(Dated: January 17, 2024)

Jahn-Teller (JT) systems with strong and intermediate vibronic coupling are described in terms of local JT active vibrational modes. In JT crystals, the elastic interaction of these modes at different JT centers plays a crucial role, for instance, in determining critical temperature of structural phase transitions. Despite their importance, the parameters of elastic interaction between JT centers have not been accessed yet by first-principles calculations. In this paper, we develop an effective Hamiltonian methodology for the thorough description of the elastic interactions in cooperative Jahn-Teller problems, which treats the interactions with both phonons and uniform strains. All the microscopic parameters, such as lattice Green's functions, elastic modulus, can be obtained or calculated base on first-principles the calculation. The method has been applied to a series of $5d^1$ double perovskites. Such effective Hamiltonian methodology can be, in general, used to investigate the APES of any type of the local distortions, such as impurities, defects, etc.

I. INTRODUCTION

Multi-center vibronic interactions are found in a wide number of systems such as impurity Jahn-Teller (JT) centers[1], multi-center molecular clusters [2] and JT crystals [3, 4]. In these compounds, except for the $E \otimes b_1$, $E \otimes b_2$, and $T \otimes e$ the vibronic problem, where the vibronic interaction on the centers does not mix different electronic functions, the vibronic problem becomes rather involved, because the localized electrons in degenerated orbital states interact with the JT active distortions of the JT centers, while these JT centers interact via the common vibrational modes (phonons) of the system [5, 6].

Regarding the co-operative JT effect, an one-center nuclear coordinates based approach was proposed for the investigation of the adiabatic potential of molecular systems[7, 8]. However, such an approach seems to be less adequate in the case of two interacting Jahn-Teller impurities in the crystal, in which the derivation of the model Hamiltonian for the static JT effect [9] lack of substantiation. Another method, assuming that the displacement fields due to JT impurities are independent, has been developed, as a perfect approximation for the system where the JT impurities are sufficiently distant [10, 11]. Thus, the theory of vibronic interactions in these systems is not well-developed compared with one-center systems.

In this paper, with the microscopic parameters from first-principles calculations, an effective Hamiltonian for a static cooperative JT effect is proposed. This methodology is then applied to a series of double perovskites (DP) $A_2B'BX_6$.

B'-site ordered double perovskites, of which the structure is shown in Fig. 1 (a),, have attracted increasing interests because of its potential to host diverse exotic states of matter[12]. Different combination of magnetic or nonmagnetic cations of A, B' and B sites will lead to different magnetic phases[13]. There are three series of these DP materials with B electronic configurations nd^1 (T_{2g}^1), nd^2 (T_{2g}^2), and nd^3 (T_{2g}^3), of which each series presents different issues. For example, the crystallographic distortions of T_{2g}^1 and T_{2g}^2 ions are potentially attributed to JT effect, while T_{2g}^3 ions are not. In addition, the orbital moment is not fully quenched in T_{2g}^1 and T_{2g}^2 ions while nd^3 ions are orbital singlets. Recent publications summarize in tabular form what is known about the T_{2g}^2 and T_{2g}^3 cases[14–16]. For the simplicity, $5d^1$ (T_{2g}^1) double perovskites will be the targeted materials for the application.

II. EFFECTIVE HAMILTONIAN FOR COOPERATIVE JAHN-TELLER EFFECT

The basic mechanism for the JT effect is the interaction between nuclei vibrations and the electronic states. For isolated JT active centers, the methodology is clear as discussed by plenty of articles [4, 17–19]. When the JT centers are embedded in crystals, the properties of nuclei vibrations and the electronic structure will be altered by the collective vibrations in the crystal and the symmetry of crystal field, respectively. The properties of one JT active centers may be influenced by the neighboring JT active centers or even the JT active centers far way via phonons. Therefore in the study of cooperative JT effect, the vibrational part should be substituted by the analysis of phonon properties. Specially, when the JT active

* zhishuohuang@gmail.com

† liviu.chibotaru@kuleuven.be

centers presenting in a crystal lattice have a sufficiently high concentration, the stability of the entire crystal can be destroyed, which leads to the uniform strains. Thus, the thorough understanding of cooperative JT effect in crystals should consist of the investigation of the phonon contribution (elastic interaction part) and the uniform strain contribution [5, 6].

A. Contribution from phonons

The potential energy of the Jahn-Teller crystal is described by the operator

$$\hat{H} = \sum_{\mathbf{k}j} \frac{1}{2} \omega_{\mathbf{k}j}^2 Q_{\mathbf{k}j} Q_{\mathbf{k}j}^* + \sum_{\mathbf{n}} \hat{U}_{vib}^{\mathbf{n}}(\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}) \quad (1)$$

where \mathbf{k} and j denote the wave vector and phonon branch, respectively, $Q_{\mathbf{k}j}$ is the phonon modes and $\omega_{\mathbf{k}j}$ the corresponding frequency. $\hat{U}_{vib}^{\mathbf{n}}$, expressed on the basis of a set of (pseudo)degenerate electronic functions localizing at the corresponding center, describes the vibronic interaction with local nuclear distortions, denoted by $q_{\mu\Gamma\gamma}^{\mathbf{n}}$, which transforms after irreducible representation Γ of the site symmetry group at the \mathbf{n} th site of the crystal lattice.

The adiabatic potential energy surface (APES) can be obtained by the summing up the diagonalized potential energy operator ($\hat{U}_{vib}^{\mathbf{n}}$) on each JT active centers [20], expressing as

$$U_{\alpha_1\alpha_2\dots} = \sum_{\mathbf{k}j} \frac{1}{2} \omega_{\mathbf{k}j}^2 Q_{\mathbf{k}j} Q_{\mathbf{k}j}^* + \sum_{\mathbf{n}} \epsilon_{\alpha_n}^{\mathbf{n}}(\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}) \quad (2)$$

where α_n numbers the eigenvalues of the vibronic operator at the \mathbf{n} th center.

Since the phonon modes $Q_{\mathbf{k}j}$ form a complete set basis for the lattice dynamics, as a complete set basis for the dynamics of local JT active centers, local JT active modes $\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}$ can be expressed by the the phonon modes by Van Vleck coefficient $a_{\mu\Gamma\gamma}^{\mathbf{n}}(\mathbf{k}j)$ [21] as:

$$q_{\mu\Gamma\gamma}^{\mathbf{n}} = \sum_{\mathbf{k}j} a_{\mu\Gamma\gamma}^{\mathbf{n}}(\mathbf{k}j) Q_{\mathbf{k}j}. \quad (3)$$

The APES extrema can usually be found by Lagrange multiplier. However, this method can only be applied straightforward for simple JT problem, such as $E \otimes b_1$, $E \otimes b_2$, $T \otimes e$, because in these systems, the non-adiabaticity is no longer important, resulting in the only shifts of equilibrium phonon coordinates. While when the interaction between different JT centers are not negligible, the eigen values $\epsilon_{\alpha_n}^{\mathbf{n}}$ are complicated functions of $Q_{\mathbf{k}j}$, which makes the extrema equations unsolvable for systems with a large number of vibrational modes. Good thing comes when comparing the applications of Lagrange multiplier[22] to both $\{Q_{\mathbf{k}j}\}$, $\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}$ based on the condition defined in Eq. 3. Due to the parity symmetry ($Q_{\mathbf{k}j} = Q_{-\mathbf{k}j}^*$) [23], the complex phonon coordinates

will not double the number of corresponding extrema equations from the Lagrange multiplier. Following the procedure in Appendix A, we have reduced the system of extrema equations for the sheet $U_{\alpha_1\alpha_2\dots}$ to a limited number of equations depending on one-center JT active modes:

$$\frac{\partial \epsilon_{\alpha_n}^{\mathbf{n}}(\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\})}{\partial q_{\mu\Gamma\gamma}} + \sum_{\mathbf{n}'\mu'\Gamma'\gamma'} K_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} q_{\mu'\Gamma'\gamma'}^{\mathbf{n}'} = 0 \quad (4)$$

with

$$K = \Xi^{-1} \quad (5)$$

$$\Xi_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} = \sum_{\mathbf{k}j} \frac{a_{\mu'\Gamma'\gamma'}^{*\mathbf{n}'}(\mathbf{k}j) a_{\mu\Gamma\gamma}^{\mathbf{n}}(\mathbf{k}j)}{\omega_{\mathbf{k}j}^2}. \quad (6)$$

Detailed analysis of Eq. 5 and Eq. 6 can be found as following.

1. Derivation of the effective force matrix

From the derivation of the effective Hamiltonian in Appendix A, the matrix Ξ and K are connected via $K = \Xi^{-1}$. Due to the periodicity, all the relevant property should be treated in reciprocal space[24], though both K and Ξ describe the elastic property in real space. To distinguish the parameters in both reciprocal space and real space, we write $\Xi_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma}$, $K_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma}$ as $\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{n})$, $\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{n})$, because they are parameters depending on the distance between different JT active centers, while the corresponding matrix elements in reciprocal space are denoted as $\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{k})$, $\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{k})$.

First, the $\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{n})$ should be transformed into its representation in reciprocal space,

$$\Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{k}) = \sum_{\mathbf{n}} \Xi_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{n}) \exp(i\mathbf{k} \cdot \mathbf{n}). \quad (7)$$

Second, for each \mathbf{k} , the inverse matrix of $\Xi(\mathbf{k})$ is calculated, which is the elastic coupling matrix in reciprocal space, $K(\mathbf{k})$.

$$K(\mathbf{k}) = \Xi^{-1}(\mathbf{k}). \quad (8)$$

Third, the inverse Fourier transformation will be applied to get the elastic coupling matrix in real space,

$$K_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{n}) = \frac{1}{N} \sum_{\mathbf{k}} K_{\mu'\Gamma'\gamma'}^{\mu\Gamma\gamma}(\mathbf{k}) \exp(-i\mathbf{k} \cdot \mathbf{n}). \quad (9)$$

Since the contribution of phonon (K and Ξ) and uniform strains (K' and Ξ') are independent degrees of freedom, the corresponding total matrix should be the summation of the independent contribution, as shown in Eq. 27 and Eq. 28, respectively. The procedure of the calculation of K matrix, as shown above, can be applied to either each contribution or the total matrix.

2. Lattice Green's functions

In general, the JT active modes are expressed as:

$$q_{\mu\Gamma\gamma}^{\mathbf{n}} = \sum_{\mathbf{n}'\kappa\alpha} c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha) \tau_{\kappa\alpha}(\mathbf{n}') \quad (10)$$

where expansion coefficients $c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha)$ are the displacement of atom κ involved in JT active mode $\mu\Gamma\gamma$, which are known for different basic geometries of the centers[4], $\tau_{\kappa\alpha}(\mathbf{n}')$ is the Cartesian displacement of the atom of type κ at the unit cell \mathbf{n}' of the crystal, α denotes the Cartesian axis (x, y, z). The presence of $\mathbf{n} - \mathbf{n}'$ in $c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha)$ is due to the fact that there might be atoms from other unit cells involved in one JT center, as the case of the JT center in fcc alkali-doped fullerides A₃C₆₀ (A is the alkali atom) in which one JT center involves 74 atoms: 60 carbon atoms, 8 cubic alkali atoms, and 6 octahedral alkali atoms, while there are only 63 atoms in the primitive unit cell [25].

In practical, the direct data from the first-principles

calculations is the phonon dispersion or dynamic matrices, by which any local distortion can be expressed by the phonon modes as[23]:

$$\tau_{\kappa\alpha}(\mathbf{n}) = \frac{1}{\sqrt{NM_\kappa}} \sum_{\mathbf{k}j} e_{\kappa\alpha}^{\mathbf{k}j} Q_{\mathbf{k}j} \exp(i\mathbf{k} \cdot \mathbf{n}) \quad (11)$$

where \mathbf{k} and j denote the momentum and the branch of the phonon, M_κ is the mass of the κ atom, N is the number of the unit cells in the crystal, and $e_{\kappa\alpha}^{\mathbf{k}j}$ denotes the polarization vector. Substituting Eq. 11 into Eq. 10, and comparing it with Eq. 3, we can easily have the expression of the Van Vleck coefficient[21]:

$$a_{\mu\Gamma\gamma}^{\mathbf{n}}(\mathbf{k}j) = \sum_{\mathbf{n}'\kappa\alpha} \frac{c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha)}{\sqrt{NM_\kappa}} e_{\kappa\alpha}^{\mathbf{k}j} \exp(i\mathbf{k} \cdot \mathbf{n}). \quad (12)$$

Substituting Eq. 12 into Eq. A6, we have the final expression for the Ξ matrix:

$$\Xi_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} = \sum_{\mathbf{l}\mathbf{m}} \sum_{\kappa'\kappa} \sum_{\alpha\beta} c_{\mu'\Gamma'\gamma'}(\mathbf{n}' - \mathbf{l}, \kappa', \beta) c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{m}, \kappa, \beta) G_{\kappa'\alpha, \kappa\beta}(\mathbf{m} - \mathbf{l}) \quad (13)$$

with $G_{\kappa'\alpha, \kappa\beta}(\mathbf{n})$ defined as:

$$G_{\kappa'\alpha, \kappa\beta}(\mathbf{n}) = \frac{1}{N} \sum_{\mathbf{k}j} \frac{e_{\kappa'\alpha}^{\mathbf{k}j*} e_{\kappa\beta}^{\mathbf{k}j}}{\sqrt{M_{\kappa'} M_\kappa \omega_{\mathbf{k}j}^2}} \exp(i\mathbf{k} \cdot \mathbf{n}). \quad (14)$$

This $G_{\kappa'\alpha, \kappa\beta}(\mathbf{n})$ is the LGFs [23, 26], which can be obtained from both calculations neutron scattering measurements. From the computational point of view, the LGFs connect the eigenvalues and eigenvectors from the first-principles phonon calculations to the elastic coupling matrix Ξ based on the local JT active modes. On the other hand, the inverse of the LGFs have the same physical meaning of the inter-atomic force constants (IFC) from the standard phonon calculations[27], which is generated from the calculation of the dynamic matrix in the reciprocal space for a grid points in the Brillouin zone (BZ)[28]. However, because of the fact that one JT center might involve more atoms in neighboring unit cells, the evaluation of the elastic coupling for a small grid of unit cells requires the IFC on a larger grid of unit cells. Direct calculation of IFC for larger grid of unit cells is expensive, while a more economic way goes from the IFC on a small grid points in BZ, of which the dynamic matrix is calculated by first-principles method, to generated all the dynamic matrix for a thorough sampling of BZ by Fourier transformation. From this thorough sampling of BZ, the LGFs thus can be computed.

3. Extrema of APES

The solution of Eq. 4 is the equilibrium values in the extrema points $q_{\mu\Gamma\gamma}^{(n,0)}$, which is expressed as:

$$Q_{\bar{\mu}\bar{\Gamma}\bar{\gamma}}^{(0)} = \frac{1}{\omega_{\bar{\mu}\bar{\Gamma}}^2} \sum_{\mathbf{n}\mu\Gamma\gamma} a_{\mu\Gamma\gamma}^{\mathbf{n}}(\bar{\mu}\bar{\Gamma}\bar{\gamma}) \sum_{\mathbf{n}'\mu'\Gamma'\gamma'} K_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} q_{\mu'\Gamma'\gamma'}^{(n',0)} \quad (15)$$

with the stabilization energy as:

$$U_{\alpha_1\alpha_2\dots} = \sum_{\mathbf{n}\mu\Gamma\gamma} \sum_{\mathbf{n}'\mu'\Gamma'\gamma'} \frac{1}{2} K_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} q_{\mu\Gamma\gamma}^{(n,0)} q_{\mu'\Gamma'\gamma'}^{(n',0)} + \sum_{\mathbf{n}} \epsilon_{\alpha_n}^{\mathbf{n}} (\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}). \quad (16)$$

In general, substituting of $q_{\mu\Gamma\gamma}^{(n,0)} q_{\mu'\Gamma'\gamma'}^{(n',0)}$ by $q_{\mu\Gamma\gamma}^{\mathbf{n}} q_{\mu'\Gamma'\gamma'}^{\mathbf{n}'}$, the properties of static JT effect around the equilibrium of extrema can be represented, thus the effective Hamiltonian for the static JT effect in multi-center JT systems can be described by:

$$\hat{H} = \sum_{\mathbf{n}\mu\Gamma\gamma} \sum_{\mathbf{n}'\mu'\Gamma'\gamma'} \frac{1}{2} K_{\mathbf{n}'\mu'\Gamma'\gamma'}^{\mathbf{n}\mu\Gamma\gamma} q_{\mu\Gamma\gamma}^{\mathbf{n}} q_{\mu'\Gamma'\gamma'}^{\mathbf{n}'} + \sum_{\mathbf{n}} U_{\alpha_n}^{\mathbf{n}} (\{q_{\mu\Gamma\gamma}^{\mathbf{n}}\}). \quad (17)$$

It should be noted that, the basic idea of such effective Hamiltonian is the downfolding of all vibrational modes or phonons onto the JT active modes, which does not mean that the contribution from any other local distortions other than these JT active modes is zero. In one word, such effective Hamiltonian can be, in general, used

to investigate the APES of any type of the local distortions, such as impurities, defects, etc.

B. Contribution from uniform strain

When the concentration of JT centers are low, which means the bulk deformation has nothing to do with JT centers, the above derivation of the effective Hamiltonian is complete. On the other hand, low-symmetry structural phases of Jahn–Teller crystals can also influence the bulk deformations[5, 29]. Besides, the phonon states and energies should be a function of the strain, however, because of the problem of applying proper boundary conditions when the crystal is stained, it is useful to treat stain separately from the phonons[6]. However, as pointed out by Born and Huang[30], the uniform strains describing the bulk deformations of the crystal cannot be reduced to a combination of phonon modes. In the following we generalize the approach by taking into account the effects of uniform strains as an independent degree of freedom.

The elastic contribution from uniform strain to the potential energy U_{us} is[31]:

$$U_{us} = \frac{1}{2} NV_0 \sum_{\alpha\beta, \alpha'\beta'} C_{\alpha\beta, \alpha'\beta'} \varepsilon_{\alpha\beta} \varepsilon_{\alpha'\beta'} \quad (18)$$

where N denotes the number of sites, V_0 is the volume of unit cell, $\varepsilon_{\alpha\beta}$ and $C_{\alpha\beta, \alpha'\beta'}$ are general strains and elastic modulus constants with α, β representing the Cartesian index (x, y, z). The definition of $\varepsilon_{\alpha\beta}$ is the same as the definition in any text book:

$$\varepsilon_{\alpha\beta} = \frac{1}{2} \left[\frac{\partial u_\alpha(\mathbf{R})}{\partial R_\beta} + \frac{\partial u_\beta(\mathbf{R})}{\partial R_\alpha} \right], \quad (19)$$

where \mathbf{R} is an arbitrary point in the crystal with \mathbf{u} the displacement field. For uniform strains, the components $\varepsilon_{\alpha\beta}$ are constants throughout the crystal.

Same as the treatment of the phonon contribution in Sec. II A, the U_{us} can be expressed by the symmetrized stains and modulus by the transformation with respect to the irreducible representation Γ of the corresponding crystalline class as:

$$U_{us} = \frac{1}{2} NV_0 \sum_{\Gamma\gamma} C_{\Gamma\gamma} \varepsilon_{\Gamma\gamma}^2 \quad (20)$$

with the transformation for strain and modulus as:

The uniform strain can be symmetrized by the same transformation as the construction of JT active modes [31]:

$$\varepsilon_{\Gamma\gamma} = \sum_{\Gamma\gamma} \Upsilon_{\alpha\beta}^{\Gamma\gamma} \varepsilon_{\alpha\beta} \quad (21)$$

$$C_{\Gamma\gamma} = \sum_{\alpha\beta} \sum_{\alpha'\beta'} C_{\alpha\beta, \alpha'\beta'} \Upsilon_{\alpha\beta}^{\Gamma\gamma} \Upsilon_{\alpha'\beta'}^{\Gamma\gamma} \quad (22)$$

where $\Upsilon_{\alpha\beta}^{\Gamma\gamma}$ is the unitary transformation from the Cartesian coordinates to the symmetrized basis, and $\varepsilon_{\Gamma\gamma}$, $C_{\Gamma\gamma}$ are the symmetrized strain and the modulus, respectively.

Based on the Kanamori's work[32], the uniform strains can be included in the theory of cooperative JT effect as additional terms of vibronic interaction at each JT center. On the other hand, with the symmetrization procedure of general strain and modulus above, the local JT active modes, $\{q_{\mu\Gamma\gamma}^n\}$, can be employed for the full description of the vibronic problems. Thus, the interaction with uniform strains can be included implicitly as additional terms in the Van Vleck expansion, Eq. 12, as independent degrees of freedom:

$$q_{\mu\Gamma\gamma}^n = \sum_{\mathbf{k}j} a_{\mu\Gamma\gamma}^n(\mathbf{k}j) Q_{\mathbf{k}j} + \sum_{\Gamma'\gamma'} a_{\mu\Gamma\gamma}^n(\Gamma'\gamma') \varepsilon_{\Gamma'\gamma'}. \quad (23)$$

Following the procedure as shown in Appendix B, the coefficients ($a_{\mu\Gamma\gamma}^n(\Gamma'\gamma')$) of uniform strain contribution has the form:

$$a_{\mu\Gamma\gamma}^{us}(\Gamma'\gamma') = \sum_{\alpha\beta} \left[\sum_{\mathbf{n}'\kappa\alpha} c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha) R_\beta(\mathbf{n}', \kappa) \right] (\Upsilon^{-1})_{\alpha\beta}^{\Gamma'\gamma'}. \quad (24)$$

Since the uniform strain is independent degrees of freedom, Eq. 6 can be employed directly with the coefficients defined as Eq. 24 for the potential contribution from uniform strain:

$$\Xi'_{\mu'\Gamma'\gamma'} = \sum_{\Gamma\bar{\gamma}} \frac{a_{\mu'\Gamma'\gamma'}(\bar{\Gamma}\bar{\gamma}) a_{\mu\Gamma\gamma}(\bar{\Gamma}\bar{\gamma})}{V_0 C_{\Gamma\bar{\gamma}}^0}. \quad (25)$$

Similar to the definition of elastic coupling matrix contributed from phonon, Eq. 5, the elastic coupling matrix contributed from the uniform strains, is calculation as:

$$K' = \Xi'^{-1}. \quad (26)$$

C. Total elastic interaction matrix

After the discussion about the two independent contributions for the elastic interaction for cooperative JT effect, we come to the total expression of the total elastic interaction matrix, expressing as:

$$\tilde{\Xi} = \Xi + \frac{1}{N} \Xi', \quad (27)$$

with Ξ , and Ξ' expressed by Eq. 13, and 25, respectively. The final expression of the elastic interaction for cooperative JT effect is reached as:

$$\tilde{K} = K + \frac{K'}{N}, \quad (28)$$

where the phonon contribution (K) and the contribution from uniform strains (K') are given by Eq. 5, and Eq. 26 respectively.

III. COOPERATIVE JAHN-TELLER EFFECTS IN $5D^1$ DOUBLE PEROVSKITES

A. Crystal Structure and Jahn-Teller centers

The interested double perovskites in this paper are: Ba_2NaOsO_6 , Ba_2LiOsO_6 , Ba_2MgReO_6 , Ba_2ZnReO_6 , Cs_2TaCl_6 , Cs_2TaBr_6 and Ba_2YWO_6 , in which the B site are Ta^{4+} , W^{5+} , Re^{6+} , Os^{7+} , with the electron occupation situations $5d^1$ (T_{2g}^1). These double perovskites, $A_2B'BX_6$, crystallize into $Fm\bar{3}m$ crystals, with the point group O_h , as shown in Fig. 1 (a), with all the structure parameters shown in Table. I, of which the full list of atomic order is shown in Table. S1 in the supporting information. The structures are taken from the experiments, either determined by neutron powder diffraction or neutron powder refinements. However, not all x coefficient of these compounds were provided, such as of Cs_2TaBr_6 , and Ba_2YWO_6 , thus x coefficient of these materials were given as a general value, which was 0.2300, not far away from the real situation. A relaxation procedure with force convergence threshold 0.1 eV/Å was further performed to get a consistent x coefficient.

In this paper, all the calculations were performed for conventional unit cell, including four JT centers (Fig. 1 (b)). Each JT center consists of the $5d$ metal atom (Ta, W, Re, and Os) surrounded by six high electronegative atoms (O, Cl or Br), forming an octahedral configuration (1 (b)). The label and position of these JT centered atoms are listed in Table. II. The relative position of these four JT centers introduces two types of interacting pairs: one is interaction pair of JTC1 and JTC2, and the other one JTC1 and JTC4. Such an orientation of four JT centers need to be considered, however the analysis will be more complicated, which will be carried out in further studies. Thus in this paper, the relative orientation of the four JT centers will be ignored.

Since there is only one electron, due to the crystal field, the $5d$ orbital splits into E_g and T_{2g} , with E_g higher than T_{2g} . The JT involved orbitals are T_{2g} . The existence of spin-orbital interaction splits T_{2g} into

Γ_7 and Γ_8 . The low lying Γ_8 is the target orbital. The irreducible representation for this system is given as $\Gamma_{vib}^{oct} = a_{1g} \oplus e_g \oplus t_{2g} \oplus t_{1u} \oplus t_{2u}$, therefore according to selection rule, the Γ_8 orbitals linearly couple to JT active modes involved in the symmetric product of Γ_8 representation: $[\Gamma_8^2] = a_{1g} \oplus e_g \oplus t_{2g}$. a_{1g} will not be considered because of the fact that it only shifts the energy levels without any orbital splitting, thus all the parameters corresponding to a_{1g} will be ignored in the following analysis.

B. Computational methods

All the DFT calculations were performed by VASP[39–42]. The plane-wave kinetic energy cutoff was set

FIG. 2. Phonon dispersions for $\text{Ba}_2\text{LiOsO}_6$ and $\text{Ba}_2\text{NaOsO}_6$, distinguished by ‘LiOs’ and ‘NaOs’, respectively.

to 400 eV for $\text{Ba}_2\text{NaOsO}_6$, $\text{Ba}_2\text{LiOsO}_6$, $\text{Ba}_2\text{MgReO}_6$, $\text{Ba}_2\text{ZnReO}_6$, and Ba_2YWO_6 , with 300 eV for Cs_2TaCl_6 , and Cs_2TaBr_6 , and a $6 \times 6 \times 6$ Monkhorst-Pack mesh was used to perform Brillouin zone (BZ) integration in order to ensure the convergence of self-consistent field calculation. The convergence threshold of total energy was set to 10^{-7} eV with that of the forces on atoms to 10^{-4} eV/Å for full relaxation calculations. Projector augmented-wave(PAW) pseudo-potentials [43, 44] are employed with the exchange and correlation approximations Generalized Gradient Approximation PBE (GGA-PBE) [45, 46].

The phonon calculations were carried out by frozen-phonon method with VASP+phonopy[47, 48], in which a $2 \times 2 \times 2$ super-cell was used, with the energy convergence threshold set as 10^{-9} eV. The LGFs are generated on a $31 \times 31 \times 31$, Monkhorst-Pack meshes in BZ. The elastic modulus was calculated by the density functional perturbation theory (DFPT)[49, 50], with a $12 \times 12 \times 12$ Monkhorst-Pack mesh to guarantee the convergence.

C. Ξ matrix

1. Phonon dispersion

The phonon dispersions of $\text{Ba}_2\text{LiOsO}_6$ and $\text{Ba}_2\text{NaOsO}_6$ are shown in Fig. 2, while the phonon dispersions of all the 7 double perovskites can be found in Fig.S1 in supporting information. $\text{Ba}_2\text{NaOsO}_6$ has more broadening dispersion than $\text{Ba}_2\text{LiOsO}_6$ because of the large ratio between the cations and anions. This is clearly from the phonon density of states (DOS), where O atoms mainly contribute to the high energy phonon DOS.

TABLE III. Ξ matrix for JT active centers in one convention unit cell. ‘PH’ and ‘US’ distinguish the parameters from phonons and uniform strain, respectively. From the left to right, and from the top to bottom, the matrix elements correspond to JTD_2, JTD_3, JTD_4, JTD_5 and JTD_6, respectively. The unit is bohr^2/Ha . ‘NaOs’ and ‘LiOs’ are for ‘ $\text{Ba}_2\text{NaOsO}_6$ ’ and ‘ $\text{Ba}_2\text{LiOsO}_6$ ’, respectively.

2. Ξ matrix from phonons

The key parameters in phonon calculation are the IFCs, which describes the response property of one atom with respect to another atom in the crystal. The real space dimension of IFC corresponds to the super-cell generated in the phonon calculation procedure. From the IFCs, by Fourier transformation, the LGFs are generated. The Ξ matrix are computed by the LGFs and the JT active modes, defined in Table. II, by Eq. 13.

The calculated Ξ matrix is shown in Table. III. The onsite coupling parameters are diagonal and have a two and three degeneracy, corresponding to the E_g and T_{2g} states.

3. Ξ matrix from uniform strain

The evaluation of Ξ matrix from uniform strain are carried out with Eq. 25. The required parameters, such as volumes of the convention unit cell and the elastic modulus are listed in Table. IV. The Ξ matrix for $\text{Ba}_2\text{NaOsO}_6$ and $\text{Ba}_2\text{LiOsO}_6$ from the uniform strain, are shown in Table. III. Similarly to that of phonon, the Ξ matrix of uniform strain for the onsite JT center is diagonal with two and three degeneracy. Besides, they have the same magnitude order. However, the LGFs are generally expected to decrease fast with the distance between the centers, as $(\mathbf{n} - \mathbf{n}')^{-3}$ [51], so as the Ξ matrix. While the contribution from uniform strains remains constant for any distance between JT centers. Therefore phonons and uniform strains contribute comparably to the interaction energy of a given JT center with all other centers of the crystal. From this aspect, it is important to include the influence of uniform strain for Cooperative JT

TABLE IV. effect.

D. Effective elastic coupling matrix K

Based on the method described in Sec. II A 1, the effective elastic coupling matrix, K , can be obtain for both phonons and uniform strains.

Though there are two types JT active modes (E_g , and T_{2g}) on each JT center, only E_g modes are considered, as the vibronic coupling constants of E_g are 6 times larger than that of T_{2g} according to N. Iwahara’s study[52], meaning that the contribution of E_g to JT energy is 36 larger than that of T_{2g} . Thus in the analysis of elastic coupling constants, T_{2g} JT active modes are ignored for simplicity.

In the previous section, $\Xi_{\mu'\gamma'}^{\mu\gamma}(\mathbf{R})$ (μ, μ' denote the four JT centers, γ, γ' denote the two components, θ, ϵ of E_g JT active mode, and \mathbf{R} represents the lattice vector) has been truncated to the 4th next nearest conventional unit cells, due to the fast decay of $\Xi_{\mu'\gamma'}^{\mu\gamma}(\mathbf{R})$ on \mathbf{R} . Thus, the elastic coupling matrix K can also be obtained for up to the 4th next nearest conventional unit cells.

The K matrix of E_g modes for Ba₂LiOsO₆ and Ba₂NaOsO₆ from the all-phonon contribution is summarized in Table. V. These parameters can also be obtained based on the IFC from first-principles phonon calculations. However, as demonstrated in the Sec. III B, the $2 \times 2 \times 2$ q-mesh is used for the phonon calculations, meaning that only IFCs on a grid of $2 \times 2 \times 2$ can be generated. While the JT centers usually involves in atoms in more than one unit cell, the direct calculation of K matrix from IFC limits the analysis of the distance-dependence of elastic coupling. A full list of K_g matrix of E_g modes for different unit cells is shown in Table. S4 in the supporting information. On the other hand, for the contribution of uniform strain, VI.

FIG. 3. Distance dependence of K based on all phonons. Red, green and blue represent the parameter $K_{E(\theta)}^{E(\theta)}(\mathbf{n})$, $K_{E(\theta)}^{E(\theta)}(\mathbf{n})$ and $K_{E(\epsilon)}^{E(\epsilon)}(\mathbf{n})$, respectively. The solid and dashed lines represents the process of calculating K matrix with and without the influence of periodicity.

IV. DISCUSSION

In order to have a straightforward comparison with other interaction strength, the elastic coupling matrix K is converted with respect to dimensionless JT active modes via $K / \sqrt{(\omega_{\Gamma\gamma}\omega_{\Gamma'\gamma'} M_{\Gamma\gamma}^{am} M_{\Gamma'\gamma'}^{am})}$, where M^{am} and $\omega_{\Gamma\gamma}$ are the mass of the corresponding atoms in JT mode $\Gamma\gamma$, and the vibration frequencies of $\Gamma\gamma$ JT active modes calculated by the K matrix, as shown in Table. VII. As discussed above, the Ξ matrix has $(\mathbf{n} - \mathbf{n}')^{-3}$ decay with respect to the distance between JT centers, which should be the same situation for elastic matrix K . The distance dependence of elastic coupling parameters ($K_{\mathbf{n}'\Gamma'\gamma'}^{\mathbf{n}\Gamma\gamma}$) in Fig. 3 (solid line). This is the effective K matrix elements including the influence of surrounding JT centers in the crystals. On the other hand, in the extreme situation where there is only one JT impurity or there are only two JT impurities. The interactions between the two JT impurities and the JT active modes on the only one JT impurity become simpler, of which the procedure is shown in D, different from that described in II A 1. The results of such JT impurities with respect to distances are shown in Fig. 3 (dashed line).

For all the elastic matrix, from phonons or uniform strain, the onsite parameters have the degeneracy of 2, corresponding to the E_g JT active modes. To evaluate the dynamic situation, we calculate the contribution of the inter site JT energy and compared to the previous study[52], which is carried out with quantum chemistry computations, as shown in Table. VIII. E_{JT}^E is the amplitude of the JT stabilization of inter site case on the

TABLE V. Contribution from uniform strain. The distance dependent $K_{\mu'\gamma'}^{\mu\gamma}(\mathbf{R})$ matrix in real space. The matrix correspond to $\begin{pmatrix} K_{E_g\theta}^{E_g\theta} & K_{E_g\theta}^{E_g\epsilon} \\ K_{E_g\theta}^{E_g\epsilon} & K_{E_g\epsilon}^{E_g\epsilon} \end{pmatrix}$. R is the crystal constant. LGF, 2body, 1body and 1body(IFC) represent the data calculated with the method proposed in this paper, two-body coupling impurity, and one-body coupling, and calculated directly with interatomic force constants from first-principles calculations, respectively. trough is about 80 times larger than that of inter site case, which indicates unquenched dynamic JTE onsite in these systems.

The E_g JT modes frequencies of Ba_2MgWO_6 are about 540 cm^{-1} based on the Raman spectra [53], which should have similar value as Ba_2MgWO_6 . Our prediction for E_g JT modes frequencies of Ba_2MgWO_6 is 543.886 cm^{-1} , which appears close to that from experiment.

V. CONCLUSIONS

In this paper, an effective Hamiltonian for a static cooperative JT effect is proposed, of which the all the necessary microscopic parameters can be obtained from first-principles calculations. This methodology is applied to a series of double perovskites $A_2B'BX_6$. This methodology can be, in general, used to investigate the APES of any type of the local distortions, such as impurities, defects, etc

Appendix A: Derivation of the effective elastic interaction matrix

Considering the following expression based on Eq. 3, and Eq. 2,

$$F_{\alpha_1 \alpha_2 \dots} = U_{\alpha_1 \alpha_2 \dots} + \sum_{\mathbf{n}} \sum_{\mu \bar{\Gamma} \bar{\gamma}} \lambda_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} \left(q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} - \sum_{\mu \Gamma \gamma} a_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} (\mu \Gamma \gamma) Q_{\mu \Gamma \gamma} \right) \quad (\text{A1})$$

with $\lambda_{\mu \Gamma \gamma}^{(\mathbf{n})}$ the Lagrange multipliers, the extrema equations are:

$$\frac{\partial F_{\alpha_1 \alpha_2 \dots}}{\partial Q_{\mu \Gamma \gamma}} = \omega_{\mu \Gamma} Q_{\mu \Gamma \gamma} - \sum_{\mathbf{n}} \sum_{\mu \bar{\Gamma} \bar{\gamma}} \lambda_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} a_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} (\mu \Gamma \gamma) = 0 \quad (\text{A2})$$

$$\frac{\partial F_{\alpha_1 \alpha_2 \dots}}{\partial q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}} = \frac{\partial \epsilon_{\alpha}^{\mathbf{n}} (\{q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}\})}{\partial q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}} + \lambda_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} = 0 \quad (\text{A3})$$

$$\frac{\partial F_{\alpha_1 \alpha_2 \dots}}{\partial \lambda_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}} = q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} - \sum_{\mu \Gamma \gamma} a_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} (\mu \Gamma \gamma) Q_{\mu \Gamma \gamma} = 0. \quad (\text{A4})$$

With the Eq. A4, and multiplying $a_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} (\mu \Gamma \gamma) / \omega_{\Gamma \gamma}^2$ to Eq. A2, we have:

$$q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} = \sum_{\mathbf{n}' \mu' \Gamma' \gamma'} \lambda_{\mu' \Gamma' \gamma'}^{\mathbf{n}'} \Xi_{\mathbf{n}' \mu' \Gamma' \gamma'}^{\mathbf{n} \bar{\Gamma} \bar{\gamma}} \quad (\text{A5})$$

where $\Xi_{\mathbf{n}' \mu' \Gamma' \gamma'}^{\mathbf{n} \bar{\Gamma} \bar{\gamma}}$ is defined as:

$$\Xi_{\mathbf{n}' \mu' \Gamma' \gamma'}^{\mathbf{n} \bar{\Gamma} \bar{\gamma}} = \sum_{\mathbf{k}j} \frac{a_{\mu' \Gamma' \gamma'}^{\mathbf{n}'} (\mathbf{k}j) a_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} (\mathbf{k}j)}{\omega_{\mathbf{k}j}^2}. \quad (\text{A6})$$

Since the matrix Ξ consisting of the elastic parameters of the multi-atomic system only, is Hermitian, of which the inverse matrix ($K = \Xi^{-1}$) is Hermitian as well, the Lagrange multipliers can be expressed as

$$\lambda_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}} = \sum_{\mathbf{n}' \mu' \Gamma' \gamma'} K_{\mathbf{n}' \mu' \Gamma' \gamma'}^{\mathbf{n} \bar{\Gamma} \bar{\gamma}} q_{\mu' \Gamma' \gamma'}^{\mathbf{n}'}. \quad (\text{A7})$$

The extrema expression based on only the local JT active modes can be obtained by substituting the expression Eq. A7 in to Eq. A3, which goes like:

$$\frac{\partial \epsilon_{\alpha}^{\mathbf{n}} (\{q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}\})}{\partial q_{\mu \bar{\Gamma} \bar{\gamma}}^{\mathbf{n}}} + \sum_{\mathbf{n}' \mu' \Gamma' \gamma'} K_{\mathbf{n}' \mu' \Gamma' \gamma'}^{\mathbf{n} \bar{\Gamma} \bar{\gamma}} q_{\mu' \Gamma' \gamma'}^{\mathbf{n}'} = 0 \quad (\text{A8})$$

Appendix B: Derivation of coefficients $a_{\mu \Gamma \gamma}^{\mathbf{n}} (\Gamma \gamma)$

The atomic displacements $u_{\kappa \alpha}(\mathbf{n})$ can be decomposed into the contributions from phonons ($u_{\kappa \alpha}^{ph}(\mathbf{n})$) and uniform strains ($u_{\kappa \alpha}^{us}(\mathbf{n})$), as

$$u_{\kappa \alpha}(\mathbf{n}) = u_{\kappa \alpha}^{ph}(\mathbf{n}) + u_{\kappa \alpha}^{us}(\mathbf{n}). \quad (\text{B1})$$

The uniform strain terms can be expressed as:

$$u_{\kappa \alpha}^{us}(\mathbf{n}) = \sum_{\beta} \tilde{\varepsilon}_{\alpha \beta} R_{\alpha}(\mathbf{n} \kappa) \quad (\text{B2})$$

where $\mathbf{R}(\mathbf{n} \kappa)$ is the position of the atom ($\mathbf{n} \kappa$) in a common coordinate system and the coefficients $\tilde{\varepsilon}_{\alpha \beta} = \partial u_{\alpha}^{us} / \partial R_{\beta}$ are constants in the case of uniform strains, of which the total number is nine. The nine coefficients includes 6 symmetric tensor elements, which are equivalent to the six tensor elements of the general strain, and 3 anti-symmetric tensor elements, describing the uniform bulk rotation of the crystal around three Cartesian axes. Thus, for the cooperative JT problem, the general strain tensor can be used as the coefficients $\tilde{\varepsilon}_{\alpha \beta}$. Thus, Eq. B2, can be written as:

$$u_{\kappa \alpha}^{us}(\mathbf{n}) = \sum_{\beta} \varepsilon_{\alpha \beta} R_{\alpha}(\mathbf{n} \kappa). \quad (\text{B3})$$

With the definition of JT active modes, Eq. 10, the uniform strains contribution, the second term in Eq. 23, becomes

$$q_{\mu \Gamma \gamma}^{\mathbf{n}} = \sum_{\alpha \beta} \left[\sum_{\mathbf{n}' \kappa \alpha} c_{\mu \Gamma \gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha) R_{\beta}(\mathbf{n}', \kappa) \right] \varepsilon_{\alpha \beta}. \quad (\text{B4})$$

The translational symmetry of the uniform strains results in the invariance of the coefficients $c_{\mu \Gamma \gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha)$,

and $\sum_{\mathbf{n}'\kappa\alpha} c_{\mu\Gamma\gamma}(\mathbf{n} - \mathbf{n}', \kappa, \alpha) = 0$, which are valid for all the JT active modes. With the transformation between general strain and the symmetric strain, Eq. 21, we can obtain the expression of the coefficients for the uniform strain contribution, Eq. 24, in which the \mathbf{n} is omitted because of the translational invariance.

Appendix C: Derivation of the symmetrized elastic modulus for cubic systems

Starting from Eq. 18, for cubic system, there are only three independent elastic modulus element, of which the relations of all the element of elastic modulus is shown as following:

$$\begin{aligned} C_{xxxx} &= C_{yyyy} = C_{zzzz} \\ C_{xxyy} &= C_{xxzz} = C_{yyzz} = C_{zzyy} = C_{zzxx} = C_{yyxx} \\ C_{xyxy} &= C_{yzyz} = C_{zxzx} \\ C_{xyzx} &= C_{xyxx} = C_{xyyy} = C_{xyzz} = C_{xyyz} = 0 \\ C_{yzxx} &= C_{yzyy} = C_{yzzz} = C_{xzxy} = C_{yzxx} = 0 \quad (\text{C1}) \\ C_{zxxx} &= C_{zzyy} = C_{zxzz} = C_{zxyy} = C_{zxyz} = 0 \\ C_{xxxy} &= C_{xxyz} = C_{xxzx} = C_{yyxy} = C_{yyyz} \\ &= C_{yyzx} = C_{zzxy} = C_{zzyz} = C_{zzzx} = 0 \end{aligned}$$

while $\varepsilon_{xy} = \varepsilon_{yx}$, $\varepsilon_{yz} = \varepsilon_{zy}$, and $\varepsilon_{zx} = \varepsilon_{xz}$, so that the Eq. 18 can be expanded as

$$\begin{aligned} U_{us} &= \frac{NV_0}{2} C_{xxxx}(\varepsilon_{xx}^2 + \varepsilon_{yy}^2 + \varepsilon_{zz}^2) \\ &+ 2NV_0 C_{xxyy}(\varepsilon_{xy}^2 + \varepsilon_{yz}^2 + \varepsilon_{zx}^2) \\ &+ NV_0 C_{xyxy}(\varepsilon_{xx}\varepsilon_{yy} + \varepsilon_{xx}\varepsilon_{zz} + \varepsilon_{yy}\varepsilon_{zz}) \quad (\text{C2}) \end{aligned}$$

The uniform strain is independent compared with the vibronic distortions for the static JT case. To study the contribution of uniform strain, we should express the contribution of uniform strain in the same basis set as the study of JT effect.

In the octahedral case, the symmetry should be O_h , where the Cartesian index, x, y, z, has the same symmetry of T_{1u} element. So the symmetrized basis set should be determined by the direct product $T_{1u} \otimes T_{1u} = A_1 \oplus E \oplus \{T_1\} \oplus T_2$. From the Koster's group tables, we have the relation between the symmetrized strains and the general strains, which are also the elements of Υ matrix defined in Eq. 21, as

$$\begin{aligned} \varepsilon_{xx} &= \frac{1}{\sqrt{3}}\varepsilon_{A_1} - \frac{1}{\sqrt{6}}\varepsilon_{E(\theta)} + \frac{1}{\sqrt{2}}\varepsilon_{E(\epsilon)} \\ \varepsilon_{yy} &= \frac{1}{\sqrt{3}}\varepsilon_{A_1} - \frac{1}{\sqrt{6}}\varepsilon_{E(\theta)} - \frac{1}{\sqrt{2}}\varepsilon_{E(\epsilon)} \\ \varepsilon_{xx} &= \frac{1}{\sqrt{3}}\varepsilon_{A_1} + \frac{\sqrt{2}}{\sqrt{3}}\varepsilon_{E(\theta)} \quad (\text{C3}) \\ \varepsilon_{yz} &= \varepsilon_{T_2(\xi)} \\ \varepsilon_{zx} &= \varepsilon_{T_2(\eta)} \\ \varepsilon_{xy} &= \varepsilon_{T_2(\zeta)} \end{aligned}$$

Substituting Eq. C3 into Eq. C2, we have

$$\begin{aligned} U_{us} &= \frac{NV_0}{2} [(C_{xxxx} + 2C_{xxyy})e_{A_1}^2 \\ &+ (C_{xxxx} - C_{xxyy})e_{E(\theta)}^2 + (C_{xxxx} - C_{xxyy})\varepsilon_{E(\epsilon)}^2 \\ &+ 4C_{xxyy}(\varepsilon_{T_2(\xi)}^2 + \varepsilon_{T_2(\eta)}^2 + \varepsilon_{T_2(\zeta)}^2)] \quad (\text{C4}) \end{aligned}$$

Comparing with the form in Eq. 20, we have the correspondence of general elastic modulus and the symmetrized elastic modulus as

$$\begin{aligned} C_{A_1} &= C_{xxxx} + 2C_{xxyy} \\ C_{E(\theta)} &= C_{E(\epsilon)} = C_{xxxx} - C_{xxyy} \\ C_{T_2(\xi)} &= C_{T_2(\eta)} = C_{T_2(\zeta)} = 4C_{xxyy} \end{aligned} \quad (\text{C5})$$

Appendix D: K matrix for isolated JT impurities

This is to check the trend of K matrix elements with respect to the distance between two JT centers, for which there are three situations: 1). only considering the isolated one JT center, 2). considering JT pairs separated with a distance \mathbf{n} . The following derivations and calculations were done with the example of $\text{Ba}_2\text{NaOsO}_6$. In order to have a better comparison of the strength of elastic interactions, K matrix is transformed based on the dimensionless JT modes: $K^{dl} = K/(\omega \times M_{am})$.

1. Case 1: 1body JT center

In this situation, JT centers are treated as impurities, which means, there are only the two JT centers in the crystals. Thus, the K matrix will be calculated directly from Ξ matrix.

For on-site situation, the Ξ matrix considered should be a 2×2 matrix as

$$\Xi_{1body} = \begin{pmatrix} \Xi_{1E_\theta}^{1E_\theta} & \Xi_{1E_\theta}^{1E_\epsilon} \\ \Xi_{1E_\epsilon}^{1E_\theta} & \Xi_{1E_\epsilon}^{1E_\epsilon} \end{pmatrix} \quad (\text{D1})$$

where, due to symmetry, $\Xi_{1E_\theta}^{1E_\theta} = \Xi_{1E_\epsilon}^{1E_\theta} = \Xi_0$, $\Xi_{1E_\theta}^{1E_\epsilon} = \Xi_{1E_\epsilon}^{1E_\theta} = 0$.

The corresponding K_{1body} matrix is determined by directly inverse the Ξ_{1body} matrix,

$$K_{1body} = \begin{pmatrix} K_{1E_\theta}^{1E_\theta} & K_{1E_\theta}^{1E_\epsilon} \\ K_{1E_\epsilon}^{1E_\theta} & K_{1E_\epsilon}^{1E_\epsilon} \end{pmatrix} = \begin{pmatrix} \frac{1}{\Xi_0} & 0 \\ 0 & \frac{1}{\Xi_0} \end{pmatrix} \quad (\text{D2})$$

and the corresponding frequencies $\omega_{1body} = \sqrt{1/(\Xi_0 * M^{am})}$.

2. Case 2: JT interacting pairs

For the interactions involving two JT centers, the Ξ matrix should be a 4×4 matrix, consisting of two 2×2 matrices corresponding to 2 JT centers, as

$$\Xi_{2body}(\mathbf{R}) = \begin{pmatrix} \Xi_{1E_\theta}^{1E_\theta} & \Xi_{1E_\epsilon}^{1E_\theta} & \Xi_{2E_\theta}^{1E_\theta}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\theta}(\mathbf{R}) \\ \Xi_{1E_\epsilon}^{1E_\theta} & \Xi_{1E_\epsilon}^{1E_\epsilon} & \Xi_{2E_\theta}^{1E_\epsilon}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\epsilon}(\mathbf{R}) \\ \Xi_{1E_\theta}^{2E_\theta}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\theta}(\mathbf{R}) & \Xi_{2E_\theta}^{2E_\theta} & \Xi_{2E_\epsilon}^{2E_\theta} \\ \Xi_{1E_\theta}^{2E_\epsilon}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\epsilon}(\mathbf{R}) & \Xi_{2E_\theta}^{2E_\epsilon} & \Xi_{2E_\epsilon}^{2E_\epsilon} \end{pmatrix} \quad (\text{D3})$$

$$= \begin{pmatrix} \Xi_{1E_\theta}^{1E_\theta} & 0 & \Xi_{2E_\theta}^{1E_\theta}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\theta}(\mathbf{R}) \\ 0 & \Xi_{1E_\epsilon}^{1E_\epsilon} & \Xi_{2E_\theta}^{1E_\epsilon}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\epsilon}(\mathbf{R}) \\ \Xi_{1E_\theta}^{2E_\theta}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\theta}(\mathbf{R}) & \Xi_{1E_\theta}^{1E_\theta} & 0 \\ \Xi_{1E_\theta}^{2E_\epsilon}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\epsilon}(\mathbf{R}) & 0 & \Xi_{1E_\epsilon}^{1E_\epsilon} \end{pmatrix} \quad (\text{D4})$$

, where $\mathbf{R} = \mathbf{n} - \mathbf{n}'$ is the vector between the two JT centers locating in \mathbf{n} , and \mathbf{n}' , respectively.

The corresponding $K_{2body}(\mathbf{R})$ matrix is determined by the direct inverse of $\Xi_{2body}(\mathbf{R})$:

$$K_{2body}(\mathbf{R}) = \text{inv} \begin{pmatrix} \Xi_{1E_\theta}^{1E_\theta} & 0 & \Xi_{2E_\theta}^{1E_\theta}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\theta}(\mathbf{R}) \\ 0 & \Xi_{1E_\epsilon}^{1E_\epsilon} & \Xi_{2E_\theta}^{1E_\epsilon}(\mathbf{R}) & \Xi_{2E_\epsilon}^{1E_\epsilon}(\mathbf{R}) \\ \Xi_{1E_\theta}^{2E_\theta}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\theta}(\mathbf{R}) & \Xi_{1E_\theta}^{1E_\theta} & 0 \\ \Xi_{1E_\theta}^{2E_\epsilon}(\mathbf{R}) & \Xi_{1E_\epsilon}^{2E_\epsilon}(\mathbf{R}) & 0 & \Xi_{1E_\epsilon}^{1E_\epsilon} \end{pmatrix} \quad (\text{D5})$$

$$= \begin{pmatrix} K_{1E_\theta}^{1E_\theta} & K_{1E_\theta}^{1E_\theta} & K_{2E_\theta}^{1E_\theta}(\mathbf{R}) & K_{2E_\epsilon}^{1E_\theta}(\mathbf{R}) \\ K_{1E_\theta}^{1E_\epsilon} & K_{1E_\epsilon}^{1E_\epsilon} & K_{2E_\theta}^{1E_\epsilon}(\mathbf{R}) & K_{2E_\epsilon}^{1E_\epsilon}(\mathbf{R}) \\ K_{1E_\theta}^{2E_\theta}(\mathbf{R}) & K_{1E_\epsilon}^{2E_\theta}(\mathbf{R}) & K_{2E_\theta}^{2E_\theta} & K_{2E_\epsilon}^{2E_\theta} \\ K_{1E_\theta}^{2E_\epsilon}(\mathbf{R}) & K_{1E_\epsilon}^{2E_\epsilon}(\mathbf{R}) & K_{2E_\theta}^{2E_\epsilon} & K_{2E_\epsilon}^{2E_\epsilon} \end{pmatrix}. \quad (\text{D6})$$

Since the 2×2 block of the onsite interaction might not be diagonal, a diagonalization procedure is required, from which the frequencies are determined from the $K_{1E_\theta}^{1E_\theta}(\mathbf{R} = \mathbf{0}, \text{diag})$: $\omega_{\text{crystal}} = \sqrt{K_{1E_\theta}^{1E_\theta}(\mathbf{R} = \mathbf{0}, \text{diag})/M^{\text{am}}}$.

Supplemental Materials: First-principles derivation of elastic interaction between Jahn-Teller centers in crystals via LGFs

Before showing the information in this document, one thing should be noted that for simplicity, ‘LiOs’, ‘NaOs’, ‘MgRe’, ‘ZnRe’, ‘YW’, ‘TaCl’, and ‘TaBr’ represent for Ba_2LiOsO_6 , Ba_2NaOsO_6 , Ba_2MgReO_6 , Ba_2ZnReO_6 , Ba_2YWO_6 , Cs_2TaCl_6 , and Cs_2TaBr_6 , respectively.

This document includes the following information:

The phonon dispersions of all the seven double perovskites studied in this paper are shown in Fig. S1.

The position order of atoms in the convention unit cell is shown in Table. S1.

The Ξ matrix from full phonons, for the inter site, the nearest, next nearest, next next nearest, next next next nearest, next next next next nearest sites, for all the double perovskites are shown in Table. S2. The Ξ matrix contributed from acoustic phonons, for the inter site, the nearest, next nearest, next next nearest, next next next nearest, next next next next nearest sites, for all the double perovskites are shown in Table. S2.

All the Ξ matrix from the uniform strain are shown in Table. S3.

The K matrix of only E_g JT active modes for the original, nearest, next nearest convention unit cells, from full phonons are shown in Table. S4.

The K matrix from the uniform strain is summarized in Table. S5.

The K matrix from IFCs are shown in Table. S6.

FIG. S1. Phonon dispersions of double perovskites.

TABLE S2. Ξ matrix for both intra and inter JT active centers. The inter site interaction is labeled as 1N, 2N, 3N, 4N, 5N, for the nearest, next nearest, next next nearest sites, respectively. JTC1, JTC2, JTC3 are the label for the JT active centers, as defined in Table. II. From the left to right, and from the top to bottom, the matrix elements correspond to JTD₂, JTD₃, JTD₄, JTD₅ and JTD₆, respectively. The unit is $m_e bohr^2/Ry$.

	Intra	1N	2N	3N	4N	5N

TABLE S5. Contribution from uniform strain: $K_{\mu'\gamma'}^{\mu\gamma}$ matrix in real space. The each 2×2 block correspond to $\begin{pmatrix} K_{E_g\theta}^{E_g\theta} & K_{E_g\theta}^{E_g\epsilon} \\ K_{E_g\epsilon}^{E_g\theta} & K_{E_g\epsilon}^{E_g\epsilon} \end{pmatrix}$ of one JT center. The unit is meV.

TABLE S6. K matrix from IFCs:: $K_{\mu'\gamma'}^{\mu\gamma}$ matrix in real space. The each 2×2 block correspond to $\begin{pmatrix} K_{E_g\theta}^{E_g\theta} & K_{E_g\theta}^{E_g\epsilon} \\ K_{E_g\theta}^{E_g\epsilon} & K_{E_g\epsilon}^{E_g\epsilon} \end{pmatrix}$ of one JT center. The unit is meV.
