omega'}$, and the thermal matrix $\hat{M}_{F,\omega} = \begin{bmatrix} 1 & F_{\omega} \\ 0 & -1 \end{bmatrix}_{\tau}$. The external frequency Ω is sent to zero for shot noise.

Expanding the trace and ignoring purely retarded/advanced contributions, we have

$$S_{\mathsf{B}} = \sigma_{\mathsf{D}} \int_{0}^{L} \frac{dx}{L} \int d\omega \frac{1}{1 - \operatorname{Im} \Sigma_{\omega}^{R}(x) / \gamma_{\mathsf{el}}} \left[1 - F_{\omega}^{2}(x) \right], \tag{S5}$$

which is Eq. (8) in the main text. We have converted $\int_{\mathbf{k}} = \nu_0 \int d\tilde{\varepsilon}_{\mathbf{k}}$, where ν_0 is the density of states on the Fermi surface.

B. Maki-Thompson diagram

Consider the Maki-Thompson diagram contribution to shot noise

$$S_{\mathsf{MT}} = \frac{iNe^2}{2d} \int_0^L \frac{dx}{L} I_{\mathsf{MT}}(x) \tag{S6}$$

where d = 2 and

 $I_{\mathsf{MT}}(x)$

$$= \lim_{\Omega \to 0} g^{2} \int_{\mathbf{k}, \mathbf{q}, \omega, \nu} \mathbf{v}_{F, \mathbf{k}} \cdot \mathbf{v}_{F, \mathbf{k} + \mathbf{q}} D_{-\nu, -\mathbf{q}}^{ss'} \mathsf{Tr} \left[\hat{\gamma}_{\omega + \Omega, \omega}^{\mathsf{cl}} \hat{G}_{\omega, \mathbf{k}} \hat{\gamma}_{\omega, \omega + \nu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{\mathsf{q}} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{\mathsf{q}} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu + \Omega}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \nu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \mathbf{k} + \mathbf{q}} \hat{\gamma}_{\omega + \nu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu, \omega + \mu}^{s} \hat{G}_{\omega + \nu, \omega + \mu}^{s} \hat{G}_$$

where $s, s' \in \{\mathsf{cl}, \mathsf{q}\},\$

$$\hat{D}_{\nu,\mathbf{q}} = \begin{bmatrix} D_{\nu,\mathbf{q}}^{K} & D_{\nu,\mathbf{q}}^{R} \\ D_{\nu,\mathbf{q}}^{A} & 0 \end{bmatrix}_{\tau}, \qquad D_{\nu,\mathbf{q}}^{K} = (D_{\nu,\mathbf{q}}^{R} - D_{\nu,\mathbf{q}}^{A})F_{B,\nu}, \qquad D_{\nu,\mathbf{q}}^{R} = -\frac{1}{2(q^{2} - i\alpha\nu + m_{b}^{2})}, \qquad m_{b}^{2} = \alpha_{m}T.$$
(S8)

Expanding the Tr by brute force and retaining terms that do not vanish under causality, we have

$$I_{\mathsf{MT}}(x) = 2g^{2} \int_{\mathbf{k},\mathbf{q},\omega,\nu} \mathbf{v}_{F,\mathbf{k}} \cdot \mathbf{v}_{F,\mathbf{k}+\mathbf{q}} (D^{R}_{-\nu,-\mathbf{q}} - D^{A}_{-\nu,-\mathbf{q}}) G^{R}_{\omega,\mathbf{k}} G^{A}_{\omega,\mathbf{k}} G^{R}_{\omega+\nu,\mathbf{k}+\mathbf{q}} G^{A}_{\omega+\nu,\mathbf{k}+\mathbf{q}} \mathcal{F}(\omega,\nu)$$

$$= 2ig^{2} \int_{\mathbf{k},\mathbf{q},\omega,\nu} \mathbf{v}_{F,\mathbf{k}} \cdot \mathbf{v}_{F,\mathbf{k}+\mathbf{q}} [2\operatorname{Im} D^{R}_{-\nu,-\mathbf{q}}] G^{R}_{\omega,\mathbf{k}} G^{A}_{\omega,\mathbf{k}} G^{R}_{\omega+\nu,\mathbf{k}+\mathbf{q}} G^{A}_{\omega+\nu,\mathbf{k}+\mathbf{q}} \mathcal{F}(\omega,\nu), \qquad (S9)$$

where the thermal factor

$$\mathcal{F}(\omega,\nu) = F_{B,-\nu} \left(F_{\omega}F_{\omega+\nu} - F_{\omega+\nu}^2 + 1 - F_{\omega}^2 \right) + F_{\omega}F_{\omega+\nu} \left(F_{\omega+\nu} - F_{\omega} \right).$$
(S10)

In Eq. (11) of the main text, we ignore finite angle scattering contributions by approximating $\mathbf{v}_{F,\mathbf{k}} \cdot \mathbf{v}_{F,\mathbf{k}+\mathbf{q}} \simeq v_F^2$.

II. FLUCTUATION-DISSIPATION THEOREM AND THE JOHNSON-NYQUIST NOISE

In this section, we verify our expression for the shot noise reduces to the Johnson–Nyquist noise at equilibrium, as required by the fluctuation-dissipation theorem. Recall that at equilibrium, the fermionic and bosonic distribution functions become

$$F_{\omega} = \tanh\left(\frac{\omega}{2T}\right), \qquad F_{B,\Omega} = \coth\left(\frac{\Omega}{2T}\right).$$
 (S11)

For the bubble diagram,

$$S_{\mathsf{B}} = \sigma_{\mathsf{D}} \int d\omega \frac{1}{1 - \operatorname{Im} \Sigma_{\omega}^{R}(x)/\gamma_{\mathsf{el}}} \operatorname{sech}^{2}\left(\frac{\omega}{2T}\right)$$
$$= \lim_{\Omega \to 0} \sigma_{\mathsf{D}} \int d\omega \frac{1}{1 - \operatorname{Im} \Sigma_{\omega}^{R}(x)/\gamma_{\mathsf{el}}} \frac{1}{2T} \operatorname{sech}^{2}\left(\frac{\omega}{2T}\right) \Omega \operatorname{coth}\left(\frac{\Omega}{2T}\right).$$
(S12)

For the MT diagram, the thermal factor at equilibrium becomes

$$\begin{aligned} \mathcal{F}(\omega,\nu) &= -F_{B,\nu} \left(F_{\omega}F_{\omega+\nu} - F_{\omega+\nu}^{2} + 1 - F_{\omega}^{2} \right) + F_{\omega}F_{\omega+\nu} \left(F_{\omega+\nu} - F_{\omega} \right) \\ &= -F_{B,\nu}(1 - F_{\omega}^{2}) + F_{B,\nu}F_{\omega+\nu} \left(F_{\omega+\nu} - F_{\omega} \right) + F_{\omega}F_{\omega+\nu} \left(F_{\omega+\nu} - F_{\omega} \right) \\ &= -F_{B,\nu}\mathrm{sech}^{2} \left(\frac{\omega}{2T} \right) + F_{B,\nu}F_{\omega} \right) \left(F_{\omega+\nu} - F_{\omega} \right) \\ &= -F_{B,\nu}\mathrm{sech}^{2} \left(\frac{\omega}{2T} \right) + \left(1 + F_{B,\nu}F_{\omega} \right) \left(F_{\omega+\nu} - F_{\omega} \right) \\ &= -F_{B,\nu}\mathrm{sech}^{2} \left(\frac{\omega}{2T} \right) + \left(F_{\omega+\nu} - F_{\omega} \right) + F_{\omega}(1 - F_{\omega}F_{\omega+\nu}) \\ &= \left(F_{\omega+\nu} - F_{B,\nu} \right)\mathrm{sech}^{2} \left(\frac{\omega}{2T} \right) \\ &= \lim_{\Omega \to 0} \left(F_{\omega+\nu} - F_{B,\nu} \right) \frac{1}{2T}\mathrm{sech}^{2} \left(\frac{\omega}{2T} \right) \Omega \, \coth \left(\frac{\Omega}{2T} \right), \end{aligned}$$

$$\tag{S13}$$

where we have used the identity $F_{\omega}F_{\omega+\nu} = 1 - F_{B,\nu}(F_{\omega+\nu} - F_{\omega})$. Thus,

$$S_{\mathsf{MT}} = \lim_{\Omega \to 0} \frac{e^2}{d} g^2 \int_{\mathbf{k}, \mathbf{q}, \omega, \nu} \mathbf{v}_{F, \mathbf{k}} \cdot \mathbf{v}_{F, \mathbf{k} + \mathbf{q}} [2 \operatorname{Im} D_{\nu, \mathbf{q}}^R] G_{\omega, \mathbf{k}}^R G_{\omega, \mathbf{k}}^A G_{\omega + \nu, \mathbf{k} + \mathbf{q}}^R G_{\omega + \nu, \mathbf{k} + \mathbf{q}}^A (F_{\omega + \nu} - F_{B, \nu}) \frac{1}{2T} \operatorname{sech}^2 \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right),$$
(S14)

which is reminiscent of the imaginary part of the retarded MT current-current correlation function [S7] multiplied by $\cosh(\Omega/2T)$, as expected by the fluctuation-dissipation theorem.

To proceed, we approximate

$$S_{\mathsf{MT}} \simeq \lim_{\Omega \to 0} \frac{Ne^2}{d} g^2 \frac{v_F^2}{\gamma_{\mathsf{el}}^2} \int_{\mathbf{k}, \mathbf{q}, \omega, \nu} 2 \operatorname{Im} D_{\nu, \mathbf{q}}^R G_{\omega, \mathbf{k}}^R G_{\omega, \mathbf{k}}^A (F_{\omega+\nu} - F_{B, \nu}) \frac{1}{2T} \operatorname{sech}^2 \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right)$$
$$\simeq \lim_{\Omega \to 0} \frac{Ne^2}{d} g^2 \frac{v_F^2}{\gamma_{\mathsf{el}}^2} \int_{\omega, \nu} \frac{-1}{4\pi} \tan^{-1} \left(\frac{\alpha\nu}{m_b^2}\right) \frac{\pi\nu_0}{\gamma_{\mathsf{el}} - \operatorname{Im} \Sigma_{\omega}^R} (F_{\omega+\nu} - F_{B,\nu}) \frac{1}{2T} \operatorname{sech}^2 \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right)$$
$$= -\lim_{\Omega \to 0} \sigma_{\mathsf{D}} \frac{\bar{g}^2}{2} \int d\omega \frac{1}{\gamma_{\mathsf{el}} - \operatorname{Im} \Sigma_{\omega}^R} \int d\nu \tan^{-1} \left(\frac{\alpha\nu}{m_b^2}\right) (F_{\omega+\nu} - F_{B,\nu}) \frac{1}{2T} \operatorname{sech}^2 \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right)$$
$$= -\lim_{\Omega \to 0} \sigma_{\mathsf{D}} \int d\omega \frac{\operatorname{Im} \Sigma_{\omega}^R / \gamma_{\mathsf{el}}}{1 - \operatorname{Im} \Sigma_{\omega}^R} \frac{1}{2T} \operatorname{sech}^2 \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right),$$

where we have used the definition of the self-energy [Eq. (9)] in the main text.

As a result, by combining Eqs. (S12) and (S15), the shot noise at equilibrium is

$$S_{\text{shot}} = S_{\text{B}} + S_{\text{MT}}$$

$$= \lim_{\Omega \to 0} \sigma_{\text{D}} \int d\omega \frac{1}{2T} \operatorname{sech}^{2} \left(\frac{\omega}{2T}\right) \Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right)$$

$$= \lim_{\Omega \to 0} \sigma_{\text{D}} 2\Omega \operatorname{coth} \left(\frac{\Omega}{2T}\right)$$

$$= 4T\sigma_{\text{D}}, \qquad (S16)$$

which is the Johnson–Nyquist noise. Notice that the MFL self-energy correction is canceled, as in the electric conductivity calculations [S2, S8, S9]. However, we emphasize that this is only the equilibrium result. In the following, we will see that the interaction correction does not drop out in a non-equilibrium situation in general.

III. DERIVATION OF THE KINETIC EQUATION

The field theoretical description of a system of disordered interacting electrons in the diffusive regime is given by the Finkel'stein nonlinear sigma model (FNLsM) [S4, S5, S10, S11]. We follow the MFL version of the FNLsM presented in our recent work [S2] within the Keldysh formalism to derive the kinetic equation governing the distribution function. We restrict our attention in this work to the particle-hole channel (unitary class [S12, S13]) and ignore the Cooperon contributions.

Consider the \hat{Q} -matrix action in the MFL-FNLsM [S2]

$$S_Q = \frac{\pi\nu_0}{4} \int_{\mathbf{x}} \left[D\operatorname{Tr}\left(\nabla\hat{Q}\nabla\hat{Q}\right) + 4i\operatorname{Tr}\left[\hat{Q}\left(\hat{\omega} - \hat{\Sigma}_{\hat{\omega}}\right)\right] \right],\tag{S17}$$

where

$$\hat{Q} = \hat{U}^{-1} \hat{Q}_{\mathsf{sp}} \hat{U}, \qquad \hat{U} = e^{\hat{W}/2}, \qquad \hat{Q}_{\mathsf{sp};t_1,t_2}(\mathbf{x}) = \begin{bmatrix} 1 & 2F_{t_1,t_2}(\mathbf{x}) \\ 0 & -1 \end{bmatrix}_{\tau} = \hat{M}_F(\mathbf{x}) \hat{q}_{\mathsf{sp}} \hat{M}_F(\mathbf{x}), \qquad \hat{q}_{\mathsf{sp}} = \hat{\tau}^3, \tag{S18}$$

 \hat{W} is the generator of rotation, and

$$\hat{\Sigma}_{\hat{\omega}} = \begin{bmatrix} \Sigma_{\omega}^{R} & \Sigma_{\omega}^{K} \\ 0 & \Sigma_{\omega}^{A} \end{bmatrix}_{\tau}.$$
(S19)

Here, $\Sigma_{\omega}^{R/A/K}$ denotes the retarded/advanced/Keldysh component of the MFL self-energy. We adopt the \hat{Q} -matrix convention in Ref. [S4] which incorporates the fermion distribution function into the matrix field, instead of using \hat{q} as in our previous works [S2, S3]. The diffusion constant D is assumed to be space-time independent. We focus on the implication of $\hat{\Sigma}_{\hat{\omega}}$ for the kinetic equation and leave quantum corrections arising from the interaction terms $S_{\text{int II}}$ and $S_{\text{int II}}$ [S2] for further studies.

Expanding to linear order of \hat{W} , we have

$$\hat{Q} = \hat{Q}_{sp} - \frac{1}{2} [\hat{W}, \hat{Q}_{sp}] + \mathcal{O}(\hat{W}^2).$$
(S20)

Using the cyclic property of Tr and integration by parts, the gradient term can be written as

$$D\operatorname{Tr}\left(\nabla\hat{Q}\nabla\hat{Q}\right) = -\operatorname{Tr}\left[D\nabla\hat{Q}_{\mathsf{sp}}\nabla(\hat{W}\hat{Q}_{\mathsf{sp}} - \hat{Q}_{\mathsf{sp}}\hat{W})\right] = 2\operatorname{Tr}\left[\hat{W}\nabla(D\hat{Q}_{\mathsf{sp}}\nabla\hat{Q}_{\mathsf{sp}})\right].$$
(S21)

The frequency term is

$$4i\operatorname{Tr}\left[\hat{\omega}\hat{Q}\right] = -2\int\operatorname{Tr}\left[\hat{W}_{t_1,t_2}(\partial_{t_1}+\partial_{t_2})\hat{Q}_{\operatorname{sp};t_2,t_1}\right].$$
(S22)

The above derivation closely follows Ref. [S4]. Modification to the kinetic equation arises from the self-energy term

 $\hat{\Sigma}_{\hat{\omega}}$:

$$-4i\operatorname{Tr}\left[\hat{\Sigma}\;\hat{Q}\right] = 2i\operatorname{Tr}\left[\hat{W}(\hat{Q}_{\mathsf{sp}}\hat{\Sigma} - \hat{\Sigma}\hat{Q}_{\mathsf{sp}})\right].$$
(S23)

By varying with respect to \hat{W} and focusing on the (1,2) component of the matrix equation, we obtain the kinetic equation

$$-D\nabla^2 F_{\omega}(t, \mathbf{x}) + \partial_t F_{\omega}(t, \mathbf{x}) = i\left[\Sigma^K + F\Sigma^A - \Sigma^R F\right] = \mathfrak{St}_{\mathsf{eb}}[F],$$
(S24)

where we have employed Wigner transformation

$$F_{t_1,t_2}(\mathbf{x}) = \int_{\varepsilon} F_{\omega}(t,\mathbf{x}) \ e^{-i\omega \ \delta t}, \qquad t = \frac{t_1 + t_2}{2}, \qquad \delta t = t_1 - t_2.$$
(S25)

Using [S2, S4]

$$\Sigma_{\omega,\mathbf{p}}^{R/A}(t,\mathbf{x}) = i g^2 \int_{\Omega,\mathbf{q}} \left[G_{\omega+\Omega,\mathbf{p}+\mathbf{q}}^{R/A}(t,\mathbf{x}) D_{\Omega,\mathbf{q}}^K(t,\mathbf{x}) + G_{\omega+\Omega,\mathbf{p}+\mathbf{q}}^K(t,\mathbf{x}) D_{\Omega,\mathbf{q}}^{A/R}(t,\mathbf{x}) \right]$$
(S26)

$$\Sigma_{\omega,\mathbf{p}}^{K}(t,\mathbf{x}) = i g^{2} \int_{\Omega,\mathbf{q}} \left[G_{\omega+\Omega,\mathbf{p}+\mathbf{q}}^{K}(t,\mathbf{x}) D_{\Omega,\mathbf{q}}^{K}(t,\mathbf{x}) - [G^{R} - G^{A}]_{\omega+\Omega,\mathbf{p}+\mathbf{q}}(t,\mathbf{x}) [D^{R} - D^{A}]_{\Omega,\mathbf{q}}(t,\mathbf{x}) \right], \qquad (S27)$$

where $G^{K} = (G^{R} - G^{A})F$ and $D^{K} = (D^{R} - D^{A})F_{B}$, the collision integral can be written as

$$\mathfrak{St}_{\mathsf{eb}}[F] = 4g^2 \int_{\Omega,\mathbf{q}} \operatorname{Im} G^R_{\omega+\Omega,\mathbf{p}+\mathbf{q}}(t,\mathbf{x}) \operatorname{Im} D^R_{\Omega,\mathbf{q}}(t,\mathbf{x}) \left\{ F_{B,\Omega}(t,\mathbf{x})[F_{\omega+\Omega}(t,\mathbf{x}) - F_{\omega}(t,\mathbf{x})] - (1 - F_{\omega+\Omega}(t,\mathbf{x})F_{\omega}(t,\mathbf{x})) \right\},$$
(S28)

which is Eq. (14) in the main text. At equilibrium, $F_{\omega} = \tanh(\omega/2T)$ and $F_{B,\Omega} = \coth(\Omega/2T)$, the thermal factor inside $\{...\}$ vanishes due to the identity

 $1 - \tanh x \tanh y = \coth(x - y)(\tanh x - \tanh y). \tag{S29}$

A. Equilibrium boson regime

We now assume that the bosons are at equilibrium, i.e. $F_{B,\Omega} = \coth\left(\frac{\Omega}{2T}\right)$ and focus on time-independent distribution functions. In the regime $l_{\mathsf{el}} \ll l_{\mathsf{eb}} \ll L$, we consider a fermionic distribution function of the form

$$F_{\omega}(x) = \tanh\left[\frac{\omega - eV\bar{x}}{2T_{\mathsf{e}}(\bar{x})}\right],\tag{S30}$$

where $\bar{x} = x/L$. We approximate the collision integral by

$$\begin{aligned} \mathfrak{St}_{\mathsf{eb}}[F] &\simeq 2g^2 \int\limits_{\Omega,\mathbf{q}} \frac{1}{\gamma_{\mathsf{el}}} \frac{\alpha \Omega}{(q^2 + m_{\mathsf{b}}^2)^2 + (\alpha \Omega)^2} \left\{ F_{B,\Omega}(x) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x)F_{\omega}(x)] \right\} \\ &= 2g^2 \int\limits_{\Omega} \int_0^\infty \frac{dx}{4\pi} \frac{1}{\gamma_{\mathsf{el}}} \frac{\alpha \Omega}{(x + m_{\mathsf{b}}^2)^2 + (\alpha \Omega)^2} \left\{ F_{B,\Omega}(t,\mathbf{x}) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x)F_{\omega}(x)] \right\} \\ &= \frac{2g^2}{(4\pi\gamma_{\mathsf{el}})(2\pi)} \int d\Omega \tan^{-1} \left(\frac{\alpha \Omega}{m_{\mathsf{b}}^2}\right) \left\{ F_{B,\Omega}(x) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x)F_{\omega}(x)] \right\} \\ &= \bar{g}^2 \int d\Omega \tan^{-1} \left(\frac{\alpha \Omega}{m_{\mathsf{b}}^2}\right) \left\{ F_{B,\Omega}(x) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x)F_{\omega}(x)] \right\}, \end{aligned}$$
(S31)

where $\bar{g}^2 = g^2/(4\pi^2\gamma_{\rm el})$.

The kinetic equation is

$$\frac{\pi^2}{6}\nabla_{\bar{x}}^2 T_{\mathsf{e}}^2(\bar{x}) = -(eV)^2 + \frac{1}{2E_{\mathsf{Th}}} \int_{-\infty}^{\infty} d\omega \,\omega \,\mathfrak{St}_{\mathsf{eb}}[F],\tag{S32}$$

where the collision integral term is

$$\int_{-\infty}^{\infty} d\omega \,\omega \,\mathfrak{St}_{\mathsf{eb}}[F] = \bar{g}^2 \int_{-\infty}^{\infty} d\omega \int_{-\infty}^{\infty} d\Omega \,\omega \, \tan^{-1} \left(\frac{\alpha \,\Omega}{m_b^2}\right) \left\{ F_{B,\Omega}(x) [F_{\omega+\Omega}(x) - F_{\omega}(x)] - [1 - F_{\omega+\Omega}(x) F_{\omega}(x)] \right\} \\
= \bar{g}^2 \int_{-\infty}^{\infty} d\omega \int_{-\infty}^{\infty} d\Omega \,\omega \, \tan^{-1} \left(\frac{\alpha \,\Omega}{\alpha_m T}\right) \left\{ \coth\left[\frac{\Omega}{2T}\right] - \coth\left[\frac{\Omega}{2T_{\mathsf{e}}(\bar{x})}\right] \right\} \\
\times \left\{ \tanh\left[\frac{\omega + \Omega - V\bar{x}}{2T_{\mathsf{e}}(\bar{x})}\right] - \tanh\left[\frac{\omega - V\bar{x}}{2T_{\mathsf{e}}(\bar{x})}\right] \right\} \\
= -2\bar{g}^2 \int_{0}^{\infty} d\Omega \, \tan^{-1} \left(\frac{\alpha \,\Omega}{\alpha_m T}\right) \left\{ \coth\left[\frac{\Omega}{2T}\right] - \coth\left[\frac{\Omega}{2T_{\mathsf{e}}(\bar{x})}\right] \right\} \Omega^2, \tag{S33}$$

and where we have used

$$\int d\omega \,\omega [\tanh(\omega+a) - \tanh(\omega+b)] = b^2 - a^2. \tag{S34}$$

For small T, we have

$$\begin{split} \int_{-\infty}^{\infty} d\omega \,\omega \,\mathfrak{St}_{\mathsf{eb}}[F] &\simeq -2\bar{g}^2 \frac{\pi}{2} \int_0^{\infty} d\Omega \left\{ \coth\left[\frac{\Omega}{2T}\right] - \coth\left[\frac{\Omega}{2T_\mathsf{e}(\bar{x})}\right] \right\} \Omega^2 \\ &= -2\bar{g}^2 \frac{\pi}{2} (2T)^3 \int_0^{\infty} dy \, y^2 \left\{ \coth y - \coth\left[\frac{T}{T_\mathsf{e}(x)}y\right] \right\} \\ &= -2\bar{g}^2 \frac{\pi}{2} (2T)^3 \frac{\zeta(3)}{2} \left[1 - \frac{T_\mathsf{e}^3(\bar{x})}{T^3} \right] \\ &= 4\pi\zeta(3)\bar{g}^2 \left[T_\mathsf{e}^3(\bar{x}) - T^3 \right], \end{split}$$
(S35)

In the long-wire limit, the left-hand side of Eq. (S32) can be dismissed and thus the effective temperature in the long wire limit is

$$T_e \simeq \left[\frac{E_{\mathsf{Th}}}{2\pi\zeta(3)\bar{g}^2} (eV)^2 + T^3\right]^{1/3},\tag{S36}$$

which is Eq. (3) in the main text.

IV. SHOT NOISE IN THE EQUILIBRIUM BOSON REGIME

Using Eqs. (7), (8), (10), (17) in the main text, we have

$$S_{\text{shot}} = 4 \,\sigma_{\text{D}} \,\int_0^1 d\bar{x} \,T_{\text{e}}(\bar{x}) \,\mathcal{J}(\bar{x}, \bar{g}^2, T), \tag{S37}$$

where

$$\mathcal{J}(\bar{x}, \bar{g}^2, T) = \frac{1}{2} \int_{-\infty}^{\infty} d\bar{\omega} \, \frac{\mathcal{I}_{\mathsf{B}}(\bar{x}, \bar{\omega}) + \mathcal{I}_{\mathsf{MT}}(\bar{x}, \bar{\omega})}{1 - \operatorname{Im} \Sigma^R_{2T_{\mathsf{e}}\bar{\omega}}(\bar{x})/\gamma_{\mathsf{el}}},\tag{S38}$$

$$\mathcal{I}_{\mathsf{B}}(\bar{\omega}) = 1 - \tanh^2(\bar{\omega} - V\bar{x}/2T_{\mathsf{e}}), \tag{S39}$$

and

$$\mathcal{I}_{\mathsf{MT}}(\bar{x},\bar{\omega}) = -\frac{\bar{g}^2 T_{\mathsf{e}}}{\gamma_{\mathsf{e}\mathsf{l}}} \int_{-\infty}^{\infty} d\bar{\nu} \, \tan^{-1}\left(\frac{2a \, T_{\mathsf{e}}\bar{\nu}}{T}\right) \mathcal{F}(2T_{\mathsf{e}}\bar{\omega}, 2T_{\mathsf{e}}\bar{\nu}). \tag{S40}$$

The function $\mathcal{F}(\omega,\nu)$ is given by Eq. (S10) and the parameter $a = \alpha/\alpha_m$. To obtain the MT contribution $\mathcal{I}_{\mathsf{MT}}(\bar{x},\bar{\omega})$, we performed the momentum integrals in a manner similar to Eq. (S15).

1. T = 0 limit

At T = 0, $F_{B,\nu} = \operatorname{sgn}(\nu)$. The frequency integral in the self-energy term [Eq. (9)] can be done exactly. The result is

$$\frac{1}{\gamma_{\mathsf{el}}} \operatorname{Im} \Sigma_{\omega}^{R}(x) \Big|_{T=0} = -\frac{\bar{g}^{2} \pi T_{\mathsf{e}}(\bar{x})}{\gamma_{\mathsf{el}}} \ln \left[2 \cosh(\bar{\omega} - V\bar{x}/2T_{\mathsf{e}}) \right].$$
(S41)

We then shift $\bar{\omega} \to \bar{\omega} + V\bar{x}/2T_{e}$ in Eq. (S38) and perform the dimensionless $\bar{\nu}$ integral in \mathcal{I}_{MT} [Eq. (S40)] to obtain

$$\mathcal{I}_{\mathsf{MT}}(\bar{x},\bar{\omega})\Big|_{T=0} = -\frac{\bar{g}^2 \pi T_{\mathsf{e}}(\bar{x})}{2\gamma_{\mathsf{e}\mathsf{l}}} K(\bar{\omega}),\tag{S42}$$

$$K(\bar{\omega}) \equiv \int_{-\infty}^{\infty} d\bar{\nu} \left\{ \begin{array}{l} -\left[\tanh\bar{\omega}\,\tanh(\bar{\omega}+\bar{\nu})+1-\tanh^{2}(\bar{\omega}+\bar{\nu})-\tanh^{2}\bar{\omega}\right] \\ +\operatorname{sgn}(\nu)\,\tanh\bar{\omega}\,\tanh(\bar{\omega}+\bar{\nu})\left[\tanh(\bar{\omega}+\bar{\nu})-\tanh\bar{\omega}\right] \end{array} \right\}$$
(S43)
$$= -\operatorname{sech}^{2}\bar{\omega}\left[2+\left(\mathrm{e}^{2\bar{\omega}}-1\right)\bar{\omega}\right]+2\tanh^{2}\bar{\omega}\,\ln(1+\mathrm{e}^{2\bar{\omega}}).$$

Combining Eqs. (S38), (S41) and (S42), we have

$$S_{\text{shot}}\Big|_{T=0} = 4\,\sigma_{\text{D}} \int_0^1 d\bar{x}\,T_{\text{e}}(\bar{x})\,\mathcal{J}_0\left[\frac{\bar{g}^2\pi\,T_{\text{e}}(\bar{x})}{\gamma_{\text{el}}}\right],\tag{S44}$$

where the dimensionless function

$$\mathcal{J}_0(y) = \int_0^\infty d\bar{\omega} \frac{(1 - \tanh^2 \bar{\omega}) - \frac{y}{2} K(\bar{\omega})}{1 + y \ln(2 \cosh \bar{\omega})}.$$
(S45)

Although $K(\bar{\omega})$ is complicated, it can be well approximated by

$$K(\bar{\omega}) \simeq -2 \operatorname{sech}^2 \bar{\omega}.$$
 (S46)

We then have

$$\mathcal{J}_{0}(y) = \int_{0}^{\infty} d\bar{\omega} \frac{\operatorname{sech}^{2}\bar{\omega}\left(1+y\right)}{1+y\ln\left(2\cosh\bar{\omega}\right)}$$
$$\simeq \int_{0}^{\infty} d\bar{\omega} \frac{\operatorname{sech}^{2}\bar{\omega}\left(1+y\right)}{1+y\ln2}$$
$$= \frac{1+y}{1+y\ln2}.$$
(S47)

In the long wire limit, T_e is approximately a constant except at the proximity of the contacts. Thus, by using Eq. (S36), we have at T = 0 that

$$S_{\text{shot}} \bigg|_{T=0} \simeq 4\sigma_{\text{D}} T_{\text{eff}} \mathcal{J}_0\left(\frac{\bar{g}^2 \pi T_{\text{eff}}}{\gamma_{\text{el}}}\right), \tag{S48}$$

which corresponds to the Fano factor in Eq. (5) of the main text.

V. COMPARISON OF THE EFFECTIVE ELECTRON TEMPERATURE TO THE HEAVY-FERMION EXPERIMENT REF. [S17]

In this section, we compare the shot noise data for the YbRh₂Si₂ nanowire measured in the experiment Ref. [S17] to the results of our theory. Specifically, we fit the noise data using Eq. (4) in the main text:

$$\delta S_{\text{shot}} = A \left\{ \left[T^4 + c(T) V^2 \right]^{1/4} - T \right\},$$
(S49)

where A and c(T) are some parameters to be determined. Since the noise data were measured relative to the equilibrium one, we subtracted off the V = 0 part in the above equation. We empirically set $A = 10^{-20} V^2/(Hz \cdot K)$ and focus on the temperature dependence of c(T). As shown in Fig. S1(a), the shot noise data can be well-described by Eq. (S49). The parameter c(T) approximately varies with T in a linear fashion [Fig. S1(b)], as expected by our theory [Eq. (4) in the main text].

However, we note that YbRh₂Si₂ exhibits linear-T resistivity while our model expects a constant Drude resistivity at the semiclassical level [S2], which potentially accounts for the deviation from the linear-T dependence in the parameter c. Moreover, this heavy-fermion material is strictly speaking three-dimensional, whereas our theory focuses on a 2D disordered marginal Fermi liquid. Whether the quantum critical fluctuations are effectively planar is still an open question. It would be interesting to explore the temperature dependence of shot noise in other (2D) quantum critical systems to further test our theory.

FIG. S1. (a) Plot of the relative shot noise versus voltage at various temperatures. The filled dots represent experimental data from Ref. [S17] and the solid curves depict the fit based on Eq. (S49). (b) Plot of the fitting parameter c(T) as a function of temperature T. The solid line is the linear fit.
