**Abstract:**

Interactions between the government officials and civilians affect public wellbeing and the state legitimacy that is necessary for the functioning of democratic society. Police officers, the most visible and contacted agents of the state, interact with the public more than 20 million times a year during traffic stops. Today, these interactions are regularly recorded by body-worn cameras (BWCs), which are lauded as a means to enhance police accountability and improve police-public interactions. However, the timely analysis of these recordings is hampered by a lack of reliable automated tools that can enable the analysis of these complex and contested police-public interactions. This article proposes an approach to developing new multi-perspective, multimodal machine learning (ML) tools to analyze the audio, video, and transcript information from this BWC footage. Our approach begins by identifying the aspects of communication most salient to different stakeholders, including both community members and police officers. We move away from modeling approaches built around the existence of a single ground truth and instead utilize new advances in soft labeling to incorporate variation in how different observers perceive the same interactions. We argue that this inclusive approach to the conceptualization and design of new ML tools is broadly applicable to the study of communication and development of analytic tools across domains of human interaction, including education, medicine, and the workplace.

**Keywords:** police, communication, machine learning, stakeholder, multimodal, multi-perspective, soft label, subjective natural language processing, traffic stop, motor vehicle stop

**Article Type:** Perspective. *A Perspective is intended to provide a forum for authors to discuss models and ideas from a personal viewpoint. Perspectives are more forward looking and/or speculative than Review Articles. They may be opinionated but should remain balanced and are intended to stimulate discussion and new approaches.*

## **Introduction:**

Interpersonal communication shapes outcomes across institutional domains.<sup>3,10,11</sup> Crucially, the content and quality of human interactions are perceived differently across individuals and groups.<sup>21</sup> Communication dynamics also influence the relationship between the state and its constituents, including during citizens' interactions with police officers during approximately 20 million yearly traffic stops.<sup>44</sup> Traffic stop interactions are unequally distributed across the population: Black people are stopped by police more frequently than whites, and their stops are more likely to be for minor violations.<sup>4,13,31</sup> Race also shapes the content and experience of police interactions. Black and Latinx motorists are more likely to be searched,<sup>31</sup> and officers use more disrespectful language with Black people during traffic stops.<sup>40</sup> These inequities perpetuate longstanding distrust of police and have far-reaching negative impacts on public health, educational attainment, and political life.<sup>9,16,25</sup>

Today, most of these stops are captured via bodyworn cameras (BWCs). The ever-expanding quantity of BWC video represents a promising resource with which to study and improve police-public interaction. However, current review of BWC video is largely limited to police-public interactions that result in violence or a public complaint,<sup>43</sup> leaving most video data unexamined.<sup>43</sup> Failure to systematically analyze these data limits the potential of BWCs to improve policing and, more broadly, impedes insight into how citizens experience interactions with the state and its agents.

There is a need for new methods that can harness the potential of BWC video data to enhance police accountability and public wellbeing. In cooperation with the Los Angeles Police Department (LAPD), our research team has established a multidisciplinary collaboration to build new, theoretically-informed machine learning (ML) tools capable of efficiently analyzing video footage of complex social interactions like those that occur during police traffic stops. In particular, our team advances a multi-perspective machine learning approach which explicitly accounts for variation in how the same interaction can be experienced in distinct ways by police officers and those whom they stop. Rather than rely on a single ground truth to construct our ML model, we leverage surveys, interviews, and focus groups with police and non-police respondents to capture differing perspectives on interactional dynamics that affect the quality of traffic stops. We then use these insights to design annotation software that allows for a diverse sample of annotators to assess the content and quality of LAPD traffic stops captured via BWC.

In this Perspective, we describe our approach to designing machine learning tools to systematically analyze video data in the context of police traffic stops. We argue that the integration of theory and method from social science, computer science, and engineering is a promising path forward to better understand and ameliorate long standing problems in policing. Further, we believe that our multidisciplinary approach provides a useful framework for the development of analytic tools across domains in which the quality of human interaction shapes inequality, including medicine, education, and the workplace.<sup>6,8</sup>

### **Diverse Stakeholders, Divergent Perspectives**

Our multiperspective measurement strategy begins with survey, interview, and focus group research to sample diverse perspectives of the groups participating in and experiencing the communication being studied. In the case of police traffic stops, our measures of communication draw on three sources covering both police and community: First, we conducted survey, interview, and focus group research with residents and community organizations from across the city of Los Angeles to assess a diverse array of community members' views on communication with the police. Second, we assessed current LAPD training materials, attended LAPD traffic stop training at the academy, and interviewed LAPD leadership to develop guidelines from which we can identify when, and to what extent, officers' communications follow their training procedures. Third, we conducted interview and focus group research with current and former officers to assess their views on how officers should be communicating.

The measurement approach we advocate is not driven by a single definition of “good” communication in a given context, but by a desire to build ML tools to capture different aspects of communication that are salient to different stakeholders. Historically, the development of a single “ground truth” is far from impartial, and has instead privileged the perspectives of the powerful.<sup>30</sup> Our approach to measuring views on communication moves away from accepting single viewpoints rooted in power differentials as representative of everyone and instead inclusively expands the social standpoint upon which ML tools are developed. We propose a necessarily broader, interdisciplinary research method focused on understanding the extent to which the communication observed aligns with the needs and preferences of different stakeholders – not simply whether it is good or bad.

Designers of new technologies are used to working in frameworks in which the purchasers and users of a technology are by far the most important stakeholders. In the context of technologies used by the police or other government officials, all civilians subject to interactions with those officers or officials are also stakeholders in the design and implementation of the technology. However, the voices of these non-user, non-purchaser stakeholders are often excluded from the design process, sometimes deliberately, given those stakeholders are traditionally the surveillance targets of such technologies. In the law enforcement context, police departments have the budgets and discretion to purchase the tools that best meet their needs, creating economic incentives for companies that design and build new technologies to be responsive to law enforcement priorities. There is much less incentive for tool builders to incorporate the views of those upon whom these tools are used – even though we are all deeply affected by the design and implementation choices that are made.

Further cementing the power of law enforcement stakeholders is the fact that the data on which ML tools might be trained, such as BWC footage and data on crime, enforcement, and police personnel, are collected and often owned and controlled by police departments themselves.<sup>18,37,39</sup> Thus, any actor who seeks to train a new ML tool must do so with the permission of law enforcement partners, and law enforcement stakeholders may end up with *de facto* veto power over the type of work that can be done in this area.

Machine learning tools can, at best, be as good as the underlying data and the human annotations that guide the training of the ML. The underlying data must reflect the diverse perspectives and experiences of the population whose communication we are trying to understand and if they do not, then the tools trained on this data will also fail to capture the complexity we are trying to understand. In addition, annotation guidelines and the human annotators themselves must also reflect, to the extent possible, the various perspectives being studied. If the data and the annotation process do not represent a wide range of perspectives, then the ML tools will also fail to do so and will instead reflect and perpetuate existing structural inequalities, rather than providing a tool to remediate them.<sup>5,17,38</sup>

### **Interdisciplinary Development of New Tools**

Several recent technological developments in the broad arena of ML have made it much easier to study in-person communication. The first is an explosion of rich audio and video data capturing interactions that previously went unrecorded. Notable among these data sources are BWCs, which are common in law enforcement and some other contexts, but everything from doorbell cameras to smart speakers offer new data on human communication. Second is the evolution of natural language processing, video processing algorithms, and related ML tools that can be trained on human-coded communications and then used to evaluate and quantify characteristics of interpersonal communication at scale. In short, we now have access to massive and detailed data on communication and the computing power and ML tools to measure that communication at scale.

What is needed, then, is an interdisciplinary framework across social, behavioral and computer sciences to define, measure, and analyze the aspects of communication most salient to affected stakeholders. This framework requires expertise on, and attention to, the laws that govern the communication itself (e.g., verbalization of the reasonable suspicion that justifies a police officer’s decision to initiate a motor vehicle stop),<sup>28</sup> the geographic location and socioeconomic characteristics of the communities in which the interaction takes place, the power dynamics between the parties communicating, and the technical and engineering strategies required to translate this largely qualitative or unstructured data into quantitative parameters and training data for large-scale models. This integration is fundamentally interdisciplinary and requires a novel framework for multi-disciplinary scaled analysis.

#### ***A). Implementing Stakeholder-Informed Measurement***

In order to train ML tools to measure communication, we must identify the aspects of communication that are salient to different stakeholder groups and then train human researchers to label (annotate) those constructs. It is then the human annotations that are used to train ML tools.

Based on our engagement with community and police stakeholders in Los Angeles, we developed measures of the most salient features of communication during traffic stops, which we group into three categories: (A) Procedural communication, (B) Respect/politeness communication, and (C) Directive communication and (de)escalation. Procedural communication focuses on procedural justice, and information exchange (e.g., officer’s explanation of the reason for the stop; driver’s explanation for their actions). This category also includes investigative questioning and drivers’ responses to it.

Respect/politeness communication is concerned with behaviors that go beyond procedure into the practice of good manners and even empathy to facilitate a more positive interaction. Directive communication and (de)escalation is the category for particular behaviors in which the officer gives directions to the driver or other civilians and they respond to those directions. All three categories have labels for communication acts by both the civilian and police officer.

#### ***B). Designing machine learning tools to bring measurement to scale***

Recent advances in the domain of multimodal signal processing, and especially egocentric audio-visual processing, provide us with a rich set of tools in order to analyze the BWC footage. Crucially, drawing inspiration from recent successes in text processing via large language models, there have been attempts to develop multimodal language models to jointly model images, audio and text. However, automated video understanding is still an under-explored domain owing to its complexity and computationally intensive nature. Most current video understanding models are restricted to short-form video clips of durations 10-20 seconds or shorter.<sup>41,42</sup> Such models are not optimal for studying BWC recordings, which span at least a few minutes on average. Furthermore, BWC videos can potentially represent a wide range of ambient conditions, challenging algorithmic robustness. Overcoming these challenges is essential for automatically analyzing the nature of interactions in traffic stop data.

The first step to enable analysis of BWC footage—comprising audio and visual data streams from the wearer’s point of view—is to temporally segment the data into speaker-specific partitions, referred to as speaker diarization. Foreground speech detection<sup>20</sup> from the audio stream of the active speaker has been studied previously in the context of egocentric recordings as seen in BWC data. However, foreground detection suffers from accurately discerning the audio boundaries of the primary officer speech<sup>14</sup> in the presence of dispatch audio and secondary officers’ speech resulting in faulty segmentation. Growing interest and targeted efforts, including the public release of large scale resources such as the Ego4D dataset,<sup>19</sup> are facilitating rapid progress in egocentric audio-video processing, including pre-training rich models that can be used to facilitate multimodal speaker diarization.

The next step in the ML pipeline is to transcribe the spoken language in the recording, commonly referred to as automatic speech recognition (ASR). Recent transformer based end-end ASR models have shown to

be very powerful at reliably transcribing speech in a variety of domains.<sup>34</sup> However, a recent study on BWC audio showed that state-of-the-art methods still fail to generalize to the challenging domain of police-civilian interactions.<sup>23</sup> Since reliable transcriptions are critical to any downstream natural language processing, existing ASR models need to be finetuned with domain-matched annotated speech recordings from BWC.

Previous work using machine learning to analyze police-civilian interactions have been limited to analyzing the transcriptions of the interactions, without considering the multimodal characteristics of human communication.<sup>36,40</sup> Computational modeling of transcriptions of interactions provides valuable insights into the transactional elements of the interaction, audio-visual signals provide us with rich complementary information, such as emotion-laden speech and facial/body language expressions in video.

Often, non-verbal cues of communication such as tone of voice, facial expressions, and body language are as important as their verbal counterparts in providing us with vital information about the interaction. They also add context to the lexical content within a conversation. These non-verbal features can be employed to identify cues of aggression and violence as well as politeness and respect during the course of these interactions. Thus, these modalities provide us with a more complete view of the interaction, allowing us to better model and understand communication patterns. However, in order to develop tools capable of integrating audio, video and transcript information in this context, there are some fundamental AI challenges in multimodal signal understanding which need to be addressed.

Another aspect of analyzing traffic stops involves inferring the affective states of the officer and community member. Although there have been audio-visual models which can infer the affective states of an individual from videos, traffic stops are distinct from everyday interactions, and there is a large domain mismatch in the available training data for these models. Hence, we will need to either fine-tune or transfer-learn from these existing models through carefully annotated data of these BWC recordings. Our approach embraces the absence of a single objective ground truth and the likelihood that annotators disagree about the affective states (and other elements) of the videos. While this makes the computational modeling more challenging it allows us to develop models that better capture the nuances and disagreement that occur in real-world situations.<sup>7</sup>

In summary, computational modeling approaches that integrate text, audio and visual modalities to extract rich information about communication, affect, and interaction patterns are essential. These can take advantage of and build upon the recent developments in deep learning and multi-modal signal processing to offer accurate, consistent, efficient and scalable processing of large amounts of BWC data.

### **Training ML Models using Soft-labels:**

In subjective natural language processing tasks, where multiple plausible interpretations exist, it is of utmost importance to consider the subjective nature of the task and the range of opinions that annotators may hold. Disagreements in labeling should not be regarded as mere statistical noise, but rather as indications of ambiguities and disparities in perceptions, influenced by the backgrounds and experiences of the annotators.<sup>1,32,33</sup> Several approaches have been proposed to move beyond the single ground-truth framework and accommodate subjective interpretations. For instance, Akhtar et al. (2020) recommend clustering annotators based on similar characteristics and establishing separate gold standards for each group.<sup>2</sup> Meanwhile, Kanclerz et al. (2022) propose the incorporation of information about each annotator to personalize models.<sup>23</sup> Mostafazadeh Davani et al. (2022) adopt a multitask approach, treating each annotator's perspective as a subtask while learning a shared representation across subtasks.<sup>27</sup> Furthermore, some methods involve learning directly from soft labels, which are probabilistic distributions obtained by aggregating annotations.<sup>29</sup> Fornaciari et al. (2021) leverage crowd disagreement in a multi-task learning setting to jointly learn to classify both hard labels (gold-standard classes) and soft labels (annotators'

annotations represented as probability distributions).<sup>15</sup> Our approach builds upon this existing body of research, wherein we strive to incorporate diverse viewpoints from various communities. The objective is to train models that have the capability to effectively capture and represent divergent perspectives.

### **Deploying New Tools with Sensitive Data**

BWC footage is a particularly powerful source of data because it captures details of police-civilian interactions that are not included in written documents or administrative data and provides a less-mediated record of events involving officers and community members.<sup>24</sup> However, the same richness that makes BWC data so valuable also introduces privacy-related concerns. BWC data typically include visually-identifiable characteristics of the civilian(s) being stopped. While these data are critical to developing ML models to evaluate the interactions between the civilians and officers, they are also highly sensitive.

A BWC recording is, at the greatest level of simplification, a recording of a conversation. Generally, legality of recording has two parts, the situation where the conversation occurs and the consent or awareness of the recording by one or more people present. The laws around recording conversations differ across federal and state jurisdictions, and in some states both parties to a conversation must consent to its recording.<sup>45</sup> In such states it may be difficult to obtain consent leading to requirements for officers to announce they are recording or requiring state legislatures to add an explicit exemption for police body cameras.<sup>26</sup> Many law enforcement agencies have determined that officers have the right to record as long as they have the legal right to be there.

Even if law enforcement agencies have the right to record interactions, there are complications around using the recordings for research or public records, because many recordings are made in an environment where people may have an expectation of privacy under the Fourth Amendment.<sup>26</sup> California, for example, requires all parties present to consent to a recording if the participants have a reasonable expectation of privacy, such as within a private home.<sup>22</sup> There is a challenge inherent in (1) protecting the data collected about civilians interacting with law enforcement in ways that ensure privacy and (2) making data about these interactions publicly available to facilitate transparency and accountability of government agents' actions. Navigating this challenge is critical to protecting individual rights while enabling effective democratic oversight.

Machine learning models provide an opportunity to study officer-civilian communication in detail, while also protecting the rights of the individuals depicted in the data. Once trained, these models can identify patterns of communication – particularly involving police or other public servants – that are of potential concern to citizens and civil society. Such patterns might include racial disparities or other disparities in treatment across communities, or poor communication performance by certain subsets of powerful individuals. Such models can facilitate effective oversight of agents of the state without violating the privacy of the people depicted in the data. Because these models can analyze BWC recordings of interactions without a human viewing those interactions, the models can reveal problematic (or laudatory) patterns in the communication behavior of public servants without revealing the details of the communication between those public servants and any specific civilian. A systems approach based on the goals of ML-enabled transparency and accountability would help support *ex ante* development of a privacy framework for the use of these types of data.<sup>12</sup>

### **Conclusion**

New technologies enable the analysis of rich data that can be used to enhance our understanding of human interaction. To accurately understand the full complexity of such interaction, however, these technologies must be designed and deployed with consideration of the often divergent perspectives of those who interact with one another. This Perspective describes a new effort to address the theoretical and practical challenges of accounting for such varied perspectives in the study of human interaction.

Drawing on social science, computer science, and engineering, we outline a means to incorporate multiple perspectives into new machine learning models that can provide systematic, scalable analysis of police-public interaction and, more expansively, human communication.

This article is an invitation to other researchers to scrutinize our approach and to adapt variations of it in other domains. We identify a range of challenges to the development of multi-perspective ML tools for analysis of video in the context of complex social and political power dynamics. These challenges are, in some ways, extremely specific to police-civilian interactions. At the same time, we suggest that variations of these challenges are likely common across a wide variety of societal domains, and we hope that refined versions of the approach we are developing here can be applied broadly.

The increasing availability of high-quality video provides promising possibilities for the application of our approach to a range of other contexts, including education, medicine, and the workplace. Better understanding of human interaction, be it between teacher and student, physician and patient, or manager and employee, holds great promise for designing processes, policies, and practices that improve the quality of such interactions
