

# SPECIAL AFFINE CONNECTIONS ON SYMMETRIC SPACES

OTHMANE DANI AND ABDELHAK ABOUQATEB

**Abstract.** Let  $(G, H, \sigma)$  be a symmetric pair and  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  the canonical decomposition of the Lie algebra  $\mathfrak{g}$  of  $G$ . We denote by  $\nabla^0$  the canonical affine connection on the symmetric space  $G/H$ . A torsion-free  $G$ -invariant affine connection on  $G/H$  is called special if it has the same curvature as  $\nabla^0$ . A special product on  $\mathfrak{m}$  is a commutative, associative, and  $\text{Ad}(H)$ -invariant product. We show that there is a one-to-one correspondence between the set of special affine connections on  $G/H$  and the set of special products on  $\mathfrak{m}$ . We introduce a subclass of symmetric pairs called strongly semi-simple for which we prove that the canonical affine connection on  $G/H$  is the only special affine connection, and we give many examples. We study a subclass of commutative, associative algebra which allows us to give examples of symmetric spaces with special affine connections. Finally we compute the holonomy Lie algebra of special affine connections.

## 1. INTRODUCTION AND MAIN RESULTS

In the literature, symmetric spaces are described in a variety of ways. An affine symmetric space in differential geometry is a connected smooth manifold  $M$  endowed with an affine connection  $\nabla$  such that for each point  $p \in M$  there is an affine transformation  $\mathfrak{s}_p \in \text{Aff}(M, \nabla)$  which fixes  $p$  and reverses every geodesic through  $p$ . On the other hand, in Lie theoretically terms, a symmetric pair is a triple  $(G, H, \sigma)$  with  $G$  is a connected Lie group,  $H$  a closed subgroup of  $G$  and  $\sigma$  an involutive automorphism of  $G$  such that  $G_\sigma^0 \subseteq H \subseteq G_\sigma$ , where  $G_\sigma$  is the fixed-point subgroup of  $\sigma$  and  $G_\sigma^0$  its identity component. The homogeneous  $G$ -space  $G/H$  is called the corresponding symmetric space. Symmetric spaces play important roles for various branches of mathematics, namely Riemannian geometry, Lie groups theory, harmonic analysis and so on (see for instance [2, 3, 5, 6, 10]). It is worth noting that for any connected Lie group  $G$ , we can associate the natural symmetric pair  $(G \times G, G, \sigma)$ , where  $\sigma(a, b) = (b, a)$ , and in this case, the corresponding symmetric space  $G \times G/G$  is identified with the  $G \times G$ -homogeneous space  $M := G$  (where

---

the transitive action of  $G \times G$  on  $G$  is given by  $(a, b) \cdot x := axb^{-1}$  for  $a, b, x \in G$ . This is why our objective in this article is to describe algebraically a class of invariant affine connections on symmetric spaces which have been explored in [1] in the particular case of Lie groups. Therefore, our current work could be seen as a natural sequel to the work present in [1], where it is proved that if  $\mathfrak{g}$  is a semi-simple Lie algebra, then there is no non-trivial Poisson structure on  $\mathfrak{g}$  (this means that there is no non-trivial commutative, associative, and  $\text{ad}(\mathfrak{g})$ -invariant product on  $\mathfrak{g}$ ). Our idea in this framework is to provide correspondences between some algebraic structures and other geometric ones, which could be very useful for geometric or other algebraic questions.

Let  $(G, H, \sigma)$  be a symmetric pair, the tangent map of  $\sigma$  at the identity element (also denoted by  $\sigma$ ) induces a splitting  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  of the Lie algebra  $\mathfrak{g}$  of  $G$  with  $\mathfrak{h} := \ker(\sigma - \text{Id}_{\mathfrak{g}})$  and  $\mathfrak{m} := \ker(\sigma + \text{Id}_{\mathfrak{g}})$ . Further, one can easily check that  $\mathfrak{h}$  is the Lie algebra of  $H$  and the following inclusions hold

$$\text{Ad}(H)(\mathfrak{m}) \subseteq \mathfrak{m}, \quad \text{and} \quad [\mathfrak{m}, \mathfrak{m}] \subseteq \mathfrak{h}. \quad (1.1)$$

The splitting  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  we just defined above is called the canonical decomposition of  $\mathfrak{g}$  (with respect to  $\sigma$ ). Moreover, since  $G/H$  is a reductive homogeneous  $G$ -space, we denote by  $\nabla^0$  its canonical affine connection, i.e., the unique torsion-free  $G$ -invariant affine connection for which the geodesics are determined by the exponential map of  $G$  (cf. [9, Theorem 10.1]). A *special* affine connection on  $G/H$  is a torsion-free  $G$ -invariant affine connection which has the same curvature as the canonical one. As a direct consequence of Nomizu's theorem on invariant affine connections, we will later see that:

**Theorem 1.1.** *Let  $(G, H, \sigma)$  be a symmetric pair,  $M$  the corresponding symmetric space and  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  the canonical decomposition of the Lie algebra  $\mathfrak{g}$  of  $G$ . There exists a one-to-one correspondence between the set of special affine connections on  $M$  and the set of special products on  $\mathfrak{m}$ , i.e., commutative, associative, and  $\text{Ad}(H)$ -invariant products on  $\mathfrak{m}$ .*

Our next result is to give some conditions on the symmetric pair  $(G, H, \sigma)$  so that the canonical affine connection is the only special affine connection on  $G/H$ . To be precise, we introduce the following definition.

**Definition 1.1.** *The symmetric pair  $(G, H, \sigma)$  is called*

- (1) *simple if the isotropy representation  $\text{ad}^{\mathfrak{m}} : \mathfrak{h} \rightarrow \text{End}(\mathfrak{m})$  is irreducible.*
- (2) *semi-simple if the isotropy representation  $\text{ad}^{\mathfrak{m}} : \mathfrak{h} \rightarrow \text{End}(\mathfrak{m})$  is completely reducible.*
- (3) *strongly semi-simple if there exists a family  $(\mathfrak{m}_i)_{i=1}^k$  of simple  $\mathfrak{h}$ -submodules of  $\mathfrak{m}$  such that*

$$\mathfrak{m} = \mathfrak{m}_1 \oplus \cdots \oplus \mathfrak{m}_k, \quad \text{and} \quad [\mathfrak{m}_i, \mathfrak{m}_i] \neq \{0\}, \quad (1.2)$$

*for all  $i \in \{1, \dots, k\}$ . Such a family is called a strongly decomposition of  $\mathfrak{m}$ .*

Clearly, simple or strongly semi-simple symmetric pairs are semi-simple; moreover, when the isotropy representation is faithful, then according to [9, pp. 56] a simple symmetric pair is strongly semi-simple if and only if  $\mathfrak{g}$  is a semi-simple Lie algebra.

Our main result is the following.

**Theorem 1.2.** *Let  $(G, H, \sigma)$  be a symmetric pair and  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  the canonical decomposition of the Lie algebra  $\mathfrak{g}$  of  $G$ . If  $(G, H, \sigma)$  is simple (with  $\dim \mathfrak{m} > 1$ ) or strongly semi-simple, then the trivial product is the only special product on  $\mathfrak{m}$ .*

Note that this result is not valid for semi-simple symmetric pairs as shown by Example (3.5).

The paper is organized as follows. In Section 2, we prove Theorem 1.1 and we show that special affine connections are semi-symmetric (see Proposition 2.1). Section 3 is devoted to proving Theorem 1.2 and providing some examples. In Section 4, we give other examples of strongly semi-simple symmetric pairs. In Section 5 we introduce a particular subclass of commutative, associative algebra, what we called commutative, 0-associative algebra, which allows us to give examples of symmetric spaces with special affine connections (see Proposition 5.2). Finally, in Section 6 we compute the holonomy Lie algebra of a special affine connection.

Until the end of this paper,  $(G, H, \sigma)$  will be a symmetric pair,  $M := G/H$  the corresponding symmetric space,  $\mathfrak{g} = \mathfrak{m} \oplus \mathfrak{h}$  the canonical decomposition of the Lie algebra  $\mathfrak{g}$  of  $G$ , and  $\text{ad}^{\mathfrak{m}} : \mathfrak{h} \rightarrow \text{End}(\mathfrak{m})$  the isotropy representation of  $\mathfrak{h}$  in  $\mathfrak{m}$ .

All vector spaces, algebras, etc. in this paper are finite dimensional and over the field of real numbers  $\mathbb{R}$ .

**ACKNOWLEDGMENT** The authors would like to thank Saïd Benayadi, University Lorraine-France, for his helpful discussions and advice concerning this paper.

## 2. SPECIAL AFFINE CONNECTIONS ON SYMMETRIC SPACES

Before going further into the proof of Theorem 1.1, let us start with some facts that should be known. First of all, since  $M$  is a reductive homogeneous  $G$ -space, then according to Nomizu's Theorem [9, Theorem 8.1] there is a one-to-one correspondence between the set of  $G$ -invariant affine connections on  $M$  and the set of bilinear maps  $\alpha : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  which are invariant by  $\text{Ad}(H)$ , i.e.,

$$\text{Ad}_h \alpha(u, v) = \alpha(\text{Ad}_h u, \text{Ad}_h v), \quad (2.1)$$

for  $u, v \in \mathfrak{m}$  and  $h \in H$ . If  $\nabla$  is a  $G$ -invariant affine connection on  $M$ , then it is obvious that the torsion  $T^\nabla$  and the curvature  $R^\nabla$  tensor fields of  $\nabla$  are also  $G$ -invariant. Thus, they are completely determined by their value at the origin  $o \in M$ . Hence, under the identification of  $T_o M$  with  $\mathfrak{m}$ , using the second inclusion of (1.1) in [9, Formulas (9.1) and (9.6)], the torsion  $T^\nabla$  and the curvature  $R^\nabla$  of

$\nabla$  can be expressed as follows:

$$T^\nabla(u, v) = \alpha^\nabla(u, v) - \alpha^\nabla(v, u); \quad (2.2)$$

$$R^\nabla(u, v)w = \alpha^\nabla(u, \alpha^\nabla(v, w)) - \alpha^\nabla(v, \alpha^\nabla(u, w)) - [[u, v], w], \quad (2.3)$$

for  $u, v, w \in \mathfrak{m}$ , where  $\alpha^\nabla : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  is the bilinear map associated to  $\nabla$ . In particular, for the canonical affine connection  $\nabla^0$ , its associated product on  $\mathfrak{m}$  is the trivial product  $\alpha^0 = 0$ . Hence it is torsion-free and its curvature is given by

$$R^0(u, v)w = -[[u, v], w] \quad \forall u, v, w \in \mathfrak{m}.$$

We can now give the following.

**Proof of Theorem 1.1.** Let  $\nabla$  be a special affine connection on  $M$ . We define a product  $\star : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  on  $\mathfrak{m}$  by

$$u \star v := \alpha^\nabla(u, v),$$

for  $u, v \in \mathfrak{m}$ , where  $\alpha^\nabla : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  is the bilinear map associated to  $\nabla$ . Clearly that the product  $\star$  is  $\text{Ad}(H)$ -invariant and since  $\nabla$  is torsion-free it is commutative by (2.2). Furthermore, using (2.3) and the commutativity of  $\star$  we obtain that  $\star$  is associative.

Conversely, given a commutative, associative and  $\text{Ad}(H)$ -invariant product  $\star$  on  $\mathfrak{m}$ , then define a bilinear map  $\alpha : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  by

$$\alpha(u, v) := u \star v.$$

Since  $\alpha$  is  $\text{Ad}(H)$ -invariant, it defines a  $G$ -invariant affine connection  $\nabla^\alpha$  on  $M$ . Moreover, since  $\star$  is commutative, we obtain by (2.2) that  $\nabla^\alpha$  is torsion-free. Furthermore, using the fact that  $\star$  is commutative, associative and (2.3) we get that  $\nabla^\alpha$  has the same curvature as  $\nabla^0$ .  $\square$

It is clear that any connected Lie group  $G$  can be considered as a symmetric space, where the symmetric pair is  $G_0 := G \times G$ ,  $H_0 := \Delta G_0$ ,  $\sigma_0 : G_0 \rightarrow G_0$ ,  $(a, b) \mapsto (b, a)$ , and the canonical decomposition of the Lie algebra  $\mathfrak{g}_0$  of  $G_0$  is  $\mathfrak{g}_0 = \mathfrak{m}_0 \oplus \mathfrak{h}_0$ , where

$$\mathfrak{h}_0 = \{(u, u) \mid u \in \mathfrak{g}\}, \quad \text{and} \quad \mathfrak{m}_0 = \{(u, -u) \mid u \in \mathfrak{g}\}.$$

Moreover, the isotropy representation of  $H_0$  in  $\mathfrak{m}_0$  is equivalent to the adjoint representation of  $G$  in  $\mathfrak{g}$ , and the canonical connection  $\nabla^0$  on  $G$  is the torsion-free bi-invariant affine connection given by

$$\nabla_{u^+}^0 v^+ = \frac{1}{2}[u^+, v^+],$$

where  $u^+, v^+$  denote the left invariant vector fields on  $G$  associated respectively to the vectors  $u, v \in \mathfrak{g}$ . So, a special affine connection on  $G$  is a torsion-free bi-invariant affine connection on  $G$  which has the same curvature as  $\nabla^0$ . On the other hand, a special product on  $\mathfrak{m}_0$  is equivalent to a Poisson structure on  $\mathfrak{g}$ , i.e., a commutative, associative, and  $\text{ad}(\mathfrak{g})$ -invariant product on  $\mathfrak{g}$ . Thus by Theorem 1.1 we get the following result obtained in [1, Theorem 2.1].

**Corollary 2.1.** *Let  $G$  be a connected Lie group and  $\mathfrak{g}$  its Lie algebra. There is a one-to-one correspondence between the set of special affine connections on  $G$  and the set of Poisson structures on  $\mathfrak{g}$ .*

In differential geometry there is a notion of semi-symmetric spaces which is a direct generalization of locally symmetric spaces, namely, smooth manifolds endowed with a torsion-free affine connection  $\nabla$  for which the curvature tensor  $R^\nabla$  satisfies

$$\nabla_X \nabla_Y R^\nabla - \nabla_Y \nabla_X R^\nabla - \nabla_{[X,Y]} R^\nabla = 0,$$

for any vector fields  $X, Y$ . It is known that the above equation is equivalent (see [10, Chap 4. Formula (26)]) to the following one

$$[R^\nabla(X, Y), R^\nabla(Z, W)] = R^\nabla(R^\nabla(X, Y)Z, W) + R^\nabla(Z, R^\nabla(X, Y)W),$$

for any vector fields  $X, Y, Z, W$ . Hence, since the curvature tensor  $R^0$  of the canonical affine connection  $\nabla^0$  satisfies this condition, we easily obtain the following proposition.

**Proposition 2.1.** *The smooth manifold  $M$  endowed with a special affine connection is semi-symmetric.*

### 3. SIMPLE AND STRONGLY SEMI-SIMPLE SYMMETRIC PAIRS

In this section we will give a proof for Theorem 1.2. We begin by the case for which  $(G, H, \sigma)$  is a simple symmetric pair (with  $\dim \mathfrak{m} > 1$ ), then we pass to the strongly semi-simple case. First notice that, if  $\text{ad}^{\mathfrak{m}} : \mathfrak{h} \rightarrow \text{End}(\mathfrak{m})$  is not trivial (which is the case if  $(G, H, \sigma)$  is simple with  $\dim \mathfrak{m} > 1$  or strongly semi-simple), then  $\mathfrak{i} := \ker \text{ad}^{\mathfrak{m}}$  is an ideal of  $\mathfrak{g}$  which is strictly contained in  $\mathfrak{h}$ . Thus we get a faithful representation  $\overline{\text{ad}}^{\mathfrak{m}} : \overline{\mathfrak{h}} \rightarrow \text{End}(\mathfrak{m})$  of the Lie algebra  $\overline{\mathfrak{h}} := \mathfrak{h}/\mathfrak{i}$ . Further, a product on  $\mathfrak{m}$  is  $\text{ad}(\mathfrak{h})$ -invariant if and only if it is  $\overline{\text{ad}}^{\mathfrak{m}}(\overline{\mathfrak{h}})$ -invariant. Hence, throughout this section we may assume without loss of generality that the isotropy representation of  $\mathfrak{h}$  in  $\mathfrak{m}$  is faithful, i.e.,  $\text{ad}^{\mathfrak{m}} : \mathfrak{h} \rightarrow \text{End}(\mathfrak{m})$  is injective.

**Proof of Theorem 1.2 in the case where  $(G, H, \sigma)$  is simple.** We start with the following remark: since  $\mathfrak{m}$  is a simple  $\mathfrak{h}$ -module and  $[\mathfrak{h}, \mathfrak{m}] \subseteq \mathfrak{m}$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$ , then it will be either  $\{0\}$  or  $\mathfrak{m}$ . But since  $\text{ad}^{\mathfrak{m}}$  is faithful it follows that  $\mathfrak{m} = [\mathfrak{h}, \mathfrak{m}]$ . Now let  $\alpha : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  be a special product on  $\mathfrak{m}$ . Define

$$\mathcal{I} := \{u \in \mathfrak{m} \mid \alpha_u = 0\}.$$

For  $a \in \mathfrak{h}$  and  $u \in \mathcal{I}$ , using (2.1) we have

$$\alpha_{[a,u]} = [\text{ad}_a, \alpha_u] = 0.$$

Thus  $\mathcal{I}$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$  and therefore either  $\mathcal{I} = \{0\}$  or  $\mathcal{I} = \mathfrak{m}$ . Suppose by contradiction that  $\mathcal{I} = \{0\}$ . The product on  $\mathfrak{m}$  given by  $u \star v := \alpha(u, v)$  for  $u, v \in \mathfrak{m}$  is a special product and hence it is commutative and associative. So for

any  $u, v \in \mathfrak{m}$  and  $n \geq 1$

$$\begin{aligned}\alpha_u^n(v) &= \alpha_u \circ \alpha_u \circ \cdots \circ \alpha_u(v) \\ &= u \star u \star \cdots \star u \star v \\ &= \alpha_{u^n}(v).\end{aligned}\tag{3.1}$$

On the other hand for  $a \in \mathfrak{h}$  and  $v \in \mathfrak{m}$ , we have

$$\mathrm{tr}(\alpha_{[a,v]}) = \mathrm{tr}([\mathrm{ad}_a, \alpha_v]) = 0.$$

Since each element of  $\mathfrak{m}$  is a linear combination of elements of  $[\mathfrak{h}, \mathfrak{m}]$ , then by (3.1) we get

$$\mathrm{tr}(\alpha_u^n) = 0 \quad \forall u \in \mathfrak{m}, n \geq 1.$$

Hence  $\alpha_u$  is a nilpotent endomorphism of  $\mathfrak{m}$ . Let  $\tilde{\mathfrak{m}}$  be the vector space

$$\tilde{\mathfrak{m}} := \left\{ \alpha_u \in \mathrm{End}(\mathfrak{m}) \mid u \in \mathfrak{m} \right\}.$$

Clearly that  $\tilde{\mathfrak{m}}$  is a Lie subalgebra of  $\mathrm{End}(\mathfrak{m})$  because  $[\alpha_u, \alpha_v] = 0$  for  $u, v \in \mathfrak{m}$ . Moreover, each element of  $\tilde{\mathfrak{m}}$  is a nilpotent endomorphism of  $\mathfrak{m}$ . Thus by Engel's Theorem there exists a nonzero element  $u_0 \in \mathfrak{m}$  such that

$$\alpha_{u_0}(u) = \alpha_u(u_0) = 0, \quad \forall u \in \mathfrak{m}.$$

So  $\alpha_{u_0} = 0$  which implies that  $u_0 \in \mathcal{I}$ . But this constitutes a contradiction and therefore proves the claim.  $\square$

**Corollary 3.1.** *If  $(G, H, \sigma)$  is simple (with  $\dim M > 1$ ), then the canonical affine connection  $\nabla^0$  is the only special affine connection on  $M$ .*

**Example 3.1.** If  $\mathfrak{g}$  is a simple Lie algebra and  $H$  is compact, then the symmetric pair  $(G, H, \sigma)$  is simple (cf. [5, Chap 11. Proposition 7.4]). Moreover, since  $\mathfrak{g}$  is simple we have that  $\dim \mathfrak{m} > 1$  (see [9, pp. 56]), and therefore the canonical affine connection  $\nabla^0$  is the only special affine connection on  $M$ .

**Example 3.2.** It is clear that the symmetric pair  $(\mathrm{SO}(n+1), \mathrm{SO}(n), \sigma_{J_n})$  is simple ( $n > 1$ ), where  $\sigma_{J_n}(A) := J_n A J_n$ , with  $J_n := \begin{pmatrix} I_n & 0 \\ 0 & -1 \end{pmatrix}$ . Thus, the canonical affine connection  $\nabla^0$  is the only special affine connection on the unit  $n$ -sphere  $\mathbb{S}^n$ .

To demonstrate Theorem 1.2 in the case where  $(G, H, \sigma)$  is strongly semi-simple we need the following lemma.

**Lemma 3.1.** *If  $(G, H, \sigma)$  is strongly semi-simple and  $(\mathfrak{m}_i)_{i=1}^k$  a strongly decomposition of  $\mathfrak{m}$ , then for each  $i, j, l \in \{1, \dots, k\}$  such that  $i \neq j$  and  $i \neq l$ , we have*

1.  $[\mathfrak{m}_i, [\mathfrak{m}_j, \mathfrak{m}_l]] = \{0\}$ .
2.  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \mathfrak{m}_i$ .
3.  $Z_i[\mathfrak{m}_i, \mathfrak{m}_i] := \left\{ u_i \in \mathfrak{m}_i \mid [u_i, w_i] = 0, \forall w_i \in [\mathfrak{m}_i, \mathfrak{m}_i] \right\} = \{0\}$ .

*Proof.* First we have by Jacobi identity  $[\mathfrak{m}_i, [\mathfrak{m}_j, \mathfrak{m}_l]] \subseteq [[\mathfrak{m}_i, \mathfrak{m}_j], \mathfrak{m}_l] + [\mathfrak{m}_j, [\mathfrak{m}_i, \mathfrak{m}_l]]$ . Thus

$$[\mathfrak{m}_i, [\mathfrak{m}_j, \mathfrak{m}_l]] \subseteq \mathfrak{m}_i \cap (\mathfrak{m}_l \oplus \mathfrak{m}_j) = \{0\}.$$

For the second one, using again Jacobi identity we get

$$\begin{aligned} [\mathfrak{h}, [\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]]] &\subseteq [[\mathfrak{h}, \mathfrak{m}_i], [\mathfrak{m}_i, \mathfrak{m}_i]] + [\mathfrak{m}_i, [\mathfrak{h}, [\mathfrak{m}_i, \mathfrak{m}_i]]] \\ &\subseteq [\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] + [\mathfrak{m}_i, [[\mathfrak{h}, \mathfrak{m}_i], \mathfrak{m}_i]] + [\mathfrak{m}_i, [\mathfrak{m}_i, [\mathfrak{h}, \mathfrak{m}_i]]] \\ &\subseteq [\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]]. \end{aligned}$$

So  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]]$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}_i$ , and therefore either  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \{0\}$  or  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \mathfrak{m}_i$ . Suppose by contradiction that  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \{0\}$ . Then by the first assertion we obtain that  $[[\mathfrak{m}_i, \mathfrak{m}_i], \mathfrak{m}] = \{0\}$ , and it follows that  $[\mathfrak{m}_i, \mathfrak{m}_i] = \{0\}$ . But this contradicts (1.2) and hence  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \mathfrak{m}_i$ . For the last one a similar argument shows that  $Z_i[\mathfrak{m}_i, \mathfrak{m}_i]$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}_i$  and therefore  $Z_i[\mathfrak{m}_i, \mathfrak{m}_i] = \{0\}$ , because otherwise we would have  $[\mathfrak{m}_i, [\mathfrak{m}_i, \mathfrak{m}_i]] = \{0\}$ , which contradicts the second assertion.  $\square$

**Proof of Theorem 1.2 in the strongly semi-simple case.** The proof is very similar to the proof of the case where  $(G, H, \sigma)$  is simple. Let  $(\mathfrak{m}_i)_{i=1}^k$  be a strongly decomposition of  $\mathfrak{m}$  and  $\alpha : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  a special product on  $\mathfrak{m}$ . Define

$$\mathcal{I} := \{u \in \mathfrak{m} \mid \alpha_u = 0\}.$$

Clearly that  $\mathcal{I}$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$ , and so our task is to proving that  $\mathcal{I} = \mathfrak{m}$ . Before doing this, we will show that the product  $\alpha$  respects the strongly decomposition of  $\mathfrak{m}$  i.e., for  $i, j \in \{1, \dots, k\}$  such that  $i \neq j$  we have

$$\alpha(\mathfrak{m}_i, \mathfrak{m}_i) \subseteq \mathfrak{m}_i, \quad \text{and} \quad \alpha(\mathfrak{m}_i, \mathfrak{m}_j) = \{0\}.$$

For  $u_i, v_i \in \mathfrak{m}_i$ ,  $\alpha(u_i, v_i)$  can be written uniquely in the form

$$\alpha(u_i, v_i) = \alpha(u_i, v_i)_1 + \dots + \alpha(u_i, v_i)_k.$$

So for each  $j \neq i$  and  $w_j \in [\mathfrak{m}_j, \mathfrak{m}_j] \subset \mathfrak{h}$ , using the  $\text{Ad}(H)$ -invariance of  $\alpha$  and the first assertion in the previous lemma, we get

$$\begin{aligned} [\alpha(u_i, v_i)_j, \omega_j] &= [\alpha(u_i, v_i), \omega_j] \\ &= \alpha([u_i, w_j], v_i) + \alpha(u_i, [v_i, w_j]) \\ &= 0. \end{aligned}$$

Thus  $\alpha(u_i, v_i)_j \in Z_j[\mathfrak{m}_j, \mathfrak{m}_j] = \{0\}$  and therefore  $\alpha(\mathfrak{m}_i, \mathfrak{m}_i) \subseteq \mathfrak{m}_i$ . A similar argument shows that  $\alpha(u_i, u_j) \in \mathfrak{m}_i \oplus \mathfrak{m}_j$  for  $u_i \in \mathfrak{m}_i$  and  $u_j \in \mathfrak{m}_j$ . Moreover, if we write  $u_l = [v_l, w_l]$ , for  $v_l \in \mathfrak{m}_l, w_l \in [\mathfrak{m}_l, \mathfrak{m}_l]$  and  $l = i, j$ , we obtain

$$\begin{aligned} \alpha(u_i, u_j) &= [\alpha(v_i, u_j), w_i] - \alpha(v_i, [u_j, w_i]) \\ &= [\alpha(v_i, u_j), w_i] \\ &= [\alpha(v_i, u_j)_i, w_i] \in \mathfrak{m}_i, \end{aligned}$$

and similarly

$$\begin{aligned} \alpha(u_i, u_j) &= [\alpha(u_i, v_j), w_j] - \alpha([u_i, w_j], v_j) \\ &= [\alpha(u_i, v_j), w_j] \\ &= [\alpha(u_i, v_j)_j, w_j] \in \mathfrak{m}_j. \end{aligned}$$

Hence  $\alpha(u_i, u_j) \in \mathfrak{m}_i \cap \mathfrak{m}_j = \{0\}$ , which implies that  $\alpha(\mathfrak{m}_i, \mathfrak{m}_j) = \{0\}$ . Now suppose by contradiction that  $\mathcal{I} \neq \mathfrak{m}$ . Since  $\mathcal{I}$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$ , then by changing the indexation of the sequence  $(\mathfrak{m}_i)_{i=1}^k$  we can assume that there exists  $1 \leq r \leq k$  such that for  $i \in \{1, \dots, r-1\}$  and  $j \in \{r, \dots, k\}$  we have

$$\mathcal{I} \cap \mathfrak{m}_i = \mathfrak{m}_i, \quad \text{and} \quad \mathcal{I} \cap \mathfrak{m}_j = \{0\}.$$

Thus  $\mathfrak{m} = \mathcal{I} + \mathcal{J}$  with  $\mathcal{J} := \mathfrak{m}_r \oplus \dots \oplus \mathfrak{m}_k$ . Indeed this is a direct sum, to see it let  $u \in \mathcal{I} \cap \mathcal{J}$ , then write  $u = u_r + \dots + u_k$  for  $u_j \in \mathfrak{m}_j$  and  $j \in \{r, \dots, k\}$ . For  $w_j \in [\mathfrak{m}_j, \mathfrak{m}_j]$  we have

$$[u_j, w_j] = [u, w_j] \in \mathcal{I} \cap \mathfrak{m}_j.$$

Hence  $u_j = 0$  and it follows that  $u = 0$ . This implies in turn that  $\mathfrak{m} = \mathcal{I} \oplus \mathcal{J}$ . On the other hand, we denote by  $\tilde{\alpha}$  the restriction of  $\alpha$  to  $\mathcal{J}$ , then the product on  $\mathcal{J}$  given by  $u \star v := \tilde{\alpha}(u, v)$  for  $u, v \in \mathcal{J}$  is a special product and hence it is commutative and associative. So for any  $u, v \in \mathcal{J}$  and  $n \geq 1$

$$\begin{aligned} \tilde{\alpha}_u^n(v) &= \tilde{\alpha}_u \circ \tilde{\alpha}_u \circ \dots \circ \tilde{\alpha}_u(v) \\ &= u \star u \star \dots \star u \star v \\ &= \tilde{\alpha}_{u^n}(v). \end{aligned}$$

Furthermore, every element  $u$  of  $\mathfrak{m}$  can be expressed as a linear combination of elements of the form  $[v_i, w_i]$  for  $v_i \in \mathfrak{m}_i, w_i \in [\mathfrak{m}_i, \mathfrak{m}_i]$  and  $i \in \{1, \dots, k\}$ . Then using this and the  $\text{Ad}(H)$ -invariance of  $\alpha$  we can easily deduce that  $\text{tr}(\alpha_u) = 0$ . Thus for  $u \in \mathcal{J}, n \geq 1$  one has  $\text{tr}(\tilde{\alpha}_u^n) = 0$ , and therefore  $\tilde{\alpha}_u$  is a nilpotent endomorphism of  $\mathcal{J}$ . Let  $\tilde{\mathcal{J}}$  be the vector space

$$\tilde{\mathcal{J}} := \left\{ \tilde{\alpha}_u \in \text{End}(\mathcal{J}) \mid u \in \mathcal{J} \right\}.$$

It is obvious that  $\tilde{\mathcal{J}}$  is a Lie subalgebra of  $\text{End}(\mathcal{J})$ . Furthermore, each element of  $\tilde{\mathcal{J}}$  is a nilpotent endomorphism of  $\mathcal{J}$ . Thus by Engel's Theorem there exists  $u_0 \in \mathcal{J} \setminus \{0\}$  such that

$$\tilde{\alpha}_{u_0}(u) = \tilde{\alpha}_u(u_0) = 0, \quad \forall u \in \mathcal{J}.$$

Hence  $\tilde{\alpha}_{u_0} = 0$ . But since the restriction of  $\alpha_{u_0}$  to  $\mathcal{I}$  vanishes, we deduce that  $\alpha_{u_0} = 0$  and then  $u_0 \in \mathcal{I}$ . This constitutes a contradiction and proves the claim.  $\square$

**Corollary 3.2.** *If  $(G, H, \sigma)$  is strongly semi-simple, then the canonical affine connection  $\nabla^0$  is the only special affine connection on  $M$ .*

**Example 3.3.** Let  $G$  be a connected semi-simple Lie group,  $\mathfrak{g}$  its Lie algebra and  $(G_0, H_0, \sigma_0)$  its associated symmetric pair. Since the isotropy representation of  $\mathfrak{h}_0 \cong \mathfrak{g}$  in  $\mathfrak{m}_0 \cong \mathfrak{g}$  is equivalent to the adjoint representation of  $\mathfrak{g}$  and  $\mathfrak{g}$  is semi-simple, there exists a family  $(\mathfrak{g}_i)_{i=1}^k$  of simple ideals of  $\mathfrak{g}$  such that

$$\mathfrak{g} = \mathfrak{g}_1 \oplus \dots \oplus \mathfrak{g}_k, \quad \text{and} \quad [\mathfrak{g}_i, \mathfrak{g}_i] = \mathfrak{g}_i, \quad \forall i \in \{1, \dots, k\}.$$

Hence the symmetric pair  $(G_0, H_0, \sigma_0)$  is strongly semi-simple.

Consequently, we obtain the following corollary.

**Corollary 3.3.** *On a semi-simple connected Lie group  $G$ , the canonical affine connection  $\nabla^0$  is the only special affine connection.*

Although the conclusion of this corollary fails if we replace the semi-simplicity by the reductivity as the next proposition shows.

**Proposition 3.1.** *Every reductive non semi-simple connected Lie group  $G$  admits a special affine connection which is different from the canonical one.*

*Proof.* Let  $e_0$  be a nonzero element in the center of the Lie algebra  $\mathfrak{g}$  of  $G$ . Define a product  $\star : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathfrak{g}$  on  $\mathfrak{g}$  as follows:

$$u \star v := \kappa_{\mathfrak{g}}(u, v)e_0,$$

where  $\kappa_{\mathfrak{g}} : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathbb{R}$  is the Killing form of  $\mathfrak{g}$ . A straightforward computation shows that  $\star$  is a non-trivial Poisson product on  $\mathfrak{g}$ . Hence the result follows by using Corollary 2.1.  $\square$

**Example 3.4.** Let  $(G_i, H_i, \sigma_i)$ ,  $i = 1, 2$  be two simple symmetric pairs and  $\mathfrak{g}_i = \mathfrak{m}_i \oplus \mathfrak{h}_i$  their corresponding canonical decompositions. We assume that  $\text{ad}^{\mathfrak{m}_i} : \mathfrak{h}_i \rightarrow \text{End}(\mathfrak{m}_i)$  are faithfuls and  $\mathfrak{g}_1, \mathfrak{g}_2$  are semi-simple Lie algebras. It is clear that  $(G^\times := G_1 \times G_2, H^\times := H_1 \times H_2, \sigma^\times := \sigma_1 \times \sigma_2)$  is a symmetric pair and the corresponding canonical decomposition is  $\mathfrak{g}^\times = \mathfrak{m}^\times \oplus \mathfrak{h}^\times$ , where

$$\mathfrak{m}^\times = \mathfrak{m}_1 \oplus \mathfrak{m}_2, \quad \text{and} \quad \mathfrak{h}^\times = \mathfrak{h}_1 \oplus \mathfrak{h}_2.$$

Since the adjoint representation of  $\mathfrak{h}_i$  in  $\mathfrak{m}_i$  is irreducible, we get that  $\mathfrak{m}_i$  is a simple  $\mathfrak{h}^\times$ -submodule of  $\mathfrak{m}^\times$ . In addition, using the fact that  $\mathfrak{g}_i$  is semi-simple we obtain (see [9, pp. 56]) that  $[\mathfrak{m}_i, \mathfrak{m}_i] = \mathfrak{h}_i$ . Hence, it follows that  $(G^\times, H^\times, \sigma^\times)$  is strongly semi-simple.

Now the question naturally arises whether an analogous statement for semi-simple symmetric pairs remains true. The answer to this question is no in general as the next example shows.

**Example 3.5.** Let  $H$  be the Lie group given by

$$H := \left\{ \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix} \mid A \in \text{SO}(3) \right\}.$$

Consider the Lie group  $G := \mathbb{R}^4 \rtimes H$  and define an involutive automorphism  $\sigma$  of  $G$  by:

$$\sigma : G \rightarrow G, \quad (x, \tilde{A}) \mapsto (-x, \tilde{A}),$$

for  $x \in \mathbb{R}^4$  and  $\tilde{A} := \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix} \in H$ . It is easy to check that  $(G, H, \sigma)$  is a symmetric pair. Moreover, the canonical decomposition of the Lie algebra  $\mathfrak{g}$  of  $G$  is  $\mathfrak{g} = \mathfrak{m} \oplus_{\rtimes} \mathfrak{h}$ , where

$$\mathfrak{m} = \{(u, 0) \in \mathfrak{g} \mid u \in \mathbb{R}^4\},$$

and

$$\mathfrak{h} = \left\{ (0, \hat{X}) \in \mathfrak{g} \mid \hat{X} := \begin{pmatrix} X & 0 \\ 0 & 0 \end{pmatrix}, X \in \mathfrak{so}(3) \right\}.$$

On the other hand, since the Lie bracket of  $\mathfrak{g}$  is given by

$$[(u, \widehat{X}), (v, \widehat{Y})] := \left( \widehat{X}v - \widehat{Y}u, \widehat{[X, Y]} \right), \quad \forall (u, \widehat{X}), (v, \widehat{Y}) \in \mathfrak{g}.$$

Then, under the identification of  $\mathfrak{m}$  with  $\mathbb{R}^4$ , we obtain that the isotropy representation of  $\mathfrak{h}$  in  $\mathfrak{m}$  is

$$\begin{aligned} \text{ad}^{\mathfrak{m}} : \quad \mathfrak{h} &\longrightarrow \mathfrak{gl}(4, \mathbb{R}) \\ (0, \widehat{X}) &\longmapsto \widehat{X}. \end{aligned}$$

Let  $(e_i)_{1 \leq i \leq 4}$  be the canonical basis of  $\mathbb{R}^4$ , then we can easily check that  $\mathfrak{m}_0 := \text{span}\{e_4\}$  and  $\mathfrak{m}_1 := \text{span}\{e_1, e_2, e_3\}$  are simple  $\mathfrak{h}$ -submodules of  $\mathfrak{m}$  such that  $\mathfrak{m} = \mathfrak{m}_0 \oplus \mathfrak{m}_1$ . Thus the isotropy representation of  $\mathfrak{h}$  in  $\mathfrak{m}$  is completely reducible and therefore  $(G, H, \sigma)$  is semi-simple. But  $(G, H, \sigma)$  is not strongly semi-simple, because  $[\mathfrak{m}, \mathfrak{m}] = \{0\}$ .

Now, we will show that there exists a non-trivial special product on  $\mathfrak{m} \cong \mathbb{R}^4$ . First we identify  $\mathbb{R}^4$  with  $\mathbb{R}^3 \times \mathbb{R}$  and we denote by  $\langle \cdot, \cdot \rangle$  the Euclidean inner product on  $\mathbb{R}^3$ . Define the following product

$$\star : \mathbb{R}^4 \times \mathbb{R}^4 \rightarrow \mathbb{R}^4, \quad \text{written } (x_1, t_1) \star (x_2, t_2) := (0, \langle x_1, x_2 \rangle).$$

It is obvious that  $\star$  is a non-trivial commutative, associative product on  $\mathbb{R}^4$ . Moreover, for  $x := (x_1, t_1), y := (x_2, t_2) \in \mathbb{R}^4$  and  $\tilde{A} \in H$ , we have

$$\begin{aligned} \tilde{A}x \star \tilde{A}y &= (Ax_1, t_1) \star (Ax_2, t_2) \\ &= (0, \langle Ax_1, Ax_2 \rangle) \\ &= (0, \langle x_1, x_2 \rangle) \\ &= \tilde{A}(x \star y). \end{aligned}$$

Thus the product  $\star$  is  $\text{Ad}(H)$ -invariant and hence it is a non-trivial special product on  $\mathfrak{m}$ .

#### 4. EXAMPLES OF STRONGLY SEMI-SIMPLE SYMMETRIC PAIRS

This section is devoted to give some examples of strongly semi-simple symmetric pairs, namely, Cartan's symmetric pairs and Semi-simple Riemannian symmetric pairs. Before going further, we start by recalling some definitions and properties that will be needed later. In what follows,  $(\mathfrak{g}, [ , ])$  will be a real Lie algebra and  $\kappa_{\mathfrak{g}} : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathbb{R}$  its Killing form.

**Definition 4.1.** *A Cartan involution of  $\mathfrak{g}$  is an involutive automorphism  $\tau$  of  $\mathfrak{g}$  such that the symmetric bilinear form  $\langle \cdot, \cdot \rangle : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathbb{R}$  written  $\langle u, v \rangle := -\kappa_{\mathfrak{g}}(u, \tau(v))$ , is positive definite.*

Note that if  $\tau$  is a Cartan involution of  $\mathfrak{g}$ , then  $\mathfrak{g}$  splits as a direct sum of  $\mathfrak{h}^{\tau} := \ker(\tau - \text{Id}_{\mathfrak{g}})$  and  $\mathfrak{m}^{\tau} := \ker(\tau + \text{Id}_{\mathfrak{g}})$ . Moreover, since  $\langle \cdot, \cdot \rangle$  is positive definite we get that the Killing form  $\kappa_{\mathfrak{g}}$  of  $\mathfrak{g}$  is negative definite on  $\mathfrak{h}^{\tau}$  and positive definite on  $\mathfrak{m}^{\tau}$ . Further,  $\langle \cdot, \cdot \rangle$  is  $\text{ad}(\mathfrak{h}^{\tau})$ -invariant and the following inclusions hold

$$[\mathfrak{h}^{\tau}, \mathfrak{h}^{\tau}] \subseteq \mathfrak{h}^{\tau}, \quad [\mathfrak{h}^{\tau}, \mathfrak{m}^{\tau}] \subseteq \mathfrak{m}^{\tau}, \quad \text{and} \quad [\mathfrak{m}^{\tau}, \mathfrak{m}^{\tau}] \subseteq \mathfrak{h}^{\tau}.$$

The decomposition  $\mathfrak{g} = \mathfrak{m}^\tau \oplus \mathfrak{h}^\tau$  is called the *Cartan decomposition* with respect to  $\tau$ , and the inclusion  $[\mathfrak{h}^\tau, \mathfrak{m}^\tau] \subseteq \mathfrak{m}^\tau$  gives rise to a representation  $\text{ad}^{\mathfrak{m}^\tau} : \mathfrak{h}^\tau \rightarrow \text{End}(\mathfrak{m}^\tau)$  which is also called the isotropy representation of  $\mathfrak{h}^\tau$  in  $\mathfrak{m}^\tau$ . Note that the fact that  $\langle \cdot, \cdot \rangle$  is positive definite implies that  $\mathfrak{g}$  is a semi-simple Lie algebra and it is compact if and only if  $\tau = \text{Id}_{\mathfrak{g}}$ .

**Proposition 4.1.** *Let  $\tau$  be a Cartan involution of  $\mathfrak{g}$  and  $\mathfrak{g} = \mathfrak{m}^\tau \oplus \mathfrak{h}^\tau$  the corresponding Cartan decomposition. Then*

1. *If  $(\mathfrak{g}_i)_{i=1}^k$  is a family of simple ideals of  $\mathfrak{g}$  such that  $\mathfrak{g} = \bigoplus_{i=1}^k \mathfrak{g}_i$ , then for  $i \neq j$ ,  $\mathfrak{g}_i$  and  $\mathfrak{g}_j$  are mutually orthogonal with respect to  $\kappa_{\mathfrak{g}}$ .*
2.  *$\mathfrak{h}^\tau$  and  $\mathfrak{m}^\tau$  are mutually orthogonal with respect to  $\kappa_{\mathfrak{g}}$ .*
3. *If  $\mathfrak{p}$  is a nonzero  $\mathfrak{h}^\tau$ -submodule of  $\mathfrak{m}^\tau$ , then  $[\mathfrak{m}^\tau, \mathfrak{p}] = [\mathfrak{p}, \mathfrak{p}]$ . In particular,  $[\mathfrak{p}, \mathfrak{p}] \neq \{0\}$  and  $\mathfrak{p} \oplus [\mathfrak{p}, \mathfrak{p}]$  is an ideal of  $\mathfrak{g}$ .*

*Proof.* The first and the second statement are clear. For the last one, let  $\mathfrak{p}$  be a nonzero  $\mathfrak{h}^\tau$ -submodule of  $\mathfrak{m}^\tau$  and denote by  $\mathfrak{p}^\perp \subset \mathfrak{m}^\tau$  its orthogonal complement with respect to  $\langle \cdot, \cdot \rangle$ , i.e.  $\mathfrak{m}^\tau = \mathfrak{p} \oplus \mathfrak{p}^\perp$ . Take  $u \in \mathfrak{p}$  and  $v \in \mathfrak{p}^\perp$ , then we have

$$\begin{aligned} \langle [u, v], [u, v] \rangle &= \kappa_{\mathfrak{g}}([v, u], [u, v]) \\ &= \kappa_{\mathfrak{g}}(v, [u, [u, v]]) \\ &= \langle [[u, v], u], v \rangle \\ &= 0. \end{aligned}$$

Thus  $[\mathfrak{p}, \mathfrak{p}^\perp] = \{0\}$  and therefore  $[\mathfrak{m}^\tau, \mathfrak{p}] = [\mathfrak{p}, \mathfrak{p}]$ . If  $[\mathfrak{p}, \mathfrak{p}] = \{0\}$ , then  $\mathfrak{p}$  will be a nonzero abelian ideal of  $\mathfrak{g}$ , which is impossible because  $\mathfrak{g}$  is semi-simple. Finally, using Jacobi identity we can easily check that  $\mathfrak{p} \oplus [\mathfrak{p}, \mathfrak{p}]$  is an ideal of  $\mathfrak{g}$ .  $\square$

**Definition 4.2.** *The symmetric pair  $(G, H, \sigma)$  is called a Cartan symmetric pair if the tangent map of  $\sigma$  at the identity element (also denoted by  $\sigma$ ) is a Cartan involution of the Lie algebra  $\mathfrak{g}$  of  $G$ .*

**Example 4.1.** The example type is  $(\text{SL}(n, \mathbb{R}), \text{SO}(n), \sigma^*)$ , where  $\sigma^*$  is given by  $\sigma^*(A) := (A^{-1})^T$ . Geometrically, the symmetric space associated to this symmetric pair is the set of all real symmetric positive definite  $n$ -matrices with determinant 1.

The following proposition shows that all Cartan's symmetric pairs are strongly semi-simple.

**Proposition 4.2.** *If  $(G, H, \sigma)$  is a Cartan symmetric pair, then it is strongly semi-simple.*

*Proof.* First, let us show that the isotropy representation of  $\mathfrak{h}$  in  $\mathfrak{m}$  is completely reducible. To do this it suffices to prove that each  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$  possesses an  $\mathfrak{h}$ -submodule complement. Let  $\mathfrak{p} \subseteq \mathfrak{m}$  be an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$  and denote by  $\mathfrak{p}^\perp \subseteq \mathfrak{m}$  its orthogonal complement with respect to  $\langle \cdot, \cdot \rangle$ . Clearly that  $\mathfrak{m} = \mathfrak{p} \oplus \mathfrak{p}^\perp$ , and for  $u \in \mathfrak{p}^\perp, v \in \mathfrak{p}, a \in \mathfrak{h}$  we have

$$\langle [a, u], v \rangle = -\langle u, [a, v] \rangle = 0.$$

Hence  $\mathfrak{p}^\perp$  is an  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$ . Now, if  $(\mathfrak{m}_i)_{i=1}^k$  is a family of simple  $\mathfrak{h}$ -submodules of  $\mathfrak{m}$  such that  $\mathfrak{m} = \bigoplus_{i=1}^k \mathfrak{m}_i$ , then using the last assertion in Proposition 4.1 we deduce that  $[\mathfrak{m}_i, \mathfrak{m}_i] \neq \{0\}$  for all  $i \in \{1, \dots, k\}$ . Thus  $(\mathfrak{m}_i)_{i=1}^k$  is a strongly decomposition of  $\mathfrak{m}$ .  $\square$

Now, recall that, if  $\mathfrak{g}$  is a simple Lie algebra and  $H$  is compact, then  $(G, H, \sigma)$  is a simple symmetric pair with  $\dim \mathfrak{m} > 1$ . It follows that the canonical affine connection is the only special affine connection on  $M$ . The following proposition shows that the last conclusion remains true if we replace the simplicity of  $\mathfrak{g}$  by the semi-simplicity.

**Proposition 4.3.** *If  $\mathfrak{g}$  is a semi-simple Lie algebra and  $H$  is compact, then the symmetric pair  $(G, H, \sigma)$  is strongly semi-simple.*

*Proof.* Since  $H$  is compact, let  $\langle \cdot, \cdot \rangle$  be an  $\text{Ad}(H)$ -invariant inner product on  $\mathfrak{g}$ , and define a linear endomorphism  $\phi : \mathfrak{m} \rightarrow \mathfrak{m}$  by

$$\kappa_{\mathfrak{g}}(u, v) = \langle \phi(u), v \rangle, \quad \forall u, v \in \mathfrak{m}.$$

A direct computation using the fact that  $\langle \cdot, \cdot \rangle$  and  $\kappa_{\mathfrak{g}}$  are both  $\text{Ad}(H)$ -invariant, symmetric bilinear forms, one can easily check that  $\phi$  is symmetric with respect to  $\langle \cdot, \cdot \rangle$  and commutes with all  $\text{ad}_u$  for  $u \in \mathfrak{h}$ . Thus, there is a direct sum decomposition  $\mathfrak{m} = \bigoplus_{i=1}^r \mathfrak{p}_i$  such that  $\phi|_{\mathfrak{p}_i} = t_i \text{Id}_{\mathfrak{p}_i}$  with  $t_i \in \mathbb{R}^*$  and  $t_i \neq t_j$  for  $i \neq j$ . Moreover,  $(\mathfrak{p}_i)_{i=1}^r$  are  $\mathfrak{h}$ -submodules of  $\mathfrak{m}$  which are mutually orthogonal with respect to  $\langle \cdot, \cdot \rangle$ . Hence there exists a direct sum decomposition  $\mathfrak{m} = \bigoplus_{i=1}^k \mathfrak{m}_i$  such that each  $\mathfrak{m}_i$  is a simple  $\mathfrak{h}$ -submodule of  $\mathfrak{m}$  which is contained in some  $\mathfrak{p}_{i'}$  and  $(\mathfrak{m}_i)_{i=1}^k$  are mutually orthogonal with respect to  $\langle \cdot, \cdot \rangle$ . Furthermore, if  $u_i \in \mathfrak{m}_i$  and  $u_j \in \mathfrak{m}_j$ , then

$$\begin{aligned} \kappa_{\mathfrak{g}}([u_i, u_j], [u_i, u_j]) &= \kappa_{\mathfrak{g}}(u_j, [[u_i, u_j], u_i]) \\ &= t_{j'} \langle u_j, [[u_i, u_j], u_i] \rangle \\ &= 0. \end{aligned}$$

Since  $\text{ad}_u : \mathfrak{g} \rightarrow \mathfrak{g}$  is skew-symmetric with respect to  $\langle \cdot, \cdot \rangle$  for  $u \in \mathfrak{h}$  and  $\mathfrak{g}$  is semi-simple, one can easily check that  $\kappa_{\mathfrak{g}}$  is negative definite on  $\mathfrak{h}$  and therefore  $[\mathfrak{m}_i, \mathfrak{m}_j] = \{0\}$ . Thus  $[\mathfrak{m}_i, \mathfrak{m}_i] \neq \{0\}$  for all  $i \in \{1, \dots, k\}$ , which proves that  $(G, H, \sigma)$  is strongly semi-simple.  $\square$

## 5. EXAMPLES OF SYMMETRIC SPACES WITH SPECIAL AFFINE CONNECTIONS

This section is devoted to give examples of symmetric spaces on which there is a special affine connection which is different from the canonical one. We start by recalling some basic facts on how one can get a symmetric space from a Jordan algebra.

**Definition 5.1.** *A Jordan algebra is a commutative algebra  $(\mathbf{A}, \cdot)$  in which the following identity*

$$x.(x^2.y) = x^2.(x.y),$$

*holds.*

**Example 5.1.** *The trivial example is a commutative, associative algebra.*

It is well known (see for example [4]) that to each Jordan algebra  $(\mathbf{A}, \cdot)$ , we can associate (Tits-Kantor-Koecher construction) a  $\mathbb{Z}_2$ -grading of a Lie algebra  $\mathfrak{g}^{\mathbf{A}} = \mathfrak{h}^{\mathbf{A}} \oplus \mathfrak{m}^{\mathbf{A}}$  as follows: we define

$$\mathfrak{g}_{-1}^{\mathbf{A}} := \mathbf{A}, \quad \mathfrak{g}_0^{\mathbf{A}} := \text{span} \{ L_x, [L_y, L_z] / x, y, z \in \mathbf{A} \} \subset \text{End}(\mathbf{A}),$$

and

$$\mathfrak{g}_1^{\mathbf{A}} := \text{span} \{ L, [L_x, L] / x \in \mathbf{A} \} \subset \text{Hom}(S^2 \mathbf{A}, \mathbf{A}),$$

where  $L(x, y) = L_x y := x \cdot y$ , and  $[L_x, L](y, z) := [L_x, L_y](z) - L_{x \cdot y}(z)$ , for  $x, y, z \in \mathbf{A}$ . Then we set

$$\mathfrak{g}^{\mathbf{A}} := \mathfrak{g}_0^{\mathbf{A}} \oplus \mathfrak{g}_{-1}^{\mathbf{A}} \oplus \mathfrak{g}_1^{\mathbf{A}},$$

and we get that  $\mathfrak{g}^{\mathbf{A}}$  is a short  $\mathbb{Z}$ -grading of a Lie algebra with the following Lie bracket:

- $[x, y] = [A, B] := 0$ , for  $x, y \in \mathfrak{g}_{-1}^{\mathbf{A}}$  and  $A, B \in \mathfrak{g}_1^{\mathbf{A}}$ ;
- $[F, x] := F(x)$ , for  $x \in \mathfrak{g}_{-1}^{\mathbf{A}}$  and  $F \in \mathfrak{g}_0^{\mathbf{A}}$ ;
- $[F, B](x, y) := F(B(x, y)) - B(F(x), y) - B(x, F(y))$ , for  $x, y \in \mathfrak{g}_{-1}^{\mathbf{A}}$ ,  $F \in \mathfrak{g}_0^{\mathbf{A}}$  and  $B \in \mathfrak{g}_1^{\mathbf{A}}$ ;
- $[B, x](y) := B(x, y)$ , for  $x \in \mathfrak{g}_{-1}^{\mathbf{A}}$  and  $B \in \mathfrak{g}_1^{\mathbf{A}}$ .

Hence, if we set  $\mathfrak{h}^{\mathbf{A}} := \mathfrak{g}_0^{\mathbf{A}}$  and  $\mathfrak{m}^{\mathbf{A}} := \mathfrak{g}_{-1}^{\mathbf{A}} \oplus \mathfrak{g}_1^{\mathbf{A}}$ , we deduce that  $\mathfrak{g}^{\mathbf{A}} = \mathfrak{h}^{\mathbf{A}} \oplus \mathfrak{m}^{\mathbf{A}}$  is a  $\mathbb{Z}_2$ -grading of a Lie algebra, i.e.,

$$[\mathfrak{h}^{\mathbf{A}}, \mathfrak{h}^{\mathbf{A}}] \subseteq \mathfrak{h}^{\mathbf{A}}, \quad [\mathfrak{h}^{\mathbf{A}}, \mathfrak{m}^{\mathbf{A}}] \subseteq \mathfrak{m}^{\mathbf{A}}, \quad \text{and} \quad [\mathfrak{m}^{\mathbf{A}}, \mathfrak{m}^{\mathbf{A}}] \subseteq \mathfrak{h}^{\mathbf{A}}.$$

In summary, any Jordan algebra  $(\mathbf{A}, \cdot)$  gives rise to a  $\mathbb{Z}_2$ -grading of a Lie algebra  $\mathfrak{g}^{\mathbf{A}} = \mathfrak{h}^{\mathbf{A}} \oplus \mathfrak{m}^{\mathbf{A}}$ , and therefore (see [2, Theorem I.1.3]) to a simply connected symmetric space  $M^{\mathbf{A}}$ .

Now, we introduce a particular subclass of associative algebras, which will be used to construct our examples.

**Definition 5.2.** *An associative algebra  $(\mathbf{A}, \cdot)$  is called 0-associative if*

$$x \cdot y \cdot z = 0, \quad \forall x, y, z \in \mathbf{A}.$$

**Example 5.2.** *Let  $(V, +)$  be an  $n$ -dimensional vector space, and  $(e_i)_{1 \leq i \leq n}$  any basis of it. For  $i_1, i_2 \in \{1, \dots, n\}$  fixed such that  $i_1 \neq i_2$ , the product given by*

$$e_{i_1} \cdot e_{i_1} = e_{i_2}, \quad \text{and} \quad e_i \cdot e_j = 0,$$

*for  $\{i, j\} \neq \{i_1, i_1\}$ , is (commutative) 0-associative.*

**Example 5.3.** *Let  $(\mathbf{A}, \cdot)$  be a symmetric Leibniz algebra, i.e., an algebra  $(\mathbf{A}, \cdot)$  such that for any  $x, y \in \mathbf{A}$ , we have*

$$[L_x, L_y] = L_{x \cdot y}, \quad \text{and} \quad [R_x, R_y] = R_{y \cdot x},$$

*where  $L_x, R_x \in \text{End}(\mathbf{A})$  are defined by  $L_x(y) := x \cdot y$  and  $R_x(y) := y \cdot x$ . If we consider the product  $*$  on  $\mathbf{A}$  given by*

$$x * y := x \cdot y + y \cdot x, \quad \forall x, y \in \mathbf{A},$$

then a small computation shows that  $(\mathbf{A}, \star)$  is a (commutative) 0-associative algebra.

The proof of the following proposition is a matter of pure computation and is thus omitted.

**Proposition 5.1.** *Let  $(\mathbf{A}, \cdot)$  be a commutative, associative algebra, then  $\mathfrak{h}^{\mathbf{A}}$  is an abelian Lie subalgebra of  $\mathfrak{g}^{\mathbf{A}}$ . Moreover, if  $(\mathbf{A}, \cdot)$  is 0-associative, then  $\mathfrak{g}^{\mathbf{A}}$  is a 2-step nilpotent algebra.*

Now, we can give a way of getting examples of symmetric spaces on which there is a special affine connection which is different from the canonical one. More precisely, we have:

**Proposition 5.2.** *Let  $(\mathbf{A}, \cdot)$  be a commutative, 0-associative algebra, then there is a special affine connection on its associated symmetric space  $M^{\mathbf{A}}$  which is different from the canonical one.*

*Proof.* According to Theorem (1.1) it suffices to define a commutative, associative, and  $\text{ad}(\mathfrak{h}^{\mathbf{A}})$ -invariant product on  $\mathfrak{m}^{\mathbf{A}}$ . We consider the following product on  $\mathfrak{m}^{\mathbf{A}}$  given by

$$\star : \mathfrak{m}^{\mathbf{A}} \times \mathfrak{m}^{\mathbf{A}} \rightarrow \mathfrak{m}^{\mathbf{A}}, \quad (x + A) \star (y + B) := x.y,$$

where " $\cdot$ " is the commutative, 0-associative product of  $\mathbf{A}$ . One can easily check that the product  $\star$  is commutative, associative, and  $\text{ad}(\mathfrak{h}^{\mathbf{A}})$ -invariant.  $\square$

## 6. HOLONOMY LIE ALGEBRA OF SPECIAL AFFINE CONNECTIONS

In this last section, we compute the holonomy Lie algebra of a special affine connection. But first, let us start with some background that should be known.

Given an affine connection  $\nabla$  on  $M$ , for any loop  $\gamma$  at  $p \in M$  the parallel transport along  $\gamma$  is a linear isomorphism of  $T_p M$ , and the set of such linear isomorphisms for all loops at  $p$  forms a group which is called the *holonomy group* of  $\nabla$  based at  $p$  and denoted by  $\text{Hol}_p(\nabla)$ . The *restricted holonomy group*  $\text{Hol}_p^0(\nabla)$  is the subgroup composed of parallel transports along all contractible loops at  $p$ . It is well known (see [5, Chap 2. Theorem 4.2]) that  $\text{Hol}_p^0(\nabla)$  is the identity component of  $\text{Hol}_p(\nabla)$  and that  $\text{Hol}_p^0(\nabla)$  is a connected Lie group. The *holonomy Lie algebra* of  $\nabla$  based at  $p$  is the Lie algebra of  $\text{Hol}_p^0(\nabla)$ . On the other hand, consider the vector subspace  $\mathfrak{hol}_p^\nabla$  of  $\text{End}(T_p M)$  which is generated by all linear endomorphisms of the form  $R^\nabla(u, v)$ ,  $(\nabla_w R^\nabla)(u, v)$ ,  $(\nabla_z \nabla_w R^\nabla)(u, v)$ ,  $\dots$ , where  $u, v, w, z, \dots$  are arbitrary tangent vectors at  $p$ . It was shown in [8, Lemma 4.2] that it is a Lie subalgebra of  $\text{End}(T_p M)$  and we call it the *infinitesimal holonomy Lie algebra* at  $p$ . The immersed Lie subgroup of  $\text{GL}(T_p M)$  generated by  $\mathfrak{hol}_p^\nabla$  is the *infinitesimal holonomy group* at  $p$ . The main result (see [8, Theorem 7]) is that the restricted holonomy group is equal to the infinitesimal holonomy group at every point.

According to our discussion above, since the curvature tensor  $R^0$  of the canonical affine connection  $\nabla^0$  is parallel (i.e.,  $\nabla^0 R^0 = 0$ ), then under the identification of  $\mathfrak{m}$

with  $T_oM$ , the holonomy Lie algebra of  $\nabla^0$  at the origin  $o \in M$  is given by

$$\mathfrak{hol}_o^{\nabla^0} = \text{ad}_{[\mathfrak{m}, \mathfrak{m}]}.$$

If  $\nabla$  is an arbitrary  $G$ -invariant affine connection on  $M$ , then by [5, Chap 10. Theorem 4.4] and under the identification of  $\mathfrak{m}$  with  $T_oM$ , the holonomy Lie algebra of  $\nabla$  at  $o \in M$  is the smallest Lie subalgebra  $\mathfrak{hol}_o^\nabla$  of  $\text{End}(\mathfrak{m})$  which satisfies the following two conditions

- (1) For all  $u, v \in \mathfrak{m}$ ,  $R^\nabla(u, v) \in \mathfrak{hol}_o^\nabla$ ;
- (2) For all  $u \in \mathfrak{m}$ ,  $[\alpha_u^\nabla, \mathfrak{hol}_o^\nabla] \subseteq \mathfrak{hol}_o^\nabla$ ,

where  $\alpha^\nabla : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  is the bilinear map associated to  $\nabla$  and  $\alpha_u^\nabla \in \text{End}(\mathfrak{m})$  is defined by  $\alpha_u^\nabla(v) := \alpha^\nabla(u, v)$ . Although the holonomy Lie algebra of a  $G$ -invariant affine connection on  $M$  is difficult to compute explicitly, it turns out that the holonomy Lie algebra of a special affine connection on  $M$  can be easily computed as the next proposition shows.

**Proposition 6.1.** *Let  $\nabla$  be a special affine connection on  $M$ . Then the holonomy Lie algebra of  $\nabla$  at the origin  $o \in M$  is given by*

$$\mathfrak{hol}_o^\nabla = \text{ad}_{[\mathfrak{m}, \mathfrak{m}]} + \alpha_{[[\mathfrak{m}, \mathfrak{m}], \mathfrak{m}]},$$

where  $\alpha^\nabla : \mathfrak{m} \times \mathfrak{m} \rightarrow \mathfrak{m}$  is the bilinear map associated to  $\nabla$ .

*Proof.* For a special affine connection  $\nabla$  on  $M$ , by (2.1) and (2.3) one has

$$[\text{ad}_{[u, v]}, \alpha_w^\nabla] = \alpha_{[[u, v], w]}^\nabla, \quad R^\nabla(u, v) = -\text{ad}_{[u, v]}, \quad \text{and} \quad [\alpha_u^\nabla, \alpha_v^\nabla] = 0,$$

for all  $u, v, w \in \mathfrak{m}$ . Thus the Lie algebra  $\text{ad}_{[\mathfrak{m}, \mathfrak{m}]} + \alpha_{[[\mathfrak{m}, \mathfrak{m}], \mathfrak{m}]}^\nabla$  satisfies 1 and 2, so it contains  $\mathfrak{hol}_o^\nabla$ . On the other hand, for  $x, y, z, u, v \in \mathfrak{m}$

$$\begin{aligned} \text{ad}_{[u, v]} + \alpha_{[[x, y], z]}^\nabla &= \text{ad}_{[u, v]} + [\text{ad}_{[x, y]}, \alpha_z^\nabla] \\ &= R^\nabla(v, u) + [\alpha_z^\nabla, R^\nabla(x, y)] \in \mathfrak{hol}_o^\nabla. \end{aligned}$$

This proves the other inclusion, and hence the claim.  $\square$

**ACKNOWLEDGMENT** We thank the referee for carefully reading the paper, as well as for his valuable suggestions and helpful corrections which significantly improved the article.
