Solving High-dimensional Parametric Elliptic Equation Using Tensor Neural Network^{*}

Hongtao Chen[†], Rui Fu[†], Yifan Wang[§], and Hehu Xie[¶]

Abstract

In this paper, we introduce a tensor neural network based machine learning method for solving the elliptic partial differential equations with random coefficients in a bounded physical domain. With the help of tensor product structure, we can transform the high-dimensional integrations of tensor neural network functions to onedimensional integrations which can be computed with the classical quadrature schemes with high accuracy. The complexity of its calculation can be reduced from the exponential scale to a polynomial scale. The corresponding machine learning method is designed for solving high-dimensional parametric elliptic equations. Some numerical examples are provided to validate the accuracy and efficiency of the proposed algorithms.

Keywords. Tensor neural network, machine learning, high-dimensional integration with high accuracy, parametric elliptic equation with random coefficient.

AMS subject classifications. 65N30, 65N25, 65L15, 65B99.

1 Introduction

Numerical methods for stochastic elliptic partial differential equations (SPDEs) are vital tools for solving equations that involve both randomness and elliptic operators. Stochastic elliptic PDEs arise in various fields, including physics, finance, and engineering. These

equations pose challenges due to the interplay between the elliptic operator and the stochastic component. Efficient numerical methods for partial differential equations (PDEs) with random field inputs is a key ingredient in uncertainty quantification (UQ). Random field inputs, such as coefficients, loadings and domain, are spatially inhomogeneous, always lead to the well-known SPDEs [2, 28].

There are several numerical methods and techniques that have been developed to tackle SPDEs. Stochastic finite element method (SFEM) [19] introduces a stochastic basis expansion to represent the random coefficients or boundary conditions and solves the resulting deterministic system of equations using standard finite element method techniques. SFEM has been extensively studied and applied to a wide range of problems. Stochastic spectral method employs orthogonal polynomials (e.g., Legendre, Hermite or Laguerre) to represent the stochastic terms. By applying the Galerkin projection, the original SPDEs are transformed into a system of deterministic equations, which can be solved using spectral techniques. The convergence rate of this method is always faster than that of other methods. The generalized polynomial chaos (gPC) method [29] is an extension of extension of the spectral method is also widely used for solving SPDEs.

Monte-Carlo and quasi-Monte-Carlo sampling strategies [22] of the random inputs, as well as stochastic collocation methods [30], which have recently gained a lot of attention. Monte-Carlo methods simulate the underlying stochastic processes and use statistical sampling techniques to obtain approximate solutions. The idea is to generate a large number of random samples and compute averages or moments of the solution. For example, Monte-Carlo finite element method, involves simulating the underlying stochastic processes and solving the deterministic equations repeatedly for different realizations. By averaging the solutions, statistical estimates (e.g., mean, variance) of the solution can be obtained.

Due to its universal approximation property, the fully-connected neural network (FNN) is the most widely used architecture to build the functions for solving high-dimensional PDEs. There are several types of FNN-based methods such as well-known the deep Ritz [8], deep Galerkin method [23], PINN [20], and weak adversarial networks [31] for solving highdimensional PDEs by designing different loss functions. Among these methods, the loss functions always include computing high-dimensional integrations for the functions defined by FNN. For example, the loss functions of the deep Ritz method require computing the integrations on the high-dimensional domain for the functions which is constructed by FNN. Direct numerical integration for the high-dimensional functions also meets the "curse of dimensionality". Always, the Monte-Carlo method is adopted to do the highdimensional integration with some types of sampling methods [8, 13]. Due to the low convergence rate of the Monte-Carlo method, the solutions obtained by the FNN-based numerical methods are difficult to obtain high accuracy and stable convergence process. This means that the Monte-Carlo method decreases computational work in each forward propagation by decreasing the simulation accuracy, efficiency and stability of the FNNbased numerical methods for solving high-dimensional PDEs.

Recently, we propose a type of tensor neural network (TNN) and the corresponding machine learning method which is designed to solve the high-dimensional problems with high accuracy. The most important property of TNN is that the corresponding highdimensional functions can be easily integrated with high accuracy and high efficiency. Then the deduced machine learning method can arrive high accuracy for solving highdimensional problems. The reason is that the integration of TNN functions can be separated into one-dimensional integrations which can be computed by the classical quadrature schemes with high accuracy. The TNN based machine learning method has already been used to solve high-dimensional eigenvalue problems and boundary value problems based on the Ritz type of loss functions [25]. Furthermore, in [27], the multi-eigenpairs can also been computed with machine learning method which is designed by combining the TNN and Rayleigh-Ritz process. The high accuracy of this type of machine learning methods depends on the fact that the high-dimensional integrations of functional of TNNs can be computed with high accuracy.

Karhunen-Loéve (KL) expansion approximates the stochastic coefficients or boundary conditions using a limited number of dominant modes. This way reduces the dimensionality of the problem and allows for efficient computations for the deduced deterministic equations which can then be solved using traditional methods like FEM or FDM. Unfortunately, the deduced deterministic problems are high-dimensional equations. Solving these high-dimensional equations by the classical numerical methods always meets the "curse of dimensionality". In the present paper, we introduce the TNN based machine learning method for solving the deterministic parametric elliptic equations in a high-(possibly infinite-) dimensional parameter space, arising as a projection of the SPDE via a truncated M-term KL expansion. We consider a class of model elliptic problems characterized by the additive dependence of the equation coefficients on the multivariate parameter, corresponding to a random field that is linear in the random variable.

An outline of the paper goes as follows. In Section 2, the model elliptic problem with random coefficient and its properties will be presented. Section 3 is devoted to introduce the TNN structure, its numerical integration method and approximation property. In Section 4, the TNN based machine learning method will be proposed to solve the deduced high-dimensional deterministic equation. Section 5 gives some numerical examples to validate the accuracy and efficiency of the proposed TNN based machine learning method. Some concluding remarks are given in the last section.

2 Model problem

In this section, we introduce the concerned model problem, the way to separate stochastic and deterministic variables in the diffusion coefficient $a(\omega, x)$ with KL expansion, the properties of the deduced deterministic problem. The content here is the preparation for designing the TNN based machine learning method for the high-dimensional parametric problems.

This paper is mainly concerned with the elliptic problem with stochastic diffusion coefficient $a(\omega, x)$. We assume the physical domain $D \subset \mathbb{R}^d$, $d \in \mathbb{N}^+$ is a bounded open set with Lipschitz boundary ∂D , and the probability space denoted by (Ω, \mathcal{B}, P) , where Ω denotes the outcomes, $\mathcal{B} \subset 2^{\Omega}$ the sigma algebra of possible events and $P : \mathcal{B} \to [0, 1]$ a probability measure. Here, we consider the following problem: Find u such that

$$\begin{cases} -\operatorname{div}(a(\omega, x)\nabla u(\omega, x)) &= f(\omega, x), \quad \text{in } D, \\ u(\omega, x) &= 0, \quad \text{on } \partial D, \end{cases}$$
(2.1)

for P-a.e. $\omega \in \Omega$, where $f \in L^2(\Omega \times D)$, the diffusion coefficient $a \in L^{\infty}(\Omega \times D)$ and the solution $u(\omega, x)$ are random fields in the spatial domain D.

In order to guarantee the existence, uniqueness and well-posedness of the problem, following [1], we make the following assumption on the diffusion coefficient $a(\omega, x)$.

Assumption 1. Let $a \in L^{\infty}(\Omega \times D)$ be strictly positive, with lower and upper bound

$$P\left\{w \in \Omega: a_{\min} \le \operatorname{ess\,inf}_{x \in D} a(\omega, x) \land \operatorname{ess\,sup}_{x \in D} a(\omega, x) \le a_{\max}\right\} = 1,$$
(2.2)

where the essential infimum and supremum are taken with respect to the Lebesgue measure in $D \subset \mathbb{R}^d$.

In order to formulate the variational formulation of the problem, we introduce the tensor Hilbert space

$$L_P^2(\Omega; H_0^1(D)) := L_P^2(\Omega) \otimes H_0^1(D),$$
(2.3)

where

$$L_P^2(\Omega) := \left\{ \xi(\omega) \Big| \int_{\Omega} \xi^2(\omega) dP(\omega) < \infty \right\}.$$

Then we multiply (2.1) with a test function $v \in L^2_P(\Omega; H^1_0(D))$, integrate by parts over the physical domain D and take expectations on both sides, yielding the variational formulation for (2.1): Find $u \in L^2_P(\Omega; H^1_0(D))$ such that for all $v \in L^2_P(\Omega; H^1_0(D))$

$$b(u,v) := \mathbb{E}\bigg[\int_D a(\omega,x)\nabla u(\omega,x) \cdot \nabla v(\omega,x)dx\bigg] = \mathbb{E}\bigg[\int_D f(\omega,x)v(\omega,x)dx\bigg].$$
(2.4)

Under Assumption 1, the bilinear form $b(\cdot, \cdot)$ is coercive and continuous. Hence, by using Lax-Milgram lemma, the equation (2.4) is uniquely solvable for every $f \in L^2_P(\Omega; H^{-1}(D))$.

Here, the KL expansion is used to separate stochastic and deterministic variables in the diffusion coefficient $a(\omega, x)$. First we assume the information about the diffusion coefficient is known including its mean field

$$\mathbb{E}_{a}(x) = \int_{\Omega} a(\omega, x) dP(\omega), \ x \in D,$$
(2.5)

and covariance

$$C_a(x,x') = \int_{\Omega} \left(a(\omega,x) - \mathbb{E}_a(x) \right) \left(a(\omega,x') - \mathbb{E}_a(x') \right) dP(\omega), \quad x,x' \in D.$$
(2.6)

In this paper, we assume $C_a(x, x')$ is an admissible covariance function which is defined as follows.

Definition 2.1. A covariance function $C_a(x, x') \in L^2(D \times D)$ given by (2.6) is said to be admissible if it is symmetric and positive definite in the following sense

$$0 \le \sum_{k=1}^{n} \sum_{j=1}^{n} a_k C_a(x_k, x_j) \overline{a}_j, \quad \forall x_k, x_j \in D, a_k, a_j \in \mathbb{C}.$$
(2.7)

Based on the random permeability $a(\omega, x) \in L^2(\Omega \times D)$, we can define the covariance operator as

$$C_a: L^2(D) \to L^2(D), \ (C_a u)(x) := \int_D C_a(x, x') u(x') dx'.$$
 (2.8)

Given an admissible covariance function $C_a(x, x')$ in the sense of Definition 2.1, the associated covariance operator C_a is a symmetric, non-negative and compact integral operator from $L^2(D)$ to $L^2(D)$. Therefore, it has a countable sequence of eigenpairs $(\lambda_m, \phi_m)_{m\geq 1}$

$$C_a \varphi_m = \lambda_m \varphi_m, \quad m = 1, 2 \dots$$

where the sequence (real and positive) of KL-eigenvalues λ_m is enumerated with decreasing magnitude and is either finite or tends to zero as $m \to \infty$. The corresponding KL eigenfunctions $\varphi_m(x)$ are assumed to be $L^2(D)$ -orthonormal, i.e.

$$\int_D \varphi_m(x)\varphi_n(x)dx = \delta_{mn}, \quad m, n = 1, 2, \dots$$

Then we have the following expansion for the diffusion coefficient $a(\omega, x)$.

Definition 2.2. The KL expansion of a random field $a(\omega, x)$ with finite mean (2.5) and admissible covariance (2.6) is given by

$$a(\omega, x) = \mathbb{E}_a(x) + \sum_{m \ge 1} \sqrt{\lambda_m} \varphi_m(x) Y_m(\omega).$$
(2.9)

The family of random variables $(Y_m)_{m\geq 1}$ is given by

$$Y_m(\omega) = \frac{1}{\sqrt{\lambda_m}} \int_D \left(a(\omega, x) - \mathbb{E}_a(x) \right) \varphi_m(x) dx : \Omega \to \mathbb{R}.$$
 (2.10)

It should be pointed out that $Y_m(\omega)$ are centered with unit variance and pairwise uncorrelated.

In order to parametrize the stochastic input, we make the following assumption on the random variables Y_m in the KL-representation (2.9) of $a(\omega, x)$.

Assumption 2. The following assumptions hold

- (1) The family $(Y_m)_{m\geq 1}: \Omega \to \mathbb{R}$ is independent.
- (2) The KL-expansion (2.9) of the input data is finite, i.e. there exists $\overline{M} < \infty$ such that $Y_m = 0$ for all $m > \overline{M}$.
- (3) Each $Y_m(\omega)$ in (2.9), (2.10) is associated a complete probability space $(\Omega_m, \Sigma_m, P_m)$, $m \in \mathbb{N}$ with the following properties:
 - (a) The range $\Gamma_m := \operatorname{Ran}(Y_m) \subseteq \mathbb{R}$ of Y_m is compact and is scaled to [-1,1] for all m.
 - (b) The probability measure P_m deduces a probability density function $\rho_m : \Gamma_m \to [0,\infty]$ such that $dP_m(\omega) = \rho_m(y_m)dy_m, m \in \mathbb{N}, y_m \in \Gamma_m$.

(c) The sigma algebras Σ_m are subsets of the Borel sets on the interval Γ_m , i.e. $\Sigma_m \subseteq \mathcal{B}(\Gamma_m)$.

In order to numerically treat the KL-expansion (2.9), we define the *M*-term truncated KL-expansion as follows

$$a_M(\omega, x) = \mathbb{E}_a(x) + \sum_{m=1}^M \sqrt{\lambda_m} \varphi_m(x) Y_m(\omega).$$
(2.11)

Replacing the random input $a(\omega, x)$ in (2.1) by its *M*-term truncated KL-expansion $a_M(\omega, x)$ in (2.12) leads to a *M*-dimensional parametric, deterministic variational formulation. In addition, we further assume that the right-hand side $f(\omega, x)$ can be represented as a finite-term K-L expansion as follows

$$f(\omega, x) = \mathbb{E}_f(x) + \sum_{m=1}^M \sqrt{\mu_m} \psi_m(x) Y_m(\omega).$$
(2.12)

Remark 2.1. This setting is referred to [5]. Since it is usual to have f and a independent, because the loads and the material properties are seldom related. In such a situation we have $a(Y_1(\omega), \dots, Y_M(\omega), x) = a(Y_{a,1}(\omega), \dots, Y_{a,M_a}(\omega), x)$ and $f(Y_1(\omega), \dots, Y_M(\omega), x) =$ $f(Y_{f,1}(\omega), \dots, Y_{f,M_f}(\omega), x)$, with random vectors $(Y_{a,1}, \dots, Y_{a,M_a})$ and $(Y_{f,1}, \dots, Y_{f,M_f})$ independent, $M = M_a + M_f$.

In order to define the variational form for the stochastic problem (2.1), we introduce the following function spaces: For

$$\Gamma := \Gamma_1 \times \Gamma_2 \times \cdots, \quad y = (y_1, y_2, \cdots) \in \Gamma$$

we denote the space of all mappings $v : \Gamma \to \mathbb{R}$ which are square integrable with respect to the measure $\rho(dy) = \rho(y)dy$ as $L^2_{\rho}(\Gamma)$, where $\rho(dy)$ is a probability measure on Γ . If H denotes a separable Hilbert space with norm $\|\cdot\|_H$, we denote the Bochner space of functions $v : \Gamma \to H$ such that $\|v(y, \cdot)\|_H : y \to \mathbb{R}$ belongs to $L^2_{\rho}(\Gamma)$. In this paper, the solution is required in the space

$$L^{2}_{\rho}(H^{1}_{0}) := L^{2}_{\rho}(\Gamma; H^{1}_{0}(D)) \simeq L^{2}_{\rho}(\Gamma) \otimes H^{1}_{0}(D),$$

where \otimes denotes the tensor product between separable Hilbert spaces.

By Assumption 2(1), the probability density $\rho(y)$ is separable, i.e.

$$\rho(y) = \prod_{m \ge 1} \rho_m(y_m) \tag{2.13}$$

with $\rho_m(y_m)$ satisfying Assumption 2(3)(b). Based on the above assumptions, we can obtain the parametric, deterministic formulation of (2.1) in variational form: Find $u_M \in L^2_{\rho}(H^1_0)$ such that

$$b_M(u_M, v) = \ell(v), \quad \forall v \in L^2_\rho(H^1_0),$$
(2.14)

with

$$b_M(u_M, v) = \mathbb{E}\left[\int_D a_M(y, x)\nabla u_M(y, x) \cdot \nabla v(y, x)dx\right]$$
$$= \int_{\Gamma} \int_D a_M(y, x)\nabla u_M(y, x) \cdot \nabla v(y, x)\rho(y)dxdy, \qquad (2.15)$$

and

$$\ell(v) = \mathbb{E}\left[\int_D f(y,x)v(y,x)dx\right] = \int_{\Gamma} \int_D f(y,x)v(y,x)\rho(y)dxdy.$$
 (2.16)

Here, based on (2.12), the truncated KL-expansion has following expansions.

$$a_M(y,x) = a_0(x) + \sum_{m=1}^M y_m \psi_m(x), \ a_0 = \mathbb{E}_a, \ \psi_m(x) := \lambda_m^{1/2} \varphi_m(x).$$
(2.17)

Now, we come to introduce some regularity results of the concerned problem (2.14). In [24], it is proved that the weak solution $u(y, \cdot) \in H_0^1(D)$ is analytic as a function of

$$y \mapsto u(y, \cdot) \in H_0^1(D)$$
 from Γ to $H_0^1(D)$.

The precise quantitative analysis on the size of the domain of analyticity is based on the decay rate of the coefficients in (2.12). Here we consider two basic cases of coefficient decay:

1. Exponential decay (see [24]):

$$\rho_m := \|a_m\|_{L^{\infty}(D)} \le C_0 \exp\left(-C_1 m^{1/d}\right), \quad \forall m \in \mathbb{N}_+.$$
(2.18)

Note that the sequence $\rho = (\rho_m)_{m=1}^{\infty}$ in (2.13) belongs to $\ell^p(\mathbb{N})$ for every p > 0.

2. Algebraic decay (see, e.g., [6, 7]): there is a constant s > 0 such that the following bounds hold

$$\rho_m := \|a_m\|_{L^{\infty}(D)} \le C_0 m^{-s/d}, \quad \forall m \in \mathbb{N}_+.$$
(2.19)

Note that the sequence $\rho = (\rho_m)_{m=1}^{\infty}$ in (2.13) belongs to $\ell^p(\mathbb{N})$ for every $p > d_0/s$.

Based on the coefficient decay condition (2.18), it has been proved in [24] that the domain of analyticity of the solution u of (2.1) as a function of y_m increases exponentially in size as $m \nearrow \infty$. The following proposition gives the explicit bounds on all derivatives of uwith respect to y_m which are suitable for either case 1 or 2.

Proposition 2.1. (see [24]). If the exponential decay condition (2.18) holds, $u = u_M(y, \cdot)$ is the exact solution of (2.1) and M is large enough, then the following estimate

$$\left\|\partial_y^{\alpha} u_M(y,\cdot)\right\|_{H^1_0(D)} \le \left(C_a^{|\alpha|} \cdot |\alpha|! \cdot \prod_{m=1}^M \rho_m^{\alpha_m}\right)$$
(2.20)

for all $y \in \Gamma$ and $\alpha \in \mathbb{N}_0^M$ where \mathbb{N}_0 denotes the set of all non-negative integers.

3 Tensor neural network and its quadrature scheme

In this section, we introduce the TNN structure and the quadrature scheme for the highdimensional TNN functions. Also included in this section are a discussion of the approximation properties, some techniques to improve the numerical stability, and the complexity estimate of the high-dimensional integrations of the TNN functions.

3.1 Tensor neural network architecture

This subsection is devoted to introducing the TNN structure and some techniques to improve the stability of the corresponding machine learning methods. The approximation properties of TNN functions have been discussed and investigated in [25]. In order to express clearly and facilitate the construction of the TNN method for solving highdimensional PDEs, here we will also introduce some important definitions and properties.

TNN is built by the tensor products of one dimension functions which come from d subnetworks with one-dimensional input and multi-dimensional output, where d denotes the spatial dimension of the concerned problems which will be solved by the machine learning method in this paper. For each $i = 1, 2, \dots, d$, we use $\Phi_i(x_i; \theta_i) = (\phi_{i,1}(x_i; \theta_i), \phi_{i,2}(x_i; \theta_i), \dots, \phi_{i,p}(x_i; \theta_i))$ to denote a subnetwork that maps a set $\Omega_i \subset \mathbb{R}$ to \mathbb{R}^p , where $\Omega_i, i = 1, \dots, d$, can be a bounded interval (a_i, b_i) , the whole line $(-\infty, +\infty)$ or the half line $(a_i, +\infty)$. The number of layers and neurons in each layer, the selections of activation functions and other hyperparameters can be different in different subnetworks. TNN consists of p correlated rank-one functions, which are composed of the multiplication of d one-dimensional input functions in different directions. Figure 1 shows the corresponding architecture of TNN.

In order to improve the numerical stability, we normalize each $\phi_{i,j}(x_i)$ and use the following normalized-TNN structure:

$$\Psi(x;c,\theta) = \sum_{j=1}^{p} c_j \widehat{\phi}_{1,j}(x_1;\theta_1) \widehat{\phi}_{2,j}(x_2;\theta_2) \cdots \widehat{\phi}_{d,j}(x_d;\theta_d) = \sum_{j=1}^{p} c_j \prod_{i=1}^{d} \widehat{\phi}_{i,j}(x_i;\theta_i), \quad (3.1)$$

where each c_j is a scaling parameter which describes the length of each rank-one function, $c = \{c_j\}_{j=1}^p$ is a set of trainable parameters, $\{c, \theta\} = \{c, \theta_1, \dots, \theta_d\}$ denotes all parameters of the whole architecture. For $i = 1, \dots, d, j = 1, \dots, p$, $\hat{\phi}_{i,j}(x_i, \theta_i)$ is a L^2 -normalized function as follows:

$$\widehat{\phi}_{i,j}(x_i,\theta_i) = \frac{\phi_{i,j}(x_i,\theta_i)}{\|\phi_{i,j}(x_i,\theta_i)\|_{L^2(\Omega_i)}}.$$
(3.2)

For simplicity of notation, $\phi_{i,j}(x_i, \theta_i)$ denotes the normalized function in the following parts.

The TNN architecture (3.1) and the architecture defined in [25] are mathematically equivalent, but (3.1) has better numerical stability during the training process. From Figure 1 and numerical tests, we can find the parameters for each rank of TNN are correlated by the FNN, which guarantee the stability of the TNN-based machine learning methods. This is also an important difference from the tensor finite element methods.

Figure 1: Architecture of TNN. Black arrows mean linear transformation (or affine transformation). Each ending node of blue arrows is obtained by taking the scalar multiplication of all starting nodes of blue arrows that end in this ending node. The final output of TNN is derived from the summation of all starting nodes of red arrows.

In order to show the reasonableness of TNN, we now introduce the approximation property from [25]. Since there exists the isomorphism relation between $H^m(\Omega_1 \times \cdots \times \Omega_d)$ and the tensor product space $H^m(\Omega_1) \otimes \cdots \otimes H^m(\Omega_d)$, the process of approximating the function $f(x) \in H^m(\Omega_1 \times \cdots \times \Omega_d)$ by the TNN defined as (3.1) can be regarded as searching for a correlated CP decomposition structure to approximate f(x) in the space $H^m(\Omega_1) \otimes \cdots \otimes H^m(\Omega_d)$ with the rank being not greater than p. The following approximation result to the functions in the space $H^m(\Omega_1 \times \cdots \times \Omega_d)$ under the sense of H^m -norm is proved in [25].

Theorem 3.1. [25, Theorem 1] Assume that each Ω_i is an interval in \mathbb{R} for $i = 1, \dots, d$, $\Omega = \Omega_1 \times \dots \times \Omega_d$, and the function $f(x) \in H^m(\Omega)$. Then for any tolerance $\varepsilon > 0$, there exist a positive integer p and the corresponding TNN defined by (3.1) such that the following approximation property holds

$$\|f(x) - \Psi(x;\theta)\|_{H^m(\Omega)} < \varepsilon.$$
(3.3)

Although there is no general result to give the relationship between the hyperparameter p and error bounds, we also provide an estimate of the rank p under a smoothness assumption. For easy understanding, we focus on the periodic setting with $I^d = I \times I \times \cdots \times I = [0, 2\pi]^d$ and the approximation property of TNN to the functions in the linear space which is defined by Fourier basises. Note that similar approximation results of TNN can be extended to the non-periodic functions. For each variable $x_i \in [0, 2\pi]$, let us define the one-dimensional Fourier basis { $\varphi_{k_i}(x_i) := \frac{1}{\sqrt{2\pi}}e^{ik_ix_i}, k_i \in \mathbb{Z}$ } and classify functions via the decay of their Fourier coefficients. Further we denote multi-index $k = (k_1, \cdots, k_d) \in \mathbb{Z}^d$ and $x = (x_1, \cdots, x_d) \in I^d$. Then the d-dimensional Fourier basis can be built in the tensor product way

$$\varphi_k(x) := \prod_{i=1}^d \varphi_{k_i}(x_i) = (2\pi)^{-d/2} e^{\mathbf{i}k \cdot x}.$$
(3.4)

We denote

$$\lambda_{\min}(k) := \prod_{i=1}^{d} (1+|k_i|) \quad \text{and} \quad \lambda_{\text{iso}}(k) := 1 + \sum_{i=1}^{d} |k_i|.$$
(3.5)

Now, for $-\infty < t, \ell < \infty$, we define the space $H^{t,\ell}_{\text{mix}}(I^d)$ as follows (cf. [10, 16])

$$H_{\min}^{t,\ell}(I^d) = \left\{ u(x) = \sum_{k \in \mathbb{Z}^d} c_k \varphi_k(x) : \|u\|_{H_{\min}^{t,\ell}(I^d)} = \left(\sum_{k \in \mathbb{Z}^d} \lambda_{\min}(k)^{2t} \cdot \lambda_{iso}(k)^{2\ell} \cdot |c_k|^2 \right)^{1/2} < \infty \right\} (3.6)$$

Note that the parameter ℓ governs the isotropic smoothness, whereas t governs the mixed smoothness. The space $H_{\text{mix}}^{t,\ell}(I^d)$ gives a quite flexible framework for the study of problems in Sobolev spaces. See [10, 11, 16] for more information on the space $H_{\text{mix}}^{t,\ell}(I^d)$.

Thus, [25] gives the following comprehensive error estimate for TNN.

Theorem 3.2. Assume function $f(x) \in H^{t,\ell}_{\text{mix}}(I^d)$, t > 0 and $m > \ell$. Then there exists a TNN $\Psi(x;\theta)$ defined by (3.1) such that the following approximation property holds

$$\|f(x) - \Psi(x;\theta)\|_{H^m(I^d)} \le C(d) \cdot p^{-(\ell-m+t)} \cdot \|u\|_{H^{t,\ell}_{\min}(I^d)},\tag{3.7}$$

where $C(d) \leq c \cdot d^2 \cdot 0.97515^d$ and c is independent of d. And each subnetwork of TNN is a FNN which is built by using $\sin(x)$ as the activation function and one hidden layer with 2p neurons, see Figure 1.

The TNN-based machine learning method in this paper will adaptively select p rank-one functions by training process. From the approximation result in Theorem 3.2, when the target function belongs to $H_{\text{mix}}^{t,\ell}(\Omega)$, there exists a TNN with $p \sim \mathcal{O}(\varepsilon^{-(m-\ell-t)})$ such that the accuracy is ε . For more details about the approximation properties of TNN, please refer to [25].

3.2 Quadrature scheme for TNN

In this section, we introduce the quadrature scheme for computing the high-dimensional integrations of the high-dimensional TNN functions. Due to the low-rank of TNN, the efficient and accurate quadrature scheme can be designed for the TNN-related high-dimensional integrations which are included in the loss functions for machine learning methods. The detailed numerical integration scheme for TNN functions with the polynomial scale computational complexity of the dimension will be designed here. When calculating the high-dimensional integrations in the loss functions, we only need to calculate one-dimensional integrations as well as their product.

The method to compute the numerical integrations of polynomial composite functions of TNN and their derivatives has already designed in [25]. For the sake of completeness, we also introduce the quadrature scheme here. For more information, please refer to [25].

In order to describe the differentiation of TNNs and their composition with a polynomial, we define the following index sets

$$\mathcal{B} := \left\{ \beta = (\beta_1, \cdots, \beta_d) \in \mathbb{N}_0^d \mid |\beta| := \sum_{i=1}^d \beta_i \le m \right\},$$
$$\mathcal{A} := \left\{ \alpha = (\alpha_\beta)_{\beta \in \mathcal{B}} \in \mathbb{N}_0^{|\mathcal{B}|} \mid |\alpha| := \sum_{\beta \in \mathcal{B}} \alpha_\beta \le k \right\},$$

where m and k are two positive integers, $|\mathcal{B}|$ and $|\mathcal{A}|$ denote the cardinal numbers of \mathcal{B} and \mathcal{A} , respectively. It is easy to know that

$$|\mathcal{B}| = \sum_{j=0}^{m} \binom{j+d-1}{j}, \quad |\mathcal{A}| = \sum_{j=0}^{k} \binom{j+|\mathcal{B}|-1}{j},$$

and the scales of magnitudes of $|\mathcal{B}|$ and $|\mathcal{A}|$ are $\mathcal{O}((d+m)^m)$ and $\mathcal{O}(((d+m)^m+k)^k)$, respectively.

In the following parts of this paper, the parameters in (3.1) will be omitted for brevity without confusion. The activation function of TNN is selected to be smooth enough such that $\Psi(x)$ has partial derivatives up to order m. In this section, we assume the integrand, denoted by F(x), includes the k-degree complete polynomial of d-dimensional TNN and its partial derivatives up to order m that can be described as follows

$$F(x) = \sum_{\alpha \in \mathcal{A}} A_{\alpha}(x) \prod_{\beta \in \mathcal{B}} \left(\frac{\partial^{|\beta|} \Psi(x)}{\partial x_1^{\beta_1} \cdots \partial x_d^{\beta_d}} \right)^{\alpha_{\beta}},$$
(3.8)

where the coefficient $A_{\alpha}(x)$ has the decomposition form with rank less than q in the tensor product space $L^2(\Omega_1) \otimes \cdots \otimes L^2(\Omega_d)$

$$A_{\alpha}(x) = \sum_{\ell=1}^{q} B_{1,\ell,\alpha}(x_1) B_{2,\ell,\alpha}(x_2) \cdots B_{d,\ell,\alpha}(x_d), \qquad (3.9)$$

where $B_{i,\ell,\alpha}(x_i)$ denotes the one-dimensional function in $L^2(\Omega_i)$ for $i = 1, \dots, d$ and $\ell = 1, \dots, q$. Thanks to the tensor product structure of F(x), the high-dimensional

multiple integral $\int_{\Omega} F(x) dx$ for the TNN can be decomposed into the sum of products of one-dimensional integrations which can be computed by common numerical quadrature. In order to describe the decomposition, for each $\alpha = (\alpha_1, \dots, \alpha_{|\mathcal{B}|}) \in \mathcal{A}$, we define the following set

$$\mathcal{B}_{\alpha} := \Big\{ \beta = (\beta_1, \cdots, \beta_d) \in \mathcal{B} \mid \alpha_{\beta} \ge 1 \Big\}.$$

By the definition of the index set \mathcal{A} , the cardinal of \mathcal{B}_{α} has the estimate $|\mathcal{B}_{\alpha}| \leq k$ for any $\alpha \in \mathcal{A}$.

With the help of TNN structure (3.1) of $\Psi(x)$, the products in (3.8) can be further decomposed as

$$\prod_{\beta \in \mathcal{B}_{\alpha}} \left(\frac{\partial^{|\beta|} \Psi(x)}{\partial x_{1}^{\beta_{1}} \cdots \partial x_{d}^{\beta_{d}}} \right)^{\alpha_{\beta}} = \sum_{\substack{\beta \in \mathcal{B}_{\alpha}, \ell=1, \cdots, \alpha_{\beta}, \\ 1 \le j_{\beta,\ell} \le p}} \left(\prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_{1}} \phi_{1,j_{\beta,\ell}}(x_{1})}{\partial x_{1}^{\beta_{1}}} \right) \cdots \left(\prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_{d}} \phi_{d,j_{\beta,\ell}}(x_{d})}{\partial x_{d}^{\beta_{d}}} \right). \quad (3.10)$$

With the help of expansion (3.10), we can give the following expansion for F(x)

$$F(x) = \sum_{\alpha \in \mathcal{A}} \sum_{\ell=1}^{q} \sum_{\substack{\beta \in \mathcal{B}_{\alpha}, \ell=1, \cdots, \alpha_{\beta}, \\ 1 \le j_{\beta,\ell} \le p}} \left(B_{1,\ell,\alpha}(x_1) \prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_1} \phi_{1,j_{\beta,\ell}}(x_1)}{\partial x_1^{\beta_1}} \right) \cdots \left(B_{d,\ell,\alpha}(x_d) \prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_d} \phi_{d,j_{\beta,\ell}}(x_d)}{\partial x_d^{\beta_d}} \right).$$
(3.11)

Based on the decomposition (3.11), the high-dimensional integration $\int_{\Omega} F(x) dx$ can be decomposed into the following one-dimensional integrations

$$\int_{\Omega} F(x) dx = \sum_{\alpha \in \mathcal{A}} \sum_{\ell=1}^{q} \sum_{\substack{\beta \in \mathcal{B}_{\alpha}, \ell=1, \cdots, \alpha_{\beta}, \\ 1 \le j_{\beta,\ell} \le p}} \int_{\Omega_{1}} \left(B_{1,\ell,\alpha}(x_{1}) \prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_{1}} \phi_{1,j_{\beta,\ell}}(x_{1})}{\partial x_{1}^{\beta_{1}}} \right) dx_{1}$$
$$\cdots \int_{\Omega_{d}} \left(B_{d,\ell,\alpha}(x_{d}) \prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_{d}} \phi_{d,j_{\beta,\ell}}(x_{d})}{\partial x_{d}^{\beta_{d}}} \right) dx_{d}.$$
(3.12)

The expansion (3.12) gives the hint to design the efficient numerical scheme to compute the high-dimensional integration of the TNN function F(x). Without loss of generality, for the *i*-th one-dimensional domain Ω_i , we choose N_i Gauss points $\{x_i^{(n_i)}\}_{n_i=1}^{N_i}$ and the corresponding weights $\{w_i^{(n_i)}\}_{n_i=1}^{N_i}$ to compute the one-dimensional integrations included in (3.12), where $i = 1, \dots, d$. Then we can give the following splitting numerical integration scheme for $\int_{\Omega} F(x) dx$:

$$\int_{\Omega} F(x) dx \approx \sum_{\alpha \in \mathcal{A}} \sum_{\ell=1}^{q} \sum_{\substack{\beta \in \mathcal{B}_{\alpha}, \ell=1, \cdots, \alpha_{\beta}, \\ 1 \leq j_{\beta,\ell} \leq p}} \left(\sum_{n_{1}=1}^{N_{1}} w_{1}^{(n_{1})} B_{1,\ell,\alpha}(x_{1}^{(n_{1})}) \prod_{\beta \in \mathcal{B}_{\alpha}} \prod_{\ell=1}^{\alpha_{\beta}} \frac{\partial^{\beta_{1}} \phi_{1,j_{\beta,\ell}}(x_{1}^{(n_{1})})}{\partial x_{1}^{\beta_{1}}} \right)$$

$$\cdots \left(\sum_{n_d=1}^{N_d} w_d^{(n_d)} B_{d,\ell,\alpha}(x_d^{(n_d)}) \prod_{\beta \in \mathcal{B}_\alpha} \prod_{\ell=1}^{\alpha_\beta} \frac{\partial^{\beta_d} \phi_{d,j_{\beta,\ell}}(x_d^{(n_d)})}{\partial x_d^{\beta_d}} \right).$$
(3.13)

The simplicity of the one-dimensional integration makes the scheme (3.13) reduce the computational work of the high-dimensional integration of the *d*-dimensional function F(x) to the polynomial scale of dimension *d*. Let us denote $N = \max\{N_1, \dots, N_d\}$ and $\underline{N} = \min\{N_1, \dots, N_d\}$. The following theorem comes from [25].

Theorem 3.3. [25, Theorem 3] Assume that the function F(x) has the expansion (3.8), where the coefficient $A_{\alpha}(x)$ has the form (3.9). We use Gauss quadrature points and corresponding weights to the integration of F(x) on the d-dimensional tensor product domain Ω . If the function $\Psi(x)$ involved in the function F(x) has TNN form (3.1), the efficient quadrature scheme (3.13) has $2\underline{N}$ -th order accuracy. Let T_1 denote the computational complexity for the 1-dimensional function evaluation operations. The computational complexity can be bounded by $\mathcal{O}(dqT_1k^2p^k((d+m)^m+k)^kN))$, which is the polynomial scale of the dimension d.

Remark 3.1. Other types of one-dimensional quadrature schemes can also be adopted to do the d-dimensional integration. In numerical examples, we decompose each Ω_i into subintervals with mesh size h and choose N_i one-dimensional Gauss points in each subinterval. Then the deduced d-dimensional quadrature scheme has accuracy $\mathcal{O}(h^{2\underline{N}}/(2\underline{N})!)$, where the included constant depends on the smoothness of F(x).

Remark 3.2. In this paper, we assume $\Omega = \Omega_1 \times \cdots \times \Omega_d$ and each Ω_i is a bounded interval (a_i, b_i) . It is worth mentioning that a similar quadrature scheme can also be given for unbounded Ω_i . In [27], in addition to Legendre-Gauss quadrature scheme for bounded domain, we discuss Hermite-Gauss quadrature scheme for the whole line $\Omega_i = (-\infty, +\infty)$ and Laguerre-Gauss quadrature scheme for the half line $\Omega_i = (a_i, +\infty)$. The computational complexity of these integrations is also polynomial order of d.

4 TNN based machine learning method

In this section, we introduce the TNN-based machine learning method to solve the elliptic diffusion problem with stochastic diffusion coefficient. We assumed the physical domain $D = D_1 \times \cdots \times D_d$ with $D_i = [a_i, b_i]$ for $i = 1, \cdots, d$. It is noted that the tensor product structure plays an important role in reducing the dependence on dimensions in numerical integration. We will find that the high accuracy of the high-dimensional integrations of TNN functions leads to the corresponding machine learning method has high accuracy for solving the high-dimensional parametric elliptic equations.

For designing the TNN based machine learning method, we build the following TNN function

$$\Psi(y,x) = \sum_{k=1}^{p} c_k \left(\prod_{j=1}^{M} \widehat{\phi}_{j,k}(y_j) \prod_{i=1}^{d} \widehat{\psi}_{i,k}(x_i) \right),$$
(4.1)

where $y = [y_1, \cdots, y_M]^\top$ and $x = [x_1, \cdots, x_d]^\top$.

In order to treat the boundary condition, following [25], for $i = 1, \dots, d$, the *i*-th subnetwork $\psi_i(x_i; \theta_i)$ is defined as follows:

$$\begin{aligned} \psi_i(x_i) &:= (x_i - a_i)(b_i - x_i)\widehat{\psi}_i(x_i) \\ &= ((x_i - a_i)(b_i - x_i)\widehat{\psi}_{i,1}(x_i), \cdots, (x_i - a_i)(b_i - x_i)\widehat{\psi}_{i,p}(x_i))^\top, \end{aligned}$$

where $\widehat{\psi}_i(x_i; \theta_i)$ is an FNN from \mathbb{R} to \mathbb{R}^p with sufficiently smooth activation functions, such that $\Psi(y, x) \in L^2_{\rho}(H^1_0)$.

The trial function set V is modeled by the TNN structure $\Psi(y, x)$ where the parameters take all the possible values and it is obvious that $V \subset L^2_{\rho}(H^1_0)$ by selecting the appropriate activation function.

Based on the Ritz method, the solution $\Psi^*(y, x)$ of the following optimization problem is the approximation to the problem (2.14)

$$\Psi^{*}(y,x) = \arg\min_{\Psi(y,x)\in V} \int_{\Gamma} \int_{D} \left[\frac{1}{2} a_{M}(y,x) \left| \nabla_{x} \Psi(y,x) \right|^{2} - f(y,x) \Psi(y,x) \right] \rho(y) dx dy.$$
(4.2)

We can also use the strong form of the stochastic partial differential equation to build the optimization problem to produce the TNN approximation. The corresponding optimization problem can be defined as follows

$$\Psi^*(y,x) = \arg\min_{\Psi(y,x)\in V} \int_{\Gamma} \int_{D} \left|\operatorname{div}\left(a_M(y,x)\nabla_x\Psi(y,x)\right) + f(y,x)\right|^2 \rho(y) dx dy.$$
(4.3)

In practical implementation, the method (4.3) always has better accuracy than the one (4.2). But the required memory for the method (4.3) is more than that for the one (4.2) since we need to compute the second order derivatives of the trial function $\Psi(y, x)$.

In this paper, the gradient descent (GD) method is adopted to minimize the loss function $L(\theta)$. The GD scheme can be described as follows:

$$\theta^{(k+1)} = \theta^{(k)} - \eta \nabla L(\theta^{(k)}), \qquad (4.4)$$

where $\theta^{(k)}$ denotes the parameters after the k-th GD step, η is the learning rate (step size). In (4.4), the loss function is defined as

$$L := \int_{\Gamma} \int_{D} \left[\frac{1}{2} a_M(y, x) \left| \nabla_x \Psi(y, x) \right|^2 - f(y, x) \Psi(y, x) \right] \rho(y) dx dy, \tag{4.5}$$

for the method (4.2) and

$$L := \int_{\Gamma} \int_{D} |\operatorname{div} \left(a_M(y, x) \nabla_x \Psi(y, x) \right) + f(y, x)|^2 \,\rho(y) dx dy, \tag{4.6}$$

for the method (4.3). In practical learning process, we use Adam optimizer [15] to choose the learning rate adaptively and get the optimal solution $\Psi^*(y, x)$.

$\mathbf{5}$ Numerical examples

In this section, we provide three numerical examples of solving the elliptic diffusion problem with stochastic diffusion coefficients by TNN-based machine learning method. Since the KL eigenpairs can be computed by some classical numerical methods, such as standard finite element method and spectral method, here we only consider analytically known KL expansions and their tensorized versions.

Generally speaking, ones are interested in deterministic statistics of $u(\omega, x)$ rather than in the random solution itself. Therefore, in the following numerical examples, we will show the results regarding the deterministic statistics of $u(\omega, x)$.

To demonstrate the convergence behavior and accuracy of approximations using TNN, we define the L^2 projection operator $\mathcal{P}: L^2_{\rho}(H^1_0) \to \operatorname{span}\{\Psi(y, x; \theta^*)\}$ as follows:

$$\langle \mathcal{P}u,v\rangle_{L^2} = \langle u,v\rangle_{L^2} := \int_{\Gamma} \int_{D} u(y,x)v(y,x)\rho(y)dxdy, \ \forall v \in \text{span}\left\{\Psi(y,x;\theta^*)\right\}$$

for $u \in L^2_{\rho}(H^1_0)$.

And we define the H^1 projection operator $\mathcal{Q}: L^2_{\rho}(H^1_0) \to \operatorname{span}\{\Psi(y, x; \theta^*)\}$ as follows:

$$\langle \mathcal{Q}u, v \rangle_{H^1} = \langle u, v \rangle_{H^1} := \int_{\Gamma} \int_{D} \nabla_x u(y, x) \cdot \nabla_x v(y, x) \rho(y) dx dy, \ \forall v \in \operatorname{span}\{\Psi(y, x; \theta^*)\},$$

for $u \in L^2_{\rho}(H^1_0)$.

Then we define the following relative errors for the approximated function $\Psi(y, x; \theta^*)$

$$e_{L^2} := \frac{\|u - \mathcal{P}u\|_{L^2_{\rho}(\Gamma; L^2(D))}}{\|f\|_{L^2(D)}}, \quad e_{H^1} := \frac{\|u - \mathcal{Q}u\|_{L^2_{\rho}(\Gamma; H^1(D))}}{\|f|_{H^1(D)}}.$$
(5.1)

5.1Zero-order coefficients

In the first example, we consider the case of spatially homogeneous stochastic coefficients,

$$a_M(y,x) = 1 + \sum_{m=1}^M a_m y_m,$$
 (5.2)

for the truncated sequence of (spatially homogeneous) coefficients $a_m = (1+m)^{-\alpha} (m =$ $1, \dots, M$ with algebra decay rates $\alpha = 2$. Here, we set D = (0, 1). The variables y_m $(m = 1, 2 \cdots, M)$ are independently and identically distributed and follow the uniform distribution on [-1,1]. Here, we wish to construct an equation that has the analytical solution $u(y,x) = \sin(\pi x) \prod_{m=1}^{M} \sin\left(\frac{\pi}{2}y_m\right)$. For this aim, the right hand side load is set to

be

$$f(y,x) = \left(1 + \sum_{i=1}^{M} a_i y_i\right) \cdot \pi^2 \sin(\pi x) \prod_{m=1}^{M} \sin\left(\frac{\pi}{2} y_m\right).$$
 (5.3)

In this example, we choose M = 10, 20, 50 and 100, the computational probability domain is set to be $\Gamma = \Gamma_1 \times \cdots \times \Gamma_M$, where $\Gamma_i = [-1, 1]$ for $i = 1, \cdots, M$. In order to do the high-dimensional integration for the TNN functions, we decompose the physical domain D and the probability space Γ_j $(j = 1, \cdots, M)$ into 200 subintervals and choose 16 Gauss points on each subinterval respectively.

Each subnetwork in TNN is set to the FNN with 3 hidden layers, 100 nodes in each layer is adopted to build the subnetwork for the TNN function. Here we select $\sin(x)$ as the activation function and choose p = 50.

For M = 10, 20, we use the strong form to build the loss function (4.6) and solve the optimization problem (4.3) to obtain the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0005 is adopted for the first 100,000 steps. Then the LBFGS optimizer with learning rate 0.5 is carried out for the next 10,000 steps. For the case of M = 50,100, we use the weak form to build the loss function (4.5) and solve the corresponding optimization problem (4.2) to produce the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0001 is adopted for the first 95,000 steps. Then the LBFGS with learning rate 0.1 is carried out for the next 5,000 steps.

The corresponding final errors are listed in the Table 1, where we can find the TNN based machine learning method can solve the high-dimensional stochastic partial differential equations with high accuracy. Figure 2 shows the relative errors e_{L^2} and e_{H^1} versus the number of epochs.

Table 1: Errors of Example 1.

M	e_{L^2}	e_{H^1}
10	6.515e-08	2.047e-07
20	3.606e-07	1.133e-06
50	5.345 e-06	1.720e-05
100	6.506e-06	$2.226\mathrm{e}{\text{-}}05$

5.2 Variable stochastic coefficients

In the second example, we consider the case of variable stochastic coefficients

$$a_M(y,x) = 1 + \sum_{m=1}^M a_m(x)y_m$$
(5.4)

for the truncated sequence of coefficients $a_m(x) = (1+m)^{-2} \sin(m\pi x)$ $(m = 1, \dots, M)$. Here, we also set D = (0, 1).

Similarly, we assume that the exact solution

$$u(y,x) = \sin(\pi x) \prod_{m=1}^{M} \sin\left(\frac{\pi y_m}{2}\right)$$

Figure 2: The relative errors during training process in Example 1.

and the load is chosen accordingly

$$f(y,x) = \pi^2 \sin(\pi x) \sum_{i=1}^M \sin\left(\frac{\pi y_i}{2}\right) + \sum_{m=1}^M \left(\frac{\pi}{1+m}\right)^2 \sin(m\pi x) \sin(\pi x) y_m \prod_{i=1}^M \sin\left(\frac{\pi y_i}{2}\right) \\ - \sum_{m=1}^M \frac{m\pi^2}{(1+m)^2} \cos(m\pi x) \cos(\pi x) y_m \prod_{i=1}^M \sin\left(\frac{\pi y_i}{2}\right).$$

In this example, we investigate the numerical performance for the cases M = 10, 20, 50and 100. Here, the computational probability domain is also set to be $\Gamma = \Gamma_1 \times \cdots \times \Gamma_M$, where $\Gamma_i = [-1, 1]$ for $i = 1, \cdots, M$. In order to do the high-dimensional integration for the TNN functions, we also decompose the physical domain D and the probability space Γ_j $(j = 1, \cdots, M)$ into 200 subintervals and choose 16 Gauss points on each subinterval respectively.

The FNN with 3 hidden layers, 100 nodes in each layer is also adopted to build the subnetwork for the TNN function. Here we select $\sin(x)$ as the activation function and choose p = 50.

For M = 10, 20, we also use the strong form to build the loss function (4.6) and solve the optimization problem (4.3) to obtain the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0005 is adopted for the first 100,000 steps. Then the LBFGS optimizer with learning rate 0.5 is carried out for the next 10,000 steps. For the case of M = 50,100, we also use the weak form to build the loss function (4.5) and solve the corresponding optimization problem (4.2) to produce the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0001 is adopted for the first 95,000 steps. Then the LBFGS with learning rate 0.1 is carried out for the next 5,000 steps.

The corresponding final errors are listed in the Table 2, where we can find the TNN based machine learning method can solve the high-dimensional stochastic partial differential

equations with high accuracy. Figure 3 shows the relative errors e_{L^2} and e_{H^1} versus the number of epochs.

Table 2: Errors of Example 2.

M	e_{L^2}	e_{H^1}

100	6.031 e-06	1.941e-05

Figure 3: The relative errors during training process in Example 2.

5.3 Exponential decay coefficients

In the third example, the variable stochastic coefficients is set to be exponential decay coefficient, i.e.,

$$a_M(y,x) = 1 + \sum_{m=1}^M 0.5 \exp(-m) \sin(m\pi x) y_m.$$
(5.5)

Here, we also set D = (0, 1). Here, in order to make the exact solution is

$$u(y,x) = \sin(\pi x) \prod_{m=1}^{M} \sin\left(\frac{\pi y_m}{2}\right),$$

we set the load to be

$$f(y,x) = \pi^2 \sin(\pi x) \sum_{i=1}^M \sin\left(\frac{\pi y_i}{2}\right) + 0.5\pi^2 \sum_{m=1}^M \exp(-m) \sin(m\pi x) \sin(\pi x) y_m \prod_{i=1}^M \sin\left(\frac{\pi y_i}{2}\right)$$

$$-0.5\pi^{2} \sum_{m=1}^{M} m \exp(-m) \cos(m\pi x) \cos(\pi x) y_{m} \prod_{i=1}^{M} \sin\left(\frac{\pi y_{i}}{2}\right)$$

In this example, the numerical experiments are performed to investigate the accuracy for the cases M = 10, 20, 50 and 100. The computational probability domain is also $\Gamma = \Gamma_1 \times \cdots \times \Gamma_M$ with $\Gamma_i = [-1, 1]$ for $i = 1, \cdots, M$. In order to do the high-dimensional integration for the TNN functions, the physical domain D and the probability space Γ_j $(j = 1, \cdots, M)$ are decomposed into 200 subintervals and 16 Gauss points are used on each subinterval.

Here, the FNN with 3 hidden layers, 100 nodes in each layer is also adopted to build the subnetwork for the TNN function. Here we select $\sin(x)$ as the activation function and choose p = 50.

For M = 10, 20, we use the loss function (4.6) and the optimization problem (4.3) to obtain the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0005 is adopted for the first 100,000 steps and the LBFGS optimizer with learning rate 0.5 for the sequent 10,000 steps. For the case of M = 50,100, we use the loss function (4.5) and the corresponding optimization problem (4.2) to produce the approximation of the problem (2.14). The Adam optimizer with learning rate 0.0001 is adopted for the first 95,000 steps and the LBFGS with learning rate 0.1 for the sequent 5,000 steps.

The final errors are listed in the Table 3 lists the final errors, which shows that the TNN based machine learning method can solve the high-dimensional stochastic partial differential equations with high accuracy. The relative errors e_{L^2} and e_{H^1} versus the number of epochs are shown in Figure 4.

6 Conclusion

In this paper, we design a type of TNN based machine learning method for solving the elliptic partial differential equations with random coefficients in a bounded physical domain. Different from the general FNN-based machine learning method, TNN has the tensor product structure and then the corresponding high-dimensional integration can be computed with high accuracy. Benefit from the high accuracy of the high-dimensional integration, the TNN based machine learning method can solve the high-dimensional differential equations with high accuracy. We believe that the ability of TNN based machine learning method will bring more applications in solving linear and nonlinear high-dimensional PDEs. These will be our future work.
