**Keywords:** Antagonistic game, game modeling, nature interaction, population, model, incentive programs, support measures, demographic trends, game theory.

## Abstract

The article constructs a game-theoretic model of preventive measures for the antagonistic game with nature, that is such a model in which two participants take part, one of which is a regulating body (government) that makes legislative decisions depending on the emerging external and internal conditions affecting the course of the demographic process, the second participant – internal and external conditions of the environment (nature). An example of such a game is given and the optimal strategy for the government is calculated.

## 1 Introduction

Virtually all countries at different periods of their history have faced the phenomenon of demographic crisis, and the Russian Federation was not left out of this trend. The last period of marked decline in the birth rate in Russia was in the 1990s and 2000s, which was associated with major changes in the post-Soviet space.

There is also a gradual process of change in the population structure from a traditional society with high birth and death rates to an industrialised and eventually post-industrial society with low birth and death rates.

The demographic situation is influenced by various factors, including the level of education, quality of life and socio-economic environment. In Russia, as in many other countries, demographic support programs are being introduced to regulate fertility. It is important to note that the impact of these programs on fertility can be diverse and depends on various factors.

However, all of them are aimed at stimulating the population to take such an important and responsible step as having children.

Let us consider what kind of demographic incentive programs can be disseminated among the population to improve fertility:

1. The program of maternal (family) capital. It is oriented towards providing money to families in the context of the birth or adoption of a first or second child. These funds, often paid in two instalments over a period of time, provide an opportunity for families to improve housing conditions or pay the education.
2. Mortgage loan packages for young families provide an opportunity to obtain favourable mortgage loan terms for the purchase of primary housing. This provides an opportunity to reduce the financial burden on young families, contributing to their stability during important life events.
3. Benefits and allowances for large families include a wide range of government incentives such as transport allowances, free school meals, utility subsidies and other forms of financial support aimed at promoting the well-being of large families.
4. The development of preschool education is supported by the State in the form of the construction of new preschool establishments and the improvement of the qualifications of teaching staff. These measures are aimed at easing the responsibility of families and ensuring high quality education for young children.
5. State medical support covers programs to reduce maternal and child mortality rates by providing free medical services for pregnant women and systematic newborn screening. These initiatives contribute to improving the overall health of mothers and children, which is strategically important for the well-being of families and society as a whole.

## 2 Antagonistic Problem Formulation

Suppose that the government needs to determine how population support programs will affect negative demographic trends. The uncertainty of long-run forecasts of external conditions makes a game-theoretic approach useful if we take the government and environmental conditions as agents I and II, respectively, who pursue directly opposite goals. Then, for a finite set of alternatives available to the government and a finite set of forecasts of environmental conditions, we can construct positional games.

Consider when one agent (the government) can undertake one of  $n$  events, with event  $j$  reducing the losses from phenomenon  $j$  to zero and affecting the losses caused by action  $i$  ( $i \neq j$ ). Let the outcome from events with flow  $j$  be  $q_j > 0$ , and the losses from phenomenon  $i$ , if a change  $j$  ( $j \neq i$ ) is made, be  $r_{ij} \geq 0$ . If the utility of nature (agent I) is understood as the loss it causes to the party in question (agent II), then this conflict can be modelled by a finite antagonistic game defined by a matrix of payoffs

$$H = \begin{pmatrix} q_1 & r_{12} + q_2 & \dots & r_{1n} + q_n \\ r_{21} + q_1 & q_2 & \dots & r_{2n} + q_n \\ \dots & \dots & \dots & \dots \\ r_{n1} + q_1 & r_{n2} + q_2 & \dots & q_n \end{pmatrix}$$

1

Obviously, agent II will try to minimise his losses and, counting on the worst case, must assume that agent I (nature) is antagonistic to him. Let us consider some cases of antagonistic games.

### 3 Solution of the task at hand

#### 3.1 Neutralising strategies of agents

Consider the case of independence. Here we assume that only event  $j$  neutralises nature's strategy  $j$ , i.e.  $r_{jj} = 0$ , and in the other cases the loss is independent of whether the event is produced or not. For nature's strategy  $j$ , we will put the loss as in the previous case equal to  $t_j$ . For convenience, we will assume that  $t_1 > t_2 > \dots > t_n$ . In addition, we will put  $q_i = 0$ . This case models conflicts in which the cost of additional interventions is negligible compared to the possible damage. Then the matrix  $H$  takes the form

$$\begin{pmatrix} 0 & t_1 & t_1 & \dots & t_1 \\ t_2 & 0 & t_2 & \dots & t_2 \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ t_n & t_n & t_n & \dots & 0 \end{pmatrix}$$

The game with the winning matrix  $H$  of the previous case is reduced to the same form on the basis of the theorem on mixed strategies of players if all  $p$  are equal to each other. Let us find the solution of the game under consideration. Let the following inequalities hold for all

$$3 \leq k \leq n$$

$$t_k > (k - 2) / \sum_{i=1}^{k-1} \frac{1}{t_i}. \quad (1.1)$$

Then for all  $j = 1, 2, \dots, n$  the following inequalities hold

$$t_j > (n - 1) / \sum_{i=1}^n \frac{1}{t_i} \quad (1.2)$$

as the numbers  $l_j$  decrease with increasing index. Due to inequalities (1.2), the strategy  $Y^*$ , whose components are determined by the following equations

$$\eta_j^* = \frac{t_j \sum_{i=1}^n 1/t_i - (n - 1)}{t_j \sum_{i=1}^n 1/t_i} \quad (1.3)$$

is the mixed strategy of agent II. Applying it against agent I's pure strategy  $i$ , he gets the value of

$$H(i, Y^*) = i_i \sum_{j \neq i} \eta_j^* = (1 - \eta_i^*) t_i = (n - 1) / \sum_{k=1}^n \frac{1}{t_k}; \quad 1 \leq i \leq n. \quad (1.4)$$

If agent I applies the strategy  $X^*$  for which

$$\xi_i^* = \left( t_i \sum_{k=1}^n \frac{1}{t_k} \right)^{-1} \quad (1.5)$$

against the pure strategy  $j$  of agent II, then he will get

$$H(X^*, j) = \sum_{i \neq j} t_i \xi_i^* = \frac{n - 1}{\sum_{k=1}^n 1/t_k}, \quad 1 \leq j \leq n. \quad (1.6)$$

It follows from (1.4) and (1.6) that the value  $(n - 1) (\sum_{k=1}^n 1/t_k)^{-1}$  is the value of the game, and the mixed strategies  $X^*$  and  $Y^*$  are the optimal mixed strategies of agents I and II.

Consider an example where the support measures add  $t_1 = 30$  thousand people,  $t_2 = 28$  thousand people,  $t_3 = 26$  thousand people, and  $t_4 = 24$  thousand people,  $t_5 = 22$  thousand people, respectively. Taking the state support measures for agent II and evaluating the utility of agent I (nature) by the loss  $t_i$ , we arrive at an antagonistic finite game, which models the considered conflict with nature and is given by the gain matrix

$$H = \begin{pmatrix} 0 & 30 & 30 & 30 & 30 \\ 28 & 0 & 28 & 28 & 28 \\ 26 & 26 & 0 & 26 & 26 \\ 24 & 24 & 24 & 0 & 24 \\ 22 & 22 & 22 & 22 & 0 \end{pmatrix}$$

It is easy to establish that this game belongs to the case of independence of the above example, and therefore for its solution we check the fulfilment of inequalities (1.2). These inequalities are fulfilled because inequalities (1.1) are true. Consequently, we can use formula (1.3) to compute the optimal strategy of the state.

As a result, we find  $Y^* = (0.315, 0.266, 0.21, 0.143, 0.066)$ , and calculate the value of the game by the formula

$$v = \frac{n-1}{\sum_{k=1}^n \frac{1}{t_k}} = 20.8$$

Thus, the optimal strategy of the government is to allocate a share  $y_i$  to the  $i$  program, and the value of the game (i.e. the expected income in the least favourable case) will be  $v = 20.8 \cdot 10^3$  newborns.

### 3.2 Mixed strategies of agents

Suppose now that inequalities (1.1) are not fulfilled for some values of  $k$ . Then there exists a minimum index  $\omega$  for which the inequalities (1.1) are still satisfied, and for  $\omega + 1$  – are violated, i.e.

$$i_k > (k-2) \left( \sum_{i=1}^{k-1} \frac{1}{t_i} \right)^{-1}, \quad 3 \leq k \leq \omega_2 \quad (1.7)$$

$$t_{\omega+1} \leq (\omega-1) \left( \sum_{i=1}^{\omega} \frac{1}{t_i} \right)^{-1} \quad (1.8)$$

By virtue of inequalities (1.7) the numbers

$$\eta_j^* = \frac{t_j \sum_{i=1}^{\omega} 1/t_i - (\omega-1)}{t_j \sum_{i=1}^{\omega} 1/i_j}, \quad 1 \leq j \leq \omega, \quad (1.9)$$

are non-negative and sum to one. Then, the strategy  $Y^* = (\eta_1^*, \dots, \eta_{\omega}^*, 0, \dots, 0)$  is determined by (1.9) and is a mixed strategy of agent II. Applying it against agent I's pure strategy  $i$ , he will lose  $H(i, Y^*)$ , and for  $i = 1, 2, \dots, \omega$  the following is true

$$H(i, Y^*) = (1 - \eta_i^*) t_i = (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1}, \quad (1.10)$$

and for  $i \geq \omega + 1$  from the fact that the numbers  $t_i$  are decreasing. It follows from inequalities (1.8) that

$$H(i, Y^*) = (1 - \eta_i^*) t_i = t_i \leq t_{\omega+1} \leq (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1}, \quad (1.11)$$

Applying the strategy  $X^* = (\xi_1^*, \xi_2^*, \dots, \xi_{\omega}^*, 0, \dots, 0)$ , where

$$\xi_i^* = \begin{cases} \left( t_i \sum_{k=1}^j \frac{1}{t_k} \right)^{-1}, & \text{for } 1 \leq i \leq \omega \\ 0, & \text{for } i > \omega \end{cases} \quad (1.12)$$

and for  $1 \leq j \leq \omega$ , agent 1 gets

Thus, it follows from (1.10) to (1.14) that

$$H(i, Y^*) \leq H(X^*, Y^*) \leq H(X^*, j), \quad (1.15)$$

$$1 \leq i \leq n, \quad 1 \leq j \leq n,$$

where

$$H(X^*, j) = \sum_{i \neq j}^{\omega} t_i \xi_i^* = (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1} \quad (1.13)$$

If  $j > \omega$ , then

$$H(X^*, j) = \sum_{i=1}^{\omega} t_i \xi_i^* = \omega \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1} > (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1} \quad (1.14)$$

$$H(X^*, Y^*) = (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1} \quad (1.16)$$

Consequently,

$$v = (\omega - 1) \left( \sum_{k=1}^{\omega} \frac{1}{t_k} \right)^{-1}, \quad (1.17)$$

and optimal strategies of agents are defined by the equations (1.9) and (1.12).

Suppose, the losses  $t_i$  ( $i = 1, 2, \dots, 5$ ) take such values that the payoff matrix of agent I has the form

$$H_1 = \begin{pmatrix} 0 & 1/3 & 1/3 & 1/3 & 1/3 \\ 1/35 & 0 & 1/35 & 1/35 & 1/35 \\ 1/4 & 1/4 & 0 & 1/4 & 1/4 \\ 1/45 & 1/45 & 1/45 & 0 & 1/45 \\ 1/5 & 1/5 & 1/5 & 1/5 & 0 \end{pmatrix}$$

Checking inequalities (1.1) shows that the minimum of the indices of  $\omega$  for which these inequalities are still satisfied is 3, while for  $\omega + 1 = 4$  they are violated. Consequently, to calculate the components of the vector of the optimal strategy of the state (agent II) we need to use formula (1.3), and the value of the game should be found by formula (1.16). Having performed the calculations, we obtain  $Y^* = (0.55, 0.31, 0.14, 0, 0, 0)$ . And the value of the game will be  $v = 0.1656$ .

## Conclusions

As a result of this work, two problems of the antagonistic game were considered - cases of neutralising and mixed strategy of agents. With the help of modern computing machines, the calculation was made and the following conclusions were obtained: the optimal strategy of the government is to under  $i$  program, and the value of the game (i.e. the expected income in the least favourable case) will be  $v = 20.8 * 10^3$  newborns. In this case, optimal resource allocation leads to an improvement in the situation, providing ample prospects for increasing fertility and hence improving the demographic situation of the country. The obtained results allow the government to make informed decisions, taking into account the least favourable variant.
