#### Abstract

Family Puzzle or Generation Problem demands an explanation of why there are 3 families or generations of quarks and leptons in the Standard Model of particle physics. Here we propose a novel solution - the multiple of 3 families of 16 Weyl fermions (namely $\left.\left(N_{f}=3\right) \times 16\right)$ in the $3+1 \mathrm{~d}$ spacetime dimensions are topologically robust due to constraints rooted in profound mathematics (such as Hirzebruch signature and Rokhlin's theorems, and cobordism) and derivable in physics (such as chiral edge states, quantized thermal Hall conductance, and gravitational Chern-Simons theory), which holds true even forgetting or getting rid of any global symmetry or gauge structure of the Standard Model. By the dimensional reduction through a sequence of sign-reversing mass domain wall of domain wall and so on, we reduce the Standard Model fermions to obtain the $\left(N_{f}=3\right) \times 16$ multiple of $1+1$ d Majorana-Weyl fermion with a total chiral central charge $c_{-}=24$. Effectively via the fermionization-bosonization, the $1+1 \mathrm{~d}$ theory becomes 3 copies of $c_{-}=8$ of $\left(\mathrm{E}_{8}\right)_{1}$ conformal field theory, living on the boundary of 3 copies of $2+1 \mathrm{~d} \mathrm{E}_{8}$ quantum Hall states. Based on the framing anomaly-free $c_{-}=0 \bmod 24$ modular invariance, the framed bordism and string bordism $\mathbb{Z}_{24}$ class, the 2 -framing and $p_{1}$-structure, the $w_{1}-p_{1}$ bordism $\mathbb{Z}_{3}$ class constraints, we derive the family number constraint $N_{f} \in\left(\frac{48}{16}=\frac{24}{8}=3\right) \mathbb{Z}$. The dimensional reduction process, although not necessary, is sufficiently supported by the $\mathbb{Z}_{16}$ class Smith homomorphism. We also comment on the $\frac{45}{15}=3$ relation: the 3 families of 15 Weyl-fermion Standard Model vacuum where the absence of some sterile right-handed neutrinos is fulfilled by additional topological field theories or conformal field theories in Ultra Unification.

## I. INTRODUCTION AND SUMMARY

## A. Family Puzzle

The 3 families or 3 generations of quarks and leptons of the Standard Model (SM) of particle physics had been advocated since the 1970s [1]. The Family Puzzle or Generation Problem demands an explanation of what dictates the SM family number $N_{f}=3$. Any valid theoretical solution to this puzzle, unraveling the SM's underlying mysterious structure, can guide us further to explore Beyond the Standard Model physics (BSM) with elevated confidence, making new predictions. What is the evidence of $N_{f}=3$ ?

On one hand, in the quark sector, the (C)KM matrix indicates that the charge-conjugation-parity CP symmetry violation of quarks via the weak interaction predicts the existence of at least 3 families of quarks in nature theoretically [2]. The discovery of the most massive known elementary particle, top quark $t$, in 1995 by the CDF and $\mathrm{D} \varnothing$ experiments at the Fermilab [3, 4] confirmed the completion of 3 families of quarks experimentally. Moreover, if there is any gapped hypothetical 4th generation of quarks massive than $t$ quark, say $t^{\prime}$ and $b^{\prime}$ quarks, the Higgs decay rate to two gluons $\phi_{H} \rightarrow g g$ through loop triangle Feynman diagrams of 3 types of virtual massive quarks $\left(t, t^{\prime}, b^{\prime}\right)$ will be enhanced by a factor of $3^{2}=9$ times larger than the SM prediction, but which possibility has been excluded [5].

On the other hand, in the lepton sector, the $Z$ boson (the third most massive known particle of about 91 GeV ) decays into at most 3 families of light neutrinos (assuming light neutrinos are lighter than about 45 GeV , namely mass $m_{\nu}<m_{Z} / 2$ ), verified at CERN's Large Electron Positron Collider (LEP) [6, 7]. In addition, the astrophysical data from the cosmic microwave background (CMB) or big bang nucleosythesis (BBN) also suggest 3 families of light neutrinos [8].

Here we show a novel theoretical solution to the Family Puzzle - the multiple of $N_{f}=3$ of 16 Weyl fermions in the $3+1$ d spacetime dimensions are robust due to the almost purely topological constraints (without requiring internal symmetry, neither global symmetry nor gauge structure) rooted in the profound mathematics and derivable in physics. ${ }^{1}$

## B. Background Information

To understand and appreciate our solution better, some prior knowledge and familiarity with literature can help:

- (1) Modular invariance of 2d conformal field theory (CFT) [12] and 3d Chern-Simons-Witten and gravitational Chern-Simons theories [13]: framing anomaly-free with chiral central charge $c_{-}=0 \bmod 24 .{ }^{2}$
- (2) Mapping between fermions by domain-wall reduction (see Fig. 1 and Fig. 2): crossing different dimensions by the sign-reversing mass domain wall of domain wall and so on. We will introduce a toy model (following [14]) as the explicit mass domain wall $m(x)$ reincarnation version of Jackiw-Rebbi [15] or Callan-Harvey [16] where they introduce instead some additional scalar field $\Phi(x)$. Our mass domain wall does not require extra scalar field and does not necessarily implement symmetry-breaking mass; in contrast, other related (similar but not exactly the same) recent models that explore the symmetry-breaking domain wall and anomaly inflow include [17-20]. A lattice version of our model can be implemented as the domain wall of the domain wall fermion of Kaplan's [21] and so on.
- (3) Cobordism theory $[22,23]$ and Atiyah-Patodi-Singer (APS) eta invariant $\eta[24]$. Given the spacetime and internal symmetry $G$ structure of manifold ${ }^{3}$

$$
\begin{equation*}
G \equiv\left(\frac{G_{\text {spacetime }} \ltimes G_{\text {internal }}}{N_{\text {shared }}}\right) \equiv G_{\text {spacetime }} \ltimes_{N_{\text {shared }}} G_{\text {internal }} \tag{1}
\end{equation*}
$$

we will apply the data of bordism group $\Omega_{D}^{G}$ that classifies the $G$-structure $D$-dimensional ( $D \mathrm{~d}$ ) manifold $M^{D}$ up to the cobordant relation (identified by bounding the $(D+1)$ d manifold), and the Anderson dual version of the cobordism group $\mathrm{TP}_{D}^{G}$ that classifies the $D$ d invertible field theories or $D$ d Symmetry-Protected Topological states (SPTs)

[^1]realized in quantum condensed matter, and their boundary's $(D-1)$ d quantum anomalies (e.g., [25-29]). ${ }^{4}$ Later we will use freely these relation between the co/bordism and the classification of manifolds vs invertible field theories. The $G_{\text {internal }}$ implies the structure group of the principal bundle and gauge connection. The $G_{\text {spacetime }}=\operatorname{Spin}, \operatorname{Pin}{ }^{ \pm}, \ldots$ can contain the fermionic Lorentz group structure (rotation + boost) such as Spin group or the time-reversal or reflection-symmetry enhanced $\mathrm{Pin}^{ \pm}$group [22]. Moreover, we emphasize that our Family Puzzle solution require nothing of any specific $G_{\text {internal }}$ of the SM nor any specific $G_{\text {spacetime }}$, except only the tangential structure of manifold (denoted Struct). We will apply the data of bordism group $\Omega_{d}^{\text {Struct }}$ and cobordism group $\mathrm{TP}_{d}^{\text {Struct }}$ where the tangential structure can include the characteristic class [34] defined by tangent bundles: the Steifel-Whitney class (e.g. w1, w $w_{2}$ ) or String structure, and the Pontryagin class (e.g. $p_{1}$ ), or Witten's framing structure [13], or Atiyah's 2-framing structure [35]. In particular, we will study the 3 -manifold bounding the boundary of a 4 -manifold, and we will use the relation between (a) framing provides the String structure, and (2) 2-framing provides the $w_{1}-p_{1}$-structure. For Family Puzzle, we will need the following structures:

Structure $:=\left\{\begin{array}{l}\text { (a) framing (fr): trivialization of tangent bundle } T M \\ \simeq \text { String structure: trivialization of } w_{1}(T M), w_{2}(T M) \text {, and } \frac{1}{2} p_{1}(T M) \text {. } \\ (\mathrm{b}) \text { 2-framing (2-fr): trivialization of the spin bundle of } 2 \text { copies of the tangent bundle } T M \oplus T M \\ \simeq w_{1}-p_{1} \text {-structure: trivialization of } w_{1}(T M) \text { and } p_{1}(T M) .\end{array}\right.$

- (4) Atiyah-Singer index theorem (e.g.[36]), specifically Hirzebruch signature [10] and Rokhlin's [37] theorems.

## II. PHYSICS MODEL SETUP

Standard Model (SM) [38] is a 4d chiral gauge theory with Yang-Mills spin-1 gauge fields of the Lie algebra $\mathcal{G}_{\mathrm{SM}} \equiv s u(3) \times s u(2) \times u(1)_{\tilde{Y}}$ (with four compatible Lie group $G_{\mathrm{SM}_{\mathrm{q}}} \equiv \frac{\operatorname{SU}(3) \times \operatorname{SU}(2) \times \mathrm{U}(1)_{\tilde{r}}}{\mathbb{Z}_{\mathrm{q}}}$, with $\mathrm{q}=1,2,3,6$ ) coupling to $N_{f}=3$ families of 15 or 16 Weyl fermions (spin- $\frac{1}{2}$ Weyl spinor in the $\mathbf{2}_{L}^{\mathbb{C}}$ representation of the spacetime symmetry $\operatorname{Spin}(1,3)$, written as a left-handed 15 - or 16 -plet $\left.\psi_{L}\right)$ in the following $\mathcal{G}_{\text {SM }}$ representation

$$
\begin{equation*}
\left(\psi_{L}\right)_{\mathrm{I}}=\left(\bar{d}_{R} \oplus l_{L} \oplus q_{L} \oplus \bar{u}_{R} \oplus \bar{e}_{R}\right)_{\mathrm{I}} \oplus n_{\nu_{\mathrm{I}, R}} \bar{\nu}_{\mathrm{I}, R} \sim\left((\overline{\mathbf{3}}, \mathbf{1})_{2} \oplus(\mathbf{1}, \mathbf{2})_{-3} \oplus(\mathbf{3}, \mathbf{2})_{1} \oplus(\overline{\mathbf{3}}, \mathbf{1})_{-4} \oplus(\mathbf{1}, \mathbf{1})_{6}\right)_{\mathrm{I}} \oplus n_{\nu_{\mathrm{I}, R}}(\mathbf{1}, \mathbf{1})_{0} \tag{4}
\end{equation*}
$$

for each family label $\mathrm{I}=1,2,3$. The right-handed neutrino $\bar{\nu}_{R}$ is written as right-handed anti-particle so to be regarded as a left-handed particle. The $n_{\nu_{e, R}}, n_{\nu_{\mu, R}}, n_{\nu_{\tau, R}} \in\{0,1\}$ for $\mathrm{I}=1,2,3$ labels either the absence or presence of electron $e$, muon $\mu$, or tauon $\tau$ types of sterile neutrinos (i.e., "right-handed" neutrinos sterile to $\mathcal{G}_{\text {SM }}$ gauge forces). There are also additional Yukawa-Higgs terms. But none of these are crucial to our solution except the total number of Weyl fermions -

$$
\begin{equation*}
\left(N_{f}=3\right) \times 15+n_{\nu_{e, R}}+n_{\nu_{\mu, R}}+n_{\nu_{\tau, R}}=45,46,47,48, \ldots \tag{5}
\end{equation*}
$$

For simplicity, we focus on the 48-Weyl-fermion SM first in the limit of massless fermions, turning off the SM gauge structure and SM Higgs mechanism while relegating those extra refined structures to later discussions. ${ }^{5}$ We will comment on other fermion numbers later.

[^2][^3]
## A. General Arguments: $c_{-}=24$ and $3\left(\mathrm{E}_{8}\right)_{1}$ Conformal Field Theories

What absolutely crucial is the dimension-reduction relationship between $3+1 \mathrm{~d}$ 's 48 Weyl fermions in (5) and the $1+1 \mathrm{~d} 48$ Majorana-Weyl fermion (each with chiral central charge $c_{-}=\frac{1}{2}$ ) with a combined chiral central charge

$$
\begin{equation*}
c_{-} \equiv c_{L}-c_{R}=\frac{1}{2} 48=24 . \tag{6}
\end{equation*}
$$

Here are the steps of our arguments (here succinctly summarizing the main logic, later we will fill in more details):
(1): Mass domain wall reduction maps between fermions as Lorentz $\operatorname{Spin}(d, 1)$ spinors crossing different dimensions (see Fig. 1 (a)):
$4+1 \mathrm{~d}$ Dirac $\psi_{\mathrm{D}}^{5 d} \rightarrow 3+1 \mathrm{~d}$ Weyl $\psi_{\mathrm{W}}^{4 d} \sim 3+1 \mathrm{~d}$ Majorana $\psi_{\mathrm{M}}^{4 d} \rightarrow 2+1 \mathrm{~d}$ Majorana $\psi_{\mathrm{M}}^{3 d} \rightarrow 1+1 \mathrm{~d}$ Majorana-Weyl $\psi_{\mathrm{MW}}^{2 d} \cdot$
(i): A single $(d+1) \mathrm{d}$ Dirac or Majorana fermion allows to pair themselves with Dirac or Majorana mass term respectively by the fermion bilinear $m \bar{\psi} \psi \equiv m \psi^{\dagger} \Gamma^{0} \psi$.
(ii): Whenever the massive fermion $\psi^{d+1}$ is allowed in $(d+1) \mathrm{d}$, with time and space coordinates $\left(t, x_{1}, x_{2}, \ldots, x_{d}\right)$, we may consider the spatial-dependent mass profile $m\left(x_{d}\right) \bar{\psi} \psi$ such that

$$
m\left(x_{d}\right)=\left\{\begin{array}{r}
|m|, \quad x_{d} \gg 1  \tag{8}\\
0, \quad x_{d}=0 \\
-|m|, \quad x_{d} \ll 1
\end{array}\right.
$$

The $(d+1)$ d fermion obeys the Lagrangian $\mathcal{L}_{(d+1) \mathrm{d}}=\bar{\psi}^{d+1}\left(\mathrm{i} \Gamma^{\mu} \partial_{\mu}-m(x)\right) \psi^{d+1}$ with the spacetime indices $\mu=0,1, \ldots, d$, then there is an effective massless $d \mathrm{~d}$ domain wall fermion theory $\psi^{d}$ at $x_{d}=0$, with its time and space coordinates $\left(t, x_{1}, x_{2}, \ldots, x_{d-1}\right)$, which is obtained by the projection $\mathrm{P}_{ \pm}=\frac{1 \pm \mathrm{i} \Gamma^{d}}{2}, \mathrm{so}^{6}$

$$
\begin{equation*}
\psi_{ \pm}^{d}=\mathrm{P}_{ \pm} \psi^{d+1}=\frac{1 \pm \mathrm{i} \Gamma^{d}}{2} \psi^{d+1} \tag{9}
\end{equation*}
$$

We get a dd domain wall fermion Lagrangian, either + or - version of $\mathcal{L}_{d \mathrm{~d}, \pm}=\psi_{ \pm}^{d \dagger} \mathrm{i}\left(\partial_{t}-\Gamma^{0} \Gamma^{j} \partial_{j}\right) \psi_{ \pm}^{d}$ depending on the orientation of the kink of the domain wall, with the spatial indices $j=1, \ldots, d-1$. Importantly, either of a single kink domain wall fermion $\psi_{ \pm}^{d}$ carries $1 / 2$ of degrees of freedom of the bulk fermion $\psi^{d+1}$, while the combined $\psi_{+}^{d}+\psi_{-}^{d}$ reproduces the full bulk $\psi^{d+1}$ degrees of freedom (DOF). This DOF counting combined with the spinor representation theory unambiguously suggests a unique domain wall reduction path in Fig. 1 (a) from the 4 d Weyl fermion $\psi_{\mathrm{W}}^{4 d}$ of the SM. This approach works in any dimension, but we focus on the reduction from 5 d to 2 d in Fig. 1 (a):
Dirac $\psi_{\mathrm{D}}^{5 d}$ in $4^{\mathbb{C}}$, Weyl $\psi_{\mathrm{W}}^{4 d}$ in $2_{L}^{\mathbb{C}}$ equivalently as Majorana $\psi_{\mathrm{M}}^{4 d}$ in $4^{\mathbb{R}}$, Majorana $\psi_{\mathrm{M}}^{3 d}$ in $2^{\mathbb{R}}$, Majorana-Weyl $\psi_{\mathrm{MW}}^{2 d}$ in $1_{L}^{\mathbb{R}}$.

For $N_{f}$-family $n$-Weyl fermion SM (e.g. $N_{f}=3 \mathbb{Z}$ and $n=16$ ), we obtain a reduction map following:

$$
\begin{align*}
& N_{f} n \psi_{\mathrm{D}}^{5 d} \rightarrow N_{f} n \psi_{\mathrm{W}}^{4 d} \sim N_{f} n \psi_{\mathrm{M}}^{4 d} \rightarrow N_{f} n \psi_{\mathrm{M}}^{3 d} \rightarrow N_{f} n \psi_{\mathrm{MW}}^{2 d} \\
\Rightarrow \quad & 48 \mathbb{Z} \psi_{\mathrm{D}}^{5 d} \rightarrow 48 \mathbb{Z} \psi_{\mathrm{W}}^{4 d} \sim 48 \mathbb{Z} \psi_{\mathrm{M}}^{4 d} \rightarrow 48 \mathbb{Z} \psi_{\mathrm{M}}^{3 d} \rightarrow 48 \mathbb{Z} \psi_{\mathrm{MW}}^{2 d} . \tag{11}
\end{align*}
$$

The reduced $1+1$ d theory has a total chiral central charge $c_{-} \in \frac{1}{2} 48 \mathbb{Z}=24 \mathbb{Z}$. We thus reduced the standard $3+1 d$ left-handed Weyl fermion theory with Pauli's gamma matrices to $1+1$ d chiral Majoarna-Weyl theory:

$$
\begin{equation*}
\mathcal{L}_{4 \mathrm{~d}}=\sum_{I=1}^{N_{f} n} \psi_{\mathrm{W}, I}^{4 d \dagger} \mathrm{i} \bar{\sigma}^{\mu} \partial_{\mu} \psi_{\mathrm{W}, I} \longmapsto \mathcal{L}_{2 \mathrm{~d}}=\sum_{I=1}^{N_{f} n} \psi_{\mathrm{MW}, I}^{2 d} \mathrm{i}\left(\partial_{t}-\partial_{x}\right) \psi_{\mathrm{MW}, I}^{2 d} . \tag{12}
\end{equation*}
$$

[^4]

FIG. 1. (a) This subfigure is a key step in our argument. Here the left column $d$ labels the total spacetime dimension of fermionic theories in the same row. For example, in $d=2$, we have Majorana-Weyl (MW) $\psi_{\text {MW }}^{2 d}$ in $1_{L}^{\mathbb{R}}$, Majorana (M) $\psi_{\mathrm{M}}^{2 d}$ in $1_{L}^{\mathbb{R}} \oplus 1_{R}^{\mathbb{R}}$, Weyl (W) in $1_{L}^{\mathbb{C}}$, and Dirac ( D ) in $1_{L}^{\mathbb{C}} \oplus 1_{R}^{\mathbb{C}}$. Here $\mathbb{R}$ and $\mathbb{C}$ for real and complex values, $L$ and $R$ for the left and right chirality. The key dimensional reduction path along the color path with arrows from 5 d to $2 \mathrm{~d}\left(4^{\mathbb{C}} \rightarrow 2_{L}^{\mathbb{C}} \sim 4^{\mathbb{R}} \rightarrow 2^{\mathbb{R}} \rightarrow 1_{L}^{\mathbb{R}}\right)$ follows (7) and (10), its intentional colors match with the colors of bulks or domain walls in Fig. 2. (b) This subfigure is not a key step in our argument. This shows the cobordism $\left(\mathrm{TP}_{d}\right)$ and bordism $\left(\Omega_{d}\right)$ version of the Smith homomorphism [39]. This Smith homomorphism helps to group the minimal representation of fermions (as the $(d-1) \mathrm{d}$ free fermion boundary of the cobordism invariant of the $\mathrm{TP}_{d}$ for anomaly matching) in $0 \bmod 16$ or $0 \bmod 8 \operatorname{manner}$, which is supportive and sufficient, but not necessarily required for solving the Family Puzzle.
(2): The $1+1 d$ reduced theory has chiral central charge $c_{-}=0 \bmod 24$ thus framing anomaly free [12, 13]. The $3+1$ d SM and the $1+1$ d reduced theories all have the fermion parity symmetry $\mathbb{Z}_{2}^{\mathrm{F}}$, which acts on fermions by $\psi \mapsto-\psi$. Moreover, we can do fermionization-bosonization $\left(\psi_{I} \sim: \exp \left(\mathrm{i} \phi_{I}\right)\right.$ : of compact boson $\phi_{I}$ with proper normal ordering) to map the (12)'s 2d $16 N_{f}$ Majorana-Weyl fermions to 2d $8 N_{f}$ Weyl fermions, to the bosonized version, and then by summing over all Spin structures of the 2 -manifold of the 2 d theory, ${ }^{7}$ which becomes $N_{f}$ (e.g., $3 \mathbb{Z}$ ) copies of $1+1 \mathrm{~d}\left(\mathrm{E}_{8}\right)_{1}$ bosonic CFT or Wess-Zumino-Witten (WZW) model: ${ }^{8}$

$$
\mathcal{L}_{2 \mathrm{~d}}^{\mathrm{B}}=\sum_{\mathrm{I}=1}^{N_{f}} \sum_{I, J}^{8} \frac{1}{4 \pi}\left(\left(K_{\mathrm{E}_{8}}\right)_{I J} \partial_{t} \phi_{I}-V_{I J} \partial_{x} \phi_{I}\right) \partial_{x} \phi_{J} . K_{\mathrm{E}_{8}} \equiv\left(\begin{array}{cccccccc}
2 & -1 & 0 & 0 & 0 & 0 & 0 & 0  \tag{13}\\
-1 & 2 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & 2 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 2 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 2 & -1 & 0 & -1 \\
0 & 0 & 0 & 0 & -1 & 2 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 2 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 2
\end{array}\right), V=\mathbb{\square}_{8}, \quad I, J \in\{1, \ldots, 8\},
$$

where $K_{\mathrm{E}_{8}}$ is the unimodular symmetric bilinear form's $K$ matrix (corresponding to the gapless boundary of $2+1 \mathrm{~d}$ abelian Chern-Simons theory as $2+1 \mathrm{~d}$ invertible TFT that corresponds to the unimodular $|\operatorname{det}(K)|=1)$, here the rank8 Cartan matrix of $\mathrm{E}_{8}$. When $N_{f} \in 3 \mathbb{Z}$, we have in total $\mathbb{Z}$ copies of $1+1 \mathrm{~d} 3\left(\mathrm{E}_{8}\right)_{1}$ CFT where the combined rank- 24 $K_{3 \mathrm{E}_{8}}$ matrix is the 3 block diagonal copies of $K_{\mathrm{E}_{8}}$ :

$$
\begin{equation*}
K_{3 \mathrm{E}_{8}} \equiv K_{\mathrm{E}_{8}} \oplus K_{\mathrm{E}_{8}} \oplus K_{\mathrm{E}_{8}} . \tag{14}
\end{equation*}
$$

[^5]See further discussions about $3 \mathrm{E}_{8}$ and Leech lattices in Sec. IV [42]. To have the 2d theory well-defined on a generic orientable 2-manifold (a genus-g Riemann surface) imposed additional constraints. In particular, we can consider a genus-one 2-torus $T^{2}$. Recall the 2-torus partition function of 2 d CFT is

$$
\begin{equation*}
\mathbf{Z}(\tau)=\operatorname{Tr}\left(\exp \left(2 \pi \mathrm{i}\left(\tau_{1} P-\tau_{2} H\right)\right)\right)=\operatorname{Tr}\left(\mathrm{e}^{2 \pi \mathrm{i} \tau\left(L_{0}-\frac{c}{24}\right)} \mathrm{e}^{-2 \pi \mathrm{i} \bar{\tau}\left(\bar{L}_{0}-\frac{\bar{c}}{24}\right)}\right)=\operatorname{Tr}\left(q^{L_{0}-\frac{c}{24}} \bar{q}^{\bar{L}_{0}-\frac{\bar{c}}{24}}\right) \tag{15}
\end{equation*}
$$

in terms of holomorphic and anti-holomorphic Virasoro generators $L_{0}$ and $\bar{L}_{0}$, the modular parameter $\tau=\tau_{1}+\mathrm{i} \tau_{2}$ identifies lattice vectors $w \simeq w+2 \pi \simeq w+2 \pi \tau$ as a 2 -torus on the complex plane $w=\sigma_{1}+\mathrm{i} \sigma_{2}, q=\mathrm{e}^{2 \pi \mathrm{i} \tau}$, and trace $(\mathrm{Tr})$ over states in the Hilbert space. The central charges of holomorphic and anti-holomorphic sectors are denoted as $c=c_{L}$ (left-moving) and $\bar{c}=c_{R}$ (right-moving) respectively. ${ }^{9}$
Modular invariance demands the $\mathbf{Z}(\tau)$ is invariant under the modular (P) $\mathrm{SL}(2, \mathbb{Z})$ transformations (i.e., the Mapping Class Goup of 2-torus $\operatorname{MCG}\left(T^{2}\right)$ ) generated by $\mathcal{S}: \tau \rightarrow-\tau^{-1}$ and the Dehn twist $\mathcal{T}: \tau \rightarrow \tau+1$, so $\mathbf{Z}\left(-\tau^{-1}\right)=\mathbf{Z}(\tau)$ and $\mathbf{Z}(\tau+1)=\mathbf{Z}(\tau)$. Modular invariance happens when the chiral central charge

$$
\begin{equation*}
c_{-}=c-\bar{c}=c_{L}-c_{R}=0 \quad \bmod 24 . \tag{17}
\end{equation*}
$$

thus also framing anomaly free [12, 13]. In our SM reduced model (11), we do have $c_{L}=24 \mathbb{Z}$ and $c_{R}=0$ satisfy (17). Although a generic $c_{-}=24 \mathbb{Z} \neq 02$ d theory still suffers from a 2 d perturbative gravitational anomaly that corresponds to 4 d anomaly polynomial $\frac{c_{-}}{24} p_{1}$ with the 1 st Pontryagin class $p_{1}$, but the modular invariance demands the theory have quantized integer spin and angular momentum, which is nice quantum mechanically. We will fill in more details in Sec. IV.
(3): The $1+1 d$ reduced massless system can be attached to a $2+1 d$ bulk of a trivial class 0 in the $3 d$ framed cobordism and string cobordism: $0 \in \mathrm{TP}_{3}^{\mathrm{fr}} \cong \mathrm{TP}_{3}^{\text {String }} \cong \mathbb{Z}_{24}$. The corresponding manifold generator is also in the trivial class of 3 d framed bordism and string bordism: $0 \in \Omega_{3}^{\mathrm{fr}} \cong \Omega_{3}^{\text {String }} \cong \mathbb{Z}_{24} \cdot{ }^{10}$ Our SM reduced model (11) obeys this, detailed in Sec. IV.
(4): The $1+1 \mathbf{d}$ reduced massless system can be attached to a $\mathbf{2}+\mathbf{1 d} \mathbf{b u l k}$ of a trivial class $\mathbf{0}$ in the $\mathbf{3 d} w_{1}-p_{1}$ cobordism: $0 \in \mathrm{TP}_{3}^{w_{1}-p_{1}} \cong \mathbb{Z}_{3}$. The corresponding manifold generator is also in the trivial class of $3 \mathrm{~d} w_{1}-p_{1}$ bordism: $0 \in \Omega_{3}^{w_{1}-p_{1}} \cong \mathbb{Z}_{3}$. Our SM reduced model (11) obeys this, detailed in Sec. IV.
(5): Smith homomorphism [39]: This step is not necessary but only for further supporting our argument sufficiently. Only for the convenience of reducing from $3+1 \mathrm{~d}$ to $1+1 \mathrm{~d}$, we may implement Wilczek-Zee's $\mathbb{Z}_{4, X}$ symmetry (more discussions in Sec. II B) in the SM [47, 48], so the following Smith homomorphism between bordism groups of Pin structure manifolds [49] (see Fig. 1 (b) and Fig. 2)

$$
\begin{equation*}
\cdots \rightarrow \Omega_{5}^{\mathrm{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}}=\mathbb{Z}_{16} \rightarrow \Omega_{4}^{\mathrm{Pin}^{+}}=\mathbb{Z}_{16} \rightarrow \Omega_{3}^{\mathrm{Spin} \times \mathbb{Z}_{2}}=\mathbb{Z}_{8} \rightarrow \Omega_{2}^{\mathrm{Pin}^{-}}=\mathbb{Z}_{8} \rightarrow \ldots \tag{18}
\end{equation*}
$$

can guide us to map between fermions in different dimensions as (11), in particular in a multiple of 16 , detailed in Sec. II B.

We emphasize that our Family Puzzle solution is more topologically robust (depending mainly on (1), (2), (3), (4)) without really relying on any specific global symmetry or any specific gauge group (such as the $\mathbb{Z}_{4, X}$ of (5)). Even breaking $\mathbb{Z}_{4, X}$ symmetry in the SM , our argument still holds.

## B. Mass Domain Wall of Domain Wall Reduction Toy Model

The purpose of this subsection is to introduce a concrete model filling the Argument (5) in Sec. II A. As emphasized a few times already, the additional discrete symmetries are not crucial (for solving Family Puzzle), nonetheless

[^6]supportive to realize not only dimensional reduction of Fig. 1(a) but also the Smith map of Fig. 1(b) simultaneously in one model.

Only for the convenience of the Argument (5) (but not necessary for Argument (1)- (4)), we recall that the SM has an excellent discrete order-four finite abelian group $\mathbb{Z}_{4, X}$ unitary symmetry, where $X \equiv 5(\mathbf{B}-\mathbf{L})-\frac{2}{3} \tilde{Y}=$ $\frac{5}{N_{c}}\left(\mathbf{Q}-N_{c} \mathbf{L}\right)-\frac{2}{3} \tilde{Y}$ is a linear combination of the conventional baryon minus lepton $\mathbf{B}-\mathbf{L}$ charge (but more precisely the properly quantized quark number $\mathbf{Q}$ minus $N_{c}$ times lepton number $\mathbf{L}$ ) and the properly integer quantized hypercharge $\tilde{Y}[47,48]$. All the quarks and leptons have a unit charge 1 under $\mathbb{Z}_{4, X}$, also $X^{2}=(-1)^{\mathrm{F}}$, so $\mathbb{Z}_{4, X} \supset \mathbb{Z}_{2}^{\mathrm{F}}$. Thus this $\mathbb{Z}_{4, X}$ symmetry is not only preserved with or without SM gauge group $G_{\text {SM }_{\mathrm{q}}}$, but also robust even including four-fermion BSM interaction deformation deviated from the SM fixed point. Given the family number $N_{f}$ and the total number of sterile right-handed neutrino type $n_{\nu_{R}}=n_{\nu_{e, R}}+n_{\nu_{\mu, R}}+n_{\nu_{\tau, R}}+\ldots$, there is an index $-N_{f}+n_{\nu_{R}}$ $\bmod 16$ nonperturbative global anomaly classified by $\mathbb{Z}_{16}$ (from the bordism group $\Omega_{5}^{\text {Spin } \times \mathbb{Z}_{2} \mathbb{Z}_{4}} \cong \mathbb{Z}_{16}$ and cobordism group $\mathrm{TP}_{5}^{\mathrm{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}} \cong \mathbb{Z}_{16}$ in [17, 50-54], studied recently in the context of SM in [11,51,54-59]) captured by the large gauge-diffeomorphism transformations. We shall leave the more formal discussions and mathematical forms of anomaly derivations into Sec. III and in [42].

FIG. 2. Domain wall of domain wall reduction and so on. The extra discrete symmetries (namely, the extra $\mathbb{Z}_{2}$ quotient in $\operatorname{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}, \mathrm{Pin}^{+}$, $\operatorname{Spin} \times \mathbb{Z}_{2}, \mathrm{Pin}^{-}$) are not necessary for solving the Family Puzzle, but they are supportive to realize not only dimensional reduction of Fig. 1(a) but also the Smith map of Fig. 1(b) simultaneously in this model. The colors (purple, blue, green, red) are intentionally meant to match the colors of the dimensional reduction path in Fig. 1(a).

Let us discuss Fig. 2 step by step.
(a): Step 1 Fig. 2 (a), 5 d to 4 d : We have a 5 d bulk massive Dirac fermion of $m\left(x_{4}\right)$ profile (purple) given by (8). The 5 d mass term $m \bar{\psi}_{\mathrm{D}}^{5} \psi_{\mathrm{D}}^{5}$ preserves the $\mathbb{Z}_{4, X}$ symmetry: $\psi_{\mathrm{D}}^{5} \mapsto \mathrm{i} \psi_{\mathrm{D}}^{5}$. The $\mathbb{Z}_{4, X}$ symmetry projects to 4 d massless Weyl fermion that also preserves the $\mathbb{Z}_{4, X}: \psi_{\mathrm{W}}^{4 d} \mapsto \mathrm{i} \psi_{\mathrm{W}}^{4 d}$. So this Step 1 scenario is a 5 d bulk $\mathbb{Z}_{4, X}$-SPTs ( $5 \mathrm{~d} \mathbb{Z}_{4, X}$-topological superconductor) classified by $\mathrm{TP}_{5}^{\mathrm{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}} \cong \mathbb{Z}_{16}$ with a symmetry-preserving massless (gapless) 4 d boundary (blue) at $x_{4}=0$. The $5 \mathrm{~d}-4 \mathrm{~d}$ bulk-boundary system thus far has unitary $X^{2}=(-1)^{\mathrm{F}}$ thus $\operatorname{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}$ symmetry.
5 d Dirac mass term breaks the charge conjugation C and reflection R symmetries. But the $\mathrm{R}_{4}$ symmetry (spatial reflection along $x_{4}$ ) becomes an internal symmetry at $x_{4}$, which turns out to be the same internal symmetry $X$ we desired for: $\mathrm{R}_{4}\left(x_{4}=0\right)=X$.
(b): Step 2 Fig. 2 (b), 4d to 3 d : We then give the 4 d Weyl fermion a 4 d Majorana mass of $m\left(x_{3}\right)$ profile (blue) given by (8). We then obtain the domain wall inside the domain wall. The 4 d Majorana mass $m \psi_{\mathrm{W}}^{\mathrm{T}}\left(-\mathrm{i} \sigma^{2}\right) \psi_{\mathrm{W}}+$ h.c. breaks the $\mathbb{Z}_{4, X}: \psi_{\mathrm{W}}^{4 d} \mapsto \mathrm{i} \psi_{\mathrm{W}}^{4 d}$. But there is an antiuntary $\mathbb{Z}_{4}^{\mathrm{T}}$ symmetry that both the 4 d Majorana fermion with Majorana mass
preserves and the 3 d massless Majorana fermion at $x_{3}=0$ preserves. So this Step 2 scenario is a 4 d bulk $\mathbb{Z}_{4}^{\mathrm{T}}$-SPTs ( $4 \mathrm{~d} \mathbb{Z}_{4}^{\mathrm{T}}$-topological superconductor $[60,61]$ classified by $\mathrm{TP}_{4}^{\mathrm{Pin}^{+}} \cong \mathbb{Z}_{16}[23,26]$ ) with a symmetry-preserving massless (gapless) Majorana fermion 3d boundary (green) at $x_{3}=0$. The $4 \mathrm{~d}-3 \mathrm{~d}$ bulk-boundary system thus far has antiunitary $\mathrm{T}^{2}=(-1)^{\mathrm{F}}$ thus Pin ${ }^{+}$symmetry.
(c): Step 3 Fig. 2 (c), 3d to 2d: We then give the 3d Majorana fermion a Majorana mass of $m\left(x_{2}\right)$ profile (green) given by (8). We then obtain the domain wall inside the domain wall inside the domain wall. The 3d Majorana mass breaks the $\mathbb{Z}_{4}^{\mathrm{T}}$, while the 2 d domain wall's Majorana-Weyl fermion (at $x_{2}=0$ ) also breaks $\mathbb{Z}_{4}^{\mathrm{T}}$ symmetry down to $\mathbb{Z}_{2}^{\mathrm{F}}$.

In summary of the above, we not only realize (7):

$$
4+1 \mathrm{~d} \text { Dirac } \psi_{\mathrm{D}}^{5 d} \rightarrow 3+1 \mathrm{~d} \text { Weyl } \psi_{\mathrm{W}}^{4 d} \sim 3+1 \mathrm{~d} \text { Majorana } \psi_{\mathrm{M}}^{4 d} \rightarrow 2+1 \mathrm{~d} \text { Majorana } \psi_{\mathrm{M}}^{3 d} \rightarrow 1+1 \mathrm{~d} \text { Majorana-Weyl } \psi_{\mathrm{MW}}^{2 d}
$$ but also enhanced it by cobordism version of Smith map (18):

$$
\begin{equation*}
\cdots \rightarrow \mathrm{TP}_{3}^{\mathrm{Spin} \times \mathbb{Z}_{2}}=\mathbb{Z} \oplus \mathbb{Z}_{8} \rightarrow \mathrm{TP}_{4}^{\mathrm{Pin}^{+}}=\mathbb{Z}_{16} \rightarrow \mathrm{TP}_{5}^{\text {Spin } \times \mathbb{Z}_{2} \mathbb{Z}_{4}}=\mathbb{Z}_{16} \rightarrow \ldots \tag{19}
\end{equation*}
$$

The anomaly indices of (7) are mapped under (19) as

$$
\begin{equation*}
\left.\left(v^{\prime}=2\left(c_{L}-c_{R}\right)=1, v_{2}=0\right)\right|_{\in \mathbb{Z} \oplus \mathbb{Z}_{8}} \rightarrow v_{3}=\left.1\right|_{\in \mathbb{Z}_{16}} \rightarrow v_{4}=\left.1\right|_{\in \mathbb{Z}_{16}} \tag{20}
\end{equation*}
$$

This satisfies a constraint derived in [17]: $\boldsymbol{v}^{\prime}+2 \boldsymbol{v}_{2}=2\left(c_{L}-c_{R}\right)+2 \boldsymbol{v}_{2}=\boldsymbol{v}_{3} \bmod 16$. We also complete the Argument (5). ${ }^{11}$

## III. FROM 6D ANOMALY POLYNOMIAL, 5D CONVERTIBLE FIELD THEORY, 4D ANOMALY OF THE SM TO 3D GRAVITATIONAL CHERN-SIMONS TERM

The purpose of this subsection is to fill the anomaly perspectives of the Argument (1), (2), (3), and (4) in Sec. II A.
Follow the SM computation in [11], the anomaly polynomial of Weyl fermions follows the Atiyah-Singer index theorem. The 4 d anomaly of a single Weyl fermion in 4 d is the degree 6 part of the 6 d anomaly polynomial from $\hat{A} \operatorname{ch}(\mathcal{E}) .{ }^{12}$ The explicit expression in terms of Pontryagin and Chern characteristic classes [62-64], $p_{j}$ and $c_{j}$, can be obtained using the expansions of $\hat{\mathrm{A}}$ and $\operatorname{ch}(\mathcal{E})$ :

$$
\begin{align*}
\hat{\mathrm{A}} & =1-\frac{p_{1}}{24}+\frac{7 p_{1}^{2}-4 p_{2}}{5760}+\ldots  \tag{21}\\
\operatorname{ch}(\mathcal{E}) & =\operatorname{rank} \mathcal{E}+c_{1}(\mathcal{E})+\frac{1}{2}\left(c_{1}^{2}(\mathcal{E})-2 c_{2}(\mathcal{E})\right)+\frac{1}{6}\left(\left(c_{1}^{3}(\mathcal{E})-3 c_{1}(\mathcal{E}) c_{2}(\mathcal{E})+3 c_{3}(\mathcal{E})\right)+\ldots\right. \tag{22}
\end{align*}
$$

The explicit 6d anomaly polynomial for the gauge, global, and diffeomorphism symmetries of the 4 d SM, $G=$ $\operatorname{Spin} \times \mathrm{U}(1)_{\mathbf{Q}} \times \mathrm{U}(1)_{\mathbf{L}} \times G_{\mathrm{SM}_{\mathbf{q}}}$ (or more properly $G=\operatorname{Spin} \times \mathbb{Z}_{2}^{\mathrm{F}} \mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}} \times{ }_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathbb{Z}_{2 N_{c} N_{f}, \mathbf{Q}+N_{c} \mathbf{L}} \times G_{\mathrm{SM}_{\mathrm{q}}}$ concerning the extra $\mathrm{U}(1)$ to be mixed $G_{\mathrm{SM}_{\mathrm{q}}}$-anomaly free), with the matter representation given in (4) becomes: ${ }^{13}$

$$
\begin{align*}
I_{6} \equiv\left(N_{c} c_{1}\left(\mathrm{U}(1)_{\mathbf{Q}}\right)+c_{1}\left(\mathrm{U}(1)_{\mathbf{L}}\right)\right) N_{f}\left(-18 \frac{c_{1}\left(\mathrm{U}(1)_{\tilde{Y}}\right)^{2}}{2}-\right. & \left.c_{2}(\mathrm{SU}(2))\right) \\
& +\left(N_{f}-n_{\nu_{R}}\right)\left(\frac{c_{1}\left(\mathrm{U}(1)_{\mathbf{L}}\right)^{3}}{6}-\frac{c_{1}\left(\mathrm{U}(1)_{\mathbf{L}}\right) p_{1}(T M)}{24}\right) \tag{23}
\end{align*}
$$

When $M^{6}$ is a closed 6 -manifold, then $\int_{M^{6}} I_{6} \in \mathbb{Z}$, and there is a 6 d invertible topological field theory (iTFT) with the partition function $\exp \left(\mathrm{i} \int \theta I_{6}\right)$ where $\theta \in[0,2 \pi)$. When $M^{6}$ has a boundary $\partial M^{6}=M^{5}$, we can consider this $M^{5}$ as a 5 d interface between two 6 d bulks with the Lagrangian density $\theta I_{6}$ such that $\theta=0$ on one 6 d side and $\theta=2 \pi$ on

[^7]the other 6 d side. On the $M^{5}$ interface, we have an iTFT with the action $S_{5}=2 \pi \int_{M^{5}} I_{5} \in 2 \pi \mathbb{R}$ from $I_{6}=\mathrm{d} I_{5}$. The 5 d iTFT partition function is $\exp \left(\mathrm{i} S_{5}\right) \in \mathrm{U}(1)$. The $S_{5}$ value modulo $2 \pi$ is independent of the choice of $M^{6}$. From the 6 d anomaly polynomial (23), the explicit 5 d iTFT is
\[

$$
\begin{equation*}
S_{5} \equiv \int_{M^{5}}\left(N_{c} A_{\mathbf{Q}}+A_{\mathbf{L}}\right) N_{f}\left(-18 \frac{c_{1}\left(\mathrm{U}(1)_{\tilde{Y}}\right)^{2}}{2}-c_{2}(\mathrm{SU}(2))\right)+\left(N_{f}-n_{\nu_{R}}\right) A_{\mathbf{L}}\left(\frac{c_{1}\left(\mathrm{U}(1)_{\mathbf{L}}\right)^{2}}{6}-\frac{p_{1}(T M)}{24}\right) \tag{24}
\end{equation*}
$$

\]

Here $A_{\mathbf{Q}}$ and $A_{\mathbf{L}}$ are background fields for $\mathrm{U}(1)_{\mathbf{Q}}$ and $\mathrm{U}(1)_{\mathbf{L}}$ symmetries respectively. This 5 d TQFT encodes the anomaly of the 4 d SM by the anomaly inflow.

## A. $\quad$ Spin $\times_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}} \equiv \operatorname{Spin}^{c}$ and $\operatorname{Spin} \times_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathbb{Z}_{4, X}$ with a vector $\mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}}$ and a chiral $X$

Concerning the $\operatorname{Spin} \times_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathrm{U}(1) \equiv \operatorname{Spin}^{c}$ structure with $A_{\mathbf{Q}-N_{c} \mathbf{L}}$ background field for $\mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}}$, the (24) becomes

$$
\begin{equation*}
S_{5} \equiv\left(-N_{f}+n_{\nu_{R}}\right) \int_{M^{5}} A_{\mathbf{Q}-N_{c} \mathbf{L}}\left(N_{c}^{3} \frac{c_{1}\left(\mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}}\right)^{2}}{6}-N_{c} \frac{p_{1}(T M)}{24}\right) \tag{25}
\end{equation*}
$$

In the familiar form, we have the relation between Pontryagin class $p_{1}$ and gravitational Chern-Simons (GCS) 3-form:

$$
\begin{align*}
p_{1} & :=-\frac{1}{8 \pi^{2}} \operatorname{Tr}[R \wedge R]=-\mathrm{dGCS} /(2 \pi), \\
\mathrm{GCS} & :=\frac{1}{4 \pi} \operatorname{Tr}\left[\omega \wedge \mathrm{~d} \omega+\frac{2}{3} \omega \wedge \omega \wedge \omega\right] \tag{26}
\end{align*}
$$

(where $R=\mathrm{d} \omega+\omega \wedge \omega$ is the curvature 2-form of the Levi-Civita spin-connection 1-form $\omega$ ) and the relation between Chern class and Chern-Simons (CS) 3-form:

$$
\begin{align*}
-c_{2}+\frac{1}{2} c_{1}^{2} & :=\frac{1}{8 \pi^{2}} \operatorname{Tr}(F \wedge F)=\frac{1}{2 \pi} \mathrm{dCS} \\
\mathrm{CS} & :=\frac{1}{4 \pi} \operatorname{Tr}\left[A \wedge d A+\frac{2}{3} A \wedge A \wedge A\right] \tag{27}
\end{align*}
$$

( $F=\mathrm{d} A+A \wedge A$ is the curvature 2-form of gauge connection 1-form). Note however the topologically invariant data from a characteristic class is not captured by its local expression in a single patch or chart, but instead is typically captured by the transition functions between different overlapping patches. So in order to define characteristic classes differential-geometrically, we cannot just use differential forms locally, but we need to define them globally. We will also write down the more well-defined global expression later [42].

By restricting Spin $\times_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathrm{U}(1) \equiv \operatorname{Spin}^{c}$ to $\operatorname{Spin} \times_{\mathbb{Z}_{2}} \mathbb{Z}_{4}$ (e.g. $\mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}} \supset \mathbb{Z}_{4, X} \supset \mathbb{Z}_{2}^{\mathrm{F}}$ ), the (25) becomes a $\mathbb{Z}_{16}$ class 5d iTFT: ${ }^{14}$

$$
\begin{equation*}
\left.S_{5} \equiv\left(-N_{f}+n_{\nu_{R}}\right) \frac{2 \pi}{16} \eta_{4 \mathrm{~d}}\left(\operatorname{PD}\left(A_{\mathbb{Z}_{2, X}}\right)\right)\right|_{M^{5}} \tag{28}
\end{equation*}
$$

Let us comments about the physics of the $\left(-N_{f}+n_{\nu_{R}}\right)$ coefficient in (25) and (28):

- For $N_{f}=3$ with 16 Weyl-fermion SM scenario, the $-N_{f}+n_{\nu_{R}}=-3+3=0$, so all these $\mathbb{Z}$ and $\mathbb{Z}_{16}$ anomalies in (25) and (28) cancel. There is no anomaly descendant to 2 d theory that we can look for.
- However, when $-N_{f}+n_{\nu_{R}} \neq 0$, like the scenario of Ultra Unification [55-59], we do have a room to descend the $\mathrm{U}(1)^{3}, \mathrm{U}(1)$-gravity, and $\mathbb{Z}_{4}$-gravity anomalies in 4 d to the $\mathrm{U}(1)^{2}$ and gravity-gravity anomalies in 2 d . This descended anomaly in 2 d can give constraints on the dimensional reduced domain wall theory.

[^8]- The $\mathrm{U}(1)_{\mathbf{Q}-N_{c} \mathbf{L}}$ is a vector symmetry with properly quantized charge of $\mathbf{B}-\mathbf{L}$. Due to the vector $\mathrm{U}(1)$ symmetry, the anomalies of left-handed and right-handed Weyl fermions in the SM cancel nicely (nearly, except that if $\left.-N_{f}+n_{\nu_{R}} \neq 0\right) .{ }^{15}$ However, we are motivated to resolve the Family Puzzle by thinking of more robust topological constraint without symmetry, thus we should forget the SM internal (gauge or global) symmetry structure. Once $G_{\mathrm{SM}_{\mathrm{q}}}$ is removed, we can consider the chiral $\mathrm{U}(1)$ symmetry of the Weyl fermions, which has a stronger constraint of the modular invariance of 2 d theory and the framing anomaly of the 3d TQFT (as we will show in Sec. III B).

## B. Another $\operatorname{Spin} \times{ }_{\mathbb{Z}_{2}^{F}} U(1) \equiv \operatorname{Spin}^{c}$ with a chiral $U(1): 3\left(E_{8}\right)_{1}$ quantum Hall states

For a single left-handed Weyl fermion of charge $q$ in 4 d , we take $\mathcal{E}$ to be the complex line bundle associated with the corresponding representation of $\mathrm{U}(1)$. The fermionic 6 d anomaly polynomial that captures the 4 d anomaly is

$$
\begin{equation*}
I_{6, f}=[\hat{\mathrm{A}} \operatorname{ch}(\mathcal{E})]_{6}=q^{3} \frac{c_{1}^{3}}{6}-q \frac{c_{1} p_{1}}{24}, \quad \int_{M^{6}} I_{6, f} \in \mathbb{Z} \tag{29}
\end{equation*}
$$

Consider a collection of left-handed Weyl fermions in 4 d with the global $\mathrm{U}(1)$ symmetry charges $q_{i}=1$ with $i=1, \ldots, N_{f} n$ for $N_{f}$ families of $n$ fermions per family (e.g. $N_{f}=3$ and $n=15,16$ ).

The dimensional reduced 2d theory potential has $\mathrm{U}(1)^{2}$ and gravity-gravity anomalies (2-point function under oneloop diagram) in 2d. However, the domain wall construction given in Sec. II can break all U(1) symmetries, thus we are left with only the perturbative gravitational anomalies, captured by the gravity-gravity 2-point function under one-loop diagram, 3 d GCS, $4 \mathrm{~d} p_{1}$ and the signature $\sigma$ of 4 -manifold with proper coefficients given in (31): ${ }^{16}$

$$
\begin{array}{llllll}
p_{1} \in \frac{24}{c_{-}} \mathbb{Z}, & \frac{\sigma}{8} c_{-}=\frac{c_{-}}{24} p_{1}, & \frac{c_{-}}{24} \mathrm{GCS}=\frac{c_{-}}{96 \pi} \operatorname{Tr}\left[\omega \mathrm{~d} \omega+\frac{2}{3} \omega^{3}\right], & c_{-}, & \kappa_{x y}=2 c_{-} \kappa_{x y}^{\mathrm{MW}}, & c_{-} \text {Gapless/CFT } \\
\hline p_{1} \in 48 \mathbb{Z}, & \frac{\sigma}{16}=\frac{1}{48} p_{1}, & \frac{1}{48} \mathrm{GCS}=\frac{1}{192 \pi} \operatorname{Tr}\left[\omega \mathrm{~d} \omega+\frac{2}{3} \omega^{3}\right], & c_{-}=\frac{1}{2}, & \kappa_{x y}=\kappa_{x y}^{\mathrm{MW}}, & \text { Majorana-Weyl } \\
p_{1} \in 24 \mathbb{Z}, & \frac{\sigma}{8}=\frac{1}{24} p_{1}, & \frac{1}{24} \mathrm{GCS}=\frac{1}{96 \pi} \operatorname{Tr}\left[\omega \mathrm{~d} \omega+\frac{2}{3} \omega^{3}\right] & c_{-}=1, & \kappa_{x y}=2 \kappa_{x y}^{\mathrm{MW}}, & \text { Weyl with U(1) symmetry } \\
p_{1} \in 3 \mathbb{Z}, & \sigma=\frac{1}{3} p_{1}, & \frac{1}{3} \mathrm{GCS}=\frac{1}{12 \pi} \operatorname{Tr}\left[\omega \mathrm{~d} \omega+\frac{2}{3} \omega^{3}\right], & c_{-}=8, & \kappa_{x y}=16 \kappa_{x y}^{\mathrm{MW}}, & \left(\mathrm{E}_{8}\right)_{1} \text { chiral boson } \\
& 3 \sigma=p_{1}, & \mathrm{GCS}=\frac{1}{4 \pi} \operatorname{Tr}\left[\omega \mathrm{~d} \omega+\frac{2}{3} \omega^{3}\right], & c_{-}=24, & \kappa_{x y}=48 \kappa_{x y}^{\mathrm{MW}}, & 3\left(\mathrm{E}_{8}\right)_{1} \text { or Leech chiral boson }  \tag{31}\\
&
\end{array}
$$

Under (7), the 4 d Weyl $\psi_{\mathrm{W}}^{4 d}$ is reduced to 2d Majorana-Weyl $\psi_{\mathrm{MW}}^{2 d}$ with $c_{-}=1 / 2$; the 48 of 4 d Weyl $\psi_{\mathrm{W}}^{4 d}$ is reduced to 48 of 2 d Majorana-Weyl $\psi_{\text {MW }}^{2 d}$ with $c_{-}=24$.

## C. Index Theorem and (Gravitational) Chern-Simons: Framing, String, 2-Framing, and $w_{1}-p_{1}$ structures

Eq. (31) also shows the information of the topology of 4-manifolds. Hirzebruch signature [10] writes in terms of the $L$ genus: For the dimension $d=0 \bmod 4$, the signature $\sigma(M) \in \mathbb{Z}$ of manifold $M^{d}$ is

$$
\begin{align*}
\sigma\left(M^{d}\right) & =\int_{M^{d}} L_{n}=\int_{M^{d}} L_{d / 4} \equiv\left\langle L_{d / 4},\left[M^{d}\right]\right\rangle \\
L & =L_{0}+L_{1}+L_{2}+\cdots=1+\frac{p_{1}}{3}+\frac{-p_{1}^{2}+7 p_{2}}{45}+\ldots \tag{32}
\end{align*}
$$

and the $\left[M^{d}\right]$ is the fundamental class of $M^{d}$. For example, 4-manifold $\sigma\left(M^{4}\right)=\left\langle\frac{p_{1}}{3},\left[M^{4}\right]\right\rangle \equiv \frac{p_{1}}{3}$.
Under the Special Orthogonal SO structure, the SO (non-Spin) 4-manifold has a signature $\sigma=\frac{p_{1}}{3} \in \mathbb{Z}$.
Under the Spin structure, the Rokhlin's theorem [37] says the $\sigma=\frac{p_{1}}{3} \in 16 \mathbb{Z}$ for 4-manifolds.
By (7), the 4 d Weyl $\psi_{\mathrm{W}}^{4 d}$ is reduced to 2 d Majorana-Weyl $\psi_{\mathrm{MW}}^{2 d}$ with $c_{-}=1 / 2$ which is attached to a 3 d bulk of $\frac{1}{48}$ GCS. However, GCS written as Levi-Civita spin-connection 1-form $\omega$ is metric dependent thus not strictly mathematically topological.

Here are some issues:

[^9]1. We like to address the issue of how to make the theory metric independent thus strictly mathematically topological.
2. We shall impose framing anomaly-free in 3d TQFT thus related to the modular invariance of 2d CFT (on the boundary).
3. We aim to define GCS globally instead of locally.

The answers to address the above issues are:

1. Metric independent and (mathematically) topological: Follow [13], we not only need the 3d GCS in (31), but also the 3d CS gauge theory with a CS action $S(A)$ such as $\left(\mathrm{E}_{8}\right)_{1} \mathrm{CS}$ with the gauge field $A$. We also need gravitational eta invariant $\eta_{\text {grav }}$ [13]. We write

$$
\begin{align*}
S(A)+c_{-} \frac{1}{24} \mathrm{GCS} & =c_{-}\left(\frac{\pi}{2} \eta_{\text {grav }}+\frac{1}{24} \mathrm{GCS}\right)+\left(S(A)-c_{-} \frac{\pi}{2} \eta_{\text {grav }}\right) \\
& =c_{-}\left(\frac{\pi}{2}\right)\left(\eta_{\text {grav }}+\frac{1}{12 \pi} \mathrm{GCS}\right)+\left(S(A)-c_{-} \frac{\pi}{2} \eta_{\text {grav }}\right) \tag{33}
\end{align*}
$$

- $S(A)$ : 3d CS gauge theory action of the gauge field $A$ : It is metric-dependent (not topological), but no framing is required.
- $\frac{\pi}{2} \eta_{\text {grav }}$ : The gravitational eta invariant version of CS (e.g., of the $\left.\left(\mathrm{E}_{8}\right)_{1} \mathrm{CS}\right)$. It is also metric-dependent (not topological), but no framing is required.
- $\left(S(A)-c_{-} \frac{\pi}{2} \eta_{\text {grav }}\right)$ is metric-independent (topological) and no framing is required.
- GCS is indeed the gravitational counter term (invertible field theory iFT) from the free part of $\Omega_{4}$ bordism group. GCS is metric-dependent (non-topological), framing-dependent.
- $\eta_{\text {grav }}+\frac{1}{12 \pi}$ GCS is metric-independent but framing-dependent.
- The combined $S(A)+c_{-} \frac{1}{24}$ GCS is generally metric-independent but framing-dependent.

2. Framing anomaly: The partition function / path integral on an oriented 3-manifold $M^{3}$ defined by the action (33) is in principle framing anomalous under the change of framing $f \in \pi_{3}(\mathrm{SO}(3))=\mathbb{Z}$ or $\mathrm{H}^{3}\left(M^{3}, \mathbb{Z}\right)=\mathbb{Z}$,

$$
\begin{equation*}
\mathbf{Z} \mapsto \mathbf{Z} \exp \left(2 \pi \mathrm{i} f \frac{c_{-}}{24}\right) \tag{34}
\end{equation*}
$$

Only when $c_{-}=0 \bmod 24$, which we like to impose, then the theory is not only metric-independent (topological) but also framing anomaly-free. This theory is particularly good like the $3\left(\mathrm{E}_{8}\right)_{1}$ quantum Hall state in Sec. IIID.
3. Define GCS or CS globally instead of locally: Recall (3) we define GCS (or CS) globally by putting it on the 3-manifold $M^{3}=\partial M^{4}$ bounding the boundary of a 4-manifold $M^{4}$, and we will use the relation between (a) framing provides the String structure, and (2) 2-framing provides the $w_{1}-p_{1}$-structure. For Family Puzzle, we will need the following structures:

Structure $:=\left\{\begin{array}{l}(\mathrm{a})(\text { Fermionic }) \text { GCS on Spin manifold - framing }(\mathrm{fr}) \text { : trivialization of tangent bundle } T M \\ \simeq \text { String structure: trivialization of } w_{1}(T M), w_{2}(T M), \text { and } \frac{1}{2} p_{1}(T M) . \\ (\mathrm{b}) \text { (Bosonic) GCS on non-Spin manifold }-2 \text {-framing }(2-\mathrm{fr}) \text { : trivialization of the spin bundle of } 2 \text { copies } \\ \simeq w_{1}-p_{1} \text {-structure: trivialization of } w_{1}(T M) \text { and } p_{1}(T M) .\end{array}\right.$
Follow [11],

- For 2 -framing, the relative characteristic number $\frac{1}{2} p_{1}(2 T M, \beta) \in \mathbb{Z}$ with a trivialization $\beta$ of the spin bundle of 2 copies of the tangent bundle $2 T M$. Using this number, one can then define the value of gravitational Chern-Simons action in $\mathbb{R}$ (instead of just in $\mathbb{R} /(2 \pi \mathbb{Z})$ ):

$$
\begin{equation*}
\frac{c_{-}}{24} \int_{M^{3}} \mathrm{GCS}=\frac{c_{-}}{24} 2 \pi\left(\frac{1}{8 \pi^{2}} \int_{M^{4}} \operatorname{Tr}[R \wedge R]+\frac{1}{2} p_{1}\left(2 T M^{4}, \beta\right)\right) \tag{36}
\end{equation*}
$$

- For $p_{1}$-structure $\beta^{\prime}$ on $M^{4}$ as a choice of the trivialization of the first Pontryagin class $p_{1}\left(T M^{3}\right)=0$ (which vanishes exactly in 3d by dimensional reasons). Similarly extending $M^{3}$ to a 4-manifold $M^{3}$, we have an integral
relative characteristic number $p_{1}\left(T M^{4}, \beta^{\prime}\right) \in \mathbb{Z}$, which can be used to define the value of the gravitational ChernSimons action in $\mathbb{R}$ (instead of just in $\mathbb{R} /(2 \pi \mathbb{Z})$ ) as follows:

$$
\begin{equation*}
\frac{c_{-}}{24} \int_{M^{3}} \mathrm{GCS}=\frac{c_{-}}{24} 2 \pi\left(\frac{1}{8 \pi^{2}} \int_{M^{4}} \operatorname{Tr}[R \wedge R]+p_{1}\left(T M^{4}, \beta^{\prime}\right)\right) \tag{37}
\end{equation*}
$$

Similarly, for CS , we also write $($ defined $\bmod \mathbb{R} /(2 \pi \mathbb{Z}))$ related to $2 \pi \int_{M^{4}}\left(-c_{2}+\frac{1}{2} c_{1}^{2}\right)$ :

$$
\begin{equation*}
k \int_{M^{3}} \operatorname{CS}(A)=2 \pi \frac{k}{8 \pi^{2}} \int_{M^{4}} \operatorname{Tr}(F \wedge F) \tag{38}
\end{equation*}
$$

## D. Cobordism constraints of Framing, String, 2-Framing, and $w_{1}-p_{1}$ structures

Finally, we like to check the bordism and cobordism constraints from the given structures (Framing, String, 2Framing, and $w_{1}-p_{1}$ structures). We show that when we have $N_{f}=3$ families or 48 Weyl fermions in 4 d SM, or $c_{-}=24$ in 2 d , the theory nicely sits in the trivial cobordism class. This will completely prove Argument (3), and (4) in Sec. II A.

First recall, the bordism map of manifolds suggests by the Whitehead tower relation is

$$
\begin{array}{lccr} 
& \Omega_{d}^{\text {String }} \rightarrow \Omega_{d}^{\text {Spin }} \rightarrow \Omega_{d}^{\text {SO }} \\
d=3 & \mathbb{Z}_{24} & 0 & 0 \\
d=4 & 0 & \mathbb{Z} \xrightarrow{\times 16} \mathbb{Z}
\end{array}
$$

Second, the cobordism map of iFT or iTQFT as Framing or String cobordism invariants becomes ${ }^{17}$

$$
\begin{align*}
& \mathrm{TP}_{d}^{\text {String }} \leftarrow \mathrm{TP}_{d}^{\mathrm{Spin}} \leftarrow \mathrm{TP}_{d}^{\mathrm{SO}} \\
& d=3 \quad \mathbb{Z}_{24} \stackrel{\bmod 24}{\longleftarrow} \mathbb{Z} \stackrel{\times 16}{\longleftarrow} \mathbb{Z} \\
& 16 \stackrel{\bmod 24}{\longleftarrow} 16 \stackrel{\times 16}{\longleftarrow} 1 \\
& 0 \stackrel{\bmod 24}{\longleftarrow} 48 \stackrel{\times 16}{\longleftarrow} 3 . \tag{39}
\end{align*}
$$

We show that $p_{1} / 3$ maps to $16 \bmod 24\left(\right.$ thus $\left.c_{-}=0 \bmod 8\right)$ in the string cobordism $\mathrm{TP}_{3}^{\text {String }}$ which is nonzero. But the $p_{1}$ maps to $3 \times 16=48=0 \bmod 24\left(\right.$ thus $\left.c_{-}=0 \bmod 24\right)$ in the $\mathrm{TP}_{3}^{\text {String }}$ which vanishes!

Third, the cobordism map of iFT or iTQFT as 2-Framing or $w_{1}-p_{1}$ cobordism invariants becomes ${ }^{18}$

$$
d=3 \quad \begin{gather*}
\mathrm{TP}_{d}^{w_{1}, p_{1}} \leftarrow \mathrm{TP}_{d}^{\mathrm{SO}} \\
\mathbb{Z}_{3} \stackrel{\bmod 3}{ } \mathbb{Z} \\
1 \longleftarrow \bmod 3 \\
 \tag{40}\\
0 \longleftarrow \bmod 3^{\bmod } 3
\end{gather*}
$$

We show that $p_{1} / 3$ maps to $1 \bmod 3\left(\right.$ thus $\left.c_{-}=0 \bmod 8\right)$ in the $w_{1}-p_{1}$ cobordism $\operatorname{TP}_{3}^{w_{1}, p_{1}}$ which is nonzero. But the $p_{1}$ maps to $3=0 \bmod 3\left(\right.$ thus $\left.c_{-}=0 \bmod 24\right)$ in the $\mathrm{TP}_{3}^{w_{1}, p_{1}}$ which vanishes!

## IV. CONCLUSION AND COMPARISON

Above we have presented a theoretical solution as to why the family number $N_{f}=3$ or its multiple $N_{f} \in 3 \mathbb{Z}$ is favored due to modular invariant and framing anomaly-free. Especially with 16 Weyl fermion per generation in the SM, we map this $N_{f} \in 3 \mathbb{Z}$ SM to a $1+1$ d chiral central charge $c_{-}=24 \mathbb{Z}$ CFT by the dimensional reduction.

We address additional refined questions about our proposed solution:

17 We derive $\mathrm{TP}_{d}^{\text {String }}$ (trivialize $w_{1}, w_{2}, \frac{1}{2} p_{1}$ [framing]) from the ratio of the allowed relative $\frac{1}{2} p_{1}$ class: $\frac{\frac{1}{2} p_{1} \in \mathbb{Z}}{\frac{1}{3} p_{1} \in 16 \mathbb{Z}}=\frac{p_{1} \in 2 \mathbb{Z}}{p_{1} \in 48 \mathbb{Z}}=\mathbb{Z} 24$. 18 We derive $\mathrm{TP}_{d}^{w_{1}, p_{1}}$ (trivialize $w_{1}, p_{1}$ [Atiyah's 2-framing]) from the ratio of the allowed relative $p_{1}$ class: $\frac{p_{1} \in \mathbb{Z}}{\frac{1}{3} p_{1} \in \mathbb{Z}}=\frac{p_{1} \in \mathbb{Z}}{p_{1} \in 3 \mathbb{Z}}=\mathbb{Z} 3$.

## 1: The 4th family? More than $N_{f}=3$ families?

I the hypothetical 4th family or more new families of quarks and leptons do not couple to the SM Higgs nor gain mass from the SM Higgs mechanism, and also if these new families are heavier than $m_{Z} / 2$, then the contemporary experiments have not yet ruled out those possibilities - they are novel mass-generating mechanisms (without symmetry-breaking Higgs fields) known as Symmetric Mass Generation (SMG, see a recent overview [67]). The SMG gapping out the 4th family SM can still survive under the known experimental constraints above as a valid theoretical possibility [68-73], potentially relevant for the Strong CP problem as well [73, 74]. If $N_{f} \in 3 \mathbb{Z}$ constraint still holds, it may suggests a group of 3 more families at much higher-energy above the low-energy SM . It seems more likely that $N_{f} \in 3 \mathbb{Z}$ only constrains more on the lower energy spectrum. It will be interesting to sharpen the statement regarding the energy scales.

## 2: 16 Weyl fermions vs 15 Weyl fermions?

We can comment on the 3 families of 15 Weyl fermions, the absence of sterile right-handed neutrino replaced by topological field theory, and its $\frac{45}{15}=3$ relation to Ultra Unification. Notice that the missing sterile neutrinos also appear to be 3 (so far). So the ratio $\frac{45}{15}=3$ holds. For the reduced 2 d CFT, we can obtain $c_{-}=45 / 2$ but we miss $c_{-}=3 / 2$, which suggests a possible extra Pfaffian-like non-abelian Quantum Hall states [75] with $c_{-}=3 / 2$ in the dimensional reduced 3d bulk as well. This picture could match with the TQFT sector for Ultra Unification.

3: Our argument is topologically robust without requiring any global symmetry and gauge group structure: Even breaking or forgetting all SM gauge group structures or global symmetry structures, our constraints ((1), (2), (3), (4) in Sec. II A) still favor the $N_{f} \in 3 \mathbb{Z}$ family.

In comparison to the literature, we requires no $\mathbb{Z}_{4, X}$ symmetry's $\mathbb{Z}_{16}$ nonperturbative anomaly in 4 d , nor additional $\mathbb{Z}_{3}$ symmetry's $\mathbb{Z}_{9}$ nonperturbative anomaly in 4 d for baryon triality or proton hexality in [51], nor the homotopy group analysis of $G_{\mathrm{SM}_{\mathrm{q}}}[76] .{ }^{19}$ Our solution is entirely distinct from the previous proposals [51, 76] that require specific global or gauge internal symmetry constraints.

## 4: $\mathrm{E}_{8}, 3 \mathrm{E}_{8}$, and Leech lattices: Prediction of additional gapped sectors above the SM?

Along the discussion in (13), indeed there exists proper $\operatorname{SL}(N, \mathbb{Z})$ transformations to map between the fermionic $K_{f}=\square_{8}$ matrix of 8 Weyl fermions to the bosonic $K_{\mathrm{E}_{8}}$ by enlarging the matrix along the diagonal block via introducing extra rank-2 canonical unimodular fermionic matrix $K_{f, 2} \equiv\left(\begin{array}{cc}1 & 0 \\ 0 & -1\end{array}\right)$. There exists also $\mathrm{SL}(N, \mathbb{Z})$ transformations to map between $K_{3 \mathrm{E}_{8}} \equiv K_{\mathrm{E}_{8}} \oplus K_{\mathrm{E}_{8}} \oplus K_{\mathrm{E}_{8}}$ to the other 23 out of the 24 unimodular rank-24 Niemeier lattices, by enlarging the matrix along the diagonal block via introducing extra rank-2 canonical unimodular bosonic matrix $K_{b, 2} \equiv\left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right)$. One of the most famous kind of Niemeier lattices is the rank-24 Leech lattice $K_{\text {Leech }}$. (Beware that there are also other $1+1 \mathrm{~d}$ holomorphic but also meromorphic $c_{-}=24$ CFT [78].) Recall that both the $\mathrm{E}_{8}$ lattice and Leech lattice (as a discrete subgroup of $\mathbb{R}^{8}$ and $\mathbb{R}^{24}$ respectively) are the solutions to the Spherical Packing Problem [79] in 8 and 24 dimensions [80, 81]. Since the 48 Weyl-fermion version of the $3+1 \mathrm{~d}$ SM can be mapped to $1+1 \mathrm{~d} 3\left(\mathrm{E}_{8}\right)_{1} \mathrm{CFT}$ of $K_{3 \mathrm{E}_{8}}$, one could ask what does the $1+1 \mathrm{~d}$ Leech lattice CFT of $K_{\text {Leech }}$ imply? - Does the rank-24 Leech lattice have any use of prediction about the $3+1 \mathrm{~d}$ SM and BSM real-world physics? It implies that by adding additional gapped bosonic sectors from copies of $1+1 \mathrm{~d}$ non-chiral bosonic or fermion CFT of $K_{b, 2}$ or $K_{f, 2}$, bringing these gapped sector down and allowing interactions between new sectors and the SM sector, we can deform the SM's $3\left(\mathrm{E}_{8}\right)_{1}$ CFT to the Leech lattice CFT. The inverse map from the copies of $1+1$ d non-chiral bosonic CFT sector to the $3+1 \mathrm{~d}$ sectors may predict other hidden BSM sectors [42].

5: Apparently since we refer to the $\mathrm{E}_{8}$ lattice and Leech lattice in the Spherical Packing, potential relation to the Conformal Bootstrap, Moonshine (Monstrous moonshine, Mathieu moonshine), Sporadic group and Monster CFT may also help to connect to the Family $N_{f} \in 3 \mathbb{Z}$ structure in the SM.

[^0]:    * jw@cmsa.fas.harvard.edu; http://sns.ias.edu/~juven/

[^1]:    ${ }^{1}$ One inspiration of this work is noticing that the deep UV regularization of $2+1 \mathrm{~d} \mathrm{E}_{8}$ quantum Hall state required more strict branchdependent structure on the triangulation of the manifold, while the $2+1 \mathrm{~d} 3 \mathrm{E}_{8}$ quantum Hall state required less strict branch-independent structure on the triangulation of the manifold [9]. The branch structure seems to be related to the framing structure of the manifold in some way. The author realizes that the Hirzebruch signature [10], framing-anomaly, and modular invariance may give rise to the purely topological constraint on the Family Puzzle $N_{f} \in 3 \mathbb{Z}$. Another inspiration comes from studying the anomalies of SM by the index theorem in [11].
    ${ }^{2}$ For spacetime dimensionality, we either denote the space + time dimension (e.g. $1+1 \mathrm{~d}$ CFT) or the total dimension (e.g. 2d CFT).
    ${ }^{3}$ The semi-direct product $\ltimes$ specifies a group extension. The $N_{\text {shared }}$ is the shared common normal subgroup symmetry between $G_{\text {spacetime }}$ and $G_{\text {internal }}$, e.g. $N_{\text {shared }}$ can be the fermion parity symmetry $\mathbb{Z}_{2}^{\mathrm{F}}$.

[^2]:    ${ }^{4}$ Freed-Hopkins version of cobordism group $\operatorname{TP}_{D}^{G}=\Omega_{D+1}^{G ; \text { free }} \oplus \Omega_{D}^{G ; \text { torsion }}$ [23] consists of the integer free $\mathbb{Z}$ class of $\Omega_{D+1}^{G ; \text { free }}$ and the finite group torsion $\mathbb{Z}_{n}$ class of $\Omega_{D}^{G ; \text { torsion }}$. In summary,

[^3]:    ${ }^{5}$ It may still be possible to have $0,1,2,3$, or more than 3 sterile neutrinos. Also, turning off gauge and Higgs fields is highly-motivated for the high-energy early universe scenario - the fermions become massless. In addition, any Grand Unification with an appropriate semi-simple compact Lie group and with these amounts of fermions exhibits asymptotic freedom like free quarks at higher energy. Here we also clarify the physical meanings of energy spectrum. Typically for particle physics, whenever the particle field description is available, we have massless or massive spectrum. On the other hand, for interacting CFT, it is better to refer its spectrum as gapless; for interacting topological quantum field theory (TQFT), it is better to refer its spectrum as gapped above the (possibly degenerate) ground state(s). Thus, gapless vs gapped are more general than massless vs massive.
    Moreover, the "heavy mass" concept in quantum matter context may mean something different: the inverse of the curvature of the energy dispersion $E(p)$ of momentum $p$, namely $\left(\nabla_{p}^{2} E(p)\right)^{-1}$. This "heavy mass" can coincidentally coincide with the mass gap for Lorentz invariant particle theory, but the Lorentzian coincidence between these masses in general fail either in non-Lorentz invariant or in interacting many-body quantum systems. Regardless of these subtleties of massive or gapped systems, we only focus on Lorentz invariant theories in this work.

[^4]:    ${ }^{6}$ Follow [14], for any dimension $d+1$, we write down a set of Gamma matrices satisfy $\left\{\Gamma^{\mu}, \Gamma^{\nu}\right\}=2 \eta^{\mu \nu}$ for a proper Lorentzian Minkowski metric $\eta^{\mu \nu}=\operatorname{diag}(+,-, \ldots,-)$ in any dimension with spacetime indices $\mu, \nu=0,1, \ldots, d-1, d$. Note that $\mathrm{P}_{ \pm}^{2}=\mathrm{P}_{ \pm}$and $\mathrm{P}_{+} \mathrm{P}_{-}=\mathrm{P}_{-} \mathrm{P}_{+}=0$ and $\mathrm{i} \Gamma^{d} \mathrm{P}_{ \pm}= \pm \mathrm{P}_{ \pm}$.

    - For even $d$, we can choose the chiral or Weyl representation, $\Gamma^{0}=\left(\begin{array}{cc}0 & 0 \\ 0 & 0\end{array}\right), \Gamma^{j}=\left(\begin{array}{cc}0 & \gamma^{j} \\ -\gamma^{j} & 0\end{array}\right)$ for $j=1, \ldots, d-1$ with $\left\{\gamma^{i}, \gamma^{j}\right\}=2 \delta^{i j}$, $\Gamma^{d}=\operatorname{idiag}(-\llbracket, 0)$, so $\mathrm{P}_{ \pm}=\operatorname{diag}(0,0)$ or $\operatorname{diag}(0,0)$. The Gamma matrices $\Gamma^{\mu}$ in $d \mathrm{~d}$ are the same as those in $(d+1) \mathrm{d}$ for even $d$. The $\mathrm{P}_{ \pm}$projection maps a $(d+1)$ d Dirac (or Majorana) fermion to a $d \mathrm{~d}$ chiral Weyl (or Majorana-Weyl) fermion. The $\mathrm{P}_{ \pm}$decouples the left-handed and right-handed Weyl (Majorana-Weyl) fermion in $d \mathrm{~d}$ at $x_{d}=0$ with $m\left(x_{d}\right)=0$. We get a $d \mathrm{~d}$ domain wall fermion Lagrangian $\mathcal{L}_{d \mathrm{~d}}=\psi_{ \pm}^{d \dagger} \mathrm{i}\left(\partial_{t} \mp \gamma^{j} \partial_{j}\right) \psi_{ \pm}^{d}$.
    - For odd $d$, the projection maps a $(\bar{d}+1)$ d Dirac (Majorana) fermion to a $d$ d Dirac (Majorana) fermion. See Fig. 1 (a).

[^5]:    ${ }^{7}$ For standard terminology, the fermionic theory is called Spin that requires a spacetime manifold with Spin structure so to be compatible with fermions as spinors; the bosonic theory is called non-Spin that spacetime manifold requires no Spin structure. For example, on a 2-torus, we have periodic ( P or Ramond $[\mathrm{R}]$ ) and anti-periodic (AP or Neveu-Schwarz [NS]) boundary conditions along each 1-cycle, so that odd Spin structure includes P-P, while even Spin structure includes AP-AP, P-AP, and AP-P. Bosonization requires to sum over all Spin structures.
    ${ }^{8}$ There is a boundary-bulk correspondence between $1+1 \mathrm{~d}\left(\mathrm{E}_{8}\right)_{1} \mathrm{CFT}$ and $2+1 \mathrm{~d}\left(\mathrm{E}_{8}\right)_{1}$ TQFT.
    The $1+1 \mathrm{~d}\left(\mathrm{E}_{8}\right)_{1} \mathrm{CFT}$ is a unique holomorphic Vertex Operator Algebra (VOA) with $c_{-}=8$.
    The $2+1 \mathrm{~d}\left(\mathrm{E}_{8}\right)_{1}$ TQFT is also known as the $\mathrm{E}_{8}$ quantum Hall state [40].
    There are at least three different constructions of these $1+1 \mathrm{~d}$ and $2+1 \mathrm{~d}$ theories:
    $(1)\left(\mathrm{E}_{8}\right)_{1}$ : based on the $\mathrm{E}_{8}$ affine Lie algebra in WZW model and the level-1 non-abelian exceptional simple Lie $\mathrm{E}_{8}$ gauge group ChernSimons theory.
    (2) $\mathrm{SO}(16)_{1}$ up to stack with a trivial $\mathrm{SO}(0)_{1}$ Spin-TQFT: $\mathrm{SO}(16)_{1}$ is Spin-TQFT, which $\left(\mathrm{E}_{8}\right)_{1}$ non-Spin-TQFT stacked with an $\mathrm{SO}(0)_{1}$ spin-TQFT [41].
    (3) $K_{\mathrm{E}_{8}}$ matrix: The $1+1 \mathrm{~d}$ compact chiral boson with $\mathrm{U}(1)^{8}$ global symmetry, or the $2+1 \mathrm{~d}$ abelian Chern-Simons theory with $\mathrm{U}(1)^{8}$ gauge group, which that the symmetric bilinear form pairing between fields is the Cartan $\mathrm{E}_{8}$ matrix $K_{\mathrm{E}_{8}}$. The rank- $8 K_{\mathrm{E}_{8}}$ matrix is unimodular, positive definite, even and symmetric rank-8 matrix. The $K_{\mathrm{E}_{8}}$ is also the intersection form of the unique compact simply connected topological $\mathrm{E}_{8} 4$-manifold which has a signature $\sigma=8$.

[^6]:    ${ }^{9}$ Momentum $P=L_{0}-\bar{L}_{0}$ generates the $\sigma_{1}$ translation, and Hamiltonian $H=L_{0}+\bar{L}_{0}-\frac{1}{24}(c+\bar{c})$ generates the $\sigma_{2}$ translation. Viasoro algebra for $m, n \in \mathbb{Z}$ satisfies

    $$
    \begin{equation*}
    \left[L_{m}, L_{n}\right]=(m-n) L_{m+n}+\frac{c}{12}\left(m^{3}-m\right) \delta_{m+n, 0} \tag{16}
    \end{equation*}
    $$

    while $\left[\bar{L}_{m}, \bar{L}_{n}\right]$ obeys the same but replaced with $\bar{c}$, and $\left[L_{m}, \bar{L}_{n}\right]=0$. The factor of 12 or 24 here comes from Riemann zeta function regularization

    $$
    \zeta(s)=\sum_{n=1}^{\infty} \frac{1}{n^{s}}=1^{-s}+2^{-s}+3^{-s}+\ldots \text { and } \zeta(-1)=\sum_{n=1}^{\infty} n=\frac{-1}{12}
    $$

    which appears in Casimir energy of the quantum vacuum.
    10 Note that Pontryagin-Thom [43-46] construction bridges between geometric manifold and algebraic homotopy aspects of topology. Under Pontryagin-Thom isomorphism, the inherently geometric aspects of framed cobordism theory (such as $d$-dimensional framed bordism group $\Omega_{d}^{\mathrm{fr}}$ ) is mapped to the algebraic and topological structure of stable homotopy theory (such as $\lim _{n \rightarrow \infty} \pi_{d+n} S^{n}$ ). So we have $\Omega_{d}^{\mathrm{fr}} \cong \lim _{n \rightarrow \infty} \pi_{d+n} S^{n}$, here $\Omega_{3}^{\mathrm{fr}} \cong \lim _{n \rightarrow \infty} \pi_{3+n} S^{n}=\mathbb{Z} / 24 \mathbb{Z}=\mathbb{Z}_{24}$. See more in Sec. III and [42].

[^7]:    ${ }^{11}$ From this domain wall reduction discussion, we indeed physically "prove" the ratio of $\Omega_{4}^{\text {SO }}=\mathbb{Z}$ over $\Omega_{4}^{\text {Spin }}=16 \mathbb{Z}$ is isomorphic to $\mathbb{Z} /(16 \mathbb{Z})=\mathbb{Z}_{16} \cong \Omega_{4}^{\text {Pin }^{+}} \cong \Omega_{5}^{\operatorname{Spin} \times \mathbb{Z}_{2} \mathbb{Z}_{4}}$.
    ${ }^{12}$ Here $\hat{\mathrm{A}}$ is the A-roof genus of the spacetime tangent bundle $T M$ over the base spacetime manifold $M$, expressed in terms of $j$-th Pontryagin classes $p_{j}$, while the ch is the total Chern character expressed in terms of $j$-th Chern classes $c_{j}$, and $\mathcal{E}$ is the complex vector bundle associated with the representation of the fermion. We also use the properties $\operatorname{ch}\left(\mathcal{E}_{1} \oplus \mathcal{E}_{2}\right)=\operatorname{ch}\left(\mathcal{E}_{1}\right)+\operatorname{ch}\left(\mathcal{E}_{2}\right)$, and $\operatorname{ch}\left(\mathcal{E}_{1} \otimes \mathcal{E}_{2}\right)=\operatorname{ch}\left(\mathcal{E}_{1}\right) \operatorname{ch}\left(\mathcal{E}_{2}\right)$.
    ${ }^{13}$ To obtain the polynomial coefficients correctly, here we use the convention such that every fermion in 4 d is written as a left-handed Weyl spinor in 4 d (left-handed particle $\psi_{L}$ or right-handed anti-particle $\mathrm{i} \sigma_{2} \psi_{R}^{*}$ ). Every particle contributes +1 (e.g., $\psi_{L}$ ) and every anti-particle contributes -1 (e.g., $\mathrm{i} \sigma_{2} \psi_{R}^{*}$ ), to the quark $\mathbf{Q}$ or lepton $\mathbf{L}$ number, namely the integer charge representation of $\mathrm{U}(1)_{\mathbf{Q}}$ or $\mathrm{U}(1)_{\mathbf{L}}$. We abbreviate $c_{j}\left(\mathcal{E}_{G}\right) \equiv c_{j}(G)$ the $j$-th Chern class of the vector bundle $\mathcal{E}_{G}$ associated with the defining representation of $G$, and $p_{j}(T M)$ is the $j$-th Pontryagin class of the spacetime tangent bundle $T M$.

[^8]:    ${ }^{14}$ Some explanation about the notation [11]:

    - Because all the quarks and leptons have charge 1 under $\mathbb{Z}_{4, X}$, there is no $N_{c}$ factor in this 5 d iTFT.
    $\bullet$ The background gauge field $A_{\mathbb{Z}_{2, X}} \in \mathrm{H}^{1}\left(M^{5}, \mathbb{Z}_{2}\right)$ is obtained by the quotient map down to $\mathbb{Z}_{2, X} \equiv \mathbb{Z}_{4, X} / \mathbb{Z}_{2}^{\mathrm{F}}$ from the $\operatorname{Spin} \times{ }_{\mathbb{Z}_{2}^{\mathrm{F}}} \mathbb{Z}_{4, X^{-}}$ structure on the 5 d spacetime manifold $M^{5}$.
    - Here the 5 d Atiyah-Patodi-Singer (APS) eta-invariant $\eta_{5 \mathrm{~d}}=\eta_{4 \mathrm{~d}}\left(\operatorname{PD}\left(A_{\mathbb{Z}_{2, X}}\right)\right)$ is valued in $\mathbb{Z}_{16} \equiv \mathbb{Z} /(16 \mathbb{Z})$ and is written as the 4 d eta invariant $\eta_{4 \mathrm{~d}} \in \mathbb{Z}_{16}$ on the $4 \mathrm{~d} \operatorname{Pin}^{+}$submanifold representing Poincare dual (PD) to $A_{\mathbb{Z}_{2, X}}$. The Pin ${ }^{+}$structure is obtained from the 5 d bulk Spin $\times \mathbb{Z}_{2}^{\mathrm{F}} \mathbb{Z}_{4, X}$-structure by Smith isomorphism: $\Omega_{5}^{\text {Spin } \times \mathbb{Z}_{2} \mathbb{Z}_{4}} \cong \Omega_{4}^{\mathrm{Pin}+} \cong \mathbb{Z}_{16}$ [17, 50,52, 53]. The eta invariant $\eta_{4 \mathrm{~d}} \in \mathbb{Z}_{16}$ is the effective topological action of the interacting fermionic time-reversal symmetric topological superconductor of condensed matter in three spatial dimensions with an anti-unitary time-reversal symmetry $\mathbb{Z}_{4}^{\mathrm{TF}}$ such that the time-reversal symmetry generator $T$ squares to the fermion parity operator, namely $\mathrm{T}^{2}=(-1)^{\mathrm{F}}$. The symmetry can be defined by the nontrivial group extension $1 \rightarrow \mathbb{Z}_{2}^{\mathrm{F}} \rightarrow \mathbb{Z}_{4}^{\mathrm{TF}} \rightarrow \mathbb{Z}_{2}^{\mathrm{T}} \rightarrow 1$ (see a review [27, 65]). In contrast, in the SM, we have the unitary $\mathbf{B}-\mathbf{L}$-like symmetry $\mathbb{Z}_{4, X}$ whose generator $X$ squares to $X^{2}=(-1)^{\mathrm{F}}$. The symmetry again can be defined by the nontrivial group extension $1 \rightarrow \mathbb{Z}_{2}^{\mathrm{F}} \rightarrow \mathbb{Z}_{4, X} \rightarrow \mathbb{Z}_{2, X} \rightarrow 1$.

[^9]:    ${ }^{15}$ For a unit charge 1 of an axial $\mathrm{U}(1)$ symmetry in the Weyl fermion basis, we choose the left-handed particle and right-handed antiparticle to have $q=1$. We choose the right-handed particle and left-handed anti-particle to have $q=-1$.
    For a unit charge 1 of a vector $\mathrm{U}(1)$ symmetry in the Weyl fermion basis, we choose the left-handed particle and right-handed particle to have $q=1$. We choose the left-handed anti-particle and right-handed anti-particle to have $q=-1$.
    ${ }^{16}$ For condensed matter related physical observable, we write the Thermal Hall conductance [66] in the unit

    $$
    \begin{equation*}
    \kappa_{x y}^{\mathrm{MW}}=\frac{\pi k_{B}^{2} T}{12 \hbar}=\frac{\pi^{2} k_{B}^{2} T}{6 h} . \tag{30}
    \end{equation*}
    $$

[^10]:    19 Although [76] uses the 6d homotopy group, $\pi_{6}(\mathrm{SU}(2))=\mathbb{Z}_{12}, \pi_{6}(\mathrm{SU}(3))=\mathbb{Z}_{6}$ and $\pi_{6}\left(G_{2}\right)=\mathbb{Z}_{3}$, to argue the nonperturbative global anomaly constraints in 6 d , we find that the cobordism classification of nonperturbative global anomaly constraints showing them vanish thus these anomaly constraints may not really exist: $\Omega_{7}^{\operatorname{Spin} \times G_{\mathrm{SM}_{\mathrm{q}}}}=0$ [77] shows no 6d nonperturbative global anomalies.
