Tighter Lower Bounds on Aperiodic Ambiguity Function and Their Asymptotic Achievability

Lingsheng Meng, Yong Liang Guan, Senior Member, IEEE, Yao Ge, Member, IEEE, Zilong Liu, Senior Member, IEEE, and Pingzhi Fan, Fellow, IEEE

Abstract

This paper presents tighter lower bounds on the maximum aperiodic ambiguity function (AF) magnitude of unimodular sequences under certain delay-Doppler low ambiguity zones (LAZ). These bounds are derived by exploiting the upper and lower bounds on the Frobenius norm of the weighted auto- and cross-AF matrices, with the introduction of two weight vectors associated with the delay and Doppler shifts, respectively. As a second major contribution, we demonstrate that our derived lower bounds are asymptotically achievable with selected Chu sequence sets by analyzing their maximum auto- and cross- AF magnitudes within certain LAZ.

Index Terms

Ambiguity function, lower bounds, unimodular sequences, delay-Doppler low ambiguity zone, Chu sequences.

I. INTRODUCTION

MBIGUITY function (AF) is an important concept in communication, radar, and sonar systems [1]–[3]. Unlike the traditional correlation functions, an AF characterizes the receiver's response to both Delay and Doppler shifts, serving as a pivotal tool for mobile wireless system design. By sending a preamble/sensing sequence over a wireless channel, for example, the AF of such a sequence can be used to measure the ranges and velocities of different targets in complex environments [4].

The maximum magnitude of the AF sidelobes critically influences the target detection and delay-Doppler estimation capabilities of sequences, as the AF peaks of weaker targets may be buried by the sidelobes of strong targets [4]. To achieve reliable detection and estimation, the ideal sequence sets are expected to have zero periodic/aperiodic auto-ambiguity function (AAF) and cross-ambiguity function (CAF) values, except for the AAF peak at the origin of the delay-Doppler plane. However, such sequence sets are impossible due to the limited volume of AFs [4]. In practical applications, a feasible approach is to optimize the local AF sidelobes of sequences over a low ambiguity zone (LAZ) [5] in the delay-Doppler plane, since the maximum delay and Doppler values are generally much smaller than the signal duration and bandwidth, respectively [6]–[11].

Correlation functions can be considered as a special case of AFs with zero Doppler. In the literature, two important correlation lower bounds are the Welch bound [12] and the Levenshtein bound [13]–[15]. These bounds are useful measures of sequence sets operating under static (or quasi-static) wireless environments. In contrast, the upcoming sixth generation (6G) mobile systems need to deal with 1) highly dynamic environments with high mobility of 1000 km/h (or higher) [16], [17] and 2) integrated sensing and communication (ISAC), as one out of the three new key 6G use scenarios, which is evident from the recently finalized IMT-2030 framework [18], [19]. Driven by these two important applications, it is desirable to understand the AF lower bounds in order to measure the optimality of sequence sets deployed over asynchronous mobile channels. Although the periodic AF lower bounds are investigated in [20] and [5], a comprehensive study of the aperiodic AF lower bounds is missing. There is an aperiodic AF lower bound in [5] but it is derived by extending methodologies from the periodic case. Furthermore, the trade-offs between the lower bounds of the aperiodic AAF and CAF are largely untouched, to the best of our knowledge.

From the construction perspective, while sequences with low aperiodic correlation have been investigated with respect to the Welch bound [12] and the Pursley-Sarwate criterion [21] in [22]–

[26], little is known on systematically constructed sequences having low aperiodic AF sidelobes. Specifically, the asymptotic behavior of Chu sequence pair [27] was studied in [22] and [23] showing that the maximum auto-correlation and cross-correlation magnitudes of the primary Chu sequence and its conjugate can asymptotically beat the Welch bound [12]. This observation demonstrates that the aperiodic Welch bound is asymptotically achievable, highlighting the effectiveness of Chu sequences. However, similar evidence supporting the achievability of the aperiodic AF lower bounds remains absent.

In this paper, compared to the bound in [5, Theorem 4], we introduce tighter aperiodic AF lower bounds for unimodular sequences with certain LAZ. We also establish trade-offs between the lower bounds of aperiodic AAF and CAF of sequences. Motivated by the Levenshtein bound [13], our core idea is to exploit some properties of the weighted aperiodic AF. However, instead of using a single weight vector in the bounding equation, we introduce a pair of weight vectors to study the different impacts of the delay and Doppler shifts, respectively. Moreover, the structural properties of aperiodic AF with zero delay and the last several delays are also utilized in the derivation.

It is shown that our proposed aperiodic AF lower bounds include several aperiodic correlation bounds as special cases with zero Doppler, such as the Welch bound [12], Sarwate Bound [28], Levenshtein bound [13], Peng-Fan bound [29], and Arlery-Tan-Rabaste bound [15]. Additionally, our analysis reveals the optimal weight vector for the Doppler shift, making the derived aperiodic AF bound a function of the weight vector for the delay shift only. Such an optimal Doppler weight vector evenly weights the Doppler bins within the LAZ, aligning with the cyclic nature of the Doppler domain of the aperiodic AF. In contrast, due to the non-cyclic characteristics of the delay domain of the aperiodic AF, certain delay weight vectors lead to tighter aperiodic AF bounds. Consequently, with the optimal Doppler weight vector, the proposed bounds are shown to be tighter than the aforementioned correlation bounds in non-zero Doppler cases.

Additionally, by analyzing the maximum aperiodic AAF and CAF magnitudes of Chu sequences, we show that certain pairs/sets of Chu sequences are asymptotically order-optimal with respect to our proposed AF bounds over certain LAZ. This analysis substantiates the achievability of these bounds. Finally, we demonstrate the tightness of the proposed bounds through asymptotic analysis and numerical examples.

The remainder of this paper is organized as follows. In Section II, we introduce preliminary definitions and describe several properties of aperiodic AF. Section III presents our proposed

aperiodic AF lower bounds. In Section IV, we analyze the maximum aperiodic AAF and CAF magnitudes of Chu sequences in certain LAZ. Comparison and tightness analyses of the proposed aperiodic AF lower bounds are presented in Section V. Section VI concludes the paper.

Notations: In the following, we use boldface letters to denote matrices and vectors. $(\cdot)^*$, $(\cdot)^T$, $(\cdot)^H$ stand for the conjugate, transpose, and conjugate transpose, respectively. $|| \cdot ||_F$, $\lceil \cdot \rceil$ and $\lfloor \cdot \rfloor$ represent the Frobenius norm, round up and round down operations. The imaginary unit is denoted by $j = \sqrt{-1}$. In addition, we define the circulant matrix $\mathbf{c}(\boldsymbol{x})$ specified by any vector $\boldsymbol{x} = [x_0, x_1, \cdots, x_{L-1}]$ of length L as:

$$\mathbf{c}(\boldsymbol{x}) = \begin{bmatrix} x_0 & x_1 & \cdots & x_{L-2} & x_{L-1} \\ x_{L-1} & x_0 & \cdots & x_{L-3} & x_{L-2} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_1 & x_2 & \cdots & x_{L-1} & x_0 \end{bmatrix} = \begin{bmatrix} \mathbf{c}(\boldsymbol{x})_0 \\ \mathbf{c}(\boldsymbol{x})_1 \\ \vdots \\ \mathbf{c}(\boldsymbol{x})_{L-1} \end{bmatrix}$$

where the *i*-th row vector of $\mathbf{c}(\boldsymbol{x})$ is denoted as $\mathbf{c}(\boldsymbol{x})_i$.

II. PRELIMINARY

A. Definitions

We consider unimodular sequence set $S = \{x^m\}_{m=1}^M$ with M sequences of length N. Each sequence $x^m = [x_0^m, x_1^m, \dots, x_{N-1}^m]$ satisfies $|x_t^m|^2 = 1$ for $t = 0, 1, \dots, N-1$, meaning that the energy of each sequence equals to N.

The discrete aperiodic AF of $x^m, x^{m'} \in S$ at delay shift au and Doppler shift u is defined as

$$A_{\boldsymbol{x}^{m},\boldsymbol{x}^{m'}}(\tau,\nu) = \begin{cases} \sum_{\substack{t=0\\N-1+\tau\\\sum_{t=0}^{N-1+\tau}} x_{t}^{m} \left(x_{t+\tau}^{m'}\right)^{*} e^{\frac{j2\pi\nu t}{N}}, & 0 \le \tau \le N-1; \\ \sum_{t=0}^{N-1+\tau} x_{t-\tau}^{m} \left(x_{t}^{m'}\right)^{*} e^{\frac{j2\pi\nu t}{N}}, & 1-N \le \tau \le -1, \end{cases}$$
(1)

where $|\tau|, |\nu| \in \mathbb{Z}_N$. When $m \neq m'$, $A_{x^m, x^{m'}}(\tau, \nu)$ is known as the aperiodic CAF; otherwise, aperiodic AAF denoted by $A_{x^m}(\tau, \nu)$. It is worth noting that the aperiodic correlation can be seen as a special case of the aperiodic AF when $\nu = 0$, which is represented by $R_{x^m, x^{m'}}(\tau)$.

We define the LAZ in the delay-Doppler plane as

$$\Gamma = \{ (\tau, \nu) | \tau \in (-Z_x, Z_x), \nu \in (-Z_y, Z_y) \},$$
(2)

where $Z_x, Z_y \in [1, N]$. In practical applications, Z_x and Z_y are determined by the maximum Doppler frequency and the maximum delay [5], [30]. When $Z_x = Z_y = N$, Γ refers to the global AF region. The maximum (non-trivial) aperiodic AAF magnitude θ_a of S and the maximum aperiodic CAF magnitude θ_c associated to the LAZ Γ are defined by

$$\theta_a^2 = \max_{\substack{m \in [1,M], \ (\tau,\nu) \neq (0,0), \\ |\tau| \le Z_x - 1, \ |\nu| \le Z_y - 1}} |A_{x^m}(\tau,\nu)|^2,$$
(3a)

$$\theta_c^2 = \max_{\substack{m, \ m' \in [1,M], \ m \neq m', \\ |\tau| \le Z_x - 1, \ |\nu| \le Z_y - 1}} |A_{\boldsymbol{x}^m, \boldsymbol{x}^{m'}}(\tau, \nu)|^2.$$
(3b)

The maximum aperiodic (non-trivial) AF magnitude¹ θ_{max} of S associated to Γ is defined by

$$\theta_{\max}^2 = \max\left\{\theta_a^2, \theta_c^2\right\}.$$
(4)

Throughout the paper, such a sequence set S with the maximum aperiodic AF magnitude θ_{max} is denoted as $(N, M, \theta_{\text{max}}, \Gamma)$ -S.

B. Properties of Aperiodic AF

Before presenting the aperiodic AF lower bounds, we demonstrate some inherent structural properties of the aperiodic AF of unimodular sequences through the following lemmas:

Lemma 1 (Zero delay): For any unimodular sequence x, its aperiodic AAF satisfies

$$A_{\boldsymbol{x}}(0,\nu) = 0, \qquad \forall \ \nu \neq 0.$$
(5)

Proof: For any delay τ in aperiodic scenario, define $x_{t+\tau}^{m'} = 0$ for $|t+\tau| \ge N$, we have

$$\sum_{\nu=0}^{N-1} |A_{\boldsymbol{x}^{m},\boldsymbol{x}^{m'}}(\tau,\nu)|^{2} = \sum_{\nu=0}^{N-1} \sum_{t=0}^{N-1} x_{t}^{m} \left(x_{t+\tau}^{m'}\right)^{*} e^{\frac{j2\pi\nu t}{N}} \sum_{s=0}^{N-1} (x_{s}^{m})^{*} x_{s+\tau}^{m'} e^{\frac{-j2\pi\nu s}{N}}$$
$$= \sum_{t=0}^{N-1} \sum_{s=0}^{N-1} x_{t}^{m} \left(x_{t+\tau}^{m'}\right)^{*} (x_{s}^{m})^{*} x_{s+\tau}^{m'} \sum_{\nu=0}^{N-1} e^{\frac{j2\pi\nu(t-s)}{N}}$$
$$= N \sum_{t=0}^{N-1} |x_{t}^{m}|^{2} \left|x_{t+\tau}^{m'}\right|^{2}$$
$$= N \left(N - |\tau|\right).$$
(6)

When m = m', $\tau = 0$, since $A_{\boldsymbol{x}}(0,0) = N$, we have

$$\sum_{\nu=1}^{N-1} |A_{\boldsymbol{x}}(0,\nu)|^2 = \sum_{\nu=0}^{N-1} |A_{\boldsymbol{x}^m}(0,\nu)|^2 - N^2 = 0.$$
(7)

¹Also referred to as peak sidelobe level (PSL) of aperiodic AF.

Therefore, for any $\nu > 0$, $|A_x(0,\nu)|^2 = 0$, leading to the conclusion that $A_x(0,\nu) = 0$. Based on $A_x(\tau,\nu) = A_x(-\tau,-\nu)^*$, we obtain (5).

Lemma 1 also holds for periodic AF [5]. However, (6) reveals some unique properties of aperiodic AF that are further elaborated in *Corollary 1*.

Another property of the aperiodic AF can be derived based on the Cauchy-Schwarz inequality. Let $d = N - |\tau|$, $d \in [1, N]$, the d-th last delay of the aperiodic AF satisfies:

Lemma 2: For any unimodular sequences x^m and $x^{m'}$ of length N, we have

$$|A_{x^{m},x^{m'}}(\tau,\nu)|^{2} \le d^{2}, \quad \forall \ |\tau|, |\nu| \in [0, N-1].$$
 (8)

Proof: For $0 \le \tau \le N - 1$, we have

$$\begin{aligned} \left| A_{\boldsymbol{x}^{m},\boldsymbol{x}^{m'}}(\tau,\nu) \right|^{2} &= \left| \sum_{t=0}^{N-1-\tau} x_{t}^{m} \left(x_{t+\tau}^{m'} \right)^{*} e^{\frac{j2\pi\nu t}{N}} \right|^{2} \\ &\leq \left(\sum_{t=0}^{N-1-\tau} x_{t}^{m} e^{\frac{j2\pi\nu t}{N}} \left(x_{t}^{m} e^{\frac{j2\pi\nu t}{N}} \right)^{*} \right) \left(\sum_{t=0}^{N-1-\tau} x_{t+\tau}^{m'} x_{t+\tau}^{m'} \right) \\ &= (N-\tau)^{2}. \end{aligned}$$
(9)

Similarly, $|A_{\boldsymbol{x}^m, \boldsymbol{x}^{m'}}(\tau, \nu)|^2 \leq (N + \tau)^2$ for $N - 1 \leq \tau \leq 0$.

III. APERIODIC AF LOWER BOUNDS OF UNIMODULAR SEQUENCES

A. Aperiodic AF Lower Bounds Associated to the LAZ

In this subsection, we present our proposed aperiodic AF lower bounds of θ_{\max} , θ_a and θ_c for S associated to the LAZ Γ with $1 \le Z_x \le N$ and $1 \le Z_y \le N$. First, for a unimodular sequence set S, we define Z_y Doppler shifted sequences for each $x^m \in S$ as

$$\widetilde{\boldsymbol{x}}^{m,r} = \left[x_0^m, x_1^m e^{\frac{j2\pi r}{N}}, \cdots, x_{N-1}^m e^{\frac{j2\pi (N-1)r}{N}} \right],$$

for $m = 1, 2, \cdots, M$ and $r = 0, 1, \cdots, Z_y - 1.$ (10)

We define sequences $x^{m,r}$ of length 2N-1 by concatenating $\tilde{x}^{m,r}$ with zero vector $\mathbf{0}_{1\times N-1}$, as follows:

$$\boldsymbol{x}^{m,r} = \left[\widetilde{\boldsymbol{x}}^{m,r}, \boldsymbol{0}_{1 \times (N-1)} \right].$$
(11)

We define two weight vectors $\mathbf{w} = [w_0, w_1, \cdots, w_{Z_x-1}]^T$ and $\mathbf{p} = [p_0, p_1, \cdots, p_{Z_y-1}]^T$, for delay and Doppler shifts, respectively. \mathbf{w} and \mathbf{p} satisfy the following conditions:

$$\sum_{i=0}^{Z_x-1} w_i = 1, \ w_i \ge 0, \ i = 0, 1, \cdots, Z_x - 1,$$
(12a)

$$\sum_{r=0}^{Z_y-1} p_r = 1, \quad p_r \ge 0, \quad r = 0, 1, \cdots, Z_y - 1.$$
(12b)

Then, we define the matrix U of size $MZ_xZ_y \times (2N-1)$ as follows:

$$\mathbf{U} = \begin{bmatrix} \mathbf{U}^{1} \\ \mathbf{U}^{2} \\ \vdots \\ \mathbf{U}^{M} \end{bmatrix}, \text{ with } \mathbf{U}^{m} = \begin{bmatrix} \boldsymbol{u}(\boldsymbol{x}^{m,0}) \\ \boldsymbol{u}(\boldsymbol{x}^{m,1}) \\ \vdots \\ \boldsymbol{u}(\boldsymbol{x}^{m,Z_{y}-1}) \end{bmatrix} \text{ for } m = 1, 2, \cdots, M,$$
(13)

where $\boldsymbol{u}(\boldsymbol{x}^{m,r})$ represents the weighted matrix of size $Z_x \times (2N-1)$, constructed from the first Z_x row-vectors of the circulant matrix $\mathbf{c}(\boldsymbol{x}^{m,r})$ in conjunction with weight vectors \mathbf{w} and \mathbf{p} . $\boldsymbol{u}(\boldsymbol{x}^{m,r})$ is defined as

$$\boldsymbol{u}(\boldsymbol{x}^{m,r}) = \begin{bmatrix} \boldsymbol{u}(\boldsymbol{x}^{m,r})_{0} \\ \boldsymbol{u}(\boldsymbol{x}^{m,r})_{1} \\ \vdots \\ \boldsymbol{u}(\boldsymbol{x}^{m,r})_{Z_{x}-1} \end{bmatrix} = \begin{bmatrix} \sqrt{p_{r}}\sqrt{w_{0}}\mathbf{c}(\boldsymbol{x}^{m,r})_{0} \\ \sqrt{p_{r}}\sqrt{w_{1}}\mathbf{c}(\boldsymbol{x}^{m,r})_{1} \\ \vdots \\ \sqrt{p_{r}}\sqrt{w_{Z_{x}-1}}\mathbf{c}(\boldsymbol{x}^{m,r})_{Z_{x}-1} \end{bmatrix}.$$
(14)

We set the (k + 1)-th element of $\boldsymbol{u}(\boldsymbol{x}^{m,r})_i$ as $u(\boldsymbol{x}^{m,r})_{i,k}$, so we have

$$u(x^{m,r})_i = [u(x^{m,r})_{i,0}, u(x^{m,r})_{i,1}, \cdots, u(x^{m,r})_{i,2N-2}].$$

Example: Set N = 3, M = 2, $Z_x = 3$, and $Z_y = 2$. The matrix U results in a size of 12×5 :

$$\mathbf{U} = \begin{bmatrix} \sqrt{p_0}\sqrt{w_0}x_0^1 & \sqrt{p_0}\sqrt{w_0}x_1^1 & \sqrt{p_0}\sqrt{w_0}x_2^1 & 0 & 0 \\ 0 & \sqrt{p_0}\sqrt{w_1}x_0^1 & \sqrt{p_0}\sqrt{w_1}x_1^1 & \sqrt{p_0}\sqrt{w_1}x_2^1 & 0 \\ 0 & 0 & \sqrt{p_0}\sqrt{w_2}x_0^1 & \sqrt{p_0}\sqrt{w_2}x_1^1 & \sqrt{p_0}\sqrt{w_2}x_2^1 \\ \sqrt{p_1}\sqrt{w_0}x_0^1 & \sqrt{p_1}\sqrt{w_0}x_1^1e^{\frac{j2\pi}{N}} & \sqrt{p_1}\sqrt{w_0}x_2^1e^{\frac{j4\pi}{N}} & 0 & 0 \\ 0 & \sqrt{p_1}\sqrt{w_1}x_0^1 & \sqrt{p_1}\sqrt{w_1}x_1^1e^{\frac{j2\pi}{N}} & \sqrt{p_1}\sqrt{w_1}x_2^1e^{\frac{j4\pi}{N}} & 0 \\ 0 & 0 & \sqrt{p_1}\sqrt{w_2}x_0^1 & \sqrt{p_1}\sqrt{w_2}x_1^1e^{\frac{j2\pi}{N}} & \sqrt{p_1}\sqrt{w_2}x_2^1e^{\frac{j4\pi}{N}} \\ \sqrt{p_0}\sqrt{w_0}x_0^2 & \sqrt{p_0}\sqrt{w_0}x_1^2 & \sqrt{p_0}\sqrt{w_0}x_2^2 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \sqrt{p_1}\sqrt{w_2}x_0^2 & \sqrt{p_1}\sqrt{w_2}x_1^2e^{\frac{j2\pi}{N}} & \sqrt{p_1}\sqrt{w_2}x_2^2e^{\frac{j4\pi}{N}} \end{bmatrix}_{12\times5} \end{bmatrix}_{12\times5}$$

Note that the following identity is satisfied:

$$\left\|\mathbf{U}^{H}\mathbf{U}\right\|_{F}^{2} = \left\|\mathbf{U}\mathbf{U}^{H}\right\|_{F}^{2}.$$
(15)

We first consider the left-hand side of (15).

Lemma 3: $\left\|\mathbf{U}^{H}\mathbf{U}\right\|_{F}^{2}$ can be lower-bounded by

$$\left\|\mathbf{U}^{H}\mathbf{U}\right\|_{F}^{2} \ge M^{2}\left(N - \sum_{s,t=0}^{Z_{x}-1} l_{s,t,N}w_{s}w_{t}\right),\tag{16}$$

with $l_{s,t,N} = \min\{|t-s|, 2N-1-|t-s|\}.$

Proof: From the construction of U, we have

$$\left\|\mathbf{U}^{H}\mathbf{U}\right\|_{F}^{2} = \sum_{k,k'=0}^{2N-2} \left|\sum_{m=1}^{M} \sum_{r=0}^{Z_{y}-1} \sum_{i=0}^{Z_{x}-1} u(\boldsymbol{x}^{m,r})_{i,k} \left(u(\boldsymbol{x}^{m,r})_{i,k'}\right)^{*}\right|^{2}$$
(17a)

$$\geq \sum_{k=0}^{2N-2} \left(\sum_{r=0}^{Z_y-1} p_r \sum_{m=1}^{M} \sum_{i=0}^{Z_x-1} |c(\boldsymbol{x}^{m,0})_{i,k}|^2 w_i \right)^2$$
(17b)

$$=\sum_{k=0}^{2N-2} \left(\sum_{i=0}^{Z_x-1} |c(\boldsymbol{x}^{m,0})_{i,k}|^2 w_i\right)^2$$
(17c)

$$=M^{2}\left(N-\sum_{s,t=0}^{Z_{x}-1}l_{s,t,N}w_{s}w_{t}\right),$$
(17d)

where the inequality (17b) is obtained by removing all terms $k \neq k'$ in (17a). Equation (17c) is derived based on the condition (12b) of the weight vector **p**. The proof of (17d) is similar to [15, Appendix B] and hence omitted here.

Now we consider the right-hand side of (15).

Lemma 4: $\left\|\mathbf{U}\mathbf{U}^{H}\right\|_{F}^{2}$ can be upper-bounded by

$$\begin{aligned} |\mathbf{U}\mathbf{U}^{H}||_{F}^{2} \leq \theta_{c}^{2}M(M-1) \left(1 - \sum_{d=E}^{D} \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1} w_{s}w_{t}\right) \\ &+ \theta_{a}^{2}M \left(1 - \sum_{i=0}^{Z_{x}-1} w_{i}^{2} - \sum_{d=E}^{D} \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1} w_{s}w_{t}\right) \\ &+ MN^{2} \sum_{r=0}^{Z_{y}-1} p_{r}^{2} \sum_{i=0}^{Z_{x}-1} w_{i}^{2} + M^{2} \sum_{d=E}^{D} d^{2} \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1} w_{s}w_{t}, \end{aligned}$$
(18)

and

$$||\mathbf{U}\mathbf{U}^{H}||_{F}^{2} \leq M^{2}\theta_{\max}^{2} + M\left(N^{2}\sum_{r=0}^{Z_{y}-1}p_{r}^{2} - \theta_{\max}^{2}\right)\sum_{i=0}^{Z_{x}-1}w_{i}^{2}$$
$$-\sum_{d=E}^{D}\left(M^{2}\left(\theta_{\max}^{2} - d^{2}\right)\sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1}w_{s}w_{t}\right),$$
(19)

where $D \in [0, N - 1]$ represents the number of last delays taken into consideration and $E = N - Z_x + 1$.

Proof: Based on Lemma 1 and Lemma 2, we have

$$\begin{aligned} ||\mathbf{U}\mathbf{U}^{H}||_{F}^{2} &= \sum_{m,m'=1}^{M} \sum_{r,r'=0}^{Z_{y}-1} \sum_{i,i'=0}^{Z_{x}-1} |A_{x^{m},x^{m'}}(\tau_{i,i'},\nu_{r,r'})|^{2} p_{r} p_{r'} w_{i} w_{i'} \\ &\leq \sum_{m,m'=1}^{M} \sum_{r,r'=0}^{Z_{y}-1} \sum_{i,i'=0}^{Z_{x}-1} \theta_{c}^{2} p_{r} p_{r'} w_{i} w_{i'} + \sum_{m=1}^{M} \sum_{r,r'=0}^{Z_{y}-1} \sum_{i,i'=0}^{Z_{x}-1} \theta_{a}^{2} p_{r} p_{r'} w_{i} w_{i'} \\ &+ M \left(N^{2} - \theta_{a}^{2} \right) \sum_{r=0}^{Z_{y}-1} p_{r}^{2} \sum_{i=0}^{Z_{x}-1} w_{i}^{2} - \sum_{m=1}^{M} \sum_{\substack{r,r'=1\\r \neq r'}}^{Z_{y}-1} \sum_{i=0}^{Z_{x}-1} \theta_{a}^{2} p_{r} p_{r'} w_{i}^{2} \\ &- M (M-1) \sum_{d=E}^{D} \left(\theta_{c}^{2} - d^{2} \right) \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1} w_{s} w_{t} - M \sum_{d=E}^{D} \left(\theta_{a}^{2} - d^{2} \right) \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_{x}-1} w_{s} w_{t}. \end{aligned}$$

$$(20)$$

By substituting (12) into (20), we conclude (18) and (19).

Based on (20), when the following property is satisfied:

$$\exists (w_s, w_t) \text{ s.t.} \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_x-1} w_s w_t \neq 0, \quad \theta_{\max}^2 > d^2,$$
(21)

there exists a positive integer D > E - 1 such that (19) is tighter than the case with D = 0. A similar property for (18) can also be easily derived.

Based on the weighting condition (12b) and by utilizing the Cauchy-Schwarz inequality, we can determine that the minimum value of $\sum_{r=0}^{N-1} p_r^2$ in (19) is $\frac{1}{Z_y}$. This minimum value is achieved if and only if

$$\mathbf{p} = \hat{\mathbf{p}} = \left[\frac{1}{Z_y}, \frac{1}{Z_y}, \cdots, \frac{1}{Z_y}\right].$$
(22)

Hence, $\hat{\mathbf{p}}$ is the optimal choice of weight vector \mathbf{p} for *Lemma 4*, as it yields the tightest upper bound of $\|\mathbf{U}\mathbf{U}^H\|_F^2$.

Remark 1: It is interesting to note that since *Lemma 3* is independent of the weight vector \mathbf{p} , while the optimal choice of \mathbf{p} for *Lemma 4* is $\hat{\mathbf{p}}$ in (22), therefore $\hat{\mathbf{p}}$ is also the optimal Doppler weight vector for the desired aperiodic AF lower bounds.

Then, from the above lemmas and this optimal weight vector $\hat{\mathbf{p}}$, we can deduce the aperiodic AF lower bounds with respect to the LAZ. We first define matrices $J_{Z_x}^d$ and L_{Z_x} such that:

$$\sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{Z_x-1} w_s w_t = \mathbf{w}^T \boldsymbol{J}_{Z_x}^d \mathbf{w},$$
$$\sum_{s,t=0}^{Z_x-1} l_{s,t,N} w_s w_t = \mathbf{w}^T \boldsymbol{L}_{Z_x} \mathbf{w}.$$

Theorem 1 (Aperiodic AF lower bounds associated to an LAZ): For any weight vector w satisfying the weighting condition (12a), aperiodic AF lower bounds associated to any LAZ Γ $(1 < Z_x \leq N \text{ and } 1 \leq Z_y \leq N)$ for any sequence set $(N, M, \theta_{\max}, \Gamma)$ -S is given by:

$$\theta_{c}^{2}(M-1)\left(1-\mathbf{w}^{T}\sum_{d=E}^{D}\boldsymbol{J}_{Zx}^{d}\mathbf{w}\right)+\theta_{a}^{2}\left(1-\mathbf{w}^{T}\left(\boldsymbol{I}_{Zx}+\sum_{d=E}^{D}\boldsymbol{J}_{Zx}^{d}\right)\mathbf{w}\right)$$

$$\geq M\left(N-Q\left(\mathbf{w},\frac{N^{2}}{MZ_{y}},\sum_{d=E}^{D}d^{2}\boldsymbol{J}_{Zx}^{d}\right)\right),$$
(23a)

$$\theta_{\max}^{2} \geq N - \frac{\mathcal{Q}\left(\mathbf{w}, \frac{N(N-Z_{y})}{MZ_{y}}, \sum_{d=E}^{D} (d^{2}-N) \mathbf{J}_{Z_{x}}^{d}\right)}{1 - \mathbf{w}^{T} \left(\frac{1}{M} \mathbf{I}_{Z_{x}} + \sum_{d=E}^{D} \mathbf{J}_{Z_{x}}^{d}\right) \mathbf{w}},$$
(23b)

where $\mathcal{Q}(\mathbf{w},\eta, \mathbf{B}) = \mathbf{w}^T(\eta \mathbf{I}_{Z_x} + \mathbf{B} + \mathbf{L}_{Z_x})\mathbf{w}, E = N - Z_x + 1 \text{ and } D \in [0, N - 1].$

Proof: Based on equation (15), substituting the optimal weight vector $\hat{\mathbf{p}}$ from (22) into *Lemma 4* and combining it with *Lemma 3* yields (23).

As special cases, the correlation lower bound and AF lower bound for global AF can be derived from *Theorem 1*.

Remark 2: When $Z_y = 1$ and D = 0, the proposed bounds in (23) reduce to the Peng-Fan bounds [29, Theorem 2] for aperiodic correlation in the low correlation zone. This correlation bound is equivalent to the AF bound for $Z_y > 1$ derived from *Lemma 3* and *Lemma 4* using the non-optimal weight vector $\mathbf{p} = [1, 0, \dots, 0]^T$. Therefore, for cases with non-zero Doppler shifts,

the proposed bound (23) is strictly tighter than the Peng-Fan bound [29, Theorem 2], owing to the optimal weight vector $\hat{\mathbf{p}}$.

Corollary 1 (Aperiodic AF lower bound for global AF): For any set S of M unimodular sequences of length N, the global aperiodic AF lower bound (i.e., $Z_x = Z_y = N$) is given by:

$$\theta_{\max}^2 \ge \begin{cases} N-1, & M=1; \\ N, & M>1. \end{cases}$$
(24a)

For any LAZ Γ with $1 < Z_x \leq N$ and $Z_y = N$, the bound in (24) still holds.

Proof: For $Z_x = Z_y = N$, according to (6) and *Lemma 1*, we have

$$\begin{aligned} \theta_{c}^{2} &\geq \max_{\substack{m, \ m' \in [1,M], \ m \neq m', \\ |\tau| \leq Z_{x} - 1}} \left\{ \frac{\sum_{\nu=0}^{N-1} \left| A_{x^{m}, x^{m'}}(\tau, \nu) \right|^{2}}{N} \right\} \\ &\geq \max_{\substack{|\tau| \leq Z_{x} - 1 \\ 1 \leq |\tau| \leq Z_{x} - 1}} \left\{ N - |\tau| \right\} = N; \end{aligned}$$
(25a)
$$\theta_{a}^{2} &\geq \max_{\substack{m \in [1,M], \\ 1 \leq |\tau| \leq Z_{x} - 1}} \left\{ \frac{\sum_{\nu=0}^{N-1} \left| A_{x^{m}, x^{m'}}(\tau, \nu) \right|^{2}}{N} \right\} \\ &\geq \max_{1 \leq |\tau| \leq Z_{x} - 1} \left\{ N - |\tau| \right\} = N - 1, \end{aligned}$$
(25b)

For M > 1, the global AF lower bound of θ_{max}^2 in (24) is determined by the CAF bound (25a); for M = 1, it is determined by the AAF bound (25b).

Remark 3: The bounds for global AF in (24) is also a special case of the proposed bound (23b) for delay-Doppler LAZ. When $Z_y = N$ and $M \ge 2$, the proposed bound (23b) is equal to (24a) by choosing weight vector $\mathbf{w} = [1, 0, \dots, 0]^T$. When $Z_y = N$ and M = 1, the proposed bound (23b) is equal to (24a) with weight vector $\mathbf{w} = [0.5, 0.5, 0, \dots, 0]^T$.

Next, we investigate different weight vectors w for the bound (23). We first consider (23) with D = 0.

1) Weight vector A ($\mathbf{w}^{A,q}$): An intuitive weight vector, denoted as $\mathbf{w}^{A,q}$, can be defined as

$$w_i^{A,q} = \begin{cases} \frac{1}{q}, & 0 \le i \le q - 1; \\ 0, & q \le i \le Z_x - 1, \end{cases}$$
(26)

where $1 \leq q \leq Z_x$.

Corollary 2: For any LAZ Γ and any integer $q \in [1, Z_x]$, we have

$$\theta_c^2 3q Z_y(M-1) + \theta_a^2 \left(3q Z_y - 3Z_y \right) \ge 3q M N Z_y - \left(q^2 - 1\right) M Z_y - 3N^2, \tag{27a}$$

$$\theta_{\max}^2 \ge \frac{3qMNZ_y - 3N^2 - q^2MZ_y + MZ_y}{3(qM - 1)Z_y}.$$
(27b)

Proof: By substituting $\mathbf{w}^{A,q}$ and D = 0 into (23a),

$$\theta_{c}^{2}(M-1) + \theta_{a}^{2}\left(1-\frac{1}{q}\right) \geq M\left(N-\sum_{s,t=0}^{Z_{x}-1}l_{s,t,N}w_{s}w_{t}-\frac{N^{2}}{MZ_{y}}\sum_{i=0}^{Z_{x}-1}w_{i}^{2}\right)$$
$$= M\left(N-\sum_{s,t=0}^{q-1}|s-t|\frac{1}{q^{2}}-\frac{N^{2}}{qMZ_{y}}\right)$$
$$= M\left(N-\frac{(q-1)(q+1)}{3q}-\frac{N^{2}}{qMZ_{y}}\right).$$
(28)

This completes the proof of (23a). Based on $\theta_{\max}^2\left(M-\frac{1}{q}\right) \ge \theta_c^2(M-1) + \theta_a^2\left(1-\frac{1}{q}\right)$, we have (23b).

A more optimal choice of q can lead to further improvement of (27).

Corollary 3: For any LAZ Γ satisfying $Z_x > \sqrt{\frac{3N^2}{MZ_y}}$ with the condition that $MZ_y \ge 3$, we have

$$\theta_c^2(M-1) + \theta_a^2 \left(1 - \frac{\sqrt{MZ_y}}{\sqrt{3N}}\right) \ge MN \frac{\sqrt{3MZ_y} - 2}{\sqrt{3MZ_y}},\tag{29a}$$

$$\theta_{\max}^2 \ge N - \frac{2N}{\sqrt{3MZ_y}}.$$
(29b)

Proof: When $MZ_y \ge 3$, there is an integer \hat{q} satisfies $1 \le \hat{q} \le N$, and $\hat{q} = \sqrt{\frac{3N^2}{MZ_y}} - \epsilon$, where $0 \le \epsilon < 1$,

$$\theta_c^2(M-1) + \theta_a^2 \left(1 - \frac{1}{\sqrt{\frac{3N^2}{MZ_y}}}\right) \ge \theta_c^2(M-1) + \theta_a^2 \left(1 - \frac{1}{\hat{q}}\right)$$
$$\ge M \left(N - \frac{\hat{q}^2 - 1}{3q} - \frac{N^2}{\hat{q}MZ_y}\right)$$
$$\ge M \left(N - \frac{2N}{\sqrt{3MZ_y}}\right). \tag{30}$$

2) Weight vector $B(\mathbf{w}^{B,q})$: First, to facilitate the subsequent analysis, we consider a simplified version of the bound (23):

Corollary 4: For any weight vector w satisfying the weighting condition (12a), and any sequence set $(N, M, \theta_{\text{max}}, \Gamma)$ -S,

$$\theta_c^2(M-1) + \theta_a^2 \ge M\left(N - \mathcal{Q}\left(\mathbf{w}, \frac{N^2}{MZ_y}, \mathbf{0}_{Z_x}\right)\right),\tag{31a}$$

$$\theta_{\max}^2 \ge N - \mathcal{Q}\left(\mathbf{w}, \frac{N^2}{MZ_y}, \mathbf{0}_{Z_x}\right).$$
(31b)

$$\theta_{\max}^{2} \geq \frac{M\left(N - \sum_{s,t=0}^{Z_{x}-1} l_{s,t,N} w_{s} w_{t}\right) - \frac{N^{2}}{Z_{y}} \sum_{i=0}^{Z_{x}-1} w_{i}^{2}}{M - \sum_{i=0}^{Z_{x}-1} w_{i}^{2}}$$
$$\geq \frac{M\left(N - \sum_{s,t=0}^{Z_{x}-1} l_{s,t,N} w_{s} w_{t}\right) - \frac{N^{2}}{Z_{y}} \sum_{i=0}^{Z_{x}-1} w_{i}^{2}}{M}$$
$$= N - \mathcal{Q}\left(\mathbf{w}, \frac{N^{2}}{MZ_{y}}, \mathbf{0}_{Z_{x}}\right).$$
(32)

(31a) can be obtained similarly and hence omitted.

Based on (31), a weight vector can be obtained by minimizing the following function using the Lagrange multiplier [31]:

$$L_q(\mathbf{w}) = \mathcal{Q}\left(\mathbf{w}, \frac{N^2}{MZ_y}, \mathbf{0}_{Z_x}\right) - 2\lambda\left(\sum_{i=0}^{q-1} w_i - 1\right),\tag{33}$$

where $2 \le q \le Z_x - 1$, with $w_i = 0$, for $i = q, q + 1, \dots, Z_x - 1$. Let $\gamma = \arccos\left(1 - \frac{MZ_y}{N^2}\right)$, $MZ_y \le N^2$, and q be an even positive integer such that $q\gamma \le \pi + \gamma$. By setting $\gamma_0 = \frac{\pi - q\gamma + \gamma}{2}$, one can obtain the following weight vector² by relating the quadratic minimization solution of $L_q(\mathbf{w})$ to the Chebyshev polynomials of the second kind:

$$w_i^{B,q} = \begin{cases} \frac{\sin\frac{\gamma}{2}}{\sin\frac{q\gamma}{2}} \sin(\gamma_0 + i\gamma), & 0 \le i \le q - 1; \\ 0, & q \le i \le Z_x - 1. \end{cases}$$
(34)

Substituting $\mathbf{w}^{B,q}$ and D = 0 into (23), the AF lower bounds below can be obtained.

Corollary 5: For any LAZ Γ such that $MZ_y \leq N^2$, and any integer q satisfying $1 \leq q < \min\left\{Z_x + 1, \frac{\pi}{\gamma} + 1\right\}$, we have

$$\theta_{\max}^{2} \geq \frac{\theta_{c}^{2}(M-1) + \theta_{a}^{2}}{M}$$

$$\geq N - \frac{q-1}{2} - \frac{\sin\frac{q\gamma}{2} - \sin\frac{(q-2)\gamma}{2}}{2(1-\cos\gamma)\sin\frac{q\gamma}{2}}.$$
(35)

Particularly, when $Z_x > \frac{\pi}{\gamma}$, one can minimize $L_q(\mathbf{w})$ in (33) over different values of q by setting $q = \left\lfloor \frac{\pi}{\gamma} \right\rfloor + 1$.

²Although it looks similar to that in [13, Lemma 2] for aperiodic correlation, it is more generic as it considers the Doppler components in the aperiodic AF ($Z_y > 1$).

Corollary 6: For any LAZ Γ satisfying $Z_x > \frac{\pi}{\gamma}$ and $5 \leq MZ_y \leq N^2$, we have

$$\theta_{\max}^{2} \geq \frac{\theta_{c}^{2}(M-1) + \theta_{a}^{2}}{M}$$
$$\geq N - \left[\frac{\pi N}{\sqrt{8MZ_{y}}}\right]. \tag{36}$$

Based on these weight vectors above, we consider other values of D for (23). We denote the optimal D as D_{opt} , which makes (23b) the tightest under a given weight vector among different values of D. If (21) is satisfied for a weight vector \mathbf{w} , then there exists $D_{opt} > E - 1$. Let (23b) with D = 0 be denoted as AFB_{ref}. Then, from Lemma 2 and (21), we have $D_{opt} \approx \lfloor \sqrt{\text{AFB}_{ref}} \rfloor$. Conversely, consideration of D_{opt} is only necessary when $Z_x \ge N - \lfloor \sqrt{\text{AFB}_{ref}} \rfloor$. For weight vectors such as $\mathbf{w}^{A,q}$ and $\mathbf{w}^{B,q}$ which have only the first q elements non-zero, this condition becomes $q \ge N - \lfloor \sqrt{\text{AFB}_{ref}} \rfloor$.

B. LAZ with $Z_x = N$ Case

Aperiodic AF lower bound associated to the LAZ Γ with $Z_x = N$ and $1 \le Z_y \le N$ can be considered as a special case of (23). Nevertheless, a generalization of the weight vector w for this $Z_x = N$ case can be achieved. Essentially, the bound (23) leverages the first Z_x row-vectors of the circulant matrix $\mathbf{c}(\mathbf{x}^{m,r})$ in (14). Due to the cyclic property of $\mathbf{c}(\mathbf{x}^{m,r})$, when $Z_x = N$, $u(\mathbf{x}^{m,r})$ in (14) can incorporate all the 2N-1 row-vectors of $\mathbf{c}(\mathbf{x}^{m,r})$. In other words, when the maximum delay of interest is N-1, the absolute value of the delay between any two row-vectors in $\mathbf{c}(\mathbf{x}^{m,r})$ is less than or equal to N-1. Thus, the weighting condition (12a) can be replaced by:

$$\sum_{i=0}^{2N-2} w_i = 1, \ w_i \ge 0, \ i = 0, 1, \cdots, 2N - 2.$$
(37)

Following the same steps as in (10) to (23), generalized aperiodic AF lower bounds for the LAZ Γ with $Z_x = N$ can be derived as follows:

Theorem 2 (Aperiodic AF lower bounds for LAZ with $Z_x = N$): For any weight vector w satisfying the weighting condition (37), and any LAZ Γ with $Z_x = N$ and $1 \leq Z_y \leq N$, the aperiodic AF lower bound for any sequence set $(N, M, \theta_{\max}, \Gamma)$ -S is given by:

$$\theta_{c}^{2}(M-1)\left(1-\mathbf{w}^{T}\sum_{d=1}^{D}\boldsymbol{J}_{2N-1}^{d}\mathbf{w}\right)+\theta_{a}^{2}\left(1-\mathbf{w}^{T}\left(\boldsymbol{I}_{2N-1}+\sum_{d=1}^{D}\boldsymbol{J}_{2N-1}^{d}\right)\mathbf{w}\right)$$

$$\geq M\left(N-Q\left(\mathbf{w},\frac{N^{2}}{MZ_{y}},\sum_{d=1}^{D}d^{2}\boldsymbol{J}_{2N-1}^{d}\right)\right),$$
(38a)

$$\theta_{\max}^{2} \geq N - \frac{\mathcal{Q}\left(\mathbf{w}, \frac{N(N-Z_{y})}{MZ_{y}}, \sum_{d=1}^{D} (d^{2}-N) \boldsymbol{J}_{2N-1}^{d}\right)}{1 - \mathbf{w}^{T} \left(\frac{1}{M} \boldsymbol{I}_{2N-1} + \sum_{d=1}^{D} \boldsymbol{J}_{2N-1}^{d}\right) \mathbf{w}},$$
(38b)

where $\mathcal{Q}(\mathbf{w}, \eta, \mathbf{B}) = \mathbf{w}^T (\eta \mathbf{I}_{2N-1} + \mathbf{B} + \mathbf{L}_{2N-1})\mathbf{w}$ and $D \in [0, N-1]$. Remark 4:

- When Z_y = 1, the proposed bound (38b) reduces to the Arlery-Tan-Rabaste bound [15, Theorem 2] for aperiodic correlation, which exactly represents the generalized Levenshtein bound when D = 0 [13, Theorem 1]. Again, these correlation bounds are equivalent to the AF bounds for Z_y > 1 obtained using the non-optimal weight vector p = [1, 0, ···, 0]^T, so the proposed bound (38b) is strictly tighter than them for Z_y > 1.
- Compared to the original weighting condition (12a) with Z_x = N, weighting condition (37) provides enhanced flexibility in selecting weight vectors for LAZ with Z_x = N case. For a weight vector w with non-zero values present only in the first N elements, the bounds (38) and (23) are equivalent.

1) Weight vector C (\mathbf{w}^{C}): We demonstrate the significance of the new weighting condition (37) by using the most straightforward weight vector \mathbf{w}^{C} , which is defined as

$$w_i^C = \frac{1}{2N-1}, \quad i = 0, 1, \cdots, 2N-2.$$
 (39)

Corollary 7: For any LAZ Γ with $Z_x = N$ and $1 \leq Z_y \leq N$, we have

$$\theta_c^2(M-1) + \theta_a^2 \frac{2N}{2N-1} \ge N^2 \frac{MZ_y - 1}{(2N-1)Z_y},$$
(40a)

$$\theta_{\max}^2 \ge N^2 \frac{MZ_y - 1}{M(2N - 1)Z_y - Z_y}.$$
(40b)

Proof: The proof of (40) is similar to that of *Corollary 3* by substituting \mathbf{w}^C and D = 0 into (38b), note that $\sum_{s,t=0}^{2N-2} l_{s,t,N} w_s w_t = \frac{N(N-1)}{2N-1}$ for \mathbf{w}^C .

Remark 5: When $Z_y = 1$, bound (40a) reduces to the Sarwate bound for auto- and cross-correlation [28], bound (40b) reduces to the Welch bound [12] for aperiodic correlation.

Based on the following analysis, \mathbf{w}^C is the optimal weight vector for bound (38b) with D = 0in certain scenarios. Specifically, for the quadratic function $\mathcal{Q}(\mathbf{w}, \frac{N(N-Z_y)}{MZ_y}, \mathbf{0}_{2N-1})$ in (38b), when the following condition of M, N and Z_y is satisfied [32]:

$$\forall k \in [1, 2N - 1] \text{ s.t. } \lambda_k = \frac{N(N - Z_y)}{MZ_y} - \frac{1}{4\sin^2 \frac{\pi}{2N - 1}} \ge 0,$$

weight vector \mathbf{w}^{C} minimizes $\mathcal{Q}(\mathbf{w}, \frac{N(N-Z_y)}{MZ_y}, \mathbf{0}_{2N-1})$. Additionally, \mathbf{w}^{C} also minimizes $\mathbf{w}^{T}\mathbf{w}$ in (38b), and consequently, it maximizes (38b) in the case when D = 0. Based on these observations, the following remark can be made.

Remark 6: The bound in (40b) cannot be further improved by substituting any other weight vector w into (38b) with D = 0 in the following scenarios:

- $N \ge 2$ with $M = Z_y = 1$ or M = 2 and $Z_y = 1$;
- $N \ge 7$ with M = 1 and $Z_y = 2$.

This confirms that the increased weight vector flexibility introduced by the new weighting condition (37) potentially allows the bound (38b) to be tighter than the bound (23b). When the conditions specified in *Remark* 6 are not met, there exist weight vectors superior to \mathbf{w}^{C} . The bound in (40b) can be improved by utilizing weight vectors like $\mathbf{w}^{A,q}$ and $\mathbf{w}^{B,q}$, but with a length of 2N - 1.

Again, for a given weight vector w that satisfies (37) and

$$\exists (w_s, w_t) \text{ s.t.} \sum_{\substack{s,t=0\\l_{s,t,N}=N-d}}^{2N-2} w_s w_t \neq 0, \quad \theta_{\max}^2 > d^2,$$
(41)

we can conclude that there exist $D_{\text{opt}} > 0$. Let (38b) with D = 0 be denoted as $\widehat{AFB}_{\text{ref}}$, we have $D_{\text{opt}} \approx \left| \sqrt{\widehat{AFB}_{\text{ref}}} \right|$.

IV. ASYMPTOTICALLY ORDER-OPTIMAL SEQUENCE SET FOR AF IN THE LAZ

According to Corollary 1-7, θ_{max} should be at least $\mathcal{O}(\sqrt{N})$, when the order of the size of the LAZ (i.e. the order of $Z_x Z_y$) is no less than $\mathcal{O}(N)$ (see Table I for more examples). Therefore, a sequence set with θ_{max} asymptotically equal to $\mathcal{O}(\sqrt{N})$ is said to be "order-optimal" in this paper.

To find such order-optimal sequence sets, we consider Chu sequences [27]. A Chu sequence set can be defined as $\mathcal{A} = {\mathbf{s}^m}_{m=1}^M$, with each $\mathbf{s}^m = [s_0^{a_m}, s_1^{a_m}, \cdots, s_{N-1}^{a_m}]$ is unimodular sequences of length N given by

$$s_t^{a_m} = e^{\frac{\pi j a_m t^2}{N}},$$
 (42)

where a_m are distinct integers for different m with $|a_m| \in [1, N-1]$ [25]. Note that [27] used a slightly different definition when N is odd.

We first analyze the maximum AAF magnitude in certain LAZ for Chu sequences. Consider a Chu sequence $\mathbf{s} = [s_0^a, s_1^a, \dots, s_{N-1}^a]$, we derive the following conclusion.

Theorem 3 (Maximum AAF magnitude in the LAZ for Chu sequences): If |a| > 1, for $-|a| < \nu < |a|$ and $|\tau| \le \frac{\beta N}{|a|} - 1$, with $\frac{1}{2} < \beta < 1$, $N \ge 5|a|$, we have

$$\lim_{N \to +\infty} \frac{\max_{(\tau,\nu)} |A_{\mathbf{s}}(\tau,\nu)|}{\sqrt{N}} = \frac{0.4802}{\sqrt{|a|}}.$$
(43)

Proof: Since $A_{s}(\tau,\nu) = A_{s}(-\tau,-\nu)^{*}$, we only need to consider $\tau > 0$ to analyze the maximum AF magnitude in a given LAZ. Note that if $\nu - a\tau \neq uN$ for any integer u, $\sum_{n=0}^{N-1} e^{\frac{j2\pi(\nu-a\tau)n}{N}} = 0$ [28]. For $\tau > 0$, we have

$$|A_{\mathbf{s}}(\tau,\nu)|^{2} = \left|\sum_{n=0}^{N-1-\tau} s_{n}^{a} \left(s_{n+\tau}^{a}\right)^{*} e^{\frac{j2\pi\nu n}{N}}\right|^{2} = \left|\sum_{n=0}^{N-1-\tau} e^{\frac{j\pi a n^{2}}{N}} e^{\frac{-j\pi a (n+\tau)^{2}}{N}} e^{\frac{j2\pi\nu n}{N}}\right|^{2}$$
$$= \left|\sum_{n=0}^{N-1-\tau} e^{\frac{j2\pi(\nu-a\tau)n}{N}}\right|^{2} = \left|\sum_{l=0}^{N-1-(N-\tau)} e^{\frac{-j2\pi(\nu+a(N-\tau))l}{N}}\right|^{2}$$
$$= |A_{\mathbf{s}}(N-\tau,-\nu)|^{2}.$$
(44)

Based on (44), one can easily verify that $A_{\mathbf{s}}(\tau, \nu) = A_{\mathbf{s}'}(\tau, -\nu)$ where $\mathbf{s}' = \left[s_0^{-a}, s_1^{-a}, \cdots, s_{N-1}^{-a}\right]$. Thus, from here, we only need to consider that a < -1, $a < \nu < -a$ and $0 < \tau \le \frac{\beta N}{|a|} - 1$, $\frac{1}{2} < \beta < 1$, so we have $0 < \nu - a\tau < \beta N$. We consider the following two cases:

Case 1: $1 \le \tau \le 0.45 \sqrt{\frac{N}{|a|}}$.

According to Lemma 2 and for $\tau > 0$, we have $|A_s(\tau, \nu)|^2 \le (N - \tau)^2$. So in this case, we consider the range of τ satisfying $|A_s(\tau, \nu)|^2 \le (N - \tau)^2 \le \frac{0.81N}{4|a|}$, which implies $N - 0.45\sqrt{\frac{N}{|a|}} \le \tau \le N - 1$. From the choice of a, ν and τ , it is clear that $\nu - a\tau \ne uN$. According to (44), we have

$$\frac{|A_{\mathbf{s}}(\tau,\nu)|^2}{N} \le \frac{0.2025}{|a|}, \text{ for } 1 \le \tau \le 0.45 \sqrt{\frac{N}{|a|}}.$$
(45)

Case 2: $0.45\sqrt{\frac{N}{|a|}} < \tau \le \frac{\beta N}{|a|} - 1.$

In this case, $0 < -|a| + 1 + 0.45\sqrt{|a|N} < \nu - a\tau < \beta N$. We introduce the condition $\sqrt{N} > \frac{|a|-1}{0.45\sqrt{|a|}}$, or simply, $N \ge 5|a|$. Note that

$$A_{s}(\tau,\nu)|^{2} = \left| \sum_{n=0}^{N-1-\tau} e^{\frac{j2\pi(\nu-a\tau)(N-\tau)}{N}} \right|^{2}$$
$$= \left| \frac{1-e^{\frac{j2\pi(\nu-a\tau)(N-\tau)}{N}}}{1-e^{\frac{j2\pi(\nu-a\tau)}{N}}} \right|^{2}$$
$$= \frac{1-\cos\frac{2\pi(\nu-a\tau)(N-\tau)}{N}}{1-\cos\frac{2\pi(\nu-a\tau)}{N}}$$
$$= \frac{1-\cos\frac{2\pi(\nu-a\tau)\tau}{N}}{1-\cos\frac{2\pi(\nu-a\tau)\tau}{N}}.$$
(46)

Then, we divide Case 2 into the following two sub-cases:

Sub-case 2-1: $0.45\sqrt{\frac{N}{|a|}} < \tau \leq \frac{\beta N}{|a|} - 1$ with $(\nu - a\tau)^2 \geq \frac{5\beta^2|a|}{\sin^2(\beta\pi)}N$. Let $\varphi = \frac{2\pi(\nu - a\tau)}{N}$, since $0 < \nu - a\tau < \beta N$, we have $0 < \varphi < 2\pi\beta$. Note that $\sin\frac{\varphi}{2} \geq \frac{\sin\beta\pi}{2\beta\pi}\varphi$, so $1 - \cos\frac{2\pi(\nu - a\tau)}{N} \geq 2\left(\frac{\sin\beta\pi}{2\beta\pi} \cdot \frac{2\pi(\nu - a\tau)}{N}\right)^2 = \frac{2\sin^2(\beta\pi)}{\beta^2 N} \cdot \frac{(\nu - a\tau)^2}{N}$. Then based on (46), we have $\frac{|A_s(\tau, \nu)|^2}{N} \leq \frac{2}{\frac{2\sin^2(\beta\pi)}{\beta^2 N} \cdot \frac{(\nu - a\tau)^2}{N}N} = \frac{\beta^2}{\sin^2(\beta\pi)}\frac{N}{(\nu - a\tau)^2}$ $\leq \frac{\beta^2}{\sin^2(\beta\pi)}\frac{\sin^2(\beta\pi)}{5\beta^2|a|} = \frac{0.2}{|a|},$ for $0.45\sqrt{\frac{N}{|a|}} < \tau \leq \frac{\beta N}{|a|} - 1$ with $(\nu - a\tau)^2 \geq \frac{5\beta^2|a|}{\sin^2(\beta\pi)}N$. (47)

Sub-case 2-2: $0.45\sqrt{\frac{N}{|a|}} < \tau \leq \frac{\beta N}{|a|} - 1$ with $(\nu - a\tau)^2 < \frac{5\beta^2 |a|}{\sin^2(\beta\pi)}N$. In this sub-case, $\frac{\nu - a\tau}{N} \to 0$ as $N \to +\infty$. Following (46), for $N \to +\infty$, we have

$$|A_{\mathbf{s}}(\tau,\nu)|^{2} \rightarrow \frac{1-\cos\frac{2\pi(\nu-a\tau)\tau}{N}}{\frac{1}{2}\left(\frac{2\pi(\nu-a\tau)}{N}\right)^{2}} = \frac{1-\cos\frac{2\pi(\nu-a\tau)\tau}{N}}{\frac{\pi(\nu-a\tau)}{N\tau} \cdot \frac{2\pi(\nu-a\tau)\tau}{N}}$$
$$= \frac{N\tau}{\pi(\nu-a\tau)}F\left(\frac{2\pi(\nu-a\tau)\tau}{N}\right),$$
for $0.45\sqrt{\frac{N}{|a|}} < \tau \le \frac{\beta N}{|a|} - 1$ with $(\nu-a\tau)^{2} < \frac{5\beta^{2}|a|}{\sin^{2}(\beta\pi)}N,$ (48)

where $F(\varphi) = \frac{1-\cos\varphi}{\varphi}$ with $\varphi = \frac{2\pi(\nu-a\tau)\tau}{N} = \frac{\tau}{\nu-a\tau}\frac{2\pi(\nu-a\tau)^2}{N} < \frac{2\pi\tau}{\nu-a\tau}\cdot\frac{5\beta^2|a|}{\sin^2(\beta\pi)}$. For $\varphi > 2\pi$, $F(\varphi) \le \frac{2}{\varphi} \le \frac{1}{\pi} \approx 0.3183$. For $0 < \varphi \le 2\pi$, the maximum value of $F(\varphi)$ equals $F(\varphi_0) \approx 0.7246$, $\varphi_0 \approx 2.3311$ [23].

Then, we consider the $\frac{\tau}{\nu - a\tau}$ part in (48). Note that $0.45\sqrt{\frac{N}{|a|}} < \tau \leq \frac{\beta N}{|a|} - 1$, we have $\frac{1}{\frac{1}{0.45\sqrt{N/|a|}} - a} \leq \sqrt{\frac{N}{|a|}} \leq \frac{1}{\frac{a+1}{\beta N/|a|-1} - a}$. For $N \to +\infty$, we have $\frac{1}{\frac{1}{0.45\sqrt{N/|a|}} - a} \to \frac{1}{|a|}$ and $\frac{1}{\frac{a+1}{\beta N/|a|-1} - a} \to \frac{1}{|a|}$, so $\frac{\tau}{\nu - a\tau} \to \frac{1}{|a|}$. Thus, from (48), we have $\lim_{N \to +\infty} \frac{\max_{(\tau,\nu)} |A_{\mathbf{s}}(\tau,\nu)|^2}{N} = \frac{F(\varphi_0)}{\pi |a|} \approx \frac{0.2306}{|a|}$, for $0.45\sqrt{\frac{N}{|a|}} < \tau \leq \frac{\beta N}{|a|} - 1$ with $(\nu - a\tau)^2 < \frac{5\beta^2 |a|}{\sin^2(\beta\pi)}N$. (49)

Overall, based on the results from (45), (47), and (49), we conclude (43).

This indicates that the maximum (non-trivial) aperiodic AAF magnitude of the Chu sequence in an LAZ satisfying the conditions in *Theorem 3* is asymptotically in the order of $\mathcal{O}(\sqrt{N})$.

We then analyze the maximum CAF magnitude in the LAZ for Chu sequences. Consider two Chu sequence $s^1 = [s_0^{a_1}, s_1^{a_1}, \dots, s_{N-1}^{a_1}]$ and $s^2 = [s_0^{a_2}, s_1^{a_2}, \dots, s_{N-1}^{a_2}]$ with $a_1 > a_2$. We need the following lemma based on the Van Der Corput method [33].

Lemma 5: Let \mathbb{I} be an interval of \mathbb{R} containing ξ integers ($\xi \ge 0$). Let $f : \mathbb{I} \to \mathbb{R}$ be a twice continuously differentiable function on \mathbb{I} . If there exists a real number $\rho > 0$ and a real number $\alpha \ge 1$ such that $\forall n \in \mathbb{I}, \ \rho \le |f''(n)| \le \alpha \rho$, the exponential sum of $e^{j2\pi f(n)}$ satisfies

$$\left|\sum_{n\in\mathbb{I}}e^{j2\pi f(n)}\right| \le 3\alpha\xi\sqrt{\rho} + \frac{6}{\sqrt{\rho}}.$$
(50)

Theorem 4 (Maximum CAF magnitude in the LAZ for Chu sequences): For a Chu sequence pair s¹ and s² with $a_1 > a_2$, we have

$$|A_{\mathbf{s}^1,\mathbf{s}^2}(\tau,\nu)| \le 3\left(\sqrt{a_1 - a_2} + \frac{2}{\sqrt{a_1 - a_2}}\right)\sqrt{N} - \frac{3|\tau|\sqrt{a_1 - a_2}}{\sqrt{N}}.$$
(51)

Proof: For $\tau > 0$, we have

$$|A_{\mathbf{s}^{1},\mathbf{s}^{2}}(\tau,\nu)|^{2} = \left|\sum_{n=0}^{N-1-\tau} s_{n}^{1} s_{n+\tau}^{2*} e^{\frac{j2\pi\nu n}{N}}\right|^{2} = \left|\sum_{n=0}^{N-1-\tau} e^{j\pi \frac{(a_{1}-a_{2})n^{2}+2(\nu-a_{2}\tau)n-a_{2}\tau^{2}}{N}}\right|^{2}$$
$$= \left|\sum_{n=0}^{N-1-\tau} e^{j\pi \frac{(a_{1}-a_{2})n^{2}+2(\nu-a_{2}\tau)n}{N}}\right|^{2}.$$
(52)

Similarly, we have $|A_{s^1,s^2}(\tau,\nu)|^2 = \left|\sum_{n=0}^{N-1-\tau} e^{j\pi \frac{(a_1-a_2)n^2+2(\nu-a_1\tau)n}{N}}\right|^2$, for $\tau < 0$. According to Lemma 5, let $f(n) = \frac{(a_1-a_2)n^2+2(\nu-a_1\tau)n}{2N}$ or $f(n) = \frac{(a_1-a_2)n^2+2(\nu-a_2\tau)n}{2N}$, $\rho = \frac{a_1-a_2}{N}$, $\alpha = 1$ and $\xi = N - |\tau|$. Substituting them into (50), we obtain (51).

For sufficiently large N and $a_1 - a_2 \ll N$, the upper bound (51) of the maximum CAF magnitude for s¹ and s² is in the order of $\mathcal{O}(\sqrt{N})$.

Based on *Theorem 3* and *Theorem 4*, the following corollary can be obtained.

Corollary 8: The Chu sequence set $(N, M, \theta_{\max}, \Gamma) - \mathcal{A} = \{\mathbf{s}^m\}_{m=1}^M$ is an order-optimal sequence set for aperiodic AF in LAZ Γ with $Z_X < \left\lfloor \frac{N}{\max_m |a_m|} - 1 \right\rfloor$ and $Z_y \leq \min_m |a_m|$, if $N \geq 5 \max_m |a_m|$ and $\max_{m_1, m_2 \in [1, M]} \{a_{m_1} - a_{m_2}\} \ll N$.

V. DISCUSSIONS AND COMPARISONS

In this section, we evaluate the tightness of the proposed aperiodic AF lower bounds from two perspectives. We first demonstrate that it is tighter than the existing AF lower bound, and then we show the asymptotic achievability of our proposed AF lower bounds.

A. Comparisons with the Existing AF Lower Bound

The only existing aperiodic AF lower bound in the literature can be expressed as: Lemma 6 (Existing Bound [5, Theorem 4]): For any LAZ Γ ($1 < Z_x \leq N$ and $1 \leq Z_y \leq N$),

$$\theta_{\max}^2 \ge N^2 \frac{MZ_x Z_y - N - Z_x + 1}{(N + Z_x - 1)(MZ_x - 1)Z_y}.$$
(53)

Proof: In [5], the proof for (53) is an extension from the periodic case and is complicated. Here, we provide a concise proof using Welch's inner product method [12]. For a sequence set $\{\mu^m\}_{m=1}^{\hat{M}}$ with \hat{M} sequences of length \hat{N} and energy E, their correlations satisfy [12]

$$\sum_{m=1}^{\hat{M}} \sum_{m'=1}^{\hat{M}} \left| R_{\mu^m, \mu^{m'}}(0) \right|^2 \ge \frac{(\hat{M}E)^2}{\hat{N}}.$$
(54)

Based on (54) and Lemma 1, let $\overline{x}^{m,r} = [\widetilde{x}^{m,r}, \mathbf{0}_{1 \times Z_x}]$, since $\overline{x}^{m,r}$ is of length $\hat{N} = N + Z_x - 1$ and energy E = N, we have

$$MZ_{x}Z_{y} \left(MZ_{x}Z_{y} - Z_{y}\right)\theta_{\max}^{2} + N^{2}MZ_{x}Z_{y}$$

$$\geq \sum_{m,m'=1}^{M} \sum_{i,i'=0}^{Z_{x}-1} \sum_{r,r'=0}^{Z_{y}-1} \left|R_{\mathbf{c}(\overline{\boldsymbol{x}}^{m,r})_{i},\mathbf{c}(\overline{\boldsymbol{x}}^{m',r'})_{i'}}(0)\right|^{2}$$

$$\geq \frac{(MZ_{x}Z_{y}N)^{2}}{N + Z_{x} - 1}.$$
(55)

The bound (53) follows from (55).

We first compare the results of our proposed bound with the benchmark bound (53) when N is sufficiently large:

AF Lower Bound	M = 1	M = 2	M = 3	M = 4	$M \ge 5$
$[5, \text{Theorem } 4]^1$	$\theta_{\rm max}^2\gtrsim 0.4000N$	$\theta_{\rm max}^2\gtrsim 0.6000N$	$\theta_{\rm max}^2\gtrsim 0.6667N$	$\theta_{\rm max}^2\gtrsim 0.7000N$	$\theta_{\max}^2 \gtrsim \frac{2N(10MN-5N+4)}{5(5N-4)(MN-4)}N$
Corollary 3 ²	$\theta_{\rm max}^2\gtrsim 0.6349N$	$\theta_{\rm max}^2\gtrsim 0.7418N$	$\theta_{\rm max}^2\gtrsim 0.7892N$	$\theta_{\rm max}^2\gtrsim 0.8174N$	$ heta_{ m max}^2\gtrsim \left(1-rac{2}{\sqrt{30M}} ight)N$
Corollary 5 ³	$\theta_{\rm max}^2\gtrsim 0.6488N$	$\theta_{\rm max}^2\gtrsim 0.7516N$	$\theta_{\rm max}^2\gtrsim 0.7972N$	$\theta_{\rm max}^2\gtrsim 0.8244N$	$ heta_{ m max}^2\gtrsim \left(1-rac{\pi}{\sqrt{80M}} ight)N$

TABLE I. Asymptotic AF Lower Bound Comparison (in the LAZ with $Z_x = N/4$ and $Z_y = 10$)

¹ shown in (53);

² shown in (29), from the weight vector \mathbf{w}^A , note that $Z_x > \sqrt{\frac{3N^2}{MZ_y}}$ and $MZ_y \ge 3$; ³ shown in (36), from the weight vector \mathbf{w}^B , note that $Z_x > \frac{\pi}{\gamma}$ and $5 \le MZ_y \le N^2$.

Observation 1: For M, Z_x , Z_y satisfying $Z_x > \sqrt{\frac{3N^2}{MZ_y}}$ and $MZ_y \ge 3$ or $Z_x > \frac{\pi}{\gamma}$ and $5 \le MZ_y \le N^2$, the respective asymptotic lower bound of our proposed method is tighter than that of [5, Theorem 4].

Observation 1 can be easily verified through numerical calculations, with partial results in Table I. One can observe that both our proposed AF bounds are tighter than the bound [5, Theorem 4] for different values of M. Additionally, note that the effective ranges of the bounds in *Corollary 3* and *Corollary 5* differ, with the bound in *Corollary 5* being slightly tighter when both bounds are applicable.

We further compare our proposed bounds with the benchmark bound (53) [5] through two examples.

Example 1: In Fig.1(a), for LAZ with different Z_x and Z_y , with N = 128 and M = 6, one can observe that our proposed bounds (under the weight vector $\mathbf{w}^{B,q}$ with $q = \min \left\{ Z_x, \left\lfloor \frac{\pi}{\gamma} \right\rfloor + 1 \right\}$) are tighter than the benchmark bound (53) [5]. As analyzed in Subsection III-A, the configuration of this example satisfies $q < N - \lfloor N\sqrt{\text{AFB}_{\text{ref}}} \rfloor$, so the consideration of D_{opt} is unnecessary. Furthermore, the proposed bounds exhibit a corresponding increase as Z_x or Z_y increases, which is a distinct behavior compared to the benchmark (53). This also indicates that our proposed bounds align more with the physical significance. The rationale behind this is that achieving lower (non-trivial) AF magnitude is increasingly challenging for a larger LAZ. Therefore, it is logical that the AF lower bound should increase with the enlargement of the LAZ.

Example 2: In Fig.1(b), an example of the LAZ with $Z_x = N$ is presented with M = 1 and $Z_y = 2$. This example meets the conditions outlined in *Remark 6*, implying that \mathbf{w}^C offers the tightest bound among all different weight vectors. Again, our proposed bounds are tighter than the benchmark bounds (53). Furthermore, setting $D = D_{\text{opt}} \approx \left| N \sqrt{\widetilde{\text{AFB}}_{\text{ref}}} \right|$ effectively tightens

(a) Proposed bound versus the LAZ (with N = 128 and M = 6).

(b) Proposed bounds for LAZ versus sequence length N (with M = 1, $Z_x = N$ and $Z_y = 2$).

Fig. 1. Comparison of the proposed aperiodic AF lower bounds and the benchmark bound.

this bound further, which shows the significance of the D last delays consideration.

These examples again demonstrate that our proposed bounds are tighter than the only existing bound [5, Theorem 4].

B. Asymptotic Achievability of the Proposed Bounds

In Section IV, we have shown that our proposed AF lower bounds are asymptotically achievable in certain LAZ by the Chu sequences. In this subsection, we provide numerical examples to illustrate the closeness between the proposed aperiodic AF lower bounds and the maximum AAF

Fig. 2. Comparison of the maximum AAF/CAF magnitudes of a Chu sequence pair s^1 and s^2 ($a_1 = 20$, $a_2 = 19$) and the proposed aperiodic AAF/CAF lower bounds (29a) associated to the LAZ with $Z_x = \left| \frac{9N}{10|a_1|} \right|$ and $Z_y = a_2$.

and CAF magnitudes of Chu sequences, thereby demonstrating the tightness of our proposed bounds.

In Fig. 2, we show the maximum AAF/CAF magnitudes of a Chu sequence pair s¹ and s² with $a_1 = 20$ and $a_2 = 19$ for different values of N, along with the proposed aperiodic AF lower bounds associated to the LAZ ($Z_x = \left\lfloor \frac{9N}{10|a_1|} \right\rfloor$ and $Z_y = a_2$ according to *Corollary 8*). We set $\theta_a = 0.4802\sqrt{\frac{N}{a_1}}$ as the asymptotic value of the maximum AAF magnitude for s¹, which is smaller than that of s². According to the tradeoff between θ_a and θ_c as shown in (29a), θ_c is represented by the purple line in the figure.

One can observe that the maximum AAF magnitudes of both s^1 and s^2 asymptotically approach their respective asymptotic values, while the maximum CAF magnitude between them only slightly exceeds the bound θ_c when N is sufficiently large. Despite a certain gap, this demonstrates that the proposed bounds are quite tight for the aperiodic case, and their order is asymptotically achievable. Similarly, other Chu sequence pairs satisfying the conditions in *Corollary* 8 also exhibit maximum AF magnitudes that closely approach the proposed bounds, and such order-optimal sequence pairs are readily extendable to form order-optimal sequence sets.

VI. CONCLUSIONS

In this work, we have developed new aperiodic AF lower bounds for unimodular sequences with respect to the LAZ in the delay-Doppler plane. We have also presented the trade-offs between the lower bounds for the aperiodic AAF and CAF. Unlike the Levenshtein correlation bound, our first innovation is the introduction of two weight vectors in order to characterize the individual influences of the delay and Doppler shifts, respectively. Moreover, our bounds are derived by leveraging certain insights of the zero delay and *D* last delays that are associated with the structural properties of aperiodic AF. Existing aperiodic correlation bounds, such as the Welch bound, Sarwate Bound, Levenshtein bounds, Peng-Fan bounds, and Arlery-Tan-Rabaste bounds, can be considered as special cases of our proposed AF lower bounds. Furthermore, it has been shown that our proposed AF lower bounds are asymptotically achievable by the Chu sequence sets and are tighter than the existing benchmark bound.
